[edit logical-systems logical-system-name protocols bgp group group-name neighbor address],
```

```
[edit protocols bgp group group-name],
[edit protocols bgp group group-name neighbor address]
```

Description

Enable BGP route target filtering on the VPN.

The `family route-target` statement is useful for filtering VPN routes before they are sent. Provider edge (PE) routers inform the route reflector (RR) which routes to send, using `family route-target` to provide the route-target-interest information. The RR then sends to the PE router only the advertisements containing the specified route target.

Options

`advertise-default`—Cause the router to advertise the default route target route (`0:0:0/0`) and suppress all routes that are more specific. This can be used by a route reflector on BGP groups consisting of neighbors that act as provider edge (PE) routers only. PE routers often need to advertise all routes to the route reflector. Suppressing all route target advertisements other than the default route reduces the amount of information exchanged between the route reflector and the PE routers. The Junos OS further helps to reduce route target advertisement overhead by not maintaining dependency information unless a nondefault route is received.

`external-paths` *number*—Cause the router to advertise the VPN routes that reference a given route target. The number you specify with the `external-paths` statement determines the number of external peer routers (currently advertising that route target) that receive the VPN routes. The default value is `1`.

NOTE: `external-paths` cannot be configured under the `[edit protocols bgp group` *group-name* `neighbor` *address*`]` hierarchy level.

`prefix-limit` *number*—The number of prefixes that can be received from a peer router.

The remaining statement is described separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

```
[edit interfaces interface-name sonet-options aps]
```

Description

(M320 routers with Channelized OC3/STM1 Circuit Emulation PIC with SFP only, EX Series switches, and MX series routers with Channelized OC3/STM1 Circuit Emulation PIC with SFP only using container interfaces) Reduce the Automatic Protection Switching (APS) switchover time in Layer 2 circuits.

NOTE:

- The fast APS switching feature is supported only within a single chassis on a MX series router using a container interface.
- Configuring this statement reduces the APS switchover time only when the Layer 2 circuit encapsulation type for the interface receiving traffic from a Layer 2 circuit neighbor is SAToP.
- When the `fast-aps-switch` statement is configured in revertive APS mode, you must configure an appropriate value for revert time to achieve reduction in APS switchover time.
- To prevent the logical interfaces in the data path from being shut down, configure appropriate hold-time values on all the interfaces in the data path that support TDM.
- The `fast-aps-switch` statement cannot be configured when the APS `annex-b` option is configured.
- The interfaces that have the `fast-aps-switch` statement configured cannot be used in virtual private LAN service (VPLS) environments.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Syntax

```
fast-failover (ge | vcp disable | xe);
```

Hierarchy Level

```
[edit virtual-chassis]
```

Description

Enable the fast failover feature on an uplink Virtual Chassis port (VCP).

Fast failover is not supported on an EX2200 Virtual Chassis or EX8200 Virtual Chassis.

Default

Fast failover is enabled, by default, on dedicated VCPs.

Fast failover is not enabled on uplink VCPs, including the uplink ports that are, by default, configured as VCPs on an EX3300 switch.

Options

- **ge**—Enable fast failover on all Gigabit Ethernet uplink VCPs in the ring topology.
- **vcp disable**—Disable fast failover on all dedicated VCPs in the ring topology.
- **xe**—Enable fast failover on all 10-Gigabit Ethernet uplink VCPs in the ring topology.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

[edit logical-systems logical-system-name  interfaces interface-name unit logical-unit-number family inet6 address address vrrp-inet6-group group-id]
```

Description

Configure the interval, in milliseconds, between Virtual Router Redundancy Protocol (VRRP) advertisement packets.

All routers in the VRRP group must use the same advertisement interval.

Options

milliseconds—Interval between advertisement packets.

- **Range:**
  - 10 through 40,950 milliseconds for VRRPv3.
  - 100-999 milliseconds for VRRP.

> **NOTE**: When configuring VRRPv2, we recommend using `advertise-interval` instead of `fast-interval`.

- > **NOTE**: When configuring VRRP for IPv4, if you have chosen not to enable VRRPv3, you cannot set a value less than 100 for `fast-interval`. Commit check fails if a value less than 100 is configured.

- **Default:** 1 second

Required Privilege Level

interface—To view this statement in the configuration.

fast-lookup-filter (PTX)

IN THIS SECTION

- Syntax | 7247
- Hierarchy Level | 7247
- Description | 7247
- Required Privilege Level | 7256
- Release Information | 7256

Syntax

```
fast-lookup-filter
```

Hierarchy Level

```
[edit firewall family family-name filter output filter-name],
[edit logical-systems logical-system-name firewall family family-name filter output filter-name]
```

Description

On PTX platforms, the `fast-lookup-filter` (FFT) is available on Inet, Inet 6, Ethernet-Switching, Any, MPLS (no MPLS `label` match support) and CCC firewall filter families. Using `fast-lookup-filter` on output filters prioritizes the filters for fast processing. Applying the `fast-lookup-filter` configuration on output firewall filters, programs the firewall filters on the fast-lookup-filter block on the device, to enable high-speed line-rate (2 billion packets-per-second) processing of the firewall filters in the egress direction.

NOTE: It is mandatory to set the fast-lookup-filter knob to apply the family mpls output filter.

On PTX platforms, only the following firewall filter match conditions and actions are supported for fast look filters.

Table 49: Supported firewall filter match conditions for fast lookup filters on PTX platforms (PTX10008 and PTX10001-36MR)

NOTE: For supported firewall filter match conditions for fast lookup filters on PTX platforms (PTX10008 and PTX10001-36MR):

- Only 8 unique firewall filters per PFE are supported across all supported firewall filter families.
- Fast lookup is applicable only for output filters.
- Unsupported firewall filter matches and actions is processed from the default processing pipeline, and not programmed on the fast-lookup-filter block.
- Fast lookup filters are limited to 4096 rules of 96 bits or 2048 rules of 192 bits or 1024 rules of 384 bits.
- Maximum 256 logical interface (IFL) bindings for interface specific filter per PFE.

- The `fast-lookup-filter` configuration cannot be applied on input filters.
- There is no support for split filter or filter chaining.
- The `fast-lookup-filter` configuration cannot be used to prioritize amongst the 8 unique fast lookup filters.
- Fast lookup filters do not support slow counters. Counter scale is limited to 48 thousand counter per PFE (Packet Forwarding Engine).

Table 50: Supported firewall filter match conditions for fast lookup filters on PTX platforms (PTX10002-36QDD and PTX12008)

CLI	IPv6	IPv4	MPLS	Ethernet switching	Any	CCC	Except match

Table 50: Supported firewall filter match conditions for fast lookup filters on PTX platforms (PTX10002-36QDD and PTX12008) ***(Continued)***

CLI	IPv6	IPv4	MPLS	Ethernet switching	Any	CCC	Except match
exp0-except	No	No	Yes	No	No	No	No
exp1	No	No	Yes	No	No	No	No
exp1-except	No	No	Yes	No	No	No	No
label0	No	No	Yes	No	No	No	No
label0-except	No	No	Yes	No	No	No	No
label1	No	No	Yes	No	No	No	No
label1-except	No	No	Yes	No	No	No	No
ttl0	No	No	Yes	No	No	No	No
ttl0-except	No	No	Yes	No	No	No	No
ttl1	No	No	Yes	No	No	No	No
ttl1-except	No	No	Yes	No	No	No	No

NOTE: MPLS exp bits are overwritten by DSCP rewrite rules (if its not explicitly configured, then default rules will be applied) before the packet comes to FFT. Match needs to be applied on the overwritten exp bits.

NOTE: For supported firewall filter match conditions for fast lookup filters on PTX platforms (PTX10002-36QDD and PTX12008):

- Total 128 filters will be supported with maximum 8192 firewall filter rules
- Fast lookup is applicable only for output filters.
- Unsupported firewall filter matches and actions is processed from the default processing pipeline, and not programmed on the fast-lookup-filter block.
- The `fast-lookup-filter` configuration cannot be applied on input filters.
- There is no support for split filter or filter chaining.
- Support of virtual filter numbers and hence support of 32K IFL attachment
- Support for maximum 256 counters per filter for interface-specific filters. Support for more than 256 counters is supported for non-interface-specific filters.
- FFT supports both slow and fast counters.
- FFT supports IPv4, IPv6, MPLS and ANY firewall filter families. IPv4, IPv6 and MPLS firewall filters can be attached to the same logical interface (IFL) at the same time.

Table 51: Supported firewall filter actions for fast lookup filters on PTX platforms

Syntax

```
fast-lookup-filter;
```

Hierarchy Level

```
[edit firewall family family-name filter filter-name],
[edit logical-systems logical-system-name firewall family family-name filter filter-name]
```

Description

The `fast-lookup-filter` is available for the inet and inet6 protocol families for both static and dynamic profiles. Junos installs firewall filters created under this hierarchy to the accelerated filter block available in the certain MPCs, which provides enhanced performance.

Juniper recommends that you use the `payload-protocol` term rather than the `next-header` term when configuring a firewall filter with match conditions for IPv6 traffic. Although either can be used, `payload-protocol` provides the more reliable match condition because it uses the actual payload protocol to find a match, whereas `next-header` simply takes whatever appears in the first header following the IPv6 header, which may or may not be the actual protocol. In addition, if `next-header` is used with IPv6, the accelerated filter block lookup process is bypassed and the standard filter used instead.

See *Firewall Filter Match Conditions for IPv6 Traffic* for more information about firewall filters and terms.

Fast lookup filters can boost filtering performance by as much as three to four times for filters under 3000 terms. Firewall instances from the same firewall block can also be attached to multiple interfaces.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.3R3 for MX 240, MX 480, MX 960, MX 2010, and MX 2020 routers with MPC5E, MPC5EQ, or MPC6E, and later for MPC7E, MPC8E, and MPC9E MPCs.

Support for the `next-header` firewall match condition was added in Junos OS Release 13.3R6

Support for MPC2E-NG and MPC3E-NG MPCs was added in Junos OS Release 15.1R1.

Change History Table

fast-lookup-tuple

IN THIS SECTION

- Syntax | 7259
- Hierarchy Level | 7259
- Description | 7259
- Default | 7260
- Required Privilege Level | 7260
- Release Information | 7260

Syntax

```
fast-lookup-tuple
```

Hierarchy Level

```
[edit firewall family inet filter firewall filter name term term name from]
```

Description

Use `fast-lookup-tuple` for better firewall filter processing performance by matching exact values of the five tuple or five combined match conditions. It enables high scale firewall filter performance improvement with only 5-tuple configurations per term without range configurations by avoiding execution of multiple terms in sequence. You can also use `fast-lookup-tuple-list` to match five tuple list template defined under policy options.

`fast-lookup-tuple` is only for INET firewall filter family. No range of values is supported for each of the 5-tuple fields. `fast-lookup-tuple` can be applied at all bind points including chain filters, list filters, and nested filters. Next-term action is not supported for `fast-lookup-tuple` match. `fast-lookup-tuple` cannot be defined for fast lookup filters.

The following is a sample configuration.

```
set firewall family inet filter f1 term t1 from fast-lookup-tuple
10.11.12.13:20.21.22.23:17:168:65535
```

Default

l3 byte value - `<dest-ip-in-regular-format>:<src-ip-in-regular-format>:<proto>:<src-port>:<dest-port>`

- `<dest-ip-in-regular-format>`: Destination IP address as <a.b.c.d>. Where a, b, c and d are in decimal values. Example: 10.11.12.13 as standard IP notation.
- `<src-ip-in-regular-format>`: Source IP address as <a.b.c.d>. Where a, b, c and d are in decimal values. Example: 10.12.13.14 as standard IP notation.
- `<proto>`: Single byte protocol value in decimal format. Note - Standard protocol names are not allowed for protocol value.
- `<src-port>`: Two bytes port values in decimal format.
- `<dest-port>`: Two bytes port values in decimal format.

Description

Match any of the list of 5-tuple (fast-lookup-tuple) combinations. The list is defined under policy options.

`fast-lookup-tuple-list` is only for INET firewall filter family. No range of values is supported for each of the 5-tuple fields. `fast-lookup-tuple-list` can be applied at all bind points including chain filters, list filters, and nested filters.

The following is an example of a configuration.

```
set policy-options fast-lookup-tuple-list five-tuple-list 10.11.12.13:20.21.22.23:17:168:65535
```

Default

`fast-lookup-tuple-list` *`list name`* - the name of the list of 5-tuple combinations defined under policy options.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

- Required Privilege Level | 7264

Syntax

```
fast-poe;
```

Hierarchy Level

```
[edit poe]
```

Release Information

Statement introduced in Junos OS Release 21.1.

Description

Fast Power over Ethernet (fast PoE) delivers PoE power to devices connected to the ports even before the switch is fully operational. This is beneficial when the connected devices need only power, and not network connectivity.

> **NOTE**: Fast PoE is disabled if and when you issue commands to zeroize the switch, do a USB install, or load the factory default.

Syntax

```
fast-reroute-priority (high | low | medium);
```

Hierarchy Level

```
[edit forwarding-options]
[edit logical-systems logical-system-name routing-instances routing-instance-name forwarding-
options],
[edit routing-instances routing-instance-name forwarding-options]
```

Description

Specify the fast reroute priority for a VPLS routing instance. You can configure `high`, `medium`, or `low` fast reroute priority to prioritize specific VPLS routing instances for faster convergence and traffic restoration. Because the router repairs next hops for high-priority VPLS routing instances first, the traffic traversing a VPLS routing instance configured with `high` fast reroute priority is restored faster than the traffic for VPLS routing instances configured with `medium` or `low` fast reroute priority.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Default

`low`

Options

`high`—Set the fast reroute priority for a VPLS routing instance to high. During a fast reroute event, the router repairs next hops for high-priority VPLS routing instances first.

`low`—Set the fast reroute priority for a VPLS routing instance to low, which is the default. During a fast reroute event, the router repairs next hops for low-priority VPLS routing instances last.

`medium`—Set the fast reroute priority for a VPLS routing instance to medium. During a fast reroute event, the router repairs next hops for medium-priority VPLS instances after high-priority VPLS routing instances but before low-priority VPLS routing instances.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

fast-synchronize

IN THIS SECTION

- Syntax | 7270
- Hierarchy Level | 7270
- Description | 7270
- Required Privilege Level | 7271
- Release Information | 7271

Syntax

```
fast-synchronize;
```

Hierarchy Level

```
[edit system commit]
```

Description

Configure commits to run in parallel (simultaneously) on both the primary and backup Routing Engines to reduce the time required for commit synchronization. The `fast-synchronize` configuration is valid only on systems with two Routing Engines.

NOTE: Starting in Junos OS Release 18.2R1, Junos OS does not support the configuration option `commit fast-synchronize` at the `[edit system]` hierarchy level for all the products with single Routing Engine for which `chassis redundancy graceful-switchover` is not supported. This option is disabled from the CLI.

NOTE:

- When the `fast-synchronize` statement is configured, the commits on the primary Routing Engine and the backup Routing Engine run in parallel. In this process, the configuration is validated only on the Routing Engine where you execute the `commit` command. Therefore, it is recommended not to include too many configuration details in groups like re0 and re1, because the configuration specified in group re0 is applied only if the current Routing Engine is in slot 0. Likewise, the configuration specified in group re1 is applied only if the current Routing Engine is in slot 1.
- Ensure that the Junos OS software version running on both the Routing Engines is same.
- We support fast-synchronize commit model as the default commit model for all Junos OS and Junos OS Evolved dual Routing Engine devices, EX Series Virtual Chassis, and MX Series Virtual Chassis. In this model, the system executes commit check and activation simultaneously on both the Routing Engines, reducing commit latency and improving operational efficiency. However, for Junos OS Evolved, configuration validation is performed only on the Routing Engine on which the commit command is executed.

Note the following prerequisites before configuring the `fast-synchronize` statement:

- Enable graceful Routing Engine switchover (GRES) by configuring the `chassis redundancy graceful-switchover` command.
- Configure the `system commit synchronize` command to automatically result in a commit synchronize action between dual Routing Engines within the same chassis.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
25.4R1	Starting in Junos OS and Junos OS Evolved 25.4R1, we support fast-synchronize commit model as the default commit model for all Junos OS and Junos OS Evolved dual Routing Engine devices, EX Series Virtual Chassis, and MX Series Virtual Chassis.

[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options],
[edit routing-options],
[edit routing-instances routing-instance-name routing-options]
```

Description

Specify a backup path in case the primary path becomes unusable.

You specify one or more objects with common characteristics within a group. All objects are treated as /32 host addresses. The objects can be a LAN interface, a router ID, or a point-to-point link. Sequence is insignificant.

Changing the fate-sharing database does not affect existing established LSPs until the next CSPF reoptimization. The fate-sharing database does affect fast-reroute detour path computations.

Options

`cost` *`value`*—Cost assigned to the group.

- **Range:** 1 through 65,535
- **Default:** 1

`from` *`address`*—Address of the router or address of the LAN/NBMA interface. For example, an Ethernet network with four hosts in the same fate-sharing group would require you to list all four of the separate `from` addresses in the group.

`group` *`group-name`*—Each fate-sharing group must have a name, which can have a maximum of 32 characters, including letters, numbers, periods (.), and hyphens (-). You can define up to 512 groups.

`to` *`address`*—(Optional) Address of egress router. For point-to-point link objects, you must specify both a `from` and a `to` address.

use-for-post-convergence-lfa—Use this fate-sharing group as a constraint for the backup path computed by topology-independent loop-free alternate (TI-LFA).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

QFX Series that Support FCoE-FC Gateway Configuration

```
[edit fc-fabrics fc-fabric-name protocols fip]
```

Description

Set the FCoE mapped address prefix (FC-MAP) value for the FCoE VLAN to match the FC switch (or FCoE forwarder) FC-MAP value for the FC fabric. The FC-MAP value is a unique MAC address prefix an FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN).

You can configure the FC-MAP value or use the default value. The default FC-MAP value is different for VN_Port to VF_Port (VN2VF_Port) FIP snooping (0x0EFC00) than for VN_Port to VN_Port (VN2VN_Port) FIP snooping.

The FC switch provides the FC-MAP value to FCoE nodes (ENodes) in the FIP discovery advertisement message. If the EX Series switch or the QFX Series FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, neither device discovers the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. The FC switch accepts only FCoE traffic that uses the correct FC-MAP value as part of the VN_Port MAC address.

When the QFX Series acts as an FCoE-FC gateway, the FC-MAP value for the gateway and the FCoE devices must match the FC switch FC-MAP value in order to communicate with the FC switch.

> **NOTE**: Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

Options

fc-map-value—FC-MAP value, hexadecimal value preceded by “0x”.

- **Range:** 0x0EFC00 through 0x0EFCFF

fcoe-lag

IN THIS SECTION

- Syntax | 7289
- Hierarchy Level | 7289
- Description | 7289
- Required Privilege Level | 7290
- Release Information | 7290

Syntax

```
fcoe-lag;
```

Hierarchy Level

```
[edit interfaces lag-interface-name aggregated-ether-options]
```

Description

Configure a special link aggregation group (LAG) to transport Fibre Channel over Ethernet (FCoE) traffic and regular Ethernet traffic across the same link aggregation bundle.

An FCoE LAG ensures that FCoE traffic uses the same link within a LAG to transmit and receive information between an FCoE device and a Fibre Channel (FC) SAN switch across a QFabric system Node device. This preserves the point-to-point link emulation that FC requires. A standard LAG uses a hashing algorithm to determine the LAG link used for each communication, so with a standard LAG, you cannot guarantee that communication between an FCoE device and the QFabric system Node device always uses the same link. If communication between the FCoE device and the QFabric system Node device uses different physical links, the SAN terminates the link.

An FCoE LAG treats regular Ethernet traffic (traffic that is not FCoE traffic) in the same way as on a standard LAG, providing link redundancy and load-balancing for the regular Ethernet traffic. An FCoE LAG does not provide link redundancy or load balancing for FCoE traffic.

On FCoE-FC gateways, if the gateway has one or more untrusted FC fabrics, you must also disable FIP snooping scaling on the gateway by including the `no-fip-snooping-scaling` option in the `[edit fc-options]` hierarchy.

Syntax

```
fcoe-trusted;
```

Hierarchy Level

Original CLI

```
[edit ethernet-switching-options secure-access-port interface interface-name]
```

ELS CLI for Platforms that Support FCoE

```
[edit vlans vlan-name forwarding-options fip-security interface interface-name]
```

> **NOTE**: The `fcoe-trusted` configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

```
[edit fc-fabrics fc-fabric-name protocols fip]
```

Description

Configure the specified 10-Gigabit Ethernet interface to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.

(QFX Series FCoE-FC gateway) Configure the specified local Fibre Channel fabric to trust FCoE traffic on all ports in the fabric. Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted by removing the `fcoe-trusted` configuration from the fabric forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.4.

Statement introduced for the FC fabric in Junos OS Release 11.3 for the QFX Series.

Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure Content Security features, antivirus, antispam, content-filtering, and web-filtering by creating feature profiles.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Starting in Junos OS Release 21.4R1, content evaluation is based of the file content. The file type-based evaluation of content is deprecated and the related configurations are hidden. So, the content filtering options in this hierarchy is deprecated and not supported from Junos OS Release 21.4R1.

You can use the legacy functionality if you do not want to migrate to enhanced content filtering functionality. You will be allowed to use the legacy configurations, but all the legacy configuration knobs are deprecated and hidden. Also, you will receive system logs and error message warnings when you use the legacy configuration options.

The Kaspersky, Express antivirus and Surf-Control features are not supported from Junos OS Release 15.1X49-D10 onwards. For previous releases, statement introduced in Release 9.5.

Starting with Junos OS Release 18.2R1, the following commands under the `[edit security utm feature-profile]` hierarchy level are deprecated:

- `set web-filtering type`
- `set web-filtering url-blacklist`
- `set web-filtering url-whitelist`
- `set web-filtering http-persist`
- `set web-filtering http-reassemble`
- `set web-filtering traceoptions`
- `set web-filtering juniper-enhanced cache`
- `set web-filtering juniper-enhanced reputation`
- `set web-filtering juniper-enhanced query-type`
- `set anti-virus mime-whitelist`

- set anti-virus url-whitelist
- set anti-virus type
- set anti-virus traceoptions
- set anti-virus sophos-engine
- set anti-spam address-blacklist
- set anti-spam address-whitelist
- set anti-spam traceoptions
- set content-filtering traceoptions

no-safe-search option added for Websense redirect and Juniper local in Junos OS Release 20.2R1.

Description

When you monitor packets, you need to specify what information you want to collect about them.

Options

aggregate-intf-member-id	ID for a member of a link aggregation group (LAG) or an equal-cost multipath (ECMP) group.
chip-delay	The amount of time the packet takes to transit the ASIC.
egress-drop-reason	The reason the packet is dropped at egress.
flow-start-end-time	The flow start and end time.
ingress-drop-reason	The reason the packet is dropped at ingress.
inter-arrival-time	The time difference between two consecutive packets at ingress.
inter-departure-time	The time difference between two consecutive packets at egress.
queue-congestion-level	Queue congestion level
security-enable	Enable security analytics; specify that Denial-of-Service (DoS) attacks are reported to the collector.
shared-pool-congestion	Shared pool congestion level

feb (Assigning a FEB to a Redundancy Group)

IN THIS SECTION

- Syntax | 7307
- Hierarchy Level | 7307
- Description | 7307
- Options | 7307
- Required Privilege Level | 7307
- Release Information | 7308

Syntax

```
feb slot-number (backup | primary);
```

Hierarchy Level

```
[edit chassis redundancy feb redundancy-group group-name]
```

Description

On M120 routers only, configure a Forwarding Engine Board (FEB) as part of a FEB redundancy group.

Options

slot-number—Slot number of the FEB. The range of values is from **0** to **5**.

backup—(Optional) For each redundancy group, you must configure exactly one backup FEB.

primary—(Optional) For each redundancy group, you can optionally configure one primary FEB.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.2.

fec(fec108 | fec74 | fec91 | none);
```

Hierarchy Level

```
[edit dynamic-profiles name interfaces name ether-options],
[edit dynamic-profiles name logical-systems name interfaces name ether-options],
[edit interfaces name ether-options]
```

Description

(PTX10001-36MR, PTX10003-8T, PTX10003-16T, PTX10004, PTX10008, QFX5220-32CD, and QFX5220-128C) Enable or disable RS-FEC (Reed-Solomon Forward Error Correction) for 25, 50, 100, 400-Gigabit Ethernet interface. By default, the Junos OS software enables or disables forward error correction based on the plugged-in optics. For instance, Junos OS software enables RS-FEC for 25G or 50G SR4 optics and disables RS-FEC for 25G or 50G LR4 optics.

If you enable or disable RS-FEC using this statement, this behavior applies to any 25-Gigabit Ethernet or 50-Gigabit Ethernet optical transceiver installed in the port associated with the interface.

You can configure forward error correction (FEC) clauses CL74 on 25-Gigabit and 50-Gigabit interfaces, and CL91 on 25-Gigabit or 50-Gigabit interfaces. Since the FEC clauses are applied by default on these interfaces, you must disable the FEC clauses if you do not want to apply them.

FEC mode is assigned by default. If there is a FEC mismatch, the link between nodes can go down. You must disable FEC mode if you do not want it assigned by default.

To view the FEC mode on an interface, use the `show interfaces interface-name` command.

For instance, consider two peer nodes, Node1 and Node2. Node1 is currently running Junos OS Evolved release 21.1R1 and the peer node (Node2) is currently running any Junos OS Evolved release prior to 21.1R1. The link between the two nodes will go down because of FEC mismatch. To enable the link to come back up, you must manually change the FEC on any one node by using the `fec` option at the `[edit interfaces <interface-name> ether-options]` hierarchy level.

Default FEC for prior to 21.1 Junos OS Evolved 21.1 is FEC74 and from 21.1 Junos OS Evolved is FEC91.

When FEC mode is FEC74 or FEC91 or NONE for all channels, FEC gets locked and interface is UP. For example, when FEC91 is configured together with FEC74 or NONE, on channel-0 and 1 or channel-2 and 3, link goes down for both channels.

Table 53: Link status for FEC combination of channel 2 and 3

Physical channel 0 (2)	Physical channel 1 (3)	Link Status
FEC74	FEC74	UP
FEC91	FEC91	UP
NONE	NONE	UP
FEC74	NONE	UP
NONE	FEC74	UP
FEC74	FEC91	DOWN

FEC91	FEC74	DOWN
FEC91	NONE	DOWN
NONE	FEC91	DOWN

There is no dependency between Channel 0(1) and channel 2(3). FEC74 can be configured with NONE to any interface et-x/y/x:(0/1/2/3) and link comes UP leads to the following:

- When you configure FEC91 on interface-x/y/z:0 then you must configure FEC91 on interface- x/y/z:1.
- When you configure FEC91 on interface-x/y/z:2 then you must configure FEC91 on interface- x/y/z:3.
- When you configure FEC74 or NONE on interface-x/y/z:0/1 then you must configure FEC74 or NONE on interface- x/y/z:2/3.

Options

fec108 IEEE 802.3by Clause 108, Reed-Solomon FEC (RS-FEC) on 25g links

fec74 FEC74 enabled

fec91 IEEE 802.3bj Clause 91, Reed-Solomon FEC (RS-FEC)

none FEC disabled

Default

Junos OS software automatically enables or disables 25-Gigabit Ethernet and 50-Gigabit Ethernet for FEC91 based on the type of pluggable optics used.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Syntax

```
fec (fec91 | fec74 | none)
```

Hierarchy Level

```
[edit interfaces interface-name gigether-options]
```

Description

Supported on the following:

- ACX6360-OX Transponders
- ACX6360 routers
- MX Series Routers with MPC7E, MPC8E, and MPC9E
- MX10003 Router with MX10003 MPC
- MX204 Router
- PTX1000
- FPC3-PTX-U2 and FPC3-PTX-U3 on PTX5000
- QFX series switches

(ACX6360-OX Transponders, ACX6360 routers, MX Series Routers with MPC7E, MPC8E, and MPC9E, MX10003 Router with MX10003 MPC, MX204 Router, PTX1000, FPC3-PTX-U2 and FPC3-PTX-U3 on PTX5000, and QFX series switches) Enable or disable Reed-Solomon Forward Error Correction (RS-FEC) for a 100-Gigabit Ethernet interface. By default, the Junos OS software enables or disables FEC based on the plugged-in optics. For example, Junos OS enables RS-FEC for 100GbE SR4 optics and disables RS-FEC for 100GbE LR4 optics.

This statement allows you to override the default behavior and explicitly enable or disable RS-FEC. For example, you can extend the reach of 100GbE LR4 optics when you explicitly enable RS-FEC for the optics. RS-FEC is compliant with IEEE 802.3-2015 Clause 91.

Once you enable or disable RS-FEC using this statement, this behavior applies to any 100-Gigabit Ethernet optical transceiver installed in the port associated with the interface.

You can configure forward error correction (FEC) clauses CL74 on 25-Gigabit and 50-Gigabit interfaces, and CL91 on 100-Gigabit interfaces. Since the FEC clauses are applied by default on these interfaces, you must disable the FEC clauses if you do not want to apply them.

> **NOTE**: FPC-PTX-P1-A and FPC2-PTX-P1A on PTX5000 routers do not support RS-FEC. FPC3-SFF-PTX-1H and FP3-SFF-PTX-1T with PE-10-U-QSFP28 PIC and LR4 optics on PTX3000 and PTX5000 routers supports RS-FEC only on port 2. For PE-10-U-QSFP28 with LR4 optics, RS-FEC is the default FEC mode on port 2 and NONE is the default FEC mode on ports 0,1,3 through 9. For PE-10-U-QSFP28 with SR4 optics, RS-FEC is enabled by default on all ports. Do not modify the FEC mode on any port irrespective of the optics installed.

To check the FEC status, use the `show interfaces` *`interface-name`* command.

Default

Junos OS software automatically enables or disables RS-FEC based on the type of pluggable optics used.

Options

fec91 Enables RS-FEC. RS-FEC is compliant with IEEE 802.3-2015 Clause 91.

fec74 Enables RS-FEC. RS-FEC is compliant with IEEE 802.3-2015 Clause 74.

none Disables RS-FEC.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

```

Hierarchy Level (ACX6360, ACX5448-D)

```
[edit interfaces interface-name optics-options]
```

Description

Enable forward error correction (FEC) mode.

Default

If you do not specify a mode, the default mode is `gfec`. On PTX Series routers with P1-PTX-2-100G-WDM, the default value is `gfec-sdfec`. On PTX Series routers with PTX-5-100G-WDM and on MX Series routers with MIC3-100G-DWDM, the default value is `sdfec`.

Options

efec—(M Series, MX Series routers and PTX Series routers only) G.975.1 I.4 enhanced forward error correction (EFEC) is configured to detect and correct bit errors. This mode is supported only on 10G ports and not supported on the 40G and 100G ports.

gfec—(M series, MX Series routers and PTX Series routers only) G.709 generic forward error correction (GFEC) mode is configured to detect and correct bit errors.

gfec-sdfec—(PTX Series routers only) GFEC and soft-decision forward error correction (SD-FEC) modes are configured to detect and correct bit errors.

hgfec—(MX Series routers only) High gain forward error correction mode is configured to detect and correct bit errors.

sdfec—(MX Series routers, PTX Series routers, and ACX6360 routers only) Sky-Compatible Soft-decision forward error correction mode is configured to detect and correct bit errors.

sdfec15—(ACX6360 routers only) Soft Decision Forward Error Correction with 15 percent overhead is configured to detect and correct bit errors.

none—(M Series and MX Series routers only) FEC mode is not configured.

> **NOTE**: On MX Series routers with MIC3-100G-DWDM and PTX Series routers with PTX-5-100G-WDM, none option is not supported. The `fec` mode must be enabled on the MIC3-100G-DWDM MIC and the PTX-5-100G-WDM PIC.

ufec—(MX Series routers and PTX Series routers only) G.975.1 I.7 Ultra Forward Error Correction (UFEC) mode is configured to detect and correct bit errors. This mode is supported only on 10G ports and not supported on the 40G and 100G ports.

Required Privilege Level

Release Information

Statement introduced in Junos OS Release 12.1X46-D25 on SRX Series Firewalls and on cSRX Container Firewall in Junos OS Release 22.2R1.

Starting with Junos OS Release 25.2R1, you can authenticate dynamic address feed servers before downloading feeds into the SRX Series devices and vSRX 3.0, using the `username` and `password` options. These new authentication options allow you to securely obtain feeds from local or remote web servers, facilitating automatic scaling of business operations and Layer 7 services.

Hierarchy Level

```
[edit chassis pem],
[edit chassis lcc lcc-number pem]
```

Description

Configure the number of input feeds connected to the six-input DC power supply on T640, T1600, or T4000 routers. The value assigned to the `feeds` statement must be equal to the number of input feeds provided to the power supply.

When providing four or five input feeds on standalone routers, you must configure the `feeds` statement at the `[edit chassis pem]` hierarchy level. When providing four or five input feeds to an LCC router in a routing matrix, you must configure the `feeds` statement at the `[edit chassis lcc lcc-number pem]` hierarchy level.

NOTE:

- Before configuring input feeds for your router, see the *T640 Core Router Hardware Guide*, *T1600 Core Router Hardware Guide*, or *T4000 Core Router Hardware Guide* for special considerations and for the number of input feeds supported by the router.
- All power supplies in the router must use the same number of inputs feeds.

Options

- **Range:** 4 through 6
- **Default:** 6

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1.

fib-install-priority

IN THIS SECTION

- Syntax (PTX10001-36MR, PTX10004, PTX10008, PTX10016 Devices) | **7329**
- Hierarchy Level | **7329**
- Description | **7330**
- Options | **7330**
- Required Privilege Level | **7330**
- Release Information | **7331**

Syntax (PTX10001-36MR, PTX10004, PTX10008, PTX10016 Devices)

```
fib-install-priority <high/medium/>
```

Hierarchy Level

```
[edit policy-options policy-statement policy-name term term-name then]
```

Description

Assign a FIB install priority, as high or low, for matching routes. Non-matching routes are by default classified as unprioritized. When the routes are installed in the forwarding table, the number of forwarding table entries that routes of a particular priority get depends on the memory percentage allotted for the priority. Refer "fib-prioritization" on page 7334 to read more.

Issue the `run show route <prefix> extensive` command as shown in the following example to view the FIB install priority of a particular route.

```
user@host# run show route 10.0.1.1 extensive

inet.0: 33 destinations, 35 routes (33 active, 0 holddown, 0 hidden)
10.0.1.1/32 (1 entry, 1 announced)
TSI:
KRT in-kernel 10.0.1.1/32 -> {10.1.2.1}
   *Static Preference: 5
       FIB Installation Priority: INSTALL PRIORITY MEDIUM
       Next hop type: Router, Next hop index: 11045
       Address: 0x55eaafc82f1c
       Next-hop reference count: 3, key opaque handle: (nil), non-key opaque handle: (nil)
       Next hop: 10.1.2.1 via et-0/0/3.0, selected
       Session Id: 9
       State: <Active Int Ext>
       Local AS:100
       Age: 26
       Validation State: unverified
       Task: RT
       Announcement bits (1): 0-KRT
       AS path: I
       Thread: junos-main
```

Options

- high – Set the FIB install priority as high.
- medium – Set the FIB install priority as medium.

Required Privilege Level

- interface—To view this statement in the configuration.

- interface-control—To add this statement to the configuration.

Release Information

Command support introduced in Junos OS Evolved Release 22.4R1 for the PTX Series.

fib-local

IN THIS SECTION

- Syntax | 7331
- Hierarchy Level | 7331
- Description | 7331
- Required Privilege Level | 7332
- Release Information | 7332

Syntax

```
fib-local;
```

Hierarchy Level

```
[edit chassis fpc fpc-number route-localization]
```

Description

Configure the Packet Forwarding Engine on an FPC as FIB-local.

NOTE: At least, one Packet Forwarding Engine must be configured as **fib-local** for the commit operation to be successful. If you do not configure **fib-local** for the Packet Forwarding Engine, the CLI displays an appropriate error message and the commit fails.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

RELATED DOCUMENTATION

fib-next-hop-split

IN THIS SECTION

- Syntax | 7332
- Hierarchy Level | 7333
- Description | 7333
- Options | 7333
- Required Privilege Level | 7333
- Release Information | 7333

Syntax

```
fib-next-hop-split {
    labeled-isis;
}
```

Hierarchy Level

```
[edit routing-options forwarding-table]
```

Description

You must configure the `fib-next-hop-split` statement in conjunction with the "egress-chaining" on page 6484 and "transit" on page 31227 statements to enable route resolution over labeled IS-IS routes using flattened router next hops. Configuring the `fib-next-hop-split` statement alone does not have any effect.

When you configure the `no-labeled-isis` statement at the `[edit routing-options forwarding-table chained-composite-next-hop transit]` hierarchy level, the labeled IS-IS routes are flattened to ensure that the segment routing traffic-engineering (SPRING-TE) routes are not resolved any further over another composite next hop.

Options

labeled-isis Create composite-chained next hops for labeled IS-IS routes.

In addition to enabling `fib-next-hop-split`, you can also configure "egress-chaining" on page 6484 to reduce the number of chained next hops present in a route that involves resolution over multiple routes with labels.

Required Privilege Level

routing

Release Information

Statement introduced in Junos OS Release 20.4R1.

fib-prioritization

IN THIS SECTION

- Syntax (PTX10001-36MR, PTX10004, PTX10008, PTX10016 Devices) | 7334
- Hierarchy Level | 7334
- Description | 7334
- Options | 7335
- Required Privilege Level | 7335
- Release Information | 7335

Syntax (PTX10001-36MR, PTX10004, PTX10008, PTX10016 Devices)

```
chassis {
    fib-prioritization {
        high-priority-memory-percent 0...100
        medium-priority-memory-percent 0...100
    }
}
```

Hierarchy Level

```
[edit chassis]
```

Description

Configure the memory allocation percent to install high and medium priority routes in the Forwarding Information Base (FIB) at device level. Reserve a percentage of memory on chassis for high-priority and medium priority routes, for IPv4, IPv6, and MPLS, BGP, IGP, static, aggregate, generated, and PRPD routes protocol data. The FIB prioritization configuration is a system-wide configuration. The amount of

high or medium priority routes supported are different, based on memory available on the FPCs. Please note, that the system must be rebooted every time the FIB prioritization is changed.

```
chassis {
    fib-prioritization {
        high-priority-memory-percent 50
        medium-priority-memory-percent 30
    }
}
```

NOTE: Total value of high priority and medium priority percentage must not exceed 100

Options

fib-prioritization—FIB prefix prioritization to install high and medium priority routes at chassis-level.

- high-priority-memory-percent – Memory allocation for high priority protocol routes. Value range for memory percent is 0 to 100.
- medium-priority-memory-percent – Memory allocation for medium priority protocol routes. Value range for memory percent is 0 to 100.

Required Privilege Level

Syntax

```
file filename {
    files number-of-files;
    size size;
}
```

Hierarchy Level

```
[edit services analytics collector local]
[edit services analytics queue-statistics]
[edit services analytics traffic-statistics]
```

Description

Enable the logging of queue or traffic monitoring statistics in a local file. This statement does not enable monitoring.

Default

This feature is disabled by default.

Options

filename Specify a filename for storing queue and traffic monitoring statistics in the Comma-separated Values (CSV) format. The file is stored in the **/var/log/** directory of your device.

If you do not specify a filename, the data is not stored in a file.

> **NOTE**: In Junos OS Release 13.2X51-D15 or later, you configure a single filename to store both queue and traffic monitoring statistics. In Junos OS Release 13.2X51-D10 and earlier, you configure separate files for storing monitoring data, one for queue statistics, and another for traffic statistics.

files ***number-of-files*** Specify the number of files to store locally. After the number of files with the maximum file size is reached, the system starts over and writes the data to the first file.

- **Range:** 2 to 1,000 files.

size ***size*** Configure the file size in megabytes (MB).

- **Syntax:** `xm` to specify MB.
- **Range:** 10 to 4095 MB

Network Analytics Overview

file (App Engine Virtual Machine Management Service)

IN THIS SECTION

- Syntax | 7352
- Hierarchy Level | 7352
- Description | 7353
- Options | 7353
- Required Privilege Level | 7354
- Release Information | 7354

Syntax

```
file {filename <files number> | match | no-world-readable | size size | world-readable
}
```

Hierarchy Level

```
[edit system processes app-engine-virtual-machine-management-service traceoptions]
```

Description

> ⚠ **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Trace file information for the Virtual Machine Management Daemon (vmmd), which communicates with the host OS.

Options

filename Name of the file in which the trace information is stored. By default, the file is created in the **/var/log** directory.

`files` ***number*** (Optional) Maximum number of trace files. When a trace file reaches the size specified by the `size` option, the filename is appended with 0 and compressed. For example, when a trace file named trace-file-log reaches size *size*, it is compressed and renamed as trace-file-log.0.gz. When trace-file-log reaches size *size* for the second time, trace-file-log.0.gz is renamed as trace-file-log.1.gz and trace-file-log is compressed and renamed as trace-file-log.0.gz. This renaming sheme ensures that the older logs have a greater index number. When number of trace files reaches *number*, the oldest file is deleted.

If you specify a maximum number of files, you also must specify a maximum file size with the `size` option and a filename.

- **Range:** 2 through 1000
- **Default:** 10

`match` Refine the output to include only those lines that match the given regular expression.

`no-world-readable` Restrict file access to the user who created the trace files.

size*size* Maximum size of each trace file . By default, the number entered is treated as bytes. Alternatively, you can include a suffix to the number to indicate kilobytes (KB), megabytes (MB), or gigabytes (GB). If you specify a maximum file size, you also must specify a maximum number of trace files with the files option.

- **Range:** 10 KB through 1 GB
- **Default:** 128 KB

`world-readable` Enable unrestricted file access.

Required Privilege Level

system-control

Release Information

Statement introduced in Junos OS Release 15.1F3.

```

```
        no-remote-trace;
    }
    username username;
}
```

Hierarchy Level

```
[edit system extensions extension-service application]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

For files in the `[edit system extensions extension-service application]` hierarchy level, specify the configuration for each file in the extension-service application.

Options

arguments *arguments*
: Specify the command-line arguments called by a JET application. A program can take any number of command-line arguments. Enter the arguments in the way the application expects. Developer must supply this information.

daemonize
: Specify the file as daemonized. An application runs as a daemonized process in the background. An application configured to run as a daemonized process is automatically triggered upon commit. A non-daemonized application must be triggered manually from the command-line client.

filename
: Local filename of the script file.

interpreter (bash | python | python3)
: Specify whether a device running Junos OS Evolved should run a daemonized on-device JET application using Bash, Python 2, or Python 3.

> **NOTE**: Starting in Junos OS Evolved Release 22.3R1, Python 2.7 is no longer supported. The `python` statement is deprecated. Use the `python3` statement instead.

`optional`
Allow the operating system to commit the configuration even if the file is not available at the **/var/db/scripts/jet** file path.

`respawn-on-normal-exit`
Automatically restart a daemonized JET application written in Python after you exit the application normally, such as when you upgrade the JET application. If this option is not configured, and if the application normally exits, it will not restart automatically. This option can only be used with Python JET applications that have been configured to run as a daemonized process using the `daemonize` option.

`username` ***`username`***
Specify the name of the user under whose privileges the extension service will execute. This user name is configured at the `[edit system login]` hierarchy level. If you do not associate a user name with an extension-service application, the application is executed as user `nobody`.

- **Default:** nobody

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

maintenance—To view or add this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

`refresh`, `refresh-from`, `respawn-on-normal-exit`, `routing-instance`, and `source` options added in Junos OS Release 18.1R1.

`interpreter` option added in Junos OS Evolved Release 20.3R1.

`optional` option added in Junos OS and Junos OS Evolved Release 23.2R1.

    match-strings string-name;
    structured-data {
        brief;
    }
}
```

Hierarchy Level

```
[edit system syslog]
```

Description

Configure the logging of system messages to a file.

Starting in Junos OS Release 20.3R1, the `change-log` is a default option at [`edit system syslog file name`] hierarchy for SRX Series Firewalls. As the default option, `change-log` records all the configuration changes. In Junos OS releases earlier than 20.2R1, you need to configure `change-log`.

Options

facility—Class of messages to log. To specify multiple classes, include multiple ***facility severity*** statements. For a list of the facilities, see *Junos OS System Logging Facilities*.

severity—Severity of the messages that belong to the facility specified by the paired ***facility*** name. Messages with severities of the specified level and higher are logged. For a list of the severities, see *System Log Message Severity Levels*.

file ***filename***—File in the **/var/log** directory in which to log messages from the specified facility. To log messages to more than one file, include more than one **file** statement.

allow-duplicates—Do not suppress the repeated messages.

archive—Specify the archive file information.

- *archive-sites*—Specify a list of destination URLs for the archived log files.
  - *url*—Specify the primary and failover URLs to receive archive files.
- *binary-data*—Mark file such that it contains binary data.
- *no-binary-data*—Do not mark the file such that it contains binary data.
- *files*—Specify the number of files to be archived. Range: 1 through 1000 files.
- *size*—Specify the size of files to be archived. Range: 65,536 through 1,073,741,824 bytes.
- *world-readable*—Allow any user to read the log file.
- *no-world-readable*—Do not allow any user to read the log file.
- *start-time*—Specify the start time for file transmission. Enter the start time in the yyyy-mm-dd.hh:mm format.
- *transfer-interval*—Specify the frequency at which to transfer the files to archive sites.

explicit-priority—Include the priority and facility in messages.

match—Specify the regular expression for lines to be logged.

structured-data—Log the messages in structured log format.

- *brief*—Omit English language text from the end of the logged message.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure the file settings for tracing resource public key infrastructure (RPKI) BGP route validation.

Options

filename Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory `/var/log`.

files *number* (Optional) Maximum number of trace files. When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`, then `trace-file.1`, and so on, until the maximum number of trace files is reached (*x*k to specify KB, *x*m to specify MB, or *x*g to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the `size` option.

- **Range:** 2 through 1000 files
- **Default:** 3 files

no-world-readable (Optional) Restrict file access to the user who created the file.

size *size* (Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`, then `trace-file.1`, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the `files` option.

- **Syntax:** *x*k to specify KB, *x*m to specify MB, or *x*g to specify GB
- **Range:** 10 KB through 1 GB
- **Default:** 128 KB

world-readable (Optional) Enable unrestricted file access.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

file archive

IN THIS SECTION

- Syntax | 7388
- Description | 7389
- Options | 7389
- Required Privilege Level | 7389
- Output Fields | 7389
- Sample Output | 7390
- Release Information | 7391

Syntax

```
file archive destination destination source source
<compress>
<exclude> filepattern
```

```
<routing-instance>
<source-address>
```

Description

Archive, and optionally compress, one or multiple local system files as a single file, locally or at a remote location.

For information on valid filename and URL formats, see *Format for Specifying Filenames and URLs in Junos OS CLI Commands*.

Options

destination ***destination***	Destination of the archived file or files. Specify the destination as a URL or filename. The Junos OS adds one of the following suffixes if the destination filename does not already have it: • For archived files—The suffix **.tar** • For archived and compressed files—The suffix **.tgz**
source ***source***	Source of the original file or files. Specify the source as a URL or filename.
compress	(Optional) Compress the archived file with the GNU zip (gzip) compression utility. The compressed files have the suffix **.tgz**.
exclude	(Optional) Specify the file pattern to exclude. `exclude` helps to exclude files that delay compression or files that need not be compressed.
routing-instance ***routing-instance-name***	(Optional) Name of the routing-instance.
source-address ***address***	(Optional) Local address to use in originating the connection.

Required Privilege Level

maintenance

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

file archive (Multiple Files)

The following sample command archives all messages files in the local directory `/var/log/` as the single file `messages-archive.tar`.

```
user@host> file archive source /var/log/messages* destination /var/log/messages-archive.tar
/usr/bin/tar: Removing leading / from absolute path names in the archive.

user@host>
```

file archive (Single File)

The following sample command archives a single messages file in the local directory `/var/log/` as the single file `messages-archive.tar`.

```
user@host> file archive source /var/log/messages destination /var/log/messages-archive.tar
/usr/bin/tar: Removing leading / from absolute path names in the archive.

user@host>
```

file archive (with Compression)

The following sample command archives and compresses all messages files in the local directory `/var/log/` as the single file `messages-archive.tar`.

```
user@host> file archive compress source /var/log/messages* destination /var/log/messages-
archive.tgz
/usr/bin/tar: Removing leading / from absolute path names in the archive.
user@host>
```

File Archive Using Secure Copy Protocol (scp) with 'source-address' and 'routing-instance' options

To use the scp command to archive a file with the `source-address` and `routing-instance` options, enter the following command:

```
user@host> file archive source source destination scp:// destination source-address address
routing-instance instance-name
```

File Archive Compress (with Exclude Option)

The following sample command archives and compresses all messages files in the local directory `/var/log/` and excludes the single file pattern specified.

```
user@host>file archive compress source /var/log destination /var/tmp/sample exclude trace*
/bin/tar: Removing leading `/' from member names
/bin/tar: /var/log/journal/dbf38b9cae4d11ec862e4fb4fcef8787/system.journal: file changed as we
read it
```

Release Information

Command introduced before Junos OS Release 7.4.

`exclude` option added in Junos OS Release 20.3R1 and Junos OS Evolved Release 20.3R1.

`routing-instance` option added in Junos OS Release 18.4R1.

`source-address` option added in Junos OS Release 18.4R1.

file change-owner

IN THIS SECTION

- Syntax | 7392
- Description | 7392
- Options | 7392
- Required Privilege Level | 7393
- Sample Output | 7393
- Release Information | 7394

Syntax

```
file change-owner filename
<user user>
<group group>
<to to>
<recurse>
```

Description

Change the ownership of a file to a specified user, group or both.

Options

filename Filename to change owner.

user New owner of the file.

group New group of the file.

to New owner:group of the file.

recurse Operate recursively. Changes the ownership of all files and subdirectories within the specified directory.

Required Privilege Level

maintenance

Sample Output

file change-owner (user)

The following sample command changes the owner of /var/tmp/config.txt to labuser. The group remains unchanged.

```
user@host> file change-owner user labuser /var/tmp/config.txt
```

file change-owner (group)

The following sample command changes the group of /var/tmp/config.txt to staff. The user remains unchanged.

```
user@host> file change-owner group staff /var/tmp/config.txt
```

file change-owner (to)

The following sample command sets the owner of the file to labuser and the group to staff.

```
user@host> file change-owner to labuser:staff /var/tmp/config.txt
```

file change-owner (recurse)

The following sample command recursively changes the ownership of all files and subdirectories within /var/home/john/config-dir directory.

```
user@host> file change-owner recurse /var/home/john/config-dir user user1
user@host:~ # file list detail /var/home/john/config-dir
total 1
-rw-r--r--  1 user1 20   0 Jun 16 15:13 1.conf
drwxr-xr-x  2 user1 20 512 Jun 16 15:13 archive-dir
```

Release Information

Command introduced before Junos OS Release 7.4.

file change-permission

IN THIS SECTION

- Syntax | 7394
- Description | 7394
- Options | 7394
- Required Privilege Level | 7394
- Sample Output | 7395
- Release Information | 7395

Syntax

```
file change-permission filename filename permission permission
```

Description

Change permission of file.

Options

filename Filename to change mode.

permission File permission, either as symbolic (go+rw) or octal (642).

Required Privilege Level

maintenance

Sample Output

file change-permission (Octal Mode)

The following sample command makes a file readable by anyone and writable by the owner only.

```
user@host> file change-permission /tmp/foo.txt permission 644
```

file change-permission (Symbolic Mode)

The following sample command makes a file readable or executable by everyone and writable by the owner only.

```
user@host> file change-permission /tmp/foo.txt permission u=rwx,go=rx
```

Release Information

Command introduced before Junos OS Release 7.4.

file checksum md5

IN THIS SECTION

- Syntax | 7396
- Description | 7396
- Options | 7396
- Required Privilege Level | 7396
- Output Fields | 7396
- Sample Output | 7396
- Release Information | 7397

Syntax

```
file checksum md5 <pathname> filename
```

Description

Calculate the Message Digest 5 (MD5) checksum of a file.

> **NOTE:**
> Junos OS uses the `md5` command to calculate file checksums while Junos OS Evolved uses the `md5sum` command instead. This difference in tools might cause variations in output format and usage. Make sure to consider these differences when verifying file integrity across platforms.

Options

pathname	(Optional) Path to a filename.
filename	Name of a local file for which to calculate the MD5 checksum.

Required Privilege Level

maintenance

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

file checksum md5

```
user@host> file checksum md5 jbundle-5.3R2.4-export-signed.tgz
MD5 (jbundle-5.3R2.4-export-signed.tgz) = $ABC123
```

Release Information

Command introduced before Junos OS Release 7.4.

file compare

IN THIS SECTION

- Syntax | **7401**
- Description | **7401**
- Options | **7401**

- Required Privilege Level | 7402
- Output Fields | 7402
- Sample Output | 7402
- Release Information | 7404

Syntax

```
file compare (files filename filename)
<context | unified>
<ignore-white-space>
```

Description

Compare two local files and describe the differences between them in default, context, or unified output styles:

- `Default`—In the first line of output, `c` means lines were changed between the two files, `d` means lines were deleted between the two files, and `a` means lines were added between the two files. The numbers preceding this alphabetical marker represent the first file, and the lines after the alphabetical marker represent the second file. A left angle bracket (<) in front of output lines refers to the first file. A right angle bracket (>) in front of output lines refers to the second file.
- `Context`—The display is divided into two parts. The first part is the first file; the second part is the second file. Output lines preceded by an exclamation point (`!`) have changed. Additions are marked with a plus sign (`+`), and deletions are marked with a minus sign (`-`).
- `Unified`—The display is preceded by the line number from the first and the second file (*xx,xxx,x*). Before the line number, additions to the file are marked with a plus sign (`+`), and deletions to the file are marked with a minus sign (`-`). The body of the output contains the affected lines. Changes are viewed as additions plus deletions.

Options

files *filename*	Names of two local files to compare.
context	(Optional) Display output in context format.

ignore-white-space	(Optional) Ignore changes in the amount of white space.
unified	(Optional) Display output in unified format.

Required Privilege Level

none

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

file compare files

```
user@host> file compare files /tmp/one /tmp/two
100c100
<             full-name "File 1";
---

file copy

IN THIS SECTION

- Syntax (Junos OS) | 7406
- Syntax (Junos OS Evolved) | 7406
- Description | 7406
- Options | 7407
- Required Privilege Level | 7408

Sample Output | 7408
Release Information | 7409

Syntax (Junos OS)

```
file copy source destination
<no-stage>
<routing-instance routing-instance-name>
<source-address source-address>
<staging-directory directory-location>
```

Syntax (Junos OS Evolved)

```
file copy source destination
<no-check-certificate>
<routing-instance routing-instance-name>
<source-address source-address>
<staging-directory directory-location>
```

Description

Copy files from one location to another location on the local device or to or from a location on a remote device reachable by the local device.

The source and destination can specify local paths and FTP, HTTP, HTTPS, and SCP URLs. For information about valid filename and URL formats, see *Format for Specifying Filenames and URLs in Junos OS CLI Commands*.

When you use the `file copy` command to transfer a file from a remote location to the Junos device or from the other Routing Engine to the local Routing Engine, the operation uses a temporary staging directory during the file transfer. The root user's staging directory is under **/var/tmp**, and the non-root user staging directory is the under the user's home directory. When the file transfer is complete, the file is moved to the destination directory. Thus, for these transfers, the staging directory must have space equal to the file's size, and the device must have space equal to twice the file's size.

Large files might exceed the space available in the default staging directory or on the device causing the file transfer to fail. If the staging directory has insufficient space, you can use the `staging-directory` option

to specify a different staging directory with more space. If the device has limited space, you can specify the `no-stage` option to bypass the staging directory and transfer the file directly to the destination directory.

> **NOTE**: If you define an ordered set of ciphers, key exchange methods, or message authentication codes (MACs) at the `[edit system services ssh]` hierarchy level, the newly-defined set is used when copying files using SCP. For more information, see *Configuring the SSH Service to Support Legacy Cryptography*.

Options

source — Specify the source URL.

destination — Specify the destination URL.

no-check-certificate — Bypass certificate validity checks when downloading a file from an HTTPS URL. We recommend that you use this option only when the server is known and trusted.

no-stage — Download a file directly to the destination directory of the device running Junos OS rather than store it in the staging directory during the file transfer.

You can use this option to download files to a device where space is limited. By bypassing the staging directory, the device only requires space equal to the file's size.

> **NOTE**: If you include the `no-stage` option and the file transfer fails, it can overwrite an existing file with the same name in the destination directory or it can result in a corrupted file. To verify the transferred file's integrity, we recommend that you compare the checksum values for the original and transferred files and ensure they match.

routing-instance *routing-instance-name* — (Optional) Specify the routing-instance to use for the connection.

`source-address` *source-address* — (Optional) Specify the local address to use in originating the connection.

`staging-directory` *directory-location* — (Optional) Specify the staging directory on the Routing Engine where a downloaded file is temporarily staged during the file transfer. Use this option when the default staging directory does not have enough space available to temporarily store the file during transfer.

- **Default:**

  (Root user) **/var/tmp/**

  (Non-root user) **/var/home/*username*/**

> **NOTE**: If you are using a literal IPv6 address in your command entry, the address must be enclosed in [ ] brackets. This format conforms to RFC 2732.

Required Privilege Level

maintenance

Sample Output

Following are some `file copy` examples.

Copy a File from the Local Device to a Personal Computer

```
user@host> file copy /var/tmp/rpd.core.4 mypc:/c/junipero/tmp

...transferring.file...... |          0 KB |   0.3 kB/s | ETA: 00:00:00 | 100%
```

Copy a Configuration File between Routing Engines

The following sample command copies a configuration file from Routing Engine 0 to Routing Engine 1:

```
user@host> file copy /config/juniper.conf re1:/var/tmp/copied-juniper.conf
```

Copy a File Using Secure Copy Protocol

The following command uses SCP to copy a file to a remote server:

```
user@host> file copy /var/log/messages scp://10.1.1.1/home/user/archive
user@10.1.1.1's password:
messages                                                      100%  521KB   1.6MB/s
00:00
```

The following command uses SCP to copy a file to a remote server as a different user:

```
user@host> file copy /var/log/messages scp://user1@10.1.1.1/home/user1/archive
user1@10.1.1.1's password:
messages                                                        100%  521KB   1.6MB/s
00:00
```

Copy a File Using File Transfer Protocol which Requires a Password

You can use FTP with the `file copy` command for additional privacy. You will be prompted for a password. Enter the following command to enable FTP:

```
root@host> file copy filename ftp://user@hostname/filename
```

In the following example, **/config/juniper.conf** is the local file and **hostname** is the FTP server:

```
root@host> file copy /config/juniper.conf ftp://user@hostname/juniper.conf
Password:
Receiving ftp: //user@hostname/juniper.conf (2198 bytes): 100%
2198 bytes transferred in 0.0 seconds (2.69 MBps)
```

NOTE: Starting in Junos OS Evolved release 22.2R2, the password prompt has changed from `Password for user@hostname:` to `Password:`

Copy a File Using a Staging Directory

The following sample command copies a file and uses a staging directory that is different from the default.

```
user@host> file copy re1:/var/tmp/junos-install-x.log /root/ staging-directory /var/tmp/tmp1
```

Release Information

Command introduced before Junos OS Release 7.4.

`source-address` option added in Junos OS Release 7.4.

`staging-directory` option added in Junos OS Release 17.3R1.

`no-check-certificate` option added in Junos OS Evolved Release 23.1R1.

`no-stage` option added in Junos OS Release 24.2R1.

Syntax

```
file list <detail | recursive> <path>
```

Description

Display a list of files on the local router or switch.

Options

none Display a list of files in the default directory. The default directory is the home directory of the user logged in to the router or switch.

detail (Optional) Display detailed information about the files. The output is similar to what is displayed by the Linux `ls -l` command.

recursive (Optional) Display detailed information about the files in the directory and all subdirectories below it.

path (Optional) List the files in a specified directory path. The path name cannot contain any special characters (`![ =;|(){}]`).

Additional Information

To view available directories, enter a space and then a slash (/) after the `file list` command. To view files within a specific directory, include a slash followed by the directory and, optionally, subdirectory name after the `file list` command.

Required Privilege Level

maintenance

Sample Output

file list

The following command lists the contents of the **/var/tmp** directory.

```
user@host> file list /var/tmp

/var/tmp:
trace_debug
package.log
pics/
downloads/
```

file list (detailed)

The following command lists detailed information about the contents of the **/var/tmp** directory.

```
user@host> file list /var/tmp detail

Release Information

Command introduced before Junos OS Release 7.4.

file rename

IN THIS SECTION

- Syntax | 7417
- Description | 7417
- Options | 7417
- Required Privilege Level | 7417
- Output Fields | 7417
- Sample Output | 7417

Release Information | 7419

Syntax

```
file rename source destination
```

Description

Rename a file on the local router or switch.

Options

destination New name for the file.

source Original name of the file. For a routing matrix, the filename must include the chassis information.

Required Privilege Level

maintenance

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

file rename

The following example lists the files in **/var/tmp**, renames one of the files, and then displays the list of files again to reveal the newly named file.

```
user@host> file list /var/tmp
dcd.core
```

```
rpd.core
snmpd.core
```

```
user@host> file rename /var/tmp/dcd.core /var/tmp/dcd.core.990413
```

```
user@host> file list /var/tmp
dcd.core.990413
rpd.core
snmpd.core
```

file rename (Routing Matrix)

The following example lists the files in **/var/tmp**, renames one of the files, and then displays the list of files again to reveal the newly named file.

```
user@host> file list lcc0-re1:/var/tmp
lcc0-re1:
--------------------------------------------------------------------------

/var/tmp:
.pccardd
sartre.conf
snmpd
syslogd.core-tarball.0.tgz

user@host> file rename lcc0-re0:/var/tmp/snmpd /var/tmp/snmpd.rr
user@host> file list lcc0-re1:/var/tmp
lcc0-re1:
--------------------------------------------------------------------------

/var/tmp:
.pccardd
sartre.conf
snmpd.rr
syslogd.core-tarball.0.tgz
```

Release Information

Command introduced before Junos OS Release 7.4.

   set $j = 0
   set $n = $arg1
   while ($j < $n)
        #printf "%x %x ",&$ch[$j],$ch[$j]
        printf "%x ",$ch[$j]
        set $j = $j + 1
        if (!($j % 16))
                printf "\n"
        end
   end
end
```

Release Information

Command introduced before Junos OS Release 7.4.

file

IN THIS SECTION

- Syntax | 7422
- Hierarchy Level | 7422
- Description | 7422
- Options | 7422
- Required Privilege Level | 7423
- Release Information | 7423

Syntax

```
file <filename> <files files> <match match> <size size> <(world-readable | no-world-readable)>;
```

Hierarchy Level

```
[edit security dynamic-vpn traceoptions (Security Dynamic VPN)]
```

Description

CAUTION: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure the trace file options. Name of the file to receive the output of the tracing operation.

In Junos OS Release 21.4R1, we've deprecated the `file` configuration statement and we might remove it completely in a future release.

Options

filename
Name of file in which to write trace information

files
Maximum number of trace files

- **Default:** 3
- **Range:** 2 through 1000

match
Regular expression for lines to be logged

no-world-readable
Don't allow any user to read the log file

size
Maximum trace file size

- **Default:** 128000
- **Range:** 10240 through 1073741824

world-readable Allow any user to read the log file

Required Privilege Level

trace

Release Information

Statement introduced in Junos OS Release 12.1X44-D10.

delete-directory | link | list | make-directory | routing-instance | rename | show | staging-
directory directory-location>
<source-address source-address>
```

Description

Archive files from the device, copy files to and from the router or switch, calculate the file checksum, compare files, delete a file from the device, list files on the device, rename a file, show file contents, or show the local address to initiate a connection.

Options

archive (Optional)	Archive, and optionally compress, one or multiple local system files as a single file, locally or at a remote location.
change-owner (Optional)	Change owner of file.
change-permission (Optional)	Change permission of file.
checksum (Optional)	Calculate the Message Digest 5 (MD5) checksum of a file.
compare (Optional)	Compare two local files and describe the differences between them in default, context, or unified output styles.
Compress (Optional)	file compress.
copy (Optional)	Copy files from one place to another on the local device or between the local device and a remote system.
delete (Optional)	Delete a file on the local device.
delete-directory (Optional)	Delete a directory.
link (Optional)	Create link between files.
list (Optional)	Display a list of files on the local device.
make-directory (Optional)	Create a new directory.
rename (Optional)	Rename a file on the local device.
routing-instance (Optional)	Name of routing instance for host attempt.
show (Optional)	Display the contents of a file.
source-address (Optional)	Specify the source address of the local file.
staging-directory (Optional)	Staging directory on Routing Engine.

Statement introduced in Junos OS Release 25.4R1.

file-serialization

IN THIS SECTION

- Syntax | 7426
- Hierarchy Level | 7426
- Description | 7427
- Required Privilege Level | 7427
- Release Information | 7427

Syntax

```
(file-serialization | no-file-serialization);
```

Hierarchy Level

```
[edit security policies],
[edit services policies]
```

Description

Perform policy changes propagation to the dataplane using file serialization. By serializing policy configurations into files, the system ensure that they are read and applied by the PFE in a controlled and reliable manner.

By default, the file-based serialization feature is enabled. You can disable the file-serialization by using the following statement:

```
[edit]
user@host# set security policies no-file-serialization
```

To re-enable the file-serialization feature, use the following statement:

```
[edit]
user@host# delete security policies no-file-serialization
```

Or use the following statement:

```
[edit]
user@host# set security policies file-serialization
```

Required Privilege Level

security—To view this statement in the configuration

security-control—To add this statement to the configuration

- Options | 7443
- Required Privilege Level | 7444
- Release Information | 7444

Syntax

```
files number;
```

Hierarchy Level

```
[edit system syslog archive],
[edit system syslog file filename archive]
```

Description

Configure the maximum number of archived log files to retain. When the Junos OS logging utility has written a defined maximum amount of data to a log file ***logfile***, it closes the file, compresses it, and renames it to ***logfile*.0.gz** (for information about the maximum file size, see "size" on page 29095). The utility then opens and writes to a new file called ***logfile***. When the new file reaches the maximum size, the ***logfile*.0.gz** file is renamed to ***logfile*.1.gz**, and the new file is closed, compressed, and renamed ***logfile*.0.gz**. By default, the logging facility creates up to ten archive files in this manner. Once the maximum number of archive files exists, each time the active log file reaches the maximum size, the contents of the oldest archive file are lost (overwritten by the next oldest file).

Options

number—Maximum number of archived files.

- **Range:** 1 through 1000
- **Default:** 10 files

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

```
fill-level low-value fill-level high-value;
```

QFX10000 Switches

```
fill-level level1 level2 ... level32;
```

Hierarchy Level

```
[edit class-of-service drop-profiles profile-name interpolate]
```

Description

When configuring weighted random early detection (WRED), map the fullness of a queue to a packet "drop-probability" on page 6235 value. You configure the `fill-level` and `drop-probability` statements in related pairs. The pairs of fill level and drop probability values set a probability of dropping packets at a specified queue fullness value.

The first fill level is the packet drop start point. Packets do not drop until the queue fullness reaches the first fill level. The last fill level is the packet drop end point. After the queue exceeds the fullness set by the drop end point, all non-ECN packets are dropped. As the queue fills from the drop start point to the drop end point, the rate of packet drop increases in a curve pattern. The higher the queue fill level, the higher the probability of dropping packets.

On switches that support only two fill level/drop probability pairs, the two pairs are the drop start point and the drop end point. On switches that support up to 32 fill level/drop probability pairs, you can configure intermediate interpolations between the drop start point and the drop end point, which provides greater flexibility in controlling the packet drop curve.

NOTE: Do not configure the last fill level as 100 percent.

Options

low-value (switches that support only two fill level/drop probability pairs)—Fullness of the queue before packets begin to drop, expressed as a percentage. The low value must be less than the high value.

- **Range:** 0 through 100

high-value (switches that support only two fill level/drop probability pairs)—Fullness of the queue before it reaches the maximum drop probability. If the queue fills beyond the fill level high value, all packets drop. The high value must be greater than the low value.

- **Range:** 0 through 100

level1 level2 ... level32 (switches that support 32 fill level/drop probability pairs)—The queue fullness level, expressed as a percentage. Each fill level pairs with a drop probability to define the probability of a packet dropping at a specified queue fullness.

- **Range:** 0 through 100

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1.

filter (Applying to a Logical Interface)

IN THIS SECTION

- Syntax | 7451
- Hierarchy Level | 7451
- Description | 7452
- Options | 7452
- Required Privilege Level | 7452
- Release Information | 7452

Syntax

```
filter {
    group filter-group-number;
    input filter-name;
    input-list [ filter-names ];
    output filter-name;
    output-list [ filter-names ];
}
```

Hierarchy Level

Protocol-independent firewall filter on MX Series router logical interface:

```
[edit interfaces interface-name unit logical-unit-number],
[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number]
```

All other standard firewall filters on all other devices:

```
[edit interfaces interface-name unit logical-unit-number family family],
[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number
family family]
```

Description

Apply a stateless firewall filter to a logical interface at a specific protocol level.

Options

`group` *`filter-group-number`*	(Only Ex, M, MX, and T Series) Number of the group to which the interface belongs. Range: 1 through 255
`input` *`filter-name`*	Name of one filter to evaluate when packets are received on the interface.
`input-list [` *`filter-names`* `]`	Names of filters to evaluate when packets are received on the interface. Up to 16 filters can be included in a filter input list.
`output` *`filter-name`*	Name of one filter to evaluate when packets are transmitted on the interface.
`output-list [` *`filter-names`* `]`	Names of filters to evaluate when packets are transmitted on the interface. Up to 16 filters can be included in a filter output list.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

            action-modifiers;
        }
    }
}
```

Hierarchy Level

```
[edit firewall                family                family-name]
```

Description

Configure firewall filters.

Options

filter-name—Name that identifies the filter. The name can contain letters, numbers, and hyphens (-), and can be up to 64 characters long. To include spaces in the name, enclose it in quotation marks.

micro-segmentation—Enables Group Based Policy (GBP) tagging for use with macro and micro segmentation on VXLAN. GBPs make use of existing layer 3 VXLAN network identifiers (VNI), in conjunction with firewall filter policies, to provide micro-segmentation at the level of device or tag, independent of the underlying network topology.

These match conditions are supported for GBP tagging:

- `ip-version ipv4` *<ip address>* | *<prefix-list>*
- `ip-version ipv6` *<ip address>* | *<prefix-list>*
- `mac-address` *<mac address>*
- `interface` *<interface_name>* vlan-id *<vlan id>*
- `vlan-id` *<vlan id>*
- `interface` *<interface_name>*

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Configuring Flow Monitoring

filter (Identity Management Advanced Query)

IN THIS SECTION

Syntax | 7467

- Hierarchy Level | 7467
- Description | 7467
- Options | 7468
- Required Privilege Level | 7469
- Release Information | 7469

Syntax

```
filter {
    domain name;
    exclude-ip {
        address-book book-name;
        address-set address-set;
    }
    include-ip {
        address-book book-name;
        address-set address-set;
    }
}
```

Hierarchy Level

```
[edit services user-identification identity-management]
```

Description

The advanced user identity query feature enables the SRX Series Firewall to communicate with the Juniper Identity Management Service (JIMS) server to obtain user identity information for an individual user (ip-query) or a group of users (batch query).

Optionally, you can configure filters to convey to the JIMS server at a more granular level the users for whom you want information, based on their IP addresses. The filter statement gives you the flexibility to specify a range of IP addresses to be excluded from the record that the JIMS server sends in response or a range of IP addresses to be included in it. You can also constrain the query target to users in one or more specific active directory domains. Only IPv4 addresses are supported.

You can configure a filter that includes all three specifications: `include-ip`, `exclude-ip`, and `domain`.

Filters are contextual. That is, you can use a different filter configuration for different requests. If you change the filter configuration, the new filter applies to subsequent user identity requests exclusively. It has no bearing on prior query requests

Use of the JIMS allows you to provision users locally and have their authentication information made available to other sites in your network for policy enforcement and reporting.

WARNING: Before you use this feature, you must disable active-directory-access and authentication-source options under the user-identification hierarchy. You cannot commit this configuration if active directory authentication or the ClearPass query and webapi functions are configured and committed.

Options

include-ip address-book *book-name* address-set *address-set-name*. Optionally, configure a filter that directs the SRX Series Firewall to issue a query to the JIMS server to include in its response record user identity information for users based on IP addresses in certain address-ranges.

The following are the two behaviors when an `include-ip` is configured:

- Batch query—An SRX Series Firewall sends a request to JIMS with the include list of IP addresses.
- IP query—If the IP address to be queried is included, then the SRX Series Firewall queries JIMS only for those IP addresses that need to be included and does not query for other IP addresses; based on the IP query, JIMS does not trigger the PC probe for the IP addresses that are not included in the IP query.

A filter can include up to twenty IP address ranges. Therefore, an address set that contains more than twenty ranges will cause the filter configuration to fail. To specify the ranges, specify the name of a predefined address set which includes them and which is included in an existing address book.

The filter for IP addresses does not support nested address sets in an address book. If an address book contains nested address sets, it is ignored.

Here is an include-ip address configuration:

```
user@host# set security address-book mybook address addr1 range-address 198.51.100.0
to 198.51.120.0
user@host# set security address-book mybook address-set myset address addr1
```

```
user@host# set service user-identification identity-management filter include-ip
address-book mybook address-set myset
```

exclude-ip address-book *book-name* address-set *address-set-name*. Optionally, configure a filter that directs the SRX Series Firewall to issue a query to the JIMS server to exclude from its response record user identity information for users based on the specified address-ranges.

The following are the two behaviors when an `exclude-ip` is configured:

- Batch query—An SRX Series Firewall sends a request to JIMS with the exclude list of IP addresses.
- IP query—If the IP address to be queried is excluded, then no request is sent from an SRX Series Firewall to JIMS.

To specify the ranges, specify the name of a predefined address set which includes them and which is included in an existing address book. The address set must not include more than twenty IP addresses, otherwise the `exclude-ip` filter will fail. Here is an `exclude-ip` address configuration similar to that of the `include-ip` filter:

```
user@host# set security address-book mybook address addr1 range-address
198.51.100.0/24 to 198.51.120.0/24
user@host# set security address-book mybook address-set myset address addr1
user@host# set service user-identification identity-management filter exclude-ip
address-book mybook address-set myset
```

Starting in Junos OS Release 18.3R1, you can include or exclude IPv6 addresses for filtering the IP addresses, in addition to IPv4 addresses.

domain One or more active directory domains of interest to the SRX Series Firewall. You can specify up to twenty domain names for the filter.

Required Privilege Level

1. services—To view this statement in the configuration.
2. services-control—To add this statement to the configuration.

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family family-name]
```

Description

Apply a firewall filter to traffic transiting a Layer 3 interface.

Default

All incoming traffic is accepted unmodified on the Layer 3 interface, and all outgoing traffic is sent unmodified from the Layer 3 interface.

Options

filter-name—Name of a firewall filter defined at the `[edit firewall family family-name filter]` hierarchy level.

`input`—Apply a firewall filter to traffic entering the Layer 3 interface.

`output`—Apply a firewall filter to traffic exiting the Layer 3 interface.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1X53-D20.

filter (memory-enhanced)

IN THIS SECTION

- Syntax | 7478
- Hierarchy Level | 7478
- Description | 7478
- Required Privilege Level | 7478
- Release Information | 7478

Syntax

```
filter;
```

Hierarchy Level

```
[edit chassis memory-enhanced]
```

Description

Enables storing of firewall filters across multiple static RAM (SRAM) segments, resulting in proper utilization of SRAM segments. This feature is useful in routers with small routing tables and large firewall filters. This statement is supported on T Series routers.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement added in Junos OS Release 11.1.

RELATED DOCUMENTATION

Allocating More Memory for Routing Tables, Firewall Filters, and Layer 3 VPN Labels

filter (routing-options)

IN THIS SECTION

- Syntax | 7479
- Hierarchy Level | 7479
- Description | 7479
- Options | 7480
- Required Privilege Level | 7480
- Release Information | 7480

Syntax

```
filter {
    input filter-name;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options rib routing-table-name],
[edit logical-systems logical-system-name routing-options rib routing-table-name],
[edit routing-instances routing-instance-name routing-options rib routing-table-name],
[edit routing-options rib routing-table-name]
```

Description

Specify the name of the routing table from which Junos OS should export routing information.

Options

input ***filter-name***—Forwarding table filter name.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Applying Forwarding Table Filters

filter (Security)

IN THIS SECTION

- Syntax | 7480
- Hierarchy Level | 7481
- Description | 7481
- Required Privilege Level | 7481
- Release Information | 7481

Syntax

```
filter threat-attack
```

Hierarchy Level

```
[edit security log stream stream-name]
```

Description

Configure the log stream filter to transmit only threat and attack logs to the ClearPass Policy Manager (CPPM). The integrated ClearPass authentication and enforcement feature sends to the CPPM threat and attack logs detected by the SRX Series Firewall security modules. You can use these reports to inform your approach to hardening the CPPM security policy. Setting the log stream filter to threat-attack ensures that the SRX Series Firewall and the log server are not overburdened by irrelevant logs.

> **NOTE**: Unlike for other features that use a filter for log streams, threat-attack is the only log stream filter supported for integrated ClearPass. Therefore, it is not shown here as an option.

Required Privilege Level

1. security—To view this statement in the configuration.
2. security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3X48-D30.

filter (VLANs)

IN THIS SECTION

- Syntax | 7482
- Hierarchy Level | 7482
- Description | 7482

Applying Forwarding Table Filters

filter

IN THIS SECTION

Syntax | 7485

- Hierarchy Level | 7485
- Description | 7485
- Options | 7485
- Required Privilege Level | 7486
- Release Information | 7486

Syntax

```
filter filter-name {
    interface-specific
    micro-segmentation;
    no-longest-prefix-match;
    term term-name {
        from {
            match-conditions;
        }
        then {
            action;
            action-modifiers;
        }
    }
}
```

Hierarchy Level

```
[edit firewall family family-name]
```

Description

Configure firewall filters.

Options

filter-name—Name that identifies the filter. The name can contain letters, numbers, and hyphens (-), and can be up to 64 characters long. To include spaces in the name, enclose it in quotation marks.

micro-segmentation—Indicates that this firewall filter is a Group Based Policy (GBP) tagging filter. A GBP tagging filter uses firewall terms to assign GBP tags for use with macro and micro segmentation on VXLAN. GBPs make use of existing layer 3 VXLAN network identifiers (VNI), in conjunction with firewall filter policies, to provide micro-segmentation at the level of device or tag, independent of the underlying network topology.

These match conditions are supported for GBP tagging:

- `ip-version ipv4` *<ip address>* | *<prefix-list>*
- `ip-version ipv6` *<ip address>* | *<prefix-list>*
- `mac-address` *<mac address>*
- `interface` *<interface_name>* vlan-id *<vlan id>*
- `vlan-id` *<vlan id>*
- `interface` *<interface_name>*

no-longest-prefix-match—Disables longest prefix match in IP-based GBP tagging filters. This causes IP-based firewall terms in GBP tagging filters to be evaluated in term order instead of by longest prefix match. This parameter is only applicable when **micro-segmentation** is enabled and is ignored otherwise. Set this parameter when you first create the filter. Do not toggle this parameter on an existing filter.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1.

Option **micro-segmentation** introduced in Junos OS Release 22.4R1 to support GBP tagging filters.

Option **no-longest-prefix-match** introduced in Junos OS Release 24.4R1 to disable longest prefix match on IP-based GBP tagging filters.

- Release Information | 7491

Syntax

```
filter-list-template;
```

Hierarchy Level

```
[edit firewall family (inet | inet6) filter filter-name],
[edit logical-systems logical-system-name firewall family (inet | inet6) filter filter-name]
```

Description

(MX5, MX10, MX40, and MX80 routers, and routers that use MX Series MPC line cards only) Configure all interfaces that use the same filter list to use a common template. This feature can be used to save microkernel memory and DMEM memory.

If the same filter list cannot be used on all interfaces, consider merging the filters and using the `from interface` firewall filter term to group the per-interface terms to produce a new common filter list.

NOTE: If you configure both `fast-lookup-filter` and `interface-specific` statements, filter list templates are also used.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.3R9.

filter-profile

IN THIS SECTION

- Syntax | 7491
- Hierarchy Level | 7492
- Description | 7492
- Options | 7492
- Required Privilege Level | 7492
- Release Information | 7492

Syntax

```
filter-profile profile-name {
    counters {
        counter-name;
    }
```

```
    file filename;
    interval minutes;
    start-time time;
}
```

Hierarchy Level

```
[edit accounting-options]
```

Description

Create a profile to filter and collect packet and byte count statistics and write them to a file in the `/var/log` directory. To apply the profile to a firewall filter, you include the `accounting-profile` statement at the `[edit firewall filter filter-name]` hierarchy level. For more information about firewall filters, see *Firewall Filters Overview*.

Options

profile-name Name of the filter profile.

start-time ***time*** (Optional) Specify the start time in *yyyy-mm-dd.hh:mm* local time format for the accounting profile. Sometimes, if the time at which the records are written to the accounting file is beyond the transfer interval window of the file, drifting of accounting records occurs. To prevent drifting and to have predictable timestamps of when accounting data is written to an accounting file, we can specify the start time option for the accounting profile.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Firewall Filters Overview

Configuring the Filter Profile

filter-specific (QFX)

IN THIS SECTION

- Syntax | 7493
- Hierarchy Level | 7493
- Description | 7493
- Required Privilege Level | 7494
- Release Information | 7494

Syntax

```
filter-specific;
```

Hierarchy Level

```
[edit firewall policer policer-name]
```

Description

Configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. If you use a filter-specific policer in multiple terms, both of the following are true:

- Traffic is policed at the aggregate rate. For example, if you create a policer that has a bandwidth limit of 100 Mbps and use the policer in two terms, the total allowed bandwidth for both terms is 100 Mbps—not 100 Mbps for each term.

- The implicit counter counts all the packets are that matched by any of the terms. For example, if you reference the same filter-specific policer in term1 and term2, and term1 matches 1000 packets and term2 matches 500 packets, the implicit counter shows 1500 matches for the policer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration

Release Information

Statement introduced in Junos OS Release 11.1.

Overview of Policers

filter-specific

IN THIS SECTION

- Syntax | 7494
- Hierarchy Level | 7495
- Description | 7495
- Required Privilege Level | 7495
- Release Information | 7495

Syntax

```
filter-specific;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name firewall policer policer-name],
[edit firewall family inet prefix-action name],
[edit firewall policer policer-name],
[edit logical-systems logical-system-name firewall policer policer-name],
[edit logical-systems logical-system-name firewall family inet prefix-action name]
```

Description

By default, a policer operates in *term-specific* mode, which means that for a given *firewall filter*the Junos OS creates a separate policer instance for every filter term that references the policer. You can, however, use a common policer instance for all terms within the same firewall filter by setting the *filter-specific* option in the policer. In addition, for IPv4 firewall filters with multiple terms that reference the same policer, filter-specific mode counts and monitors the activity of the policer at the firewall filter level.

NOTE: Both filter-specific and term-specific apply to prefix-specific policer sets.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Logical systems support introduced in Junos OS Release 9.3.

Support at the `[edit dynamic-profiles ... policer policer-name]` hierarchy level introduced in Junos OS Release 11.4.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3. The `expression` option added in Junos OS Release 11.4.

Additional tags under filters of dynamic attack groups (CVSS score, age-of-attack, file-type, vulnerability-type) are added in Junos OS Release 18.2R1 for dynamic attacks grouping of IDP signatures. The Product and Vendor tags are already supported under existing filter products. The CLI interface for

configuring these tags is more user friendly, with possible completions being available for configuration in 18.2R1.

fin-invalidate-session

IN THIS SECTION

- Syntax | 7501
- Hierarchy Level | 7501
- Description | 7501
- Required Privilege Level | 7503
- Release Information | 7503

Syntax

```
fin-invalidate-session;
```

Hierarchy Level

```
[edit security flow tcp-session]
```

Description

Invalidates a TCP session after the 4-way or 3-way handshake completes, with each session endpoint signalling conclusion of the session independently. New incoming SYN packets will need to establish a new TCP session.

When either session endpoint wants to terminate the session, it sends a FIN(ish) message. When the other session endpoint receives the packet with the FIN flag set, it sends an ACK(nowlege) message. Typically, tearing down a session involves transmission of a pair of FIN-ACK messages from each session endpoint.

After the side that sent the first FIN responds with the final ACK, it waits for a time-out period to expire before closing the connection. During the time-out period, the local port cannot be used for new connections. The time-out period protects against delayed packets from the terminating session being delivered during subsequent connections.

> **NOTE**: On SRX Series Firewalls with `fin-invalidate-session` configured the invalidation of the session occurs immediately whereas without `fin-invalidate-session` configured the session is set to time out 2 seconds after the 4-way or 3-way handshake completes.

Table 54 on page 7502 shows the sequence of packets for a 4-way handshake to terminate a session. In this case, the client signals the server that it is terminating the session. The server responds with an ACK message signaling acknowledgement of the client's FIN message. The ACK is followed immediately by a FIN message that the server sends to the client, signaling that it is terminating the session connection on its end. Finally, the client sends an ACK message to the server signalling that it received the server's FIN message.

Table 54: Terminating a Session with a 4-Way Handshake

Step	Client	Server
1.	FIN	
2.		ACK
3.		FIN • Sets session timer to 150 seconds.
4.	ACK • Sets session timer to 2 seconds.	

A session can be terminated by a 3-way handshake. In this case, the client sends a FIN message to the server. The server responds with message that combines the FIN and ACK messages. The sequence of packet exchange for a three-way handshake session close is as follows:

Step	Client	Server

1.	FIN	
2.		FIN/ ACK • sets session timer to 150 seconds
3.	ACK • sets session timer to 2 seconds	

Required Privilege Level

- Required Privilege Level | 7507
- Release Information | 7507

Syntax

```
final-response-timeout seconds;
```

Hierarchy Level

```
[edit access ocs partition partition-name]
```

Description

Configure the amount of time in seconds before an Online Charging System (OCS) partition stops attempting to send the final interrogation during the subscriber logout process. When a subscriber starts to logs out, the OCS sends a final interrogation. If there is no response within 24 hours, then the system continues and starts sending a logout message to the Policy and Charging Rule Function (PCRF). If there is no response within the next 24 hours, then the subscriber logout proceeds.

NOTE: Any configuration changes made to this statement apply to all subscribers currently waiting to log out within a 60 second period.

Options

seconds Number of seconds to wait before an OCS partition stops sending the final interrogation using a CCR-GY-T message.

- **Default:** 7200
- **Range:** 0 through 86,400 seconds (24 hours)

Required Privilege Level

Syntax

```
finger {
    connection-limit limit;
    rate-limit limit;
}
```

Hierarchy Level

```
[edit system services]
```

Description

Allow finger requests from remote systems to the local device.

Options

connection-limit *limit*

Configure the maximum number of connection sessions for the finger service per protocol (either IPv4 or IPv6).

> **NOTE**: The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured `connection-limit` value if the system resources are limited.

- **Range:** 1 through 250 connections
- **Default:** 75 connections

rate-limit *limit*

Configure the maximum number of connection attempts per minute, per protocol (either IPv6 or IPv4). For example, a rate limit of 10 allows 10 IPv6 finger session connection attempts per minute and 10 IPv4 finger session connection attempts per minute.

- **Range:** 1 through 250 connections
- **Default:** 150 connections

    }
}
```

Hierarchy Level

```
[edit security]
```

Description

CAUTION: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the

debug information, immediately disable tracing to minimize risk and restore normal system performance.

Defines the type of firewall authentication available for a logical system. Also specifies the data plane firewall authentication tracing options.

Options

- `mtls-profile`—Enable passwordless user authentication based on client/server certificate validation using a public/private key.
- `mtls-profile-fallback-password`—Enable user authentication with mTLS and fallback to standard login when it fails.
- `flag`—Trace operation to perform. To specify more than one trace operation, include multiple flag statements.
  - `all`—Enable all tracing operations.
  - `authentication`—Trace data-plane firewall authentication events.
  - `proxy`—Trace data-plane firewall authentication proxy events.
- `detail`—Display moderate amount of data.
- `extensive`—Display extensive amount of data.
- `terse`—Display minimum amount of data.

- Release Information | 7530

Syntax

```
firewall-authentication-forced-timeout minutes;
```

Hierarchy Level

```
[edit services user-identification active-directory-access]
```

Description

Configure the firewall authentication forced timeout setting to apply to entries for user who authenticate through captive portal.

When a user authenticates through captive portal, an authentication table entry is generated for that user based on the information that the SRX Series Firewall obtains from the firewall authentication module. At that point, the default traffic-based authentication timeout logic is applied to the entry. This statement gives you control over how long non-domain users who authenticate through captive portal remain authenticated.

When the firewall authentication forced timeout value is configured, it is used in conjunction with the traffic-based timeout logic.

Here is how timeout settings affect active directory authentication entries for users authenticated through captive portal.

- The firewall authentication forced timeout is set for 3 hours.

  Traffic continues to be received and generated by a device associated with an authentication entry for a user. After 3 hours the authentication entry expires, although at that time there are sessions anchored in Packet Forwarding Engine for the authentication entry.

- If set, the firewall authentication forced timeout has no effect.

  An authentication entry does not have sessions anchored to it. It expires after the time set for the authentication entry timeout, for example, 30 minutes.

- The firewall authentication forced timeout configuration is deleted.

  Firewall authentication forced timeout has no effect on new authentication entries. Firewall authentication forced timeout remains enforced for existing authentication entries to which it applied before it was deleted. That is, for those authentication entries, the original forced timeout setting remains in effect.

- The firewall authentication forced timeout configuration setting is changed.

  The new timeout setting is applied to new incoming authentication entries. Existing entries keep the original, former setting.

- The firewall authentication forced timeout is set to 0, disabling it.

  If the firewall authentication forced timeout is set to a new value, that value is assigned to all incoming authentication entries. There is no firewall authentication forced timeout setting for existing authentication entries.

- The firewall authentication forced timeout value is not configured.

  - The SRX Series Firewall generates an authentication entry for a user. The default traffic-based timeout logic is applied to the authentication entry.

  - The active directory timeout value is configured for 50 minutes. A traffic-based timeout of 50 minutes is applied to an authentication entry.

  - The active directory timeout is not configured. The default traffic-based timeout of 30 minutes is applied to an authentication entry.

Options

minutes The maximum duration for which the non-domain users who authenticate through captive portal remain authenticated.

- **Default:** 30 minutes

- **Range:** 10 through 1440 minutes

firewall-install-disable

IN THIS SECTION

- Syntax | 7532
- Hierarchy Level | 7532
- Description | 7532
- Default | 7532
- Required Privilege Level | 7533
- Release Information | 7533

Syntax

```
firewall-install-disable;
```

Hierarchy Level

```
[edit routing-options flow],
[edit logical-systems logical-system-name routing-options flow],
[edit routing-instances routing-instance-name routing-options flow],
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options flow]
```

Description

Disable installing flow-specification firewall filters in the firewall process (dfwd).

Default

For PTX Series routers, this statement appears in the default configuration, preventing installation of flow-specification firewall filters into dfwd. For other models, this setting is omitted from the default configuration, allowing installation of flow-specification firewall filters into dfwd.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Releases 12.1X48 and 12.3.

fiveqi-map

IN THIS SECTION

- Syntax | 7536
- Hierarchy Level | 7536
- Description | 7537
- Options | 7537
- Required Privilege Level | 7538
- Release Information | 7538

Syntax

```
fiveqi-map identifier {
 upstream-rewrite {
  dscp dscp;
  dscp-n3 dscp-n3;
  forwarding-class forwarding-class;
  loss-priority(high | low);
 }
}
```

Hierarchy Level

```
[edit services agf]
```

Description

Configure the Quality of Service (QoS) attributes for a 5G QoS identifier (5QI) value in the 5QI table.

Customers send data packets across the access Y5 interface to the Access Gateway Function (AGF) in clear IP text. AGF encapsulates the data packet using GPRS Tunnelling Protocol (GTP) and forwards the encapsulated packet to the 5GC. To support GTP encapsulation, AGF sets the QFI and DSCP value in the outer IP header based on the packet priority, forwarding class, and packet loss priority of the data.

AGF looks for 5QI and QoS Flow ID (QFI) values in N2 signaling messages from the Access and Mobility Function (AMF) and matches those values to parameters in the 5QI table. AGF derives the forwarding class and loss priority from the 5QI mapping table. AGF classifies data packet priority using the authorized QoS rules sent in the N1 signaling messages. AGF manages individual subscriber session and applies the QoS rules that corresponds to the 5QI in the 5QI mapping table. AGF can then update differentiated services code point (DSCP) in the payload to match the derived QoS parameters. When you configure DSCP parameters in the 5QI mapping table, AGF overrides the payload DSCP. AGF updates both the inner and outer the IP header when it forwards the GTP packet in the data plane.

This statement allows you to:

- Override the QoS attributes for the non-dynamic 5QI.
- Add a dynamic 5QI and its QoS attributes.

You can configure the following QoS attributes for each defined 5QI. AGF uses the information to update the DSCP value in the IP header as it forwards the data packet from the Y5 interface to the N3 interface.

- Forwarding Class
- Packet Loss Priority
- Upstream DSCP
- Upstream N3 DSCP

Options

identifier 5QI number

Range: 0 through 63

After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure the flags for tracing resource public key infrastructure (RPKI) BGP route validation.

Options

flag Tracing operation to perform. To specify more than one RPKI BGP route validation tracing operation, include multiple `flag` statements.

- Values:
  - all—Trace all events.
  - error—Trace errored packets.
  - keepalive— RPKI-to-router protocol keepalive messages. If you enable the BGP `update` flag only, received keepalive messages do not generate a trace message.

- nsr-synchronization— Nonstop routing synchronization events. (Not valid at [edit routing-options validation group *group-name* session *address*].
- packets—All incoming and outgoing packets.
- policy—Policy processing. (Not valid at [edit routing-options validation group *group-name* session *address*].
- state—State transitions.
- task—Routing protocol task processing.
- timer—Routing protocol timer processing.
- update—Update packets. These packets provide routing updates to BGP systems. If you enable only this flag, received keepalive messages do not generate a trace message. Use the `keepalive` flag to generate a trace message for keepalive messages.

disable (Optional) Disable the specific tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as `all`.

flag-modifier (Optional) Modifier for the tracing flag. You can specify one or more of these modifiers.

- Values:
  - detail—Provide detailed trace information.
  - receive—Trace the packets being received.
  - send—Trace the packets being transmitted.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

```

Description

Configure a flat-file accounting profile that defines the contents of a flat file that records accounting statistics collected from the Packet Forwarding Engine for an interface at regular intervals. To be used, the profile is associated with a subscriber interface. The accounting flat file is archived by the accounting-options archiving mechanism.

Options

profile-name	Name of the flat-file profile.
start-time *time*	(Optional) Specify the start time in *yyyy-mm-dd.hh:mm* local time format for the accounting profile. Sometimes, if the time at which the records are written to the accounting file is beyond the transfer interval window of the file, drifting of accounting records occurs. To prevent drifting and to have predictable timestamps of when accounting data is written to an accounting file, we can specify the start time option for the accounting profile.
use-fc-ingress-stats	Enables forwarding class counters.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1R4.

`service-accounting` option added in Junos OS Release 17.1.

Support for the `service-accounting` option removed in Junos OS Release 18.1R4.

`use-fc-ingress-stats` option added in Junos OS Release 21.2R1.

[edit tenants name routing-instances name  protocols ospf source-packet-routing (Protocols OSPF)]
```

Description

Define a flexible algorithm for OSPFv2 to compute a path based on specified parameters to thin slice a network. We recommend configuring flexible algorithms on only a couple of routers to provide redundancy and to avoid conflicts.

Configure participation of routers in a specific flexible algorithm in a network at the `[edit protocols]` hierarchy level.

> **NOTE**: Modifying the flexible algorithm definition could cause traffic disruptions until all the nodes converge on the new paths.

Options

name Specify a flexible algorithm id to identify a flexible algorithm definition.

- **Range:** 128 through 255

color Specify a color to be associated with this flexible algorithm.

The remaining statements are explained separately. See CLI Explorer.

[edit tenants name routing-instances name protocols ospf]
```

Description

Preference of flexible algorithm L-OSPF routes. You can control path selection by configuring the preference for L-OSPF Flexible Algorithm routes in `inetcolor.0` and `mpls.0` to prioritize desired routes and improve traffic engineering across IP and MPLS domains.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

`flex-algorithm-preference` statement introduced in Junos OS and Junos OS Evolved Release 25.4R1.

flex-flow-sizing

IN THIS SECTION

- Syntax | 7565
- Hierarchy Level | 7565
- Description | 7565
- Options | 7566
- Required Privilege Level | 7566
- Release Information | 7566

Syntax

```
flex-flow-sizing;
```

Hierarchy Level

```
[edit chassis fpc slot-number inline-services]
```

Description

Configure support for the service creation of flows for inline services sampling. This configuration results in a first-come-first-serve creation of flows. Whichever flow comes first, that flow is allowed to occupy the flow table if there is space in the table. Otherwise, the flow is dropped and an error count is created.

NOTE: You cannot also configure explicit flow table sizes because the `flex-flow-sizing` configuration statement and the `flow-table-size` configuration statement are mutually exclusive.

You do not need to reboot the FPC after replacing the `flex-flow-sizing` statement with the `flow-table-size` statement in the configuration.

Options

- **Default:** 1K flows for IPv6 and VPLS flows each.
- **Range:** 15 through 256K flows for IPv4.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1F5.

NOTE: The `flex-flow-sizing` configuration statement is not supported on the MX204 router until Junos OS Release 17.4R2 or Junos OS Release 18R3. If you need to set the flow size for a release prior to those releases for the MX204 router, configure the `flow-table-size` statement. Configure the `flow-table-size` statement value within the range of 1 through 15. If the `flex-flow-sizing` statement is already configured, deactivate or delete the same. After you have configured the `flow-table-size` statement, commit the configuration and reload the device. For example, here's a sample configuration for the `flow-table-size` statement:

```
flow-table-size {
    ipv4-flow-table-size 10;
    ipv6-flow-table-size 4;
}
```

flexible-cross-connect-vlan-aware

IN THIS SECTION

- Syntax | 7570
- Hierarchy Level | 7570
- Description | 7570
- Required Privilege Level | 7571
- Release Information | 7571

Syntax

```
flexible-cross-connect-vlan-aware;
```

Hierarchy Level

```
[edit logical-systems name routing-instances name protocols evpn],
[edit routing-instances name protocols evpn]
```

Description

Enable EVPN-VPWS flexible cross-connect (FXC) VLAN aware service. For FXC service, all point-to-point Ethernet services under the same EVPN-VPWS instance share the same incoming MPLS label. FXC allows you to aggregate attachment circuits in the same EVPN-VPWS instance into a single group. For FXC VLAN aware services, you assign a unique service identifier to each attachment circuits in the same group. As a result, each attachment circuit will have its own Ethernet Auto-Discovery per EVPN Instance (EVI) route. When you enable `flexible-cross-connect-vlan-aware` services, you configure the pseudowire service (PS) interface under the routing protocol EVPN hierarchy.

The following sample configuration shows an EVPN-VPWS `flexible-cross-connect-vlan-aware` routing instance:

```
routing-instances evpn-vpws-A {
   instance-type evpn-vpws;
   interface ps0.0;
   route-distinguisher 192.168.2.3:100;
   vrf-target target:100:100;
   protocols {
      evpn {
         flexible-cross-connect-vlan-aware;
         interface ps0.1 {
            vpws-service-id {
               local 101;
               remote 201;
            }
         }
      }
```

```
    }
}
```

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Syntax

```
flexible-cross-connect-vlan-unaware;
```

Hierarchy Level

```
[edit logical-systems name routing-instances name protocols evpn],
[edit routing-instances name protocols evpn]
```

Description

Enable EVPN-VPWS flexible cross-connect (FXC) VLAN unaware Service. For EVPN-VPWS FXC service, all point-to-point Ethernet services under the same EVPN VPWS instance share the same incoming MPLS label. FXC allows you to aggregate attachment circuits into a single group. When you enable `flexible-cross-connect-vlan-unaware` services, you can bundle a number of attachment circuits in the same group. The group of attachment circuits share the same VPWS service tunnel, local service instance ID, and Ethernet Auto-Discovery per EVPN Instance (EVI) route.

The following sample configuration shows a `flexible-cross-connect-vlan-unaware` routing instance.

```
routing-instances bng-2
   protocols {
      evpn {
         label-allocation per-instance;
         flexible-cross-connect-vlan-unaware;
         group ac1 {
            interface xe-0/0/32.101;
            interface xe-0/0/30.101;
            interface xe-0/0/32.102;
            service-id {
                local 101;
                remote 102;
            }
        }
    }
}
```

flexible-match-ranges

IN THIS SECTION

- Syntax | 7573
- Hierarchy Level | 7573
- Description | 7574
- Options | 7574
- Required Privilege Level | 7576
- Release Information | 7576

Syntax

```
flexible-match-ranges <flexible-ranges-name>
```

Hierarchy Level

```
[edit firewall family <inet | inet6 | ethernet-switching> filter <filter-name> term <term-name>
from]
```

Description

Configure multiple flex match ranges within the same term, allowing traffic to be filtered based on several criteria simultaneously. Supported for family inet, inet6 and ethernet-switching.

> **NOTE**: `flexible-match-ranges` and `flexible-match-range` cannot be configured in the same term.

Options

- match-start — Start point to match in packet. `payload` match-start is not supported.
- byte-offset — Byte offset after the match start point
- bit-offset — Bit offset after the (match-start + byte) offset. (0..7)
- bit-length —Length of the data to be matched in bits. (0..32)
- range — Range of values to be matched.
- flexible-range-name — Apply flexible-match template

The following example shows a configuration where flexible-match-ranges have been defined to match on multiple user-defined fields.

```
[edit]
root@host# show firewall
family inet6 {
    filter f1 {
        term t1 {
            from {
                flexible-match-ranges fr1 {
                    match-start layer-4;
                    byte-offset 4;
                    bit-offset 6;
                    bit-length 32;
                    range 200;
                }
                flexible-match-ranges fr2 {
                    match-start layer-3;
                    byte-offset 2;
                    bit-offset 6;
```

```
                    bit-length 24;
                    range 20-30;
                }
                flexible-match-ranges fr3 {
                    match-start layer-4;
                    byte-offset 4;
                    bit-offset 6;
                    bit-length 16;
                    range 0xab;
                }
            }
        then {
              accept;
         }
        }
    }
}
```

The following example shows a configuration where flexible-match-ranges have been defined using flex-match template to match on multiple user-defined fields.

Define the template

```
set firewall flexible-match fm1 match-start layer-3
set firewall flexible-match fm1 byte-offset 40
set firewall flexible-match fm1 bit-offset 4
set firewall flexible-match fm1 bit-length 24
```

Apply template on flexible-match-ranges

```
set firewall family ethernet-switching filter f1 term t1 from flexible-match-ranges fr1 range 200
set firewall family ethernet-switching filter f1 term t1 from flexible-match-ranges fr1 flexible-
range-name fm1
```

View the configuration

```
[edit]
root@host# show firewall
```

```
family ethernet-switching {
    filter f1 {
        term t1 {
            from {
                flexible-match-ranges fr1 {
                    range 200;
                    flexible-range-name fm1;
                }
            }
        }
    }
}
```

- Description | 7577
- Required Privilege Level | 7577
- Release Information | 7577

Syntax

```
flexible-queuing-mode;
```

Hierarchy Level

```
[edit chassis]
```

Description

Enable flexible queuing on a non-HQoS MPCE that is installed in an MPC slot. A maximum of up to 32,000 queues are supported per port and per card, including queues on both ingress and egress interfaces.

When flexible queuing is enabled, the non-HQoS MPC is restarted for the changes to take effect and is brought online only if the power required for the queuing component is available in the power entry module (PEM). The MPC remains offline if the PEM cannot meet the power requirement for the queuing component.

You can configure flexible queuing even when a non-HQoS MPC is not present in the chassis. The configuration takes effect when a non-HQoS MPC is installed.

For more information about the MPCs and the Junos OS release that support this feature, see *Flexible Queuing Mode Overview*.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1R1.

[edit interfaces aex],
[edit interfaces ge-fpc/pic/port],
[edit interfaces et-fpc/pic/port],
[edit interfaces ps0],
[edit interfaces xe-fpc/pic/port]
```

Description

Support simultaneous transmission of 802.1Q VLAN single-tag and dual-tag frames on logical interfaces on the same Ethernet port, and on pseudowire logical interfaces.

NOTE: The `flexible-vlan-tagging` command is supported only with either no encapsulation or VPLS VLAN encapsulation.

This statement is supported on M Series and T Series routers, for Fast Ethernet and Gigabit Ethernet interfaces only on Gigabit Ethernet IQ2 and IQ2-E, IQ, and IQE PICs, and for aggregated Ethernet

interfaces with member links in IQ2, IQ2-E, and IQ PICs or in MX Series DPCs, or on Ethernet interfaces for PTX Series Packet Transport Routers or 100-Gigabit Ethernet Type 5 PIC with CFP.

This statement is supported on Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet, and aggregated Ethernet interfaces on EX Series and QFX Series switches.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.1.

Support for aggregated Ethernet added in Junos OS Release 9.0.

For the list of products and applications that support this feature on Junos OS Evolved, see Flexible VLAN Tagging.

flood (Security ICMP)

IN THIS SECTION

- Syntax | 7580
- Hierarchy Level | 7580
- Description | 7580
- Options | 7580
- Required Privilege Level | 7580
- Release Information | 7580

Syntax

```
flood {
    threshold number;
}
```

Hierarchy Level

```
[edit security screen ids-option screen-name icmp]
```

Description

Configure the device to detect and prevent Internet Control Message Protocol (ICMP) floods. An ICMP flood occurs when ICMP echo requests are broadcast with the purpose of flooding a system with so much data that it first slows down, and then times out and is disconnected. The threshold defines the number of ICMP packets per second allowed to ping the same destination address before the device rejects further ICMP packets.

Options

`threshold` *`number`* —Number of ICMP packets per second allowed to ping the same destination address before the device rejects further ICMP packets.

- **Range:** 1 through 1,000,000 per second
- **Default:** 1,000 per second

> **NOTE**: For SRX Series Firewalls the applicable range is 1 through 4,000,000 per second.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Syntax

```
flood {
    threshold number;
    white-list name;
}
```

Hierarchy Level

```
[edit security screen ids-option screen-name udp]
```

Description

Configure the device to detect and prevent UDP floods. UDP flooding occurs when an attacker sends UDP packets to slow down the system to the point that it can no longer process valid connection requests.

The threshold defines the number of UDP packets per second allowed to ping the same destination IP address. When the number of packets exceeds this value within any 1-second period, the device generates an alarm and drops subsequent packets for the remainder of that second.

Options

`threshold` *`number`* —Number of UDP packets per second allowed to ping the same destination address before the device rejects further UDP packets.

- **Range:** 1 through 4,000,000 per second
- **Default:** 1,000 per second

For SRX300, SRX320, SRX340, and SRX345, the applicable range is 1 through 100,000 per second.

For SRX1500, SRX4100, SRX4200, and vSRX Virtual Firewall, the applicable range is 1 to 1,000,000.

For SRX4600, SRX5400, SRX5600, and SRX5800, the applicable range is 1 through 4,000,000 per second.

`white-list` *`name`* —Configure a list of IP addresses that are exempted from UDP flood detection, which occur during the UDP flood screen protection process. This list of exempted addresses is called an allowlist.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.2.

Syntax

```
flood {
    input filter-name;
}
```

Hierarchy Level

```
[edit vlans vlan-name],
[edit vlans vlan-name forwarding-options (Bridge Domains or VLANs)]
```

Description

Apply a flood filter to traffic ingressing a VLAN. Flood filters are triggered only for broadcast, unknown unicast, and multicast (BUM) traffic.

Flood filters and firewall filters can coexist on the same VLAN. If the actions in the filters are conflicting, then the firewall filter takes priority over the flood filter.

Default

All incoming traffic is accepted unmodified to a VLAN, and all outgoing traffic is sent unmodified from a VLAN.

Options

filter-name—Name of a filter defined at the `[edit firewall family family-name filter]` hierarchy level.

`input`—Apply a flood filter to VLAN ingress traffic.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

flood-as-unknown-unicast

IN THIS SECTION

- Syntax | 7586
- Hierarchy Level | 7586
- Description | 7586
- Required Privilege Level | 7587
- Release Information | 7587

Syntax

```
flood-as-unknown-unicast;
```

Hierarchy Level

```
[edit interfaces irb unit name family inet address local-ip-address/prefix-length | arp local-ip-address mac local-ip-address]
```

Description

You can configure the `flood-as-unknown-unicast` statement for IRB interfaces located in any Layer 2 domain.

You can enable the `flood-as-unknown-unicast` statement for unicast MAC addresses. When a switch receives traffic from a unicast MAC address that is the destination MAC address, the switch floods the packets on the VLAN where the IRB interface is located.

When a Microsoft load balancer cluster is connected to a device in an EVPN-VXLAN or Layer2 EVPN-MPLS domain, the nodes in the cluster don't export their virtual MAC addresses along with their address resolution protocol (ARP) packets. In this case, the switch doesn't learn the virtual MAC addresses and drops any traffic coming from those addresses. When you enable the `flood-as-unknown-unicast` statement for a virtual MAC address on your switch, the switch can learn the Microsoft load balancer node's virtual MAC address. When the virtual MAC address is the destination MAC, the switch floods the traffic on the Microsoft load balancer nodes.

> **NOTE**: If you've configured assisted replication, flooding occurs on assisted replication virtual tunnel endpoints (VTEP), not regular VTEPs.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 22.4R1.

flood-reflector (Protocols IS-IS)

IN THIS SECTION

- Syntax | 7589
- Hierarchy Level | 7589
- Description | 7590
- Options | 7590
- Required Privilege Level | 7591
- Release Information | 7591

Syntax

```
flood-reflector {
    client;
        reflector {
        cluster-id;
    }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols isis interface interface-name level level-number],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols isis interface interface-name level level-number],
[edit protocols isis interface interface-name level level-number],
[edit protocols isis level level-number],
[edit routing-instances routing-instance-name protocols isis interface interface-name level level-number]
```

Description

IS-IS supports flood-reflector interfaces. Flood reflectors enable the creation of topologies where Level 1 areas provide transit forwarding for Level 2 destinations within a Level 2 topology. This is accomplished by creating Level 2 flood-reflection adjacencies within each Level 1 area.

The Level 2 flood reflection adjacencies are used to flood Level 2 link-state packet data units (PDUs), and are used in the Level 2 SPF computation. Therefore, the flood reflectors limit link-state PDU flooding over IS-IS interfaces. We designate the Flexible Tunnel Interfaces (FTI) as flood-reflector interfaces.

Options

client Configure interface as a flood-reflector client.

reflector Configure interface as a flood reflector.

cluster-id The flood-reflector cluster identifier that allows a flood reflector client to establish flood reflector adjacencies with multiple flood reflectors.

- **Range:** 1 through 42,94,967,295

> **NOTE**:
>
> - `flood-reflector` must be configured on the FTI interface only.
> - `flood-reflector` must be configured at IS-IS Level 2 only.
> - The option `reflector` cannot be configured together with the option `client`. This enforces that the same router cannot be both a flood reflector and a flood-reflector client for the same level.
> - At the `[edit protocols isis level level number flood-reflector reflector]` hierarchy level, the `cluster-id` must be configured.
> - At the `[edit protocols isis level level number flood-reflector client]` hierarchy level, the `cluster-id` must not be configured.
> - To configure the `cluster-id` option at the `[edit protocols isis interface interface name level level number flood-reflector reflector]` hierarchy level, the `client` must be configured at the `[edit protocols isis level level number flood-reflector client]` hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 20.4R1.

[edit routing-options rib inet6.0],
[edit routing-instances routing-instance-name routing-options rib inet6.0]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure the BGP flow specification for the IPv6 address family to automate coordination of traffic filtering rules and to allow propagation of traffic flow specification rules for IPv6 and IPv6 VPN in order to mitigate distributed denial-of-service attacks. Flow specification provides protection against denial-of-service attacks and restricts bad traffic that consumes bandwidth and stops it near the source.

> **NOTE**: To propagate IPv6 flow specification routes through BGP, enable family `inet6 flow` or `inet6-vpn flow` at the `[edit protocols bgp family]` hierarchy level on BGP routers in the network.

Options

discard-action-for-unresolved-redir-addr	Configure the discard action for BGP flow specification routes that were not resolved using the redirect to IP action.
interface-group *group*<exclude>	Exclude applying flowspec filter to traffic received on specific interfaces. Use **exclude** to specify the interface group where you do not want to receive the traffic.
per-route-accounting	Enable traffic accounting per flowspec route.
no-per-route-accounting	Disable traffic accounting per flowspec route.
destination *ipv6-prefix*	IP destination address field.
destination-port *destination-port-names*	TCP or User Datagram Protocol (UDP) destination port field. You cannot specify both the `port` and `destination-port` match conditions in the same term. In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): `afs` (1483), `bgp` (179), `biff` (512), `bootpc` (68), `bootps` (67), `cmd` (514), `cvspserver` (2401), `dhcp` (67), `domain` (53), `eklogin` (2105), `ekshell` (2106), `exec` (512), `finger` (79), `ftp` (21), `ftp-data` (20), `http` (80), `https` (443), `ident` (113), `imap` (143), `kerberos-sec` (88), `klogin` (543), `kpasswd` (761), `krb-prop` (754), `krbupdate` (760), `kshell` (544), `ldap` (389), `login` (513), `mobileip-agent` (434), `mobilip-`

mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), xdmcp (177), zephyr-clt (2103), or zephyr-hm (2104).

dscp ***value***

Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant six bits of this byte form the DSCP.

- **Range:** You can specify DSCP in hexadecimal or decimal form from 0 through 63.

flow-label ***numeric-expression***

The value of this field ranges from 0 through 1048575.

This match condition is supported only on Junos devices with enhanced MPCs that are configured for enhanced-ip mode.

fragment ***fragment-value***

The keywords are grouped by the fragment type with which they are associated:

- first-fragment
- is-fragment
- last-fragment
- not-a-fragment

This match condition is supported only on Junos devices with enhanced MPCs that are configured for enhanced-ip mode.

icmp6-code ***icmp6-code-value***

ICMP6 code field. This value or keyword provides more specific information than icmp6-type. Because the value's meaning depends on the associated icmp6-type value, you must specify icmp6-type along with icmp6-code.

In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:

- parameter-problem: ip-header-bad (0), required-option-missing (1)
- redirect: redirect-for-host (1), redirect-for-network (0), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2)
- time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0)

- unreachable: communication-prohibited-by-filtering (13), destination-host-prohibited (10), destination-host-unknown (7), destination-network-prohibited (9), destination-network-unknown (6), fragmentation-needed (4), host-precedence-violation (14), host-unreachable (1), host-unreachable-for-TOS (12), network-unreachable (0), network-unreachable-for-TOS (11), port-unreachable (3), precedence-cutoff-in-effect (15), protocol-unreachable (2), source-host-isolated (8), source-route-failed (5)

icmp6-type *icmp6-type-value*

ICMP6 packet type field. Normally, you specify this match in conjunction with the protocol match statement to determine which protocol is being used on the port.

In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply (0), echo-request (8), info-reply (16), info-request (15), mask-request (17), mask-reply (18), parameter-problem (12), redirect (5), router-advertisement (9), router-solicit (10), source-quench (4), time-exceeded (11), timestamp (13), timestamp-reply (14), or unreachable (3).

packet-length *packet-length*

Total IP packet length value can range from 0 through 65535.

port *port-names*

TCP or UDP source or destination port field. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.

In place of the numeric value, you can specify one of the text synonyms listed under destination-port.

prefix-offset *number*

(Optional) Specify the number of bits that must be skipped before Junos OS starts matching the prefix.

This match condition is supported only on Junos devices with enhanced MPCs that are configured for enhanced-ip mode.

protocol *number*

For IPv6, the IP protocol field is supported only on Junos devices with MPCs that are configured for enhanced-ip mode. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), egp (8), esp (50), gre (47), icmp (1), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), tcp (6), or udp (17).

source *ipv6-prefix*

IP source address field.

source-port *source-port-names*

TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.

In place of the numeric field, you can specify one of the text synonyms listed under destination-port.

tcp-flags *tcp-flags* — TCP header format.

no-install — Prohibit installing received routes in the forwarding table.

accept — Accept a packet. This is the default value.

community *name* — Replace any communities in the route with the specified communities.

discard — Discard a packet silently, without sending an Internet Control Message Protocol (ICMP) message.

mark *value* — Set a DSCP value for traffic that matches this flow. Specify a value from 0 through 63.

This action is supported only on Junos devices with MPCs that are configured for `enhanced-ip` mode.

> **NOTE**: Junos OS supports traffic marking extended BGP `community` filtering action. For IPv4 traffic, Junos OS modifies the DiffServ code point (DSCP) bits of a transiting IPv4 packet to the corresponding value of the extended community. For IPv6 packets, Junos OS modifies the first six bits of the `traffic class` field of the transmitting IPv6 packet to the corresponding value of the extended community.

redirect — Redirect (tunnel) this flow's traffic to given next-hop address.

next-term — Continue to the next match condition for evaluation.

rate-limit *rate-limit* — Limit the bandwidth on the flow route. Express the limit in bits per second (bps).

routing-instance *route-target-extended-community* — Specify a routing instance to which packets are forwarded.

sample — Sample the traffic on the flow route.

traceoptions — Define tracing operations that track all routing protocol functionality in the routing device.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Determine how the device manages packet flow. The device can regulate packet flow in the following ways:

Options

advanced-options

Flow configuration advanced options.

- Values:
  - drop-matching-link-local-address—Drop matching link local address.
  - drop-matching-reserved-ip-address—Drop matching reserved source IP address.
  - reverse-route-packet-mode-vr—Allow reverse route lookup with packet mode vr.

allow-dns-reply

Allow unmatched incoming DNS reply packet.

allow-embedded-icmp

Allow embedded ICMP packets not matching a session to pass through.

allow-reverse-ecmp

Allow reverse ECMP route lookup.

enable-reroute-uniform-link-check

Enable reroute check with uniform link.

- Values:
  - nat—Enable NAT check.

enhanced-routing-mode

Enable enhanced route scaling.

force-ip-reassembly

Force to reassemble IP fragments.

gre-performance-acceleration

Accelerate the GRE traffic performance.

ipsec-performance-acceleration

Accelerate the IPSec traffic performance.

mcast-buffer-enhance

Allow to hold more packets during multicast session creation.

multicast-nh-resolve-retry

You can use this command configure the multicast route next-hop resolve attempts. When a multicast route next-hop resolve is unsuccessful, the SRX Series Firewall attempts to resolve the next-hop route based on the specified retry counts.

- **Default:** 0
- **Range:** 0 through 20

no-local-favor-ecmp

Does not prefer local node in HA ECMP route lookup.

pending-sess-queue-length

Maximum queued length per pending session.

- Values:
  - high—Maximum number of queued sessions.
  - moderate—Allow more queued sessions than normal.
  - normal—Normal number of sessions queued.

power-mode-ipsec

Enable power mode ipsec processing.

preserve-incoming-fragment-size

Preserve incoming fragment size for egress MTU.

route-change-timeout

Timeout value for route change to nonexistent route (seconds).

- **Default:** 6
- **Range:** 6 through 1800

strict-packet-order

You can use this command to maintain multicast traffic order and resolve packet drop issue.

syn-flood-protection-mode

TCP SYN flood protection mode.

- Values:
  - syn-cookie—Enable SYN cookie protection.
  - syn-proxy—Enable SYN proxy protection.

sync-icmp-session

Allow icmp sessions to sync to peer node.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.5. The `power-mode-ipsec` option added in Junos OS Release 18.3R1 for vSRX Virtual Firewall instances, in Junos OS Release 18.4R1 for SRX4100 and SRX4200 devices, and in Junos OS Release 18.2R2 for SRX5400, SRX5600, and SRX5800 devices. The `multicast-nh-resolve-retry` and the `strict-packet-order` options are added in Junos OS Release 20.2R2 for SRX345 and SRX1500 devices.The `gre-performance-acceleration` option added in Junos OS Release 21.1R1.

```

Description

Configure the IDP engine to manage the packet flow.

Options

allow-nonsyn-connection Allow TCP non-syn connection.

drop-if-no-policy-loaded Drop all traffic till IDP policy gets loaded.

drop-on-failover Drop traffic on HA failover sessions.

drop-on-limit Drop connections on exceeding resource limits.

fifo-max-size Maximum fifo size.

Sets the maximum FIFO size (range: 1 through 65535).

- **Range:** 1 through 65535

hash-table-size Flow hash table size. Sets the packet flow hash table size.

- **Range:** 1024 through 1000000

idp-bypass-cpu-threshold

CPU usage in percentage for IDP bypass.

- **Default:** 85
- **Range:** 0 through 99

idp-bypass-cpu-tolerance

CPU usage in percentage for IDP bypass.

- **Default:** 5
- **Range:** 1 through 99

idp-bypass-cpu-usg-overload

Enable IDP bypass of sessions or packets on CPU usage overload.

intel-inspect-cpu-usg-threshold

CPU usage threshold percentage for intelligent inspection.

- **Default:** 80
- **Range:** 0 through 99

intel-inspect-cpu-usg-tolerance

CPU usage tolerance percentage for intelligent inspection.

- **Default:** 5
- **Range:** 1 through 99

intel-inspect-disable-content-decompress

Disable payload content decompression.

intel-inspect-enable

Minimize IDP processing during system overload.

intel-inspect-free-mem-threshold

Free memory threshold percentage for intelligent inspection.

- **Default:** 15
- **Range:** 1 through 100

intel-inspect-mem-tolerance

Memory tolerance percentage for intelligent inspection.

- **Default:** 5
- **Range:** 1 through 100

intel-inspect-protocols

Protocols to be processed in intelligent inspection mode.

intel-inspect-session-bytes-depth

Session bytes scanning depth.

- **Default:** 0

- **Range:** 0 through 1000000

intel-inspect-signature-severity

Signature severities to be considered for IDP processing.

- Values:
  - critical
  - major
  - minor

log-errors

Enable the error log to generate the result of success or failure about the flow. A flow-related error is when IDP receives a packet that does not fit into the expected flow. By default an error log is enabled.

max-sessions-offset

Maximum session offset limit percentage.

Set an offset (percentage) for the maximum IDP session limit. The `max-sessions-offset` option sets an offset for the maximum IDP session limit. When the number of IDP sessions exceeds the maximum session limit, a warning is logged that conditions exist where IDP sessions could be dropped. When the number of IDP sessions drops below the maximum IDP session limit minus the offset value, a message is logged that conditions have returned to normal.

- **Range:** 0 through 99

max-timers-poll-ticks

Specify the time at which timer ticks at regular interval.

- **Syntax:** *value*—Maximum amount of time at which the timer ticks.
- **Range:** 0 through 1000 ticks
- **Default:** 1000 ticks

min-objcache-limit-lt

Memory lower threshold limit percentage.

- **Syntax:** *value*— Memory lower threshold limit percentage.
- **Range:** 1 through 100

min-objcache-limit-ut

Memory upper threshold limit percentage.

- **Syntax:** *value*— Memory upper threshold limit percentage.
- **Range:** 1 through 100

no-log-errors

Do not flow log errors.

reject-timeout

Specify the amount of time in seconds within which a response must be received.

This time-out is applied on flow when drop-connection action is taken by IPS for TCP flow.

- **Syntax:** *value*—Maximum amount of time in seconds.
- **Range:** 1 through 65535
- **Default:** 300 seconds

reset-on-policy

IDP keeps track of connections in a table. If enabled, the security module resets the flow table each time a security policy loads or unloads. If this setting is disabled, then the security module continues to retain a previous security policy until all flows referencing that security policy go away. Juniper Networks recommends that you keep this setting enabled to preserve memory.

When a new IDP policy is loaded, the existing sessions are inspected using the newly loaded policy and the existing sessions not ignored for IDP processing. The `reset-on-policy` command is used to decide whether to continue the IDP inspection with the newly loaded IDP policy or not. This command is disabled by default and all the existing sessions continue to be inspected with newly loaded IDP policy.

> **NOTE**: In Junos OS Release 18.2R1-S1and Junos OS Release 18.3R1, the `no-reset-on-policy` option is not supported on SRX5000 line of devices with SRX5K-SPC3.

session-steering

Session steering for session anticipation.

udp-anticipated-timeout

Sets the maximum UDP anticipated timeout value.

- **Range:** 1 through 65535

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

Options intel-inspect-cpu-usg-threshold, intel-inspect-cpu-usg-tolerance, intel-inspect-disable-content-decompress, intel-inspect-enable, intel-inspect-free-mem-threshold, intel-inspect-mem-tolerance, intel-inspect-protocols, intel-inspect-session-bytes-depth, and intel-inspect-signature-severity options added in Junos OS Release 19.2R1.

Starting in Junos OS Release 18.4R1, the `reset-on-policy` command is deprecated—rather than immediately removed—to provide backward compatibility and a chance to bring your configuration into compliance with the new configuration.

Description

CAUTION: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure a flow route for the IPv4 address family.

NOTE: To configure a flow route for the IPv6 address family, see "flow (IPv6)" on page 7594.

Default

`legacy`

Options

`discard-action-for-unresolved-redir-addr` For action redirect IP if redirect address is unresolved install discard action filter.

fast-lookup-filter Enable fast lookup filter.

> **NOTE**: The option fast-lookup-filter is supported on MX Series devices only.

no-fast-lookup-filter Disable fast lookup filter.

> **NOTE**: The option no-fast-lookup-filter is supported on MX Series devices only.

Default: no-fast-lookup-filter

`firewall-install-disable`—(PTX Series routers only) The `firewall-install-disable` statement appears in the default configuration, preventing installation of flow-specification firewall filters into dfwd. For other models, this setting is omitted from the default configuration, allowing installation of flow-specification firewall filters into dfwd.

`interface-group` *`group`* Interface-group for applying flowspec filter.

- *`group`*—Interface group ID to match traffic (1..255).
- `exclude`—Don't apply flowspec filter to traffic on this group.

`per-route-accounting` Enable traffic accounting per flowspec route.

`no-per-route-accounting` Disable traffic accounting per flowspec route.

`route` *`name`* Name of the flow route.

`match` *`match-conditions`* Match packets to these conditions.

`destination` *`prefix`* IP destination address field.

`destination-port` *`destination-port-names`* TCP or User Datagram Protocol (UDP) destination port field. You cannot specify both the `port` and `destination-port` match conditions in the same term.

In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), xdmcp (177), zephyr-clt (2103), or zephyr-hm (2104).

dscp ***value***

Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant six bits of this byte form the DSCP.

- **Range:** You can specify DSCP in hexadecimal or decimal form from 0 through 63.

fragment ***fragment-value***

IP header Fragment field.

The keywords are grouped by the fragment type with which they are associated:

- first-fragment
- is-fragment
- last-fragment
- not-a-fragment

icmp-code ***icmp-code-value***

ICMP code field. This value or keyword provides more specific information than icmp-type. Because the value's meaning depends on the associated icmp-type value, you must specify icmp-type along with icmp-code.

In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:

- parameter-problem: ip-header-bad (0), required-option-missing (1)
- redirect: redirect-for-host (1), redirect-for-network (0), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2)
- time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0)

- unreachable: communication-prohibited-by-filtering (13), destination-host-prohibited (10), destination-host-unknown (7), destination-network-prohibited (9), destination-network-unknown (6), fragmentation-needed (4), host-precedence-violation (14), host-unreachable (1), host-unreachable-for-TOS (12), network-unreachable (0), network-unreachable-for-TOS (11), port-unreachable (3), precedence-cutoff-in-effect (15), protocol-unreachable (2), source-host-isolated (8), source-route-failed (5)

icmp-type *icmp-type-value*

ICMP packet type field. Normally, you specify this match in conjunction with the protocol match statement to determine which protocol is being used on the port.

In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply (0), echo-request (8), info-reply (16), info-request (15), mask-request (17), mask-reply (18), parameter-problem (12), redirect (5), router-advertisement (9), router-solicit (10), source-quench (4), time-exceeded (11), timestamp (13), timestamp-reply (14), or unreachable (3).

packet-length *packet-length*

Total IP packet length value can range from 0 through 65535.

port *port-names*

TCP or UDP source or destination port field. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.

In place of the numeric value, you can specify one of the text synonyms listed under destination-port.

protocol *number*

In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), egp (8), esp (50), gre (47), icmp (1), igmp (2), ipip (4), (41), ospf (89), pim (103), rsvp (46), tcp (6), or udp (17).

source *prefix*

IP source address field.

source-port *source-port-names*

TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.

In place of the numeric field, you can specify one of the text synonyms listed under destination-port.

tcp-flags *tcp-flags*

TCP header format.

no-install

Prohibit installing received routes in the forwarding table.

then

Actions to take on matching packets.

accept

Accept a packet. This is the default value.

community *name*	Replace any communities in the route with the specified communities.
discard	Discard a packet silently, without sending an Internet Control Message Protocol (ICMP) message.
mark *value*	Set a DSCP value for traffic that matches this flow. Specify a value from 0 through 63. This action is supported only on Junos devices with MPCs that are configured for `enhanced-ip` mode.
redirect	Redirect (tunnel) this flow's traffic to given next-hop address.
next-term	Continue to the next match condition for evaluation.
rate-limit *rate-limit*	Limit the bandwidth on the flow route. Express the limit in bits per second (bps).
routing-instance *route-target-extended-community*	Specify a routing instance to which packets are forwarded.
sample	Sample the traffic on the flow route.
term-order (legacy | standard)	• `legacy`—Use version 6 of the flow-specification algorithm. • `standard`—Use version 7 of the flow-specification algorithm. **Default:** legacy
validation	Flow route validation options. Flow specifications received from peers are validated such that it is considered feasible.
traceoptions	Define tracing operations that track all routing protocol functionality in the routing device.
file	Trace file options. • *filename*—Name of file in which to write trace information. • `files`—Maximum number of trace files (2..1000). • `no-world-readable`— Don't allow any user to read the log file. • `size`—Maximum trace file size (10240..4294967295). • `world-readable`—Allow any user to read the log file.
flag	Tracing parameters.

- `all`—Trace everything.
- `flash`—Trace flash processing.
- `general`—Trace general events.
- `normal`—Trace normal events.
- `policy`—Trace policy processing
- `resolution`—Trace flow to unicast. route resolution
- `route`—Trace routing information.
- `state`—Trace state transitions.
- `task`—Trace routing protocol task processing.
- `timer`—Trace routing protocol timer processing.
  - `detail`—Trace detailed information.
  - `disable`—Disable this trace flag.
  - `receive`—Trace received packets.
  - `send`—Trace transmitted packets.

flow-active-timeout (Flow Monitoring)

IN THIS SECTION

- Syntax | 7623
- Hierarchy Level | 7623
- Description | 7623
- Options | 7623
- Required Privilege Level | 7624
- Release Information | 7624

Syntax

```
flow-active-timeout seconds;
```

Hierarchy Level

```
[edit forwarding-options accounting name output],
[edit forwarding-options monitoring name output],
[edit forwarding-options sampling instance instance-name family (inet |inet6 |mpls | vpls) output],
[edit forwarding-options sampling family (inet |inet6 |mpls |vpls) output],
[edit services flow-monitoring version9 template template-name],
[edit services flow-monitoring version-ipfix template template-name]
```

Description

Set the interval after which an active flow is exported.

NOTE:

- The router must include an Adaptive Services, Multiservices, or Monitoring Services PIC for this statement to take effect.
- For Trio-based routers, if you configure the `inline-jflow` statement at the `[edit forwarding-options sampling instance instance-name family inet output]` hierarchy level, timed-out flows are exported even if the router does not contain a Multiservices card.

Options

seconds—Duration of the timeout period.

- **Range:** 60 through 1800 seconds (for `forwarding-options` configurations); 10 through 600 seconds (for `services` configurations)
- **Default:** 1800 seconds (for `forwarding-options` configurations); 60 seconds (for `services` configurations)

NOTE: In active flow monitoring, the cflowd or flow monitoring version 9 records are exported after a time period that is a multiple of 60 seconds and greater than or equal to

the configured active timeout value. For example, if the active timeout value is 90 seconds, the cflowd or flow monitoring version 9 records are exported at 120-second intervals. If the active timeout value is 150 seconds, the cflowd or flow monitoring version 9 records are exported at 180-second intervals, and so forth.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support at the `[edit services flow-monitoring version-ipfix template template-name]` hierarchy level added in Junos OS Release 10.2.

Support at the `[edit services flow-monitoring version9 template template-name]` hierarchy level added in Junos OS Release 16.1 for MPLS traffic flows.

Flow Collection Overview

flow-control (ACX Series)

IN THIS SECTION

- Syntax | 7627
- Hierarchy Level | 7627
- Description | 7627
- Default | 7628
- Required Privilege Level | 7628
- Release Information | 7628

Syntax

```
(flow-control | no-flow-control);
```

Hierarchy Level

```
[edit interfaces interface-name aggregated-ether-options],
[edit interfaces interface-name ether-options],
[edit interfaces interface-name fastether-options],
[edit interfaces interface-name gigether-options],
[edit interfaces interface-name multiservice-options],
[edit interfaces interface-range name aggregated-ether-options],
[edit interfaces interface-range name ether-options]
```

Description

For aggregated Ethernet, Fast Ethernet, and Gigabit Ethernet interfaces only, explicitly enable flow control, which regulates the flow of packets from the router or switch to the remote side of the connection. Enabling flow control is useful when the remote device is a Gigabit Ethernet switch. Flow control is not supported on the 4-port Fast Ethernet PIC.

> **NOTE**: On the Type 5 FPC, to prioritize control packets in case of ingress oversubscription, you must ensure that the neighboring peers support MAC flow control. If the peers do not support MAC flow control, then you must disable flow control.

Default

Flow control is enabled.

> **NOTE**: Flow control is enabled by default only on physical interfaces and it is disabled by default on aggregated Ethernet interfaces.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.2 for ACX Series Universal Metro Routers.

Understanding Ethernet Interfaces

flow-control

IN THIS SECTION

- Syntax | 7630
- Hierarchy Level | 7630
- Description | 7630
- Default | 7631
- Required Privilege Level | 7631
- Release Information | 7631

Syntax

```
(flow-control | no-flow-control);
```

Hierarchy Level

```
[edit interfaces interface-name ether-options]
```

Description

Explicitly enable or disable symmetric Ethernet PAUSE flow control, which regulates the flow of packets from the switch to the remote side of the connection by pausing all traffic flows on a link during periods of network congestion. Symmetric flow control means that Ethernet PAUSE is enabled in both directions. The interface generates and sends Ethernet PAUSE messages when the receive buffers fill to a certain threshold and the interface responds to PAUSE messages received from the connected peer.

You can configure asymmetric flow control by including the `configured-flow-control` statement at the `[edit interfaces` *`interface-name`* `ether-options` hierarchy level. Symmetric flow control and asymmetric flow control are mutually exclusive features. If you attempt to configure both, the switch returns a commit error.

> **NOTE**: Ethernet PAUSE temporarily stops transmitting all traffic on a link when the buffers fill to a certain threshold. To temporarily pause traffic on individual "lanes" of traffic (each lane contains the traffic associated with a particular IEEE 802.1p code point, so there can be eight lanes of traffic on a link), use priority-based flow control (PFC).
>
> Ethernet PAUSE and PFC are mutually exclusive features, so you cannot configure both of them on the same interface. If you attempt to configure both Ethernet PAUSE and PFC on an interface, the switch returns a commit error.

- `flow-control`—Enable flow control; flow control is useful when the remote device is a Gigabit Ethernet switch.
- `no-flow-control`—Disable flow control.

Default

Whether flow control is enabled or disabled by default depends on the platform. Run `show interfaces` *`interface-name`* to see whether flow control is enabled on an interface.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1.

flow-control-options

IN THIS SECTION

- Syntax | 7632
- Hierarchy Level | 7632
- Description | 7632
- Usage Guidelines | 7633
- Required Privilege Level | 7633
- Release Information | 7633

Syntax

```
flow-control-options {
    down-on-flow-control;
    dump-on-flow-control;
    reset-on-flow-control;
    up-on-flow-control;
}
```

Hierarchy Level

```
[edit interfaces mo-fpc/pic/port multiservice-options]
```

Description

Configure the flow control options for application recovery in case of a prolonged flow control failure.

- `down-on-flow-control`—Bring interface down during prolonged flow control.
- `dump-on-flow-control`—Cause core dump during prolonged flow control.

> **NOTE**: Starting with Junos OS Release 15.1, on MX Series routers with MS-MICs and MS-MPCs, instead of an eJunos kernel core file, the multiservices PIC management daemon (mspmand) core file is generated when a prolonged flow control failure occurs and when you configure the setting to generate a core dump during prolonged flow control (by using the `dump-on-flow-control` option with the `flow-control-options` statement). The watchdog functionality continues to generate a kernel core file in such scenarios.

- `reset-on-flow-control`—Reset interface during prolonged flow control.

> **NOTE**: Starting in Junos OS Release 16.1R7, the `reset-on-flow-control` option has no effect on the MS-MIC, MS-MPC, MS-DPC, MS-PIC 100, MS-PIC 400, and MS-PIC 500 line cards. This is because starting in Release 16.1R7, Junos OS restarts these line cards to recover them from stuck state due to prolonged flow control.

- `up-on-flow-control`—Cause interface to remain in stuck state until you manually restart the PICs.

> **NOTE**: Starting in Junos OS Release 16.1R7, if interfaces on an MS-PIC or MS-DPC are in stuck state because of prolonged flow control, Junos OS restarts the service PICs to recover them from this state. However, if you want the PICs to remain in stuck state until you manually restart the PICs, configure the `up-on-flow-control` option. In releases before Release 16.1R7, there is no action taken to recover service PICs from this state unless one of the options for the `flow-control-options` statement is configured, or service PIC is manually restarted.

Usage Guidelines

See *Configuring Flow Monitoring*.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

flow-control-queue (Output Congestion Notification)

IN THIS SECTION

- Syntax | 7634
- Hierarchy Level | 7634
- Description | 7634
- Default | 7634
- Options | 7635
- Required Privilege Level | 7635
- Release Information | 7635

Syntax

```
flow-control-queue [ queue | list-of-queues ];
```

Hierarchy Level

```
[edit class-of-service congestion-notification-profile profile-name output ieee-802.1 code-point code-point-bits]
```

Description

Specify one or more output queues to pause, to support priority-based flow control (PFC). The specified queues pause when the interface receives a PFC frame with a matching IEEE 802.1p code point.

Default

Queue 3 (mapped to the fcoe forwarding class) and queue 4 (mapped to the no-loss forwarding class) are programmed as flow control queues to pause. No other output queues are programmed to pause by default.

If you configure flow control queues explicitly, only the queues that you specify are programmed to pause. The explicit flow control queue to pause configuration overrides the default setting, so the queues paused in the default configuration are no longer paused by default.

For example, if you configure queue 2 as a flow control queue, then queue 2 pauses when congestion occurs, but queues 3 and 4 do not pause because they were not explicitly specified. To enable pause on output queues 2, 3, and 4, you must explicitly configure all three of the queues as flow control queues.

The same behavior applies to the IEEE 802.1p code points (priorities) on which PFC is enabled. By default, priorities 3 (011) and 4 (100) are enabled for PFC pause. If you explicitly configure flow control queues to pause, you must also explicitly configure pause for each priority (code point) that you want to pause, because the explicit configuration overrides the default configuration.

Options

[*queue* | *list-of-queues*]—The output queue or a list of output queues to pause.

Required Privilege Level

interfaces—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

    }
    remote-ports number;
}
```

Hierarchy Level

```
[edit unified-edge pcef],
[edit services pcef]
```

Description

Specify a service data flow (SDF) filter (flow identifier) that includes one or more filtering parameters (address, protocol, and port) to identify the subscriber traffic that you want the SDF filter to detect. SDF filters are specified in a PCC rule to identify the Layer 3 or Layer 4 IP packet flows that you want to receive a particular treatment.

> **NOTE**: A PCC rule must include at least one SDF filter and can include a maximum of 15 SDF filters.

If you are using Junos OS Subscriber Aware, specify the name of the SDF filter at the `[edit unified-edge pcef]` hierarchy level.

If you are using Junos OS Broadband Subscriber Management, specify the name of the SDF filter at the `[edit services pcef]` hierarchy level.

Options

flow-identifier Name of the SDF filter.

- **Range:** 1 through 63 characters.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Exporting Flows

Configuring Passive Flow Monitoring

flow-export-rate

IN THIS SECTION

- Syntax | 7648
- Hierarchy Level | 7648
- Description | 7648
- Options | 7648
- Required Privilege Level | 7649
- Release Information | 7649

Syntax

```
flow-export-rate rate;
```

Hierarchy Level

```
[edit forwarding-options sampling instance instance-name family inet output inline-jflow]
```

Description

Specify the flow export rate of monitored packets in kpps. If you have multiple line cards of different types running on the same router, the `flow-export-rate` will be applied to each card. However, the rate applied to the PFEs on the card will vary in accordance with the number of PFEs that are on the card.

On the MX Series, the actual flow export rate might be less than the configured `flow-export-rate`. In addition, the maximum flow export rate for an FPC or MPC module cannot exceed the configured `flow-export-rate`, regardless of how many PICs or MICs are on the module.

Options

rate Flow export rate of monitored packets in kpps (from 1 through 400).

- **Default:** 1 kpps (applies to all PFEs on the FPC)

> **NOTE**: The maximum rate per PFE is 100 kpps for LU, 800 kpps for XL/EA, so for an FPC with four LU PFEs (such as AS cards) you can set a maximum `flow-export-rate` of 400. For an FPC with two LU PFEs (such as the MPC2), the maximum `flow-export-rate` is 200. For an FPC with one LU PFE (such as the MPC5), the maximum is 100. The Junos CLI accepts as valid any value within the range of 1 to 3200, but when applied the value might trigger an error message such as "The configured flow export rate is higher than supported value/chip" in the Junos message log.

flow-export-timer

IN THIS SECTION

- Syntax | 7650
- Hierarchy Level | 7650
- Description | 7650
- Default | 7650

Options | 7650
Required Privilege Level | 7650

Syntax

```
flow-export-timer seconds
```

Hierarchy Level

```
[edit system packet-forwarding-options]
```

Description

Configure the flow export period in seconds. The software exports a IPFIX packet periodically at the configured flow-export timer interval. After you configure the flow export period, you must reboot the device for it to take effect.

Default

10 seconds

Options

seconds	Range: 10 to 600 seconds.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

flow-gate

IN THIS SECTION

- Syntax | 7651
- Hierarchy Level | 7651
- Description | 7651
- Options | 7652
- Required Privilege Level | 7652
- Release Information | 7652

Syntax

```
flow-gate {
    maximum amount;
    reserved amount;
}
```

Hierarchy Level

```
[edit system security-profile]
```

Description

Specifies the number of flow gates, also known as `pinholes`, that user logical system administrators and primary logical system administrators can configure for their logical systems, if the security profile is bound to the logical systems.

The primary administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the primary logical system.

- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the primary administrator can create security profiles and bind them to logical systems.

Options

maximum *amount*

A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.

- **Range:** 0 through 1000000

reserved *amount*

A reserved quota that guarantees that the resource amount specified is always available to the logical system.

- **Default:** 0

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

flow-groups

IN THIS SECTION

- Syntax | 7653
- Hierarchy Level | 7653
- Description | 7653
- Options | 7657
- Required Privilege Level | 7658
- Release Information | 7658

Syntax

```
flow-groups {
    flow-group-name {
        node-device (node-device-name | serial-ID | alias);
        interconnect-device interconnect-device-name;
    }
    node-device (node-device-name | serial-ID | alias) {
        interconnect-device interconnect-device- name {
            preference (high | normal | never);
        }
    }
}
```

Hierarchy Level

```
[edit fabric]
```

Description

In a QFabric system, a hash function is used to select an Interconnect device to forward traffic between two ingress switches, which are called Node devices. Since this hash function is performed on all Interconnect devices, it is possible for redundant multicast streams to flow through one Interconnect

device, making that Interconnect device a potential single point of failure for the redundant flows. Some operations, such as financial transactions, require redundant data flows to use different Interconnect devices to avoid point-of-failure data loss. To enforce this in a fabric, you can create a flow group for multicast or unicast traffic from a particular ingress switch. In a flow group, switches are forced to use different, specified Interconnect devices to forward redundant traffic.

NOTE: The following rules apply to QFabric system flow control:

- A Node device can belong to only one flow group.
- A fabric can contain up to four flow groups.
- Node devices in flow groups can only use the defined Interconnect devices in their flow groups unless all defined Interconnect devices fail. In case of failure, the flow group checks for Interconnect devices with preference set to `normal`—this includes all Interconnect devices in the default group and any Interconnect devices you specifically set to preference `normal`.

The following example creates a flow group. The name of the flow group, test1, is configured first. Next, the Node device TA3713480203 is configured, and the Interconnect device IC-P6603-C is configured last.

```
[edit fabric]
root@qfabric#  set flow-groups ?
Possible completions:
<flow group name>                Flow Group name
+ apply-groups                   Groups from which to inherit configuration data
+ apply-groups-except            Don't inherit configuration data from these groups
> node-device                    Override the link preference for Node device(s)

root@qfabric#  set flow-groups test1 ?
Possible completions:
+ apply-groups                    Groups from which to inherit configuration data
+ apply-groups-except             Don't inherit configuration data from these groups
> interconnect-device             Interconnect device(s) associated with this flow group
> node-device                     Node device(s) associated with this flow group

root@qfabric#  set flow-groups test1 node-device ?

Possible completions:
<node-device-name> Serial ID or alias of node-device
P3686-C                     Node device
TA3713480203                Node device
```

```
TA3713500165                Node device
TA3713500185                Node device
TA3713500307                Node device

root@qfabric# set flow-groups test1 node-device TA3713480203 ?
Possible completions:

<Enter>                            Execute this command
+ apply-group                   Groups from which to inherit configuration data
+ apply-groups-except           Don't inherit configuration data from these groups
|                               Pipe through a command

root@qfabric# set fabric flow-groups test1 node-device TA3713480203

root@qfabric# set flow-groups test1 interconnect-device ?
Possible completions:
<interconnect-device-name>  Serial ID or alias of interconnect-device
IC-P6601-C                  Interconnect device
IC-P6603-C                  Interconnect device

root@qfabric# set flow-groups test1 interconnect-device IC-P6603-C
root@qfabric# show flow-groups
test1 {
    node-device {
        TA3713480203;
    }
    interconnect-device {
        IC-P6603-C;
    }
}
```

The following example overrides the software settings the flow group test1 Node device TA3713500307 was assigned by the software for Interconnect device IC-P6601-C. Node device TA3713500307 has its preference for Interconnect device IC-P6601-C set to `never` by the software, meaning that Node device TA3713500307 can never use Interconnect device IC-P6601-C. You can change this preference so that Interconnect device IC-P6601-C can be used by Node device TA3713500307 if the specifically-configured Interconnect devices all fail. You use the preference option of the `flow-groups` configuration statement to set Interconnect device IC-P6601-C preference to `normal` for Node device TA3713500307.

To configure the preference setting for a Node device to use a particular Interconnnect device, you first select the Node device, then specify the Interconnect device, and finally specify the preference option:

```
[edit fabric]
root@qfabric# set flow-groups ?

Possible completions:
<flow-group name>          Flow Group name
+ apply-groups             Groups from which to inherit configuration data
+ apply-groups-except      Don't inherit configuration data from these groups >
node-device               Override the link preference for Node device(s)
test1                      Flow Group name

root@qfabric# set flow-groups node-device ?

Possible completions:
<name>    serial ID or alias of node-device

P3686-C                     Node device
TA3713480203                Node device
TA3713500185                Node device
TA3713500307                Node device

root@qfabric# set fabric flow-groups node-device TA3713500307 ?
Possible completions:
+ apply-groups            Groups from which to inherit configuration data
+ apply-groups-except     Don't inherit configuration data from these groups
interconnect device

root@qfabric# set fabric flow-groups node-device TA3713500307 interconnect-device ?
Possible completions:
<name>                      Serial ID or alias of interconnect-device
 IC-P6601-C               Interconnect device
 IC-P6603-C               Interconnect device

root@qfabric# set fabric flow-groups node-device TA3713500307 interconnect-device IC-P6601-C
preference ?
Possible completions:
  high                       High link preference
  never                      Never use this link
  normal                     Normal link reference
```

```
root@qfabric# set fabric flow-groups node-device TA3713500307 interconnect-device IC-P6601-C
preference never

root@qfabric# show fabric flow-groups
test1 {
    node-device {
        TA3713480203;
    }
    interconnect-device {
        IC-P6603-C;
    }
}
node-device TA3713500307 {
    interconnect-device IC-P6601-C {
        preference never;
    }
}
```

TIP: To add a TOR to multiple flow groups:
set fabric resources node-device TOR-B interconnect-device IC-A preference HIGH
To configure a TOR to use an Interconnect device from a different flow group if none in the same flow group are available:
set fabric resources node-device TOR-B interconnect-device IC-A preference NORMAL
To increase the priority of default-flowgroup Interconnect devices for a specific TOR:
set fabric resources node-device TOR-A interconnect-device ALL_ICS preference HIGH
To configure default-flowgroup TORs to never use a particular Interconnect device:
Set fabric resources node-device ALL_TORS interconnect-device IC-A preference NEVER

Options

node-device *node-device-name*	Specify a QFabric system ingress Node switch by device name or alias in the QFabric system.
interconnect-device *interconnect-device-name*	Specify a QFabric system Interconnect device name.

preference *preference* Overrides the algorithm results that assign preference to Node devices to use particular Interconnect devices. You can set preference values for these devices to `normal`, `high`, or `never`. (See *Example: Creating a QFabric Flow Group* for more details on setting `preference` values and their meanings.

    vlan-id;
```

```
    output-interface;
}
```

Hierarchy Level

```
[edit services flow-monitoring version9 template template-name],
[edit services flow-monitoring version-ipfix template template-name]
```

Description

Include VLAN IDs in both the ingress and egress directions in the flow key, enable flow direction information in a Version 9 or IPFIX flow template, or both, and configure the output-interface for bridge or VPLS family for inline flow monitoring on the MX Series.

Options

flow-direction Enable reporting of the direction of the flow. The field contains 0x00 (ingress) or 0x01 (egress). The flow direction field in the output record contains the invalid value 0xFF if you do not configure `flow-direction`.

vlan-id Include VLAN IDs in both the ingress and egress directions in the flow key.

output-interface Configure the output-interface field as part of flow-key for bridge or VPLS family.

> **NOTE**: If the output-interface (OIF) is configured under flow-key while the flow-monitoring is in progress, all the existing flows (where OIF was not part of flow-key) report OIF field as zero in the next export. Therefore, in progress configuration of output-interface as part of flow-key is not recommended. In order to configure output-interface as part of flow-key, it is recommended to disable the bridge or vpls sampling and wait for the active flows to become zero.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

```
flow-label-receive-static;
```

Hierarchy Level

```
[edit protocols l2circuit neighbor neighbor-id interface interface-name]
[edit routing-instances instance-name protocols evpn],
[edit routing-instances instance-name protocols evpn interface interface-name]
```

Description

Configure the router to pop the flow label on pseudowire packets received from a remote provider edge (PE) router. The ingress PE router inserts the flow label in the pseudowire packet regardless of the information exchanged in the signaling plane. If the egress PE router cannot handle the pseudowire packet with the flow label, it drops the packet.

Flow-aware transport of pseudowires (FAT) flow labels enable load balancing of MPLS packets across equal-cost multipath (ECMP) paths or link aggregation groups (LAGs) without the need for deep packet inspection of the payload. You can use this statement to enable devices to pop FAT flow labels for:

- Forwarding equivalence class (FEC) 128 pseudowires in:
  - Virtual private LAN service (VPLS) networks.
  - Virtual private wire service (VPWS) networks.

  In these cases, configure this statement in the `[edit protocols l2circuit neighbor neighbor-id interface interface-name] hierarchy`.
- Pseudowires in Ethernet VPN (EVPN)-MPLS networks with VPWS (EVPN-VPWS):
  - Globally in an EVPN-VPWS routing instance.

    In this case, configure this statement in the `[edit routing-instances instance-name protocols evpn]` hierarchy.
  - For specific interfaces in an EVPN-VPWS routing instance.

    In this case, configure this statement in the `[edit routing-instances instance-name protocols evpn interface interface-name]` hierarchy.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1.

Support in a EVPN-VPWS routing instance added in Junos OS Release 21.1R1.

Syntax

```
flow-label-static;
```

Hierarchy Level

```
[edit routing-instances name protocols evpn]
```

Description

For EVPN-MPLS E-LAN services, configure the router to signal the ability to push the flow-aware transport (FAT) flow label on pseudowire packets received from a provider edge (PE) router or to pop the FAT flow label on pseudowire packets transmitted to a PE router. The ingress PE router inserts the flow label in the pseudowire packet regardless of the information exchanged in the signaling plane. If the egress PE router cannot handle the pseudowire packet with the flow label, it drops the packet. A change in FAT flow label configuration is a catastrophic event, causing traffic loss. RFC 6391 describes FAT flow labels and how they are used.

With FAT flow labels, you can load balance known unicast MPLS packets across equal-cost multipath (ECMP) paths or link aggregation groups (LAGs) without the need for deep packet inspection of the payload. You can use this statement to enable devices to pop or push FAT flow labels for these EVPN service types:

- `vlan-based`
- `vlan-bundle`
- `vlan-aware`

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

- Required Privilege Level | 7673
- Release Information | 7673

Syntax

```
flow-level-bandwidth {
    logical-interface flow-bandwidth;
    physical-interface flow-bandwidth;
    subscriber flow-bandwidth;
}
```

Hierarchy Level

```
[edit system ddos-protection protocols protocol-group packet-type]
```

Description

(MX Series routers with only MPCs, T4000 Core Routers with only FPC5s, or EX9200 switches) Configure allowed flow bandwidth for the packet type at each flow aggregation level.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

Support for Enhanced Subscriber Management added in Junos OS Release 17.3R1.

Setting Up and Using Flow Detection

flow-level-control (DDoS Flow Detection)

IN THIS SECTION

- Syntax | 7674
- Hierarchy Level | 7674
- Description | 7674
- Required Privilege Level | 7674
- Release Information | 7674

Syntax

```
flow-level-control {
    logical-interface flow-control-mode;
    physical-interface flow-control-mode;
    subscriber flow-control-mode;
}
```

Hierarchy Level

```
[edit system ddos-protection protocols protocol-group packet-type]
```

Description

(MX Series routers with only MPCs, T4000 Core Routers with only FPC5s, or EX9200 switches) Specify how traffic in the detected flow is handled for the protocol group or packet type at one or more flow aggregation levels. Use this statement to override global flow control mode settings configured with the `flow-level-control` statement at the `[edit system ddos-protection global]` hierarchy level.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

Support for Enhanced Subscriber Management added in Junos OS Release 17.3R1.

- Release Information | 7676

Syntax

```
flow-level-control flow-control-mode;
```

Hierarchy Level

```
[edit system ddos-protection global]
```

Description

(MX Series routers with only MPCs, T4000 Core Routers with only FPC5s, or EX9200 switches) Specify how traffic in the detected flow is handled globally for all protocol groups and packet types at all flow aggregation levels.

To override the global configuration for a protocol group or packet type, use the `flow-level-control` statement at the `[edit system ddos-protection protocols protocol-group packet-type]` hierarchy level to specify the flow control mode at one or more flow aggregation levels.

Options

flow-control-mode Mode for how traffic in the detected flow is controlled globally.

- `drop`—Drop all traffic in flow.
- `keep`—Keep all traffic in flow.
- `police`—Police the traffic to within its allowed bandwidth.

- **Default:** `drop`

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Example: Configuring a Multicast Flow Map

flow-monitoring (Inline Monitoring Services)

IN THIS SECTION

- Syntax | 7680
- Hierarchy Level | 7680
- Description | 7680
- Default | 7680
- Options | 7680
- Required Privilege Level | 7681
- Release Information | 7681

Syntax

```
flow-monitoring {
    counter-profile profile-identifier;
    flow-rate kbps burst-size bytes;
    flow-limit number;
    sampling-profile profile-name;
    sampling-rate bytes;
    security-enable;
}
```

Hierarchy Level

```
[edit services inline-monitoring template template-name]
```

Description

Configures optional parameters for flow-based telemetry (FBT) for the EX4100, EX4100-F, and EX4400 switches. FBT enables per-flow-level analytics, using inline monitoring services to create flows, collect them, and export them to a collector. A flow is a sequence of packets that have the same source IP, destination IP, source port, destination port, or protocol on an interface. For each flow, various parameters are collected and sent to a collector using the open standard IPFIX template to organize the flow. Once there is no active traffic for a flow, the flow is aged out after the configured inactive-timeout period (`flow-inactive-timeout` at the [edit services inline-monitoring template *template-name*] hierarchy level).

Default

Disabled

Options

counter-profile *profile-identifier*

Specify which counters should be exported to the collector, by selecting one of the pre-defined profile names.

- `Per_flow_6_counters`: packet range counter (3 counters), time-to-live (TTL) range counter, TCP window range counter, DoS attack (2 counters)

- `Per_flow_4_counters`: flow packet range (packet size 64 to 1500 bytes) counter (1 count), TTL range counter, TCP window range counter, DoS counter

flow-rate *kbps* burst-size *bytes*

Specify the meter rate for each flow, in kbps, and configure the maximum number of bytes allowed for incoming packets to burst above the flow meter rate.

Range: 8 to 10000000 kbps (flow-rate); 512 to 256000000 bytes (burst-size)

flow-limit *number*

Specify the maximum number of flows allowed.

Range: 0 through 32000

sampling-profile *profile-identifier*

Configure one of the following sampling profiles:

- `First_N_Pkt` : Sample contains the first N packets of a flow
- `Deterministic`: Sample contains every Nth packet of a flow
- `Random`:Sample contains randomly chosen packets from a flow
- `Combo1`: Sample contains the first N packets of a flow, followed by a random packet at the configured interval
- `Combo2`: Sample contains the first N packets of a flow, followed by a Deterministic 1 packet at the configured interval

sampling-rate *bytes*

Specify the rate at which packets are sampled to create flows, in bytes

Range: 1 to 65535 bytes

security-enable

Enable security analytics; specify that Denial-of-Service (DoS) attacks are reported to the collector.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 21.1R1.

[edit security flow],
```

```
[edit tenants name security flow]
```

Description

Configure flow profile for selective session synchronization in a Multinode High Availability (MNHA) deplyments.

Options

name Name for the flow-profile. This is a user defined profile where you can define selective session synchronization options. You must apply the user-defined profile to a security policy; otherwise the default profile will be applied to the security policy.

default-profile Default profile for selective session synch. By default, all the policies use the default-profile if none of the user defined profile is attached to the security policy.

session-sync Options for MNHA session synchronization.

- disabled—Disable synchronization of sessions over both inter domain (IDL) link and intra domain link (ICL). Use this option to disable synchronization for short-lived sessions or set a minimum age for session synchronization. By default, session synchronization is enabled.

session-sync-min-age Duration after which flow session synchronizes to the MNHA peer node (seconds). Use this option to synchronize the session only after it is established for minimum session age duration. The default value is 0.

- **Default:** 0 (All sessions are synchronized immediately
- **Range:** 0 through 3600

Required Privilege Level

[none specified]

Release Information

- Syntax | 7691
- Hierarchy Level | 7691
- Description | 7691
- Options | 7691
- Required Privilege Level | 7692
- Release Information | 7692

Syntax

```
flow-sample {
    ae-parent-index;
}
```

Hierarchy Level

```
[edit forwarding-options sflow]
```

Description

Configure flow sample inputs.

Options

ae-parent-index Configure to send aggregated Ethernet parent index to an sFlow datagram.

When you configure sFlow, a sampled packet is captured from the traffic stream and the packet details are added to an sFlow datagram. This datagram contains information such as source IP, destination IP, ingress SNMP index, and egress SNMP index of the respective interface.

sFlow is not supported on aggregated Ethernet bundles but you can configure sFlow on any child interface of an aggregated Ethernet interface. When you configure `flow-sample ae-parent-index`, the sFlow datagram includes the SNMP index of the parent aggregated Ethernet interface instead of the child interface.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 24.4R1.

Syntax

```
flow-server hostname {
    aggregation {
        autonomous-system;
        destination-prefix;
        protocol-port;
        source-destination-prefix {
            caida-compliant;
        }
        source-prefix;
    }
    autonomous-system-type (origin | peer);
    dscp dscp-value;
    forwarding-class class-name;
    (local-dump | no-local-dump);
    port port-number;
    source-address address;
    version format;
    version9 {
        template template-name;
    }
    version-ipfix {
        template template-name;
    }
}
```

Hierarchy Level

```
[edit forwarding-options sampling instance instance-name family (inet | inet6 | mpls | vpls |
bridge) output],
[edit forwarding-options sampling family (inet | inet6 | mpls | vpls | bridge) output]
```

Description

Configure a server to either:

- Collect an aggregate of sampled flows and send the aggregate to a specified host system that runs the collection utility cfdcollect, **or**

- Specify a host system to collect sampled flows using the version 9 or IPFIX format.

You can configure up to one version 5 and one version 8 flow format at the `[edit forwarding-options sampling family (inet | inet6 | mpls) output flow-server hostname]` hierarchy level. For the same configuration, you can specify either version 9/IPFIX flow record formats or version 5/8 formats, not both types of formats.

Options

hostname—IP address–IPv4 or IPv6–or identifier of the host system (the workstation either running the cflowd utility or collecting traffic flows using version 9 or IPFIX).

> **NOTE**: Only host systems running IPv4 are supported on QFX10000 switches.

You can configure only one host system for version 9.

> **NOTE**: IPv6 configuration for `flow-server` is supported only in Junos OS Release 12.3 and later.
>
> Note that when you configure an IPv6 address for the `flow-server` statement, you must also configure an IPv6 address for the `inline-jflow source-address` statement at the `[edit forwarding-options sampling instance instance-name family (inet | inet6 | mpls | vpls | bridge) output]` hierarchy level.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`version9` statement introduced in Junos OS Release 8.3.

Support at the following hierarchy levels introduced in Junos OS Release 18.2R1: `[edit forwarding-options sampling instance instance-name family bridge]`, , `[edit forwarding-options sampling family bridge]`.

Support for IPv6 addresses for the `flow-server address` and `source-address address` statements within sampling instances introduced in Junos OS Evolved Release 23.1R1.

RELATED DOCUMENTATION

Configuring Traffic Sampling on MX, M and T Series Routers

flow-session

IN THIS SECTION

- Syntax | 7695
- Hierarchy Level | 7695
- Description | 7695
- Options | 7696
- Required Privilege Level | 7697
- Release Information | 7697

Syntax

```
flow-session {
    maximum amount;
    reserved amount;
}
```

Hierarchy Level

```
[edit system security-profile]
```

Description

Specifies the number of flow sessions that user logical system administrators and primary logical system administrators configure for their logical systems if the security profile is bound to the logical systems.

The primary administrator:

- uses security profiles to provision logical systems with resources.

- binds security profiles to user logical systems and the primary logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the primary administrator can create security profiles and bind them to logical systems.

Options

`maximum` *`amount`*

A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.

- **Range:** 0 through 1000000

`reserved` *`amount`*

A reserved quota that guarantees that the resource amount specified is always available to the logical system.

- **Default:** 0

> **NOTE**: An IPv6 session consumes twice the memory of an IPv4 session. Therefore the number of sessions available for IPv6 is half the reserved and maximum quotas configured for the flow session resource in a security profile. Use the vty command **show usp flow resource usage cp-session** to check flow session usage.

For performance consideration, flow session rate-limiting is done on distributed central point (DCP) for SRX5400, SRX5600, and SRX5800 devices. DCP session is always created before SPU flow session on these devices. You can count DCP session instead of SPU flow session to check whether the maximum/reserved quotas are reached for a specific logical system or tenant system.

There are no differences between DCP session and SPU flow session count because a session without NAT consumes one DCP session and one SPU flow session.

For sessions with NAT configuration, one connection can consume one SPU flow session and two DCP sessions. If all sessions are NAT sessions and each session consumes two DCP sessions, then the logical system or tenant system can only reach half of the maximum quotas configured for the flow session resources.

Typically, there are sessions with NAT and non-NAT mixed traffic, so the logical system or tenant system can create flow sessions between “maximum”/2 and “maximum”.

This functionality is similar to the reserved quotas that are configured for the flow session resources in a security profile. As a logical system or tenant system can consume more resources than the reserved quotas, you can configure additional flow session resources for reserved quotas with NAT configuration, if there are free resources available in the logical system or tenant system.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

        }
    }
}
```

Hierarchy Level

```
[edit protocols oam fabric]
```

Description

Configure the fabric flow specification parameters for internal fabric monitoring. The following conditions apply:

- You must specify a protocol type for each flow specification: `unicast-ethernet`, `unicast-ethernet-ipv4`, `multicast-ipv4`, or `multicast-vlan-flood`.
- You can specify only one type for each flow specification.

- All other parameters are optional.

The remaining statements under this hierarchy level are explained separately.

Options

flow-specification-name Name of the flow specification.

- **Syntax:** 1 to 20 alphanumeric characters

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

flow-table-size (Chassis)

IN THIS SECTION

Syntax | **7700**

- Hierarchy Level | 7700
- Description | 7700
- Options | 7700
- Required Privilege Level | 7700
- Release Information | 7700

Syntax

```
flow-table-size size;
```

Hierarchy Level

```
[edit chassis fpc slot inline-video-monitoring]
```

Description

Configure the number of video flows that can be measured per Packet Forwarding Engine by an MPC at a given time. This value takes effect the next time the MPC is rebooted.

Options

size Number of video flows per Packet Forwarding Engine.

- **Range:** 16 through 8192

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

RELATED DOCUMENTATION

Configuring Inline Video Monitoring on MX Series Routers

flow-table-size

IN THIS SECTION

- Syntax | 7701
- Hierarchy Level | 7701
- Description | 7701
- Required Privilege Level | 7703
- Release Information | 7703

Syntax

```
flow-table-size {
    ipv4-flow-table-size  units;
    ipv6-extended-attrib;
    ipv6-flow-table-size units;
    mpls-flow-table-size  units;
    vpls-flow-table-size units;
}
```

Hierarchy Level

```
[edit chassis fpc slot-number inline-services]
```

Description

Configure the size of hash tables in units of 256K entries for inline services sampling. You cannot configure the size of the flow hash table for ACX Series routers running Junos OS Evolved.

Starting with Junos OS Release 15.1F2, by default, the software allocates one 1K IPv4 flow table. To allocate 15 256K IPv4 flow tables, the former default, you can enter this configuration from the `[edit]` hierarchy level:

```
[edit]
user@router# set chassis fpc inline-services flow-table-size ipv4-flow-table-size 15
```

The flow table size is the sum of all the configured flow table types. The sum of all the configured flow table types cannot exceed the maximum supported flow table size. For example, for the MPC2E, MPC3E, and MPC4E line cards, the maximum supported flow table size is 15 units. The different flow table families could be configured as follows for these line cards:

IPv4 table size: 5
IPv6 table size: 5
MPLS table size: 4
VPLS table size: 1

Total table size: 15

Starting with Junos OS Release 17.3R1, the maximum supported flow table size varies by line card type:

Table 55: Maximum Supported Flow Table Size for MX Series Routers

Line Card	Maximum Number of Units (1 unit =256K entries)
MPC2E, MPC3E, and MPC4E	15
MPC5E and MPC6E	220
MPC7E , MPC9E, LC2103, and LC480	48
MPC8E	97
MPC10E and MPC11E	48
JNP10K-LC4800, JNP10K-LC9600, and MX304-LMIC16BASE	80

NOTE: We recommend that you configure this statement during a maintenance window:

- Prior to Junos OS 16.1R1 and 15.1F2, the FPC reboots automatically after you commit this configuration change.
- Starting from Junos OS Release 16.1R1 and 15.1F2, any changes in the configured size of the flow table do not require a reboot of the FPC.

The remaining statements are defined separately.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1.

`ipv6-extended-attrib` option added in Junos OS Release 14.2 for MX Series routers.

`vpls-flow-table-size` option added in Junos OS Release 13.2 for MX Series routers.

`bridge-flow-table-size` option added in Junos OS Release 18.2R1 for MX Series routers, replacing the `vpls-flow-table-size` option, which has been deprecated.

flow-tap

IN THIS SECTION

Syntax | 7704

Hierarchy Level | 7704

- Description | 7704
- Options | 7704
- Required Privilege Level | 7705
- Release Information | 7705

Syntax

```
flow-tap {
    (interface interface-name | tunnel-interface interface-name);
    family (inet | inet6);
}
```

Hierarchy Level

```
[edit services]
```

Description

Enable the FlowTap service or FlowTapLite service on an interface. FlowTapLite is a lighter version of the flow-tap application that is available only on tunnel interfaces for those MX Series platforms and ACX Series platforms running Junos OS Evolved that support the feature.

Starting in Junos OS Release 17.3R1, the FlowTapLite service can run concurrently with the radius-flow-tap service on the same MX Series router. The radius-flow-tap service (`[edit services radius-flow-tap]`) is required for subscriber secure policy mirroring on MX Series routers.

In earlier releases, the FlowTapLite and radius-flow-tap services cannot run concurrently on an MX Series router, which prevents you from running FlowTapLite monitoring and subscriber secure policy mirroring at the same time. These services cannot run concurrently on an ACX router.

Options

interface *interface-name*	Use the specified interface for the FlowTap application.
tunnel-interface *interface-name*	Use the specified tunnel interface for the FlowTapLite application.

family (Not applicable for FlowTapLite) Apply flow-tap services to the specified family. If you do not specify an option, the FlowTap service is applied only to IPv4 traffic.

- inet—IPv4 traffic.
- inet6—IPv6 traffic.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.1.

ccc option introduced in Junos OS Release 17.2.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
17.3R1	Starting in Junos OS Release 17.3R1, the FlowTapLite service can run concurrently with the radius-flow-tap service on the same MX Series router.

Syntax | 7706

- Hierarchy Level | 7706
- Description | 7706
- Options | 7706
- Required Privilege Level | 7707
- Release Information | 7707

Syntax

```
flow-tap-dtcp {
    ssh {
        connection-limit limit;
        rate-limit limit;
    }
}
```

Hierarchy Level

```
[edit system services]
```

Description

Configure Dynamic Tasking Control Protocol (DTCP) sessions to run over SSH in support of the flow-tap, FlowTapLite, or radius-flow-tap services. Note that the flow-tap feature is not supported on outbound, or egress, traffic. Only inbound, or ingress, traffic is supported.

This statement is required for DTCP-initiated subscriber secure policy mirroring (radius-flow-tap service).

Options

`connection-limit` *`limit`*—(Optional) Maximum number of connections allowed.

- **Range:** 1 through 250
- **Default:** 75

`rate-limit` *`limit`*—(Optional) Maximum number of connection attempts allowed per minute.

- **Range:** 1 through 250
- **Default:** 150

Required Privilege Level

flow-tap—To view this statement in the configuration.

flow-tap-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.1.

flow-timeout-time (DDoS Flow Detection)

IN THIS SECTION

- Syntax | 7708
- Hierarchy Level | 7708
- Description | 7708
- Options | 7708
- Required Privilege Level | 7708
- Release Information | 7708

Syntax

```
flow-timeout-time seconds;
```

Hierarchy Level

```
[edit system ddos-protection protocols protocol-group packet-type]
```

Description

(MX Series routers with only MPCs, T4000 Core Routers with only FPC5s, or EX9200 switches) Configure the period of time that a culprit flow is suppressed for the packet type. The timeout period is effective only when timing out has been enabled with the "timeout-active-flows" on page 30520 statement.

Options

seconds—Period that the traffic is suppressed.

- **Range:** 1 through 7200 seconds
- **Default:** 300 seconds

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

Support for Enhanced Subscriber Management added in Junos OS Release 17.3R1.

flows (PCC Rules)

IN THIS SECTION

- Syntax | 7709
- Hierarchy Level | 7709
- Description | 7709
- Options | 7710
- Required Privilege Level | 7710
- Release Information | 7710

Syntax

```
flows ([flow-identifier] | any);
```

Hierarchy Level

```
[edit unified-edge pcef pcc-rules rule-name from],
[edit services pcef pcc-rules rule-name from]
```

Description

Specify the service data flow (SDF) filters (flow identifiers) that define the match criteria for the policy and charging control (PCC) rule. You can configure a maximum of 15 SDF filters. You must include the `flows` statement in a PCC rule. If you do not want to filter subscriber traffic based on SDF filters, use the `any` option.

If you are using Junos OS Subscriber Aware, specify the name of the SDF filter at the `[edit unified-edge pcef pcc-rules rule-name from]` hierarchy level.

If you are using Junos OS Broadband Subscriber Management, specify the name of the SDF filter at the `[edit services pcef pcc-rules rule-name from]` hierarchy level.

Options

flow-identifier Name of an SDF filter that is used to detect IP packet flows. You can configure a maximum of 15 SDF filters. The referenced SDF filters must be configured.

- **Range:** 1 through 63 characters.

any All IP packet flows.

Required Privilege Level

For Junos OS Subscriber Aware:

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

For Junos OS Broadband Subscriber Management:

services—To view this statement in the configuration.

services–control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Support at the `[edit services pcef pcc-rules rule-name from]` hierarchy level introduced for Junos OS Broadband Subscriber Management in Junos OS Release 17.2 on MX Series.

Support for Next Gen Services for Junos OS Broadband Subscriber Management introduced in Junos OS Release 19.3R2 on MX Series.

Hierarchy Level

```
[edit logical-systems name policy-options],
[edit policy-options]
```

Description

Attributes of a flow specification. Use in configuring policies to match certain conditions and take policy actions (accept/reject) accordingly for validating the flow specifications at the edge routers.

Options

name Flowspec attribute name

action Define flowspec action attributes

- mark—Flowspec action traffic-mark
- rate-limit—Flowspec action rate-limit
- redirect—Flowspec action redirect-ip
- routing-instance—Flowspec action redirect-routing-instance
- sample—Flowspec action sample

From a policy point of view, the actions listed above are the policy match conditions. The 'match' and 'action' keywords are route attributes used to match against a flow route.

The remaining statements are explained separately. See CLI Explorer.

force-continue (OCS Partition)

IN THIS SECTION

- Syntax | 7720
- Hierarchy Level | 7721
- Description | 7721
- Required Privilege Level | 7721
- Release Information | 7721

Syntax

```
force-continue;
```

Hierarchy Level

```
[edit access ocs partition partition-name]
```

Description

Enable subscriber traffic to flow before the first interrogation with the Online Charging System (OCS) occurs.

Wireline customers often control user services solely through the Policy Control and Charging Rules Function (PCRF) and use the OCS as a convenient real-time usage monitoring mechanism rather than as an enforcement unit. To decrease the number of possible erroneous OCS configurations, include the `force-continue` statement to force the broadband Policy and Charging Enforcement Function (BPCEF) to limit the impact of negative responses from the OCS and quota expirations, and to prevent sending OCS notifications for affected rating groups. Whenever the PCEF receives a negative response to any reported group, it stops reporting this group to the OCS.

NOTE: The `force-continue` state is required; you must configure it in the OCS partition.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.2.

force-control-packets-on-transit-path

IN THIS SECTION

- Syntax | 7722
- Hierarchy Level | 7722
- Description | 7722
- Required Privilege Level | 7723
- Release Information | 7723

Syntax

```
force-control-packets-on-transit-path;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number]
```

Description

Force host-injected control packets to follow the transit path. Host-injected control traffic reaches the GRE tunnel interface queues at the PFE when the control session is over the GRE tunnel interface. This includes control protocols OSPF, BGP, PIM, RSVP, LDP, OAM, BFD and MSDP.

Injection of control traffic ensures that the kernel includes the interface ID of the GRE logical interface and the unicast next-hop ID of the corresponding GRE physical interface along with the packet that is injected into the PFE. PFE code uses the logical interface ID and next-hop ID information to forward the packet. GRE encapsulation occurs at the PFE level and the packet gets looped back over the GRE tunnel after being subjected to CoS treatment over the GRE interface queues. The looped back packet is subjected to a second lookup and is then forwarded over the egress physical interface.

Support for control traffic to travel over the GRE tunnel with CoS intact means the `copy-tos-to-outer-ip-header` statement cannot be used. Use the `copy-tos-to-outer-ip-header-transit` configuration statement instead. With this statement, all transit packets on the GRE tunnel logical interface have the TOS copied to the outer header.

To enable this feature, configure the `force-control-packets-on-transit-path` statement on the GRE tunnel logical interface. For example:

```
gr-4/0/10 {
    unit 0 {
        tunnel {
            source 192.168.2.1
            destination 192.16.4.2;
        }
        force-control-packets-on-transit-path;
    }
}
```

This example enables Layer 2.5 injection of control protocols on the GRE tunnel `gr-4/0/10 unit 0` only.

This feature is supported on the MX204 and the MX NG MPCs (MPC2E-NG and MPC3E-NG).

Required Privilege Level | 7724
Release Information | 7724

Syntax

```
force-discover;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number dhcp-client]
```

Description

Forces the DHCP client to send a DHCP discover packet after one to three failed `dhcp-request` attempts. The `force-discover` option ensures that the DHCP server will assign the same or a new IP address to the client.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1X49-D80.

Starting with Junos OS Release 17.3R1, on all SRX Series Firewalls and vSRX Virtual Firewall instances, the CLI option `dhcp-client` at `[edit interfaces interface-name unit logical-unit-number family inet]` hierarchy is changed to `dhcp` to keep consistent with other Junos platforms. There is no change in the functionality with the changed CLI option `dhcp`.

force-fbf-terms

IN THIS SECTION

- Syntax | 7726
- Hierarchy Level | 7726
- Description | 7727
- Required Privilege Level | 7727
- Release Information | 7727

Syntax

```
force-fbf-terms
```

Hierarchy Level

```
[edit system packet-forwarding-options firewall]
```

Description

When a firewall filter is configured with two terms; the first term without filter based forwarding action, and the second term with a filter based forwarding action, the packet is assigned the routing instance specified by the filter based forwarding action in the second term. This happens even if the first term is configured with a terminating action such as *accept*. Ideally, after the first term, the packet should terminate and not be procesed by the second term. But this is the default behavior - a firewall filter term that has a filter based forwarding action is always processed first, regardless of its order of placement.

You use `force-fbf-terms` to change this default behavior. When you apply this configuration, the firewall filter terms in a firewall are always processed in the order of their placement in the configuration, irrespective of whether a firewall filter term has a filter based forwarding action.

Required Privilege Level

firewall – To view this statement in the configuration

force-premium (Firewall Filter Action)

IN THIS SECTION

- Syntax | 7729
- Hierarchy Level | 7729
- Description | 7729
- Required Privilege Level | 7730
- Release Information | 7730

Syntax

```
force-premium;
```

Hierarchy Level

```
[edit firewall family family-name filter filter-name term term-name then],
[edit logical-systems logical-system-name firewall family family-name filter filter-name term term-name then]
```

Description

Firewall filter option to force premium treatment for traffic (MX Series routers)— By default, a hierarchical policer processes the traffic it receives according to the traffic's forwarding class. Premium, expedited-forwarding traffic has priority for bandwidth over aggregate, best-effort traffic. Now you can include the `force-premium` option at the `[edit firewall filter filter-name term term-name]` hierarchy level to ensure that traffic matching the term is treated as premium traffic by a subsequent hierarchical policer, regardless of its forwarding class. This traffic is given preference over any aggregate traffic received by that policer. Consider a scenario where a firewall filter is applied to an interface that receives both expedited-forwarding voice traffic and best-effort video traffic. Traffic that matches the first term of the filter is passed to a hierarchical policer in the second term. The hierarchical policer also receives best-effort data traffic from another source. The filtered video traffic is treated the same as this data traffic, as aggregate traffic with a lower priority than the premium voice traffic. Consequently, some of the video traffic might be dropped and some of the data traffic passed on.

To avoid that situation, include the `force-premium` option in the firewall filter term that passes traffic to the hierarchical policer. This term forces the video traffic to be marked as premium traffic. The hierarchical policer gives both the voice traffic and the video traffic priority over the aggregate data traffic.

NOTE: The `force-premium` filter option is supported only on MPCs.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3 for `family inet` and `inet6`.

Support for `family vpls`, `ccc`, and `bridge` added in Junos OS Releases 13.3R8, 13.3R10, 14.1R8, 14.2R7, 15.1R4,16.1R1, and 17.1R1.

Description

For Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), VLAN Spanning Tree Protocol (VSTP), or Multiple Spanning Tree Protocol (MSTP), specifies the length of time an STP bridge port remains in the listening and learning states before transitioning to the forwarding state.

Options

seconds—(Optional) Number of seconds the bridge port remains in the listening and learning states.

- **Range:** 4 through 30
- **Default:** 15 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4.

Statement updated in Junos OS Release 9.4 for EX Series switches to add VSTP support.

Support for logical systems added in Junos OS Release 9.6.

forward-on-source-bridge-domain

IN THIS SECTION

- Syntax | **7748**
- Hierarchy Level | **7749**
- Description | **7749**
- Options | **7750**
- Required Privilege Level | **7750**
- Release Information | **7750**

Syntax

```
forward-on-source-bridge-domain {
    forward-policy [ forwarding-policy-name ... ];
}
```

Hierarchy Level

```
[edit routing-instances name protocols evpn oism enhanced]
```

Description

Enable enhanced optimized intersubnet multicast (OISM) to forward multicast data traffic on the multicast source VLAN for traffic that matches the provided forwarding policy (or policies).

When you configure enhanced OISM, you allocate an OISM supplemental bridge domain (SBD) for each Layer 3 (L3) virtual routing and forwarding (VRF) instance. You also configure the tenant VLANs on each OISM device for the hosts the device serves. By design, even if the destination OISM device hosts the multicast source VLAN, enhanced OISM routes the multicast traffic from the source VLAN to the SBD toward the remote OISM devices. The each remote OISM device locally routes the traffic from the SBD to the destination tenant VLAN.

The enhanced OISM route-to-SBD model enables efficient multicast data transfer in networks with a large number of tenant VLANs hosted by different OISM devices. However, when enhanced OISM routes multicast packets to the SBD and then to the destination VLAN, the packet time-to-live (TTL) count is decremented more than once. As a result, in that case source packets with TTL=1 won't reach the receivers.

Regular OISM forwards multicast traffic from internal sources on the source VLAN, and the remote devices then forward or route the traffic to the destination VLAN. As a result, regular OISM can successfully deliver source packets with TTL=1 to the receivers. However, regular OISM doesn't scale well in environments with many tenant VLANs, because that model requires you to configure all tenant VLANs on all OISM devices (even if a device doesn't have hosts on some of the VLANs).

If you want to use enhanced OISM instead of regular OISM with multicast source packets that have TTL=1, you can use the `forward-on-source-bridge-domain` statement to ensure those packets reach the subscribed receivers. This statement applies exception policies on the device to forward on the source VLAN (instead of routing to the SBD) for specific multicast groups, or sources and groups. You configure routing policies to match the multicast groups [(*,G)] or multicast sources and groups [(S,G)] for which you want the device to forward multicast traffic on the source VLAN. This statement essentially causes enhanced OISM devices to use the regular OISM forwarding model for particular multicast flows.

You can configure this option only when you use OISM in enhanced OISM mode. To enable enhanced OISM, see the `enhanced-oism` option at the `[edit forwarding-options multicast-replication evpn irb]` hierarchy level.

For details on how OISM works and all of the elements you need to configure OISM in an EVPN fabric, see *Optimized Inter-Subnet Multicast in EVPN Networks*.

For details and configurations examples for this feature, see *Enhanced OISM Exception Policy to Forward on Source VLAN Instead of SBD for Packets with TTL=1*.

Options

(Required) forward-policy [*forwarding-policy-name* ...]	Routing policy or policies to match multicast groups (or sources and groups) for which the device should forward that multicast traffic on the source VLAN.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS and Junos OS Evolved Release 25.2R1.

```

Description

Forward specified DHCP client packets, without creating a new subscriber session, when you use DHCP relay selective processing feature. You can configure the forwarding operation globally or for a group of interfaces, and for either DHCP or DHCPv6 relay agent. Use this command to manage subscribers, when large number of DHCP relay requests are received and license limitations are exceeded. This command uses option 82 and applies "scale-subscriber" license.

> **NOTE**: DHCP packets forwarded with the `forward-only` statement do not consider other configurations except for the `trust-option-82` option. The DHCP relay agent ignores all other configured options.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

options dhcp-relay],
[edit routing-instances routing-instance-name forwarding-options dhcp-relay]
```

Description

Configure how DHCP relay agent filters and handles DHCP snooped packets on the specified interfaces. The router or switch determines the DHCP snooping action to perform based on a combination of the `forward-snooped-clients` configuration and the configuration of either the `allow-snooped-clients` statement or the `no-allow-snooped-clients` statement.

The router (or switch) also uses this statement to determine how to handle snooped BOOTREPLY packets received on non-configured interfaces.

Options

`all-interfaces`—Perform the action on all interfaces.

- **Default:** On EX Series switches, the action is performed on all interfaces by default.

`configured-interfaces`—Perform the action only on interfaces that are configured as part of an interface group.

`non-configured-interfaces`—Perform the action only on interfaces that are not part of a group.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.4.

Support at the [`edit forwarding-options dhcp-relay dhcpv6`] hierarchy level introduced in Junos OS Release 15.1X53-D56 for EX Series switches and Junos OS Release 17.1R1.

- Options | 7768
- Required Privilege Level | 7768
- Release Information | 7768

Syntax

```
forwarding-class class-name;
```

Hierarchy Level

```
[edit class-of-service host-outbound-traffic]
```

Description

Specify the name of the forwarding class to which host outbound traffic is assigned on all egress interfaces. The output queue associated with the forwarding class must be properly configured on all interfaces. In the case of a restricted interface, the traffic flows through a restricted queue.

For egress interfaces hosted on MX Series routers, M120 routers, or Enhanced III FPCs in M320 routers, both Routing Engine sourced traffic and distributed protocol handler traffic are affected. For all other egress interfaces, only Routing Engine sourced traffic is affected.

This statement does not affect transit traffic or incoming traffic.

Default

If you do not configure an output queue for host outbound traffic, the router uses the default queue assignments for host outbound traffic.

Options

class-name—Name of the forwarding class.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

forwarding-class (Fibre Channel Interfaces)

IN THIS SECTION

- Syntax | 7770
- Hierarchy Level | 7771
- Description | 7771
- Options | 7771
- Required Privilege Level | 7772
- Release Information | 7772

Syntax

```
forwarding-class lossless-forwarding-class-name;
```

Hierarchy Level

```
[edit class-of-service interfaces fibre-channel-interface-name]
```

Description

Configure a Layer 3 fixed classifier on a Fibre Channel (FC) interface. The fixed classifier places all traffic received from the FC network into the specified forwarding class. The forwarding class must be lossless. (That is, the forwarding class must be either the default `fcoe` or `no-loss` forwarding class, or the forwarding class must be configured with the `no-loss` drop attribute.) If you attempt to specify a lossy forwarding class, the system returns a commit error.

FCoE networks typically use priority 3 (IEEE code point 011) for FCoE traffic. The QFX Series default configuration uses IEEE 802.1p priority 3 for FCoE traffic. If the IEEE 802.1p code point value that the Ethernet network uses for FCoE traffic is different than code point 3, you can rewrite the code point to the value used in your Ethernet (FCoE) network. The lossless forwarding class specified in the fixed classifier uses the `rewrite-value` statement as the IEEE 802.1p code point (priority) for FCoE traffic on the FCoE network.

To rewrite the code point value, include the `rewrite-value input ieee code-point` *`code-point-bits`* statement at the [`edit class-of-service interfaces` *`fc-interface-name`*] hierarchy level.

> **NOTE**: If you are not using the default configuration (priority 3 for FCoE traffic), the lossless forwarding class specified in the FC interface fixed classifier must be mapped to the IEEE 802.1p code point specified in the rewrite value statement.
>
> In order to avoid fate sharing (separate flows that affect each other's throughput), the code point (priority) used for the lossless forwarding class (the code point specified in the rewrite value statement) should be the only code point classified to that forwarding class (at the [`edit class-of-service classifiers`] hierarchy level). For example, if the rewrite value uses code point 101 for lossless FCoE forwarding class fcoe_fc1, then in the classifier configuration attached to ingress Ethernet interfaces, code point 101 is the only code point that should be classified to the fcoe_fc1 forwarding class. Now if you also attach a classifier to an interface that maps code point 110 to forwarding class fcoe_fc1, then congestion on priority 110 unfairly (and unintentionally) affects the FCoE traffic that uses priority 101. Both priorities 101 and 110 are classified into forwarding class fcoe_fc1, so the traffic from both priorities shares the same fate.

Options

lossless-forwarding-class-name—Name of the lossless forwarding class.

Required Privilege Level

interfaces—To view this statement in the configuration.

Hierarchy Level

```
[edit class-of-service forwarding-policy next-hop-map map-name]
[edit class-of-service forwarding-policy class class-name classification-override]
```

Description

Define forwarding class name and associated next hops.

Options

class-name	Name of the forwarding class.
non-labelled-next-hop	Match any non-labelled next hop.
match-next-hop-forwarding-class	Match any pre-defined forwarding-class or a forwarding-class that is configured using CLI.
transport-class color *color*	Match transport-class key in FRR indirect keys structure.

> **NOTE**: This option is available only at [edit class-of-service forwarding-policy next-hop-map *next-hop-map-name* forwarding-class *forwarding-class-name*] hierarchy level.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced for QFX10000 Series switches in Junos OS Release 17.1R1.

`non-labelled-next-hop` option introduced in Junos OS Release 19.1R1 for all platforms.

`match-next-hop-forwarding-class` option introduced in Junos OS Evolved Release 21.3R1 for PTX10008 platform.

forwarding-class (Fragmentation)

IN THIS SECTION

- Syntax | 7778
- Hierarchy Level | 7778
- Description | 7778
- Default | 7778
- Options | 7778
- Required Privilege Level | 7778
- Release Information | 7778

Syntax

```
forwarding-class class-name {
    drop-timeout milliseconds;
    fragment-threshold bytes;
    multilink-class number;
    no-fragmentation;
}
```

Hierarchy Level

```
[edit class-of-service fragmentation-maps map-name]
```

Description

For Multiservices and Services PICs link services IQ interfaces (`lsq`) only, define a forwarding class name and associated fragmentation properties within a fragmentation map.

The `fragment-threshold` and `no-fragmentation` statements are mutually exclusive.

Default

If you do not include this statement, the traffic in forwarding class *class-name* is fragmented.

Options

class-name—Name of the forwarding class.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

(Forwarding Class Accounting)

```
forwarding-class-accounting {
    direction
}
```

(Enhanced CoS Accounting)

```
forwarding-class-accounting {
    enhanced
}
```

Hierarchy Level

```
[edit interfaces interface-name],
[edit interfaces interface-name unit logical-unit-number]
```

Description

Forwarding class accounting (non-enhanced mode) is enabled for IPv4, IPv6, MPLS, Layer 2 and other packets simply by enabling the feature.

NOTE: Forwarding class accounting (enhanced mode) is not supported in "hyper-mode (forwarding-options)" on page 8593.

Both bytes and packet total are counted. For Layer 2 traffic, only bytes are counted. Flow rates are measured. Counters can be enabled in ingress, egress or in both directions. Statistics are accounted before queueing drop stage, so will include packets that might get dropped in queueing.

CoS-based interface counters (enhanced mode) are supported for IPv4 and IPv6 aggregate routes on Layer 2.

Both bytes and packet total are counted. Flow rates are not measured. The counters can be configured to exclude overhead bytes (such as protocol encapsulations) so end-customer packets can be differentiated from other traffic.

Disable or delete `forwarding-class-accounting` by removing the statement from the interface configuration–for example, by typing `delete interfaces interface-name forwarding-class-accounting`.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Forwarding class accounting statement (non-enhanced mode) introduced in Junos OS Release 13.3R3.

Enhanced CoS Accounting statement introduced in Junos OS Release 14.1.

        }
    }
}
```

Hierarchy Level

```
[edit class-of-service]
```

Description

Define forwarding class names and accociate with queue numbers.

SRX Series Firewalls

All traffic traversing the SRX Series Firewall is passed to an SPC to have service processing applied. Junos OS provides a configuration option to enable packets with specific Differentiated Services (DiffServ) code points (DSCP) precedence bits to enter a high-priority queue, a medium-priority queue, or a low-priority queue on the SPC. The Services Processing Unit (SPU) draws packets from the highest priority queue first, then from the medium priority queue, and last from the low priority queue. The processing of the queue is weighted-based not strict-priority-based. This feature can reduce overall latency for real-time traffic, such as voice traffic.

Initially, the spu-priority queue options were "high" and "low". Then, these options (depending on the devices) were expanded to "high", "medium-high", "medium-low", and "low". The two middle options ("medium-high" and "medium-low") have now been deprecated (again, depending on the devices) and replaced with "medium". So, the available options for spu-priority queue are "high", "medium", and "low".

We recommend that the high-priority queue be selected for real-time and high-value traffic. The other options depend on the value or sensitivity of the traffic.

MX Series and EX Series Switches

For MX Series and EX Series switches only, you can configure fabric priority queuing by including the `priority` statement. For Enhanced IQ PICs, you can include the `policing-priority` option.

> **NOTE**: The `priority` and `policing-priority` options are not supported on PTX Series routers.

EX Series Switches

For the EX Series switches, this statement associates the forwarding class with a class name and queue number. It can define the fabric queuing priority as high, medium-high, medium-low, or low.

Map one or more forwarding classes to a single output queue. Also, when configuring DSCP-based priority-based flow control (PFC), map a forwarding class to a PFC priority value to use in pause frames when traffic on a DSCP value becomes congested (see *Configuring DSCP-based PFC for Layer 3 Untagged Traffic* for details).

Switches that use different forwarding classes for unicast and multidestination (multicast, broadcast, and destination lookup fail) traffic support 12 forwarding classes and 12 output queues (0 through 11). You map unicast forwarding classes to a unicast queue (0 through 7) and multidestination forwarding classes to a multidestination queue (8 through 11). The queue to which you map a forwarding class determines if the forwarding class is a unicast or multidestination forwarding class.

Switches that use the same forwarding classes for unicast and multidestination traffic support eight forwarding classes and eight output queues (0 through 7). You map forwarding classes to output queues. All traffic classified into one forwarding class (unicast and multidestination) uses the same output queue.

You cannot configure weighted random early detection (WRED) packet drop on forwarding classes configured with the `no-loss` packet drop attribute. Do not associate a drop profile with lossless forwarding classes.

NOTE: If you map more than one forwarding class to a queue, all of the forwarding classes mapped to the same queue must have the same packet drop attribute (all of the forwarding classes must be lossy, or all of the forwarding classes mapped to a queue must be lossless).

NOTE: On switches that do not use the Enhanced Layer 2 Software (ELS) CLI, if you are using Junos OS Release 12.2, use the default forwarding-class-to-queue mapping for the lossless `fcoe` and `no-loss` forwarding classes. If you explicitly configure the lossless forwarding classes, the traffic mapped to those forwarding classes is treated as lossy (best effort) traffic and does *not* receive lossless treatment.

NOTE: On switches that do not use the ELS CLI, if you are using Junos OS Release 12.3 or later, the default configuration is the same as the default configuration for Junos OS Release 12.2, and the default behavior is the same (the `fcoe` and `no-loss` forwarding classes receive lossless treatment). However, if you explicitly configure lossless forwarding classes, you can configure up to six lossless forwarding classes by specifying the `no-loss` option. If you do not specify the `no-loss` option in an explicit forwarding class configuration, the forwarding class is lossy. For example, if you explicitly configure the `fcoe` forwarding class and you do not include the `no-loss` option, the `fcoe` forwarding class is lossy, not lossless.

Options

Available options can vary by platform and software release.

CAUTION: Do not associate a default forwarding class name with a different queue number. Use a custom forwarding class name instead. Defining customer forwarding classes with factory default forwarding class names can have unintended consequences.

class *class-name*	Define the forwarding class name.
queue-num *queue-number*	Output queue number to associate with forwarding class.
priority	Fabric priority value:

high Forwarding class fabric queuing has high priority.

low Forwarding class fabric queuing has low priority.

The `default` priority is `low`.

spu-priority SPU priority queue, `high`, `medium`, or `low`. The default `spu-priority` is `low`.

> **NOTE**: The `spu-priority` option is supported only on the SRX5000 line of firewalls.

The remaining statements are explained separately. See CLI Explorer for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

The `policing-priority` option was introduced in Junos OS Release 9.5.

Statement updated in Junos OS Release 11.4.

The `spu-priority` option was introduced in Junos OS Release 11.4R2.

The `no-loss` option was introduced in Junos OS Release 12.3.

Change from two to four queues made in Junos OS Release 12.3X48-D40 and in Junos OS Release 15.1X49-D70.

The `pfc-priority` statement was introduced in Junos OS Release 17.4R1.

The `medium-high` and `medium-low` priorities for `spu-priority` were deprecated and `medium` priority was added in Junos OS Release 19.1R1.

```

Description

The MPLS-forwarding type routing-instance can be used for segregating Inter-AS BGP neighbors that require MPLS spoof-protection to ensure the packets remain distinct from other peers.

Setting a forwarding context on a neighbor interface can be useful, for example, when configuring a common AS boundary router so that it only accepts MPLS packets from a peer AS boundary router whose labels were explicitly advertised to the common AS boundary router.

Use this statement in conjunction with `mpls-forwarding` to protect against label spoofing across AS boundary routers in the context of Inter-AS VPN Option B for AS boundary routers. Option B peers are reachable through local interfaces that are configured as part of the MPLS forwarding type routing instance.

If `forwarding-context` is not set for a VPN BGP peer both the routing instance and forwarding context are provided by the master routing instance. The master instance is the Junos default, global routing-instance, that contains the **protocols bgp** configuration.

Description

QFX10000 line of switches, and ACX7100-32C, and ACX7100-48L devices—Configure the forwarding-instance parameters for a MAC-VRF routing instance.

If you configure the forwarding instance with an identifier, then the switch maps the specified MAC-VRF routing instance to the forwarding instance specified by the *identifier* variable.

If you do not configure an identifier, then the switch maps the specified MAC-VRF routing instance to the system default forwarding instance, `default-switch`.

Options

`identifier` *`forwarding-instance-identifier`*	Forwarding instance identifier. Specify the forwarding instance identifier as an integer value. QFX10000 line of switches: Identifier number range is 1 - 99. ACX7100-32C and ACX7100-48L routers: Identifier number range is 1 - 6.

Syntax

```
forwarding-mode {
    hold;
    inline-tap;
}
```

Hierarchy Level

```
[edit security utm default-configuration anti-virus]
```

Description

The default configuration for anti-virus is to use the continuous delivery function (CDF). It holds the last packet and sends out all other packets. It saves system memory and makes the packet transmission faster. This mode sends the last packet if the result is “permit” and sends RST message to both the client and the server to reset the connection if the result is “drop”. In CDF mode, you may save an incomplete infected file because it only holds the last packet and sends out others. This file could be executable and harmful, for example, an incomplete script file. CDF mode does not support Mail protocols. Change to `hold` mode to hold all the packets until you get the final result. Configure `inline-tap` mode to permit the traffic even if it is infected. This mode is off by default. You can set the `hold` and `inline-tap` mode separately or simultaneously. When you set both modes simultaneously, `inline-tap` over-rules the `hold` mode and permits the traffic.

To delete `hold` mode use `#delete security utm default-configuration anti-virus forwarding-mode hold`, and to delete `inline-tap` mode use `#delete security utm default-configuration anti-virus forwarding-mode inline-tap`.

Options

`hold` —Hold mode (hold file until analysis is complete, default is CDF mode).

`inline-tap` —Detect-only mode without blocking (default is off).

The statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Description

Configure a unified forwarding table profile to allocate the amount of memory available for the following:

- MAC addresses.

- Layer 3 host entries.
- Longest prefix match table entries.

This feature enables you to select a profile that optimizes the amount of memory available for various types of forwarding-table entries based on the needs of your network. For example, for a switch that handles a great deal of Layer 2 traffic, such as a virtualized network with many servers and virtualized machines, you would choose the `l2-profile-one`, which allocates the highest amount of memory to MAC addresses.

You configure the memory allocation for longest prefix match (LPM) table entries differently, depending on whether you using Junos OS Release 13.2X51-D10 or Junos OS Release 13.2X51-D15 and later. For more information about configuring memory allocation for LPM table entries, see Configuring the Unified Forwarding Table on Switches.

> **NOTE**: Starting in Junos OS Release 25.2R1, the host table utilization on QFX5200-32C switches is limited at 80% when the lpm-profile is used. The host table and the LPM table share the host routes. Therefore, the total route table utilization capacity available for both LPM and host routes is reduced.

The `num-65-127-prefix` *`number`* statement is not supported on the `custom-profile` and the `lpm-profile`. The `prefix-65-127-disable` and `unicast-in-lpm` statements are supported only on the `lpm-profile`.

When you commit a configuration with a forwarding table profile change, in most cases the Packet Forwarding Engine restarts automatically to apply the new parameters, which brings the data interfaces down and then up again.

However, starting with Junos OS Releases 14.1X53-D40, 15.1R5, and 16.1R3, for a Virtual Chassis or Virtual Chassis Fabric (VCF) comprised of EX4600 or QFX5100 switches, the Packet Forwarding Engine in member switches does not automatically restart upon configuring and committing a unified forwarding table profile change. This behavior avoids having Virtual Chassis or VCF instability and a prolonged convergence period if a profile change is propagated to member switches and multiple Packet Forwarding Engines all restart at the same time. In this environment, instead of automatically restarting when you initially commit a profile configuration change, the message `Reboot required for configuration to take effect` is displayed at the primary switch CLI prompt, notifying you that the profile change does not take effect until the next time you restart the Virtual Chassis or VCF. The profile configuration change is propagated to member switches that support this feature, and a reminder that a reboot is required to apply this pending configuration change appears in the system log of the primary switch and applicable member switches. You then enable the profile change subsequently during a planned downtime period using the `request system reboot` command, which quickly establishes a stable Virtual Chassis or VCF with the new configuration.

> **NOTE**: You must plan to make unified forwarding table profile changes only when you are ready to perform a Virtual Chassis or VCF system reboot *immediately* after committing the configuration update. Otherwise, in the intervening period between committing the configuration change and rebooting the Virtual Chassis or VCF, the system can become inconsistent if a member experiences a problem and restarts. In that case, the new configuration takes effect on the member that was restarted, while the change is not yet activated on all the other members.

The remaining statements are explained separately. See CLI Explorer.

Options

profile-name name of the profile to use for memory allocation in the unified forwarding table. Table 56 on page 7821 lists the profiles you can choose that have set values and the associated values for each type of entry.

On QFX5200 Series switches only, you can also select `custom-profile`. This profile enables you to allocate from one to four banks of shared hash memory to a specific type of forwarding-table entry. Each shared hash memory bank can store a maximum of the equivalent of 32,000 IPv4 unicast addresses.

Table 56: Unified Forwarding Table Profiles

Profile Name	MAC Table	Host Table (unicast and multicast addresses)					
	MAC Addresses	IPv4 unicast	IPv6 unicast	IPv4 (*, G)	IPv4 (S, G)	IPv6 (*, G)	IPv6 (S, G)
`l2-profile-one`	288K	16K	8K	8K	8K	4K	4K
`l2-profile-two`	224K	80K	40K	40K	40K	20K	20K

Table 56: Unified Forwarding Table Profiles *(Continued)*

Profile Name	MAC Table	Host Table (unicast and multicast addresses)					
`l2-profile-three` (default)	160K	144K	72K	72K	72K	36K	36K
`l3-profile`	96K	208K	104K	104K	104K	52K	52K
`lpm-profile*`	32K	16K	8K	8K	8K	4K	4K

* This profile supports only IPv4 in Junos OS Release13.2X51-D10. Starting in Junos OS Relase13.2X51-D15, the `lpm-profile` supports IPv4 and IPv6 entries.

> **NOTE**: If the host stores the maximum number of entries for any given type, the entire table is full and is unable to accommodate *any* entries of any other type. For information about valid combinations of table entries see Understanding the Unified Forwarding Table.

l2-entries | l3-entries | lpm-entries

(`custom-profile only`) Select a type of forwarding-table entry—Layer 2, Layer 3, or LPM—to allocate a specific number of shared memory banks. You configure the amount of memory to allocate for each type of entry separately.

num-banks *number*

(`custom-profile only`) Specify the number of shared memory banks to allocate for a specific type of forwarding-table entry. Each shared memory bank stores the equivalent of 32,000 IPv4 unicast addresses.

- **Range:** 0 through 4.

> **NOTE**: There are four shared memory banks, which can be allocated flexibly among the three types of forwarding-table entries. To allocate no shared memory for a particular entry type, specify the number `0`. When you commit the configuration, the system issues a commit

check to ensure that you have not configured more than four memory banks. You do not have to configure all four shared memory banks. By default, each entry type is allocated the equivalent of 32,000 IPv4 unicast addresses in shared memory.

egress-multicast enable	Enable egress sFlow sampling of known multicast traffic.
egress-multicast max-replication-rate *rate*	Specify the maximum sFlow sample replication rate per FPC for known multicast traffic.

[edit routing-instances routing-instance-name]
```

Description

Configure traffic forwarding options. For more information about each option, click a linked statement in the Syntax section.

Options

access-security Configure IPv6 access security options.

accounting Specify the discard accounting instance name and options.

dhcp-relay Configure extended Dynamic Host Configuration Protocol (DHCP) relay and DHCPv6 relay options on the router or switch to enable the router (or switch) to function as a DHCP relay agent.

enhanced-hash-key (MX Series routers with MPCs, T4000 routers with Type 5 FPCs, and EX9200 switches) Select data used in the hash key for enhanced IP forwarding engines.

family Specify address family for filters.

fast-reroute-priority Specify the fast reroute priority for a VPLS routing instance. You can configure `high`, `medium`, or `low` fast reroute priority to prioritize specific VPLS routing instances for faster convergence and traffic restoration.

helpers Enable TFTP or DNS request packet forwarding, or configure the router, switch, or interface to act as a DHCP/BOOTP relay agent. Enable forwarding LAN broadcast traffic on custom UDP ports to particular servers as unicast traffic.

inband-telemetry Enable or disable the Inband Network Telemetry feature at the data path level, without intervention from the control plane.

ip-options-protocol-queue Configure logical queue-depth in the PFE for ip-options packets for a given protocol such as TCP, UDP, ICMP, and so on, except IGMP.

lag-heap-optimization	Improve heap memory utilization in link aggregation group (LAG) interfaces in large-scale configurations.
link-layer-broadcast-inet-check	Enable destination MAC and IP address check to prevent the router from forwarding IPv4 packets that have link layer destination address set to `broadcast` or `multicast`, unless directed to an IPv4 multicast address.
load-balance	Enable per-prefix or per-flow load balancing so that the router or switch elects a next hop independently of the route selected by other routers or switches.
load-balance-label-capability	Enable the router to push and pop the load balancing label and causes LDP and RSVP to advertise the entropy label TLV to neighboring routers.
multicast-replication	Configure the mode of multicast replication that helps to optimize multicast latency.
next-hop-group	Specify the next-hop address for sending copies of packets to an analyzer.
no-host-as-lpm	Prevent host entries from overflowing into the LPM table when the host table is full. Configuring this restarts the PFE in standalone devices. Virtual Chassis (VC) devices require a manual restart. This restart removes any previously learned host entries from the LPM table. (See *Host Entry Overflow Prevention* for details.)
no-load-balance-label-capability	Disable advertisement of entropy label capability in LDP and RSVP.
port-mirroring	Specify the input, output, and traceoptions properties for sending copies of packets to an analyzer.
rpf-loose-mode-discard	Configure unicast reverse path forwarding (unicast RPF) loose mode with the ability to discard packets with the source address pointing to the discard next hop.
sampling	Configure traffic sampling.
storm-control-profiles	Configure a storm control profile on a switch or router. Storm control is used to prevent network outages that are caused by broadcast traffic storms.

See the links in Syntax for more details on the listed options.

               }
           }
       }
}
```

Hierarchy Level

```
[edit security]
```

Description

Determine how the `inet6`, `iso`, and `mpls` protocol families manage security forwarding options.

NOTE:

- Packet-based processing is not supported on the following SRX Series Firewalls: SRX5400, SRX5600, and SRX5800.
- On SRX Series Firewalls, the default mode for processing traffic is flow mode. You can configure SRX Series Firewalls to operate in packet mode to process MPLS packets.

  To configure the packet mode on SRX Series Firewall, use the following command:

  ```
  user@host# set security forwarding-options family mpls mode packet-based
  ```

  Selective stateless packet-based services allows you to configure the device to provide only packet-based processing for selected traffic based on input filter terms.

Options

allow-dataplane-sleep Enable sleep on dataplane.

family Specify the protocol family to be used for packet forwarding.

- `inet6`—Specify forwarding options for IPv6 traffic.
  - `drop`—Drop IPv6 packets. This is the default setting.
  - `flow-based`—Perform flow-based packet forwarding.
  - `packet-based`—Perform simple packet forwarding.
- `iso`—Specify forwarding options for IS-IS traffic.
  - `packet-based`—Perform simple packet forwarding.
- `mpls`—Specify forwarding options for MPLS traffic.
  - `flow-based`—Perform flow-based packet forwarding.
  - `packet-based`—Perform simple packet forwarding.

mirror-filter Specify a mirror filter for filtering X2 packets to be mirrored and sent to a packet analyzer.

mode Specify TAP or Sniffer mode.

- `tap`—Specify TAP mode.
  - `inspect-pass-through-tunnel`—Specify TAP mode to inspect pass through IP-IP or GRE tunnel.
  - `interface`—Specify TAP mode interface name. You can configure up to eight TAP interfaces.

receive-side-scaling

Receive side scaling (RSS) enables the efficient distribution of network receive processing across multiple CPUs in multiprocessor systems.

- `nic-rss`—The NIC distributes packets by applying a filter to each packet that assigns it to one of a small number of logical flows. Packets for each flow are steered to a separate receive queue, which in turn can be processed by separate CPUs. On reception, a NIC can send different packets to different queues to distribute processing among CPUs. NIC must have same number of receiving (RX) and transmitting (TX) queues as number of vSRX data plane CPU to support multi core vSRX flavors.
  - `mode`—Specify the mode of NIC RSS.
    - `disable`—Disable the NIC RSS mode.
- `software-rss`—Software RSS (SWRSS) removes this limitation of NIC HW queues to run vSRX multi-core flavors by implementing software-based packet spraying across various FLT thread. Software RSS offloads the handling of individual flows to one of the multiple kernel, so the flow thread that takes the packets from the NIC can process more packets. SWRSS implements software model of packet distribution across FLTs after obtaining the packets from NIC receiving queues. By removing NIC HW queue limitation, SWRSS helps to scale vCPUs by supporting various vSRX instance types.
  - `io-thread-number`—Specify the software RSS IO thread number.
    - **Range:** 1 through 8
  - `mode`—Specify the mode of Software RSS.
    - `automatic`—Auto select the Software RSS mode. This is the default mode.
    - `disable`—Disable the Software RSS mode.
    - `enable`—Enable the Software RSS mode.

resource-manager

Display forward option status, the CPU, and memory allocated for the advance services to verify the vCPU allocation between routing engine and flow RT threads.

- `cpu`—Specify CPU resources.
  - **Default:** 1
  - **Range:** 1 through 3
- `enhanced-logging`—Specify a dedicated CPU resource for on-box logging.

secure-wire Specify a name for the secure wire interface mapping.

security-service Security service actions when memory resource is in shortage. The system resource management guarantees the resources are used according to priorities.

- `fail-open`—Ignores Layer 7 services with resource requirements, creates a flow session without Layer 7 services, and forward the packet out.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

`secure-wire` option introduced in Junos OS Release 19.3R1.

`resource-manager` option introduced in Junos OS Release 19.4R1 for vSRX Virtual Firewall.

`mode` option introduced in Junos OS Release 20.1R1.

`enhanced-logging` option introduced in Junos OS Release 23.1R1 to assign a dedicated CPU resource for on-box logging.

Description

Configure a unified forwarding table profile to allocate the amount of memory available for the following:

- MAC addresses.
- Layer 3 host entries.
- Longest prefix match table entries.

This feature enables you to select a profile that optimizes the amount of memory available for various types of forwarding-table entries based on the needs of your network. For example, for a switch that handles a great deal of Layer 2 traffic, such as a virtualized network with many servers and virtualized machines, you would choose the `l2-profile-one`, which allocates the highest amount of memory to MAC addresses.

For details on configuring memory allocation for LPM table entries, see .

The `num-65-127-prefix` *`number`* statement is not supported on the `custom-profile` and the `lpm-profile`. The `prefix-65-127-disable` and `unicast-in-lpm` statements are supported only on the `lpm-profile`.

When you commit a configuration with a forwarding table profile change, in most cases the Packet Forwarding Engine restarts automatically to apply the new parameters, which brings the data interfaces down and then up again.

For a Virtual Chassis or Virtual Chassis Fabric (VCF), the Packet Forwarding Engine in member switches does not automatically restart upon configuring and committing a unified forwarding table profile change. This behavior avoids having Virtual Chassis or VCF instability and a prolonged convergence period if a profile change is propagated to member switches and multiple Packet Forwarding Engines all restart at the same time. In this environment, instead of automatically restarting when you initially commit a profile configuration change, the message `Reboot required for configuration to take effect` is displayed at the primary switch CLI prompt, notifying you that the profile change does not take effect until the next time you restart the Virtual Chassis or VCF. The profile configuration change is propagated to member switches that support this feature, and a reminder that a reboot is required to apply this pending configuration change appears in the system log of the primary switch and applicable member switches. You then enable the profile change subsequently during a planned downtime period using the `request system reboot` command, which quickly establishes a stable Virtual Chassis or VCF with the new configuration.

> **NOTE**: You should plan to make unified forwarding table profile changes only when you are ready to perform a Virtual Chassis or VCF system reboot *immediately* after committing the configuration update. Otherwise, in the intervening period between committing the configuration change and rebooting the Virtual Chassis or VCF, the system can become inconsistent if a member experiences a problem and restarts. In that case, the new configuration takes effect on the member that was restarted, while the change is not yet activated on all the other members.

The remaining statements are explained separately. See those pages or CLI Explorer.

Options

custom-profile

On QFX5200 Series switches only, you can select `custom-profile`. This profile enables you to allocate from one to four banks of shared hash memory to a specific type of forwarding-table entry. Each shared hash memory bank can store a maximum of the equivalent of 32,000 IPv4 unicast addresses.

The `lpm-profile` supports IPv4 and IPv6 entries.

> **NOTE**: If the host stores the maximum number of entries for any given type, the entire table is full and is unable to accommodate *any* entries of any

other type. For information about valid combinations of table entries see Understanding the Unified Forwarding Table.

l2-entries | l3-entries | lpm-entries

(`custom-profile only`) Select a type of forwarding-table entry—Layer 2, Layer 3, or LPM—to allocate a specific number of shared memory banks. You configure the amount of memory to allocate for each type of entry separately.

num-banks *number*

(`custom-profile only`) Specify the number of shared memory banks to allocate for a specific type of forwarding-table entry. Each shared memory bank stores the equivalent of 32,000 IPv4 unicast addresses.

- **Range:** 0 through 4.

> **NOTE**: There are four shared memory banks, which can be allocated flexibly among the three types of forwarding-table entries. To allocate no shared memory for a particular entry type, specify the number `0`. When you commit the configuration, the system issues a commit check to ensure that you have not configured more than four memory banks. You do not have to configure all four shared memory banks. By default, each entry type is allocated the equivalent of 32,000 IPv4 unicast addresses in shared memory.

profile-name

Configure one of the following profiles to allocate memory:

- l2-profile-one
- l2-profile-three
- l2-profile-two
- l3-profile
- lpm-profile

See to understand the memory allocation for your platform. You can also use the `set chassis forwarding-options ?` command to view the allocations for your platform. For example:

```
user@host# set chassis forwarding-options ?
Possible completions:
+ apply-groups         Groups from which to inherit configuration data
+ apply-groups-except  Don't inherit configuration data from these groups
```

```
> l2-profile-one       MAC: 288K L3-host: 16K LPM: 16K EM:0, needs reboot for VC;
restarts PFE if standalone
> l2-profile-three     (default) MAC: 160K L3-host: 144K LPM: 16K, needs reboot for
VC;restarts PFE if standalone
> l2-profile-two       MAC: 224K L3-host: 80K LPM: 16K EM:0, needs reboot for VC;
restarts PFE if standalone
> l3-profile           MAC: 96K L3-host: 208K LPM: 16K EM:0, needs reboot for VC;
restarts PFE if standalone
> lpm-profile          MAC: 32K L3-host: 16K LPM: 128K EM:0, needs reboot for VC;
restarts PFE if standalone
```

Requires reboot of the Virtual Chassis for profile change to take effect. For standalone deployments, committing the profile configuration restarts the PFE. You can use the `show chassis forwarding-options` command to view the UFT configuration. For example:

```
user@host> show chassis forwarding-options
localre:
--------------------------------------------------------------------------
UFT Configuration:
lpm-profile
prefix-65-127 = enable
--------------Bank details for various types of entries------------------
Entry type Dedicated Bank Size(K) Shared Bank Size(K)
L2(mac) 32 32 * num shared banks
L3(unicast & multicast) 16 32 * num shared banks
Exact Match 0 16 * num shared banks
```

To support VXLAN group-based policies (GBP) on supported EX Series and QFX switches, configure one of the GBP profiles listed below with GBP policy filters:

- "vxlan-gbp-profile" on page 32193
- "vxlan-gbp-l2-profile" on page 32189
- "vxlan-gbp-l3-profile" on page 32190
- "vxlan-gbp-mc-profile" on page 32192

For details on each of the above GBP profiles, see their respective statement pages and *GBP Profiles*.

You can also use the `set chassis forwarding-options ?` command to view the allocations for your platform. For example:

```
user@host# set chassis forwarding-options ?
Possible completions:
+ apply-groups Groups from which to inherit configuration data
+ apply-groups-except Don't inherit configuration data from these groups
> vxlan-gbp-l2-profile MAC: 160K L3-host: 48K LPM(IPv4): 32K EM: 48K.(restarts PFE
if standalone system and requires reboot for VC systems)
> vxlan-gbp-l3-profile MAC: 96K L3-host: 144K LPM(IPv4): 32K EM: 32K.(restarts PFE
if standalone system and requires reboot for VC systems)
> vxlan-gbp-profile MAC: 160K L3-host: 80K LPM(IPv4): 32K EM: 32K.(restarts PFE if
standalone system and requires reboot for VC systems)
```

        packet-ordering-mode (hardware | software);
    }
    enhanced-services-mode;
}
```

Hierarchy Level

```
[edit security]
```

Description

You can configure SRX5400, SRX5600, and SRX5800 devices to switch from an integrated firewall mode to maximize Intrusion Detection and Prevention (IDP) mode to run IDP processing in tap mode and increase the capacity of processing with the `maximize-idp-sessions` option. Inline tap mode can only be configured if the forwarding process mode is set to `maximize-idp-sessions`, which ensures stability and resiliency for firewall services. You also do not need a separate tap or span port to use inline tap mode. When you maximize IDP, you are decoupling IDP processes from firewall processes, allowing the device to support the same number of firewall and IDP sessions, also run the IDP processing in tap mode.

You can configure maximum Application Layer Gateway (ALG) sessions by using the `maximize-alg-sessions` option. By default, the session capacity number for Real-Time Streaming Protocol (RTSP), FTP, and Trivial File Transfer Protocol (TFTP) ALG sessions is 10,000 per flow Services Processing Unit (SPU). You must reboot the device (and its peer in chassis cluster mode) for the configuration to take effect. The `maximize-alg-sessions` option now enables you to increase defaults as follows:

- RTSP, FTP, and TFTP ALG session capacity: 25,000 per flow SPU
- TCP proxy connection capacity: 40,000 per flow SPU

> **NOTE**: Flow session capacity is reduced to half per flow SPU; therefore the aforementioned capacity numbers will not change on central point flow.

Enable GPRS tunneling protocol, user plane(GTP-U) session distribution to distribute GTP-U traffic handled by a Gateway GPRS Support Node (GGSN) and a Serving GPRS Support Node (SGSN) pair on all Services Processing Units (SPUs). You can configure tunnel-base distribution to distribute GTP-U traffic to multiple SPUs by the `enable-gtpu-distribution` option on SRX5400, SRX5600, and SRX5800 devices , which helps to resolve the GTP-U fat session issue. Also, `enable-gtpu-distribution` command is must for enabling stateful GTP-U inspection.

Options

enhanced-services-mode Enable enhanced application services mode.

When Enhanced Service Mode is enabled, resources such as MBUF, JBUF, SERVICE-MEM, TCP-PROXY TCB, SZ-INFO and user heap are increased in size and Layer 4 session numbers are reduced by half.

The remaining statements are explained separately. See the CLI Explorer.

Required Privilege Level

security—To view this in the configuration.

security-control—To add this to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6. This statement is supported.

Option `enhanced-services-mode` introduced in Junos OS Release 20.3R1 on vSRX Virtual Firewall 3.0.

family graceful-restart]
```

NOTE: Each routing table is identified by the protocol family or address family indicator (AFI) and a subsequent address family identifier (SAFI).

Configuring LLGR does not require that BGP graceful restart also be configured. The long-lived-graceful-restart section is visible only for families l2vpn, inet labeled-unicast, inet flow and route-target. It is prohibited for inet-mvpn, inet6-mvpn and inet-mdt. It is hidden for other families.

Description

Configure the forwarding-state bit flag negotiation for BGP for all address families. In addition to the global setting for the Forwarding State bit, the Forwarding State bit behavior can be specified for individual families. Changing the forwarding-state-bit setting has no effect on any existing sessions. Per-family BGP configuration options are added to control the Forwarding State bit in graceful restart and long-lived graceful restart capability advertisements. They can be specified for the default logical system or for a specific logical system, and for the primary routing instance or a specific routing instance. The `per-family forwarding-state-bit` attribute overrides the default rules or the global configuration for setting the Forwarding State bit.

The setting of the F bit (and the "Forwarding State" bit of the accompanying GR capability) depends in part on deployment considerations. The F bit can be interpreted to indicate the helper router needs to flush associated routes (if the bit is left clear). An important scenario in which LLGR is used is for routes that are more similar to configuration than to traditional routing (hop-by-hop forwarding instead of tunnel-based routing). For such routes, it might be useful to always set the F bit, regardless of other considerations. Similarly, for control-plane-only entities such as dedicated route reflectors, that do not participate in the forwarding plane, it is preferred that the F bit be always set. Overall, the guideline to be adopted is that if loss of state on the restarting router can reasonably be expected to cause a forwarding loop or null route, the F bit must be set judiciously, depending on whether state has been retained. You can determine whether the F bit needs to be set or not, based on your deployment needs and configured settings. It might be necessary to advertise stale routes to a CE in some VPN deployments, even if the CE does not support this specification. In such a scenario, the network operator configuring their PE to advertise such routes must notify the operator of the CE receiving the routes, and the CE must be configured to depreference the routes. Typically, BGP implementations perform this behavior by matching on the LLGR_STALE community, and setting the LOCAL_PREF for matching routes to zero.

Options

`set` Causes the value to be set according to the state of the associated FIB. Changing the per-family forwarding-state-bit setting has no effect on any existing sessions.

`from-fib` Forces the Forwarding State bit to be set to 1.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1.

```

Description

Configure the forwarding-state bit flag negotiation for BGP for individual address families. In addition to the global setting for the Forwarding State bit, the Forwarding State bit behavior can be specified for individual families. Changing the forwarding-state-bit setting has no effect on any existing sessions. Per-family BGP configuration options are added to control the Forwarding State bit in graceful restart and long-lived graceful restart capability advertisements. They can be specified for the default logical system or for a specific logical system, and for the primary routing instance or a specific routing instance. The `per-family forwarding-state-bit` attribute overrides the default rules or the global configuration for setting the Forwarding State bit.

The setting of the F bit (and the "Forwarding State" bit of the accompanying GR capability) depends in part on deployment considerations. The F bit can be interpreted to indicate the helper router needs to flush associated routes (if the bit is left clear). An important scenario in which LLGR is used is for routes that are more similar to configuration than to traditional routing (hop-by-hop forwarding instead of tunnel-based routing). For such routes, it might be useful to always set the F bit, regardless of other

considerations. Similarly, for control-plane-only entities such as dedicated route reflectors, that do not participate in the forwarding plane, it is preferred that the F bit be always set. Overall, the guideline to be adopted is that if loss of state on the restarting router can reasonably be expected to cause a forwarding loop or null route, the F bit must be set judiciously, depending on whether state has been retained. You can determine whether the F bit needs to be set or not, based on your deployment needs and configured settings. It might be necessary to advertise stale routes to a CE in some VPN deployments, even if the CE does not support this specification. In such a scenario, the network operator configuring their PE to advertise such routes must notify the operator of the CE receiving the routes, and the CE must be configured to depreference the routes. Typically, BGP implementations perform this behavior by matching on the LLGR_STALE community, and setting the LOCAL_PREF for matching routes to zero.

Options

set Causes the value to be set according to the state of the associated FIB. Changing the per-family forwarding-state-bit setting has no effect on any existing sessions.

from-fib Forces the Forwarding State bit to be set to 1.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1.

```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit routing-options]
```

Description

Configure information about the routing device's forwarding table.

Some of the remaining statements are explained separately. See CLI Explorer.

Options

evpn-egress-link-protection

Enables multihomed PE devices to support fast reroutes (FFRs).

evpn-vpws-ack-disable

By default, the acknowledgement requirement prior to advertising an EVPN-VPWS route is enabled on the routing device. Use this statement to disable the acknowledgment verification requirement for EVPN VPWS routes. Disabling does not impact the network and will only disable acknowledgement for new EVPN VPWS instances.

multicast-composite-delete-defer-timeout

Use this command to delay the deletion of a composite next-hop from the FIB (in the event of dropped multicast packets following a downstream interface change). You can view the set time by running the **show krt state** command.

Range: 1 to 3600 seconds

pfe-install-error

(Junos OS Evolved only) Enable error checking for Packet Forwarding Engine route install errors. When configured, the forwarding plane can inform the control plane of any errors in next hops. If a route error is received from the Packet Forwarding Engine, the route error is directly added to the route-error list. For next-hop errors, the error is propagated to the parent route and the parent route is added to the route-error list. Two commands are available to check on these route errors after you have configured this feature:

- If the forwarding plane is not forwarding traffic, use the `show route pfe-install-error` command to check if the Packet Forwarding Engine has sent an error for the route that is dropping traffic.

- To check for next-hop errors, use the `show routing nhdb pfe-install-error` command. We support errors for routes pointing to a limited set of next hops: RT_NH_INDIRECT, RT_NH_ROUTER, RT_NH_CHAIN, RT_NH_INDXD, RT_NH_LIST, RT_NH_TUNNEL_COMP, and RT_NH_FRR_INDIRECT.

remnant-holdtime Sets the remnant hold time, which is required for the MXVC-ISSU, where the recommended value is 900.

- **Default:** 180 (For all Junos OS releases and all Junos OS Evolved releases earlier than 20.4R2)
- **Default:** 300 (For all Junos OS Evolved Release 20.4R2 and later)

route-origin-proto-tlv Configure this option to include the origin protocol information in route messages. The origin protocol is the protocol from which the route entry is learned.

srv6-chain-merge Enable merging of SRv6 chain nexthops.

vpls-hotstandby-convergence Enabled on spoke devices to support sending different advertising labels on the active and standby pseudowires.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`srv6-chain-merge` option introduced in Junos OS Release 21.3R1.

`multicast-composite-delete-defer-timeout` option introduced in Junos OS Release 22.1R2 and Junos OS Evolved Release 22.1R2.

`route-origin-proto-tlv` option introduced in Junos OS Release 22.4R1 and Junos OS Evolved Release 22.4R1.

`evpn-egress-link-protection`, `remnant-holdtime`, and `vpls-hotstandby-convergence` options introduced in Junos OS Release 24.2R1.

`pfe-install-error` option introduced in Junos OS Evolved Release 24.4R1.

Hierarchy Level

```
[edit chassis]
```

Description

Configure the FPC slot number. (ACX and PTX Series devices) Configure no VLAN tagging for a specific FPC. Additionally, configure power off configuration (PTX10003 devices only).

Options

Available command options vary based on the device model.

auto-speed detection Disables automatic speed detection.

cfp-to-et Enable ET interface and remove CFP client.

lossless-flow-control Lossless buffer config for Ethernet Mac pause.

pfe *pfe_id* **core** *core_id* **channel** *channel_id* **tunnel-services bandwidth** *bandwidth_speed* Select a bandwidth speed for your tunnel interface. Speed options start at 1 gigabit.

fpc *fpc_id* For PTX devices, *fpc_id* value is 0 to 15.

pfe-instance *pfe-instance_id* **|** **pfe** *pfe_id* **power (off | on)** Individual PFE Power off configuration. The reset-pfe error action is available for PFE power off and restart.

- Slot range for FPC is 0 to 1 for PTX10003-8T. Slot range for FPC is 0 to 3 for PTX10003-16T.
- PFE number range is 0 to 7 for all the FPCs.
- If no power configuration is present, then PFE is considered powered ON.

mic *slot* **power off** (Only for MX304) Do not provide power to MIC. To power on the MIC, you need to delete this power off configuration. Please note the following information before you commit the changes:

- If a commit includes multiple LMICs or separate commits, each LMIC undergoes operations sequentially.
- When you try to commit back-to-back changes for the same LMIC before the completion of an operation, then the system performs the last committed action and ignores the intermediate actions.

max-power*power* Configure maximum power for the FPC slot. Individual PFE maximum power configuration option is available for PTX10003 devices only.

napt Configure Network Address and Port Translation (NAPT).The option is available only on MX304, MX10004, and MX10008 (with the LC9600 line card).

no-loss buffer percentage *percent* (PTX10000 Series) Define the percentage of the buffer space reserved for lossless queues.

Range: 1-100 percent

Default: 10 percent

no-vlan-tagging Enable no-vlan-tagging on a specific FPC.

pic Configure properties for an individual PIC.

no-temperature-monitoring Disable temperature monitoring to explicitly disable optics temperature sensors for EM policy support, on specific WAN ports.

ignore-poe-feed (EX4100-H-12MP device with 12V-only PSU) Use the system with a 12V-only PSU and clear the alarm when 54V feed is not connected. The configuration is applicable for the entire fpc, including both PSU slots. You cannot configure this to ignore alarms on just one PSU slot.

Sample Output

Power off MIC (MX304 with LMIC)

```
user@host# set chassis fpc 0 mic 0 power off
```

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Platform-Specific `fpc (Chassis)` Behavior

Use Feature Explorer to confirm platform, and release support for specific features.

Use the following table to review platform-specific behaviors for your platform:

Table 57:

Platform	Difference
MX304 devices	• The `set chassis fpc` *`fpc-slot`* `pfe` *`pfe_id`* `power (off | on)` command is valid on Junos OS releases earlier than 24.4R1. • Starting in Junos OS release 24.4R1, use the `set chassis fpc` *`fpc-slot`* `mic` *`slot`* `power off` command to take the LMIC offline. When you try to commit back-to-back changes for the same LMIC before the completion of an operation, then the system performs the last committed action and ignores the intermediate actions. A 120-second delay is enforced between consecutive online or offline requests, irrespective of the request type and LMIC slot. For example, mic 0 offline/online requires 180 seconds to finish. Only after 120 seconds can the mic 1 command begin. If a configuration command is committed within 120 seconds, it will succeed. However, the command's effect will only occur 120 seconds after the last LMIC online or offline completion.

Release Information

Statement introduced in Junos OS Evolved Release 24.1R1 for ACX Series Routers.

`power-off` option introduced for PTX10003 devices in Junos OS Evolved Release 22.4R1.

`tunnel-services` and `bandwidth` options introduced for ACX Series devices in Junos OS Evolved Release 24.2R1.

`mic` *`slot`* `power off` option introduced in Junos OS 24.4R1 for MX304 devices.

fpc (DDoS)

Syntax

```
fpc slot-number;
    bandwidth-scale percentage;
    burst-scale percentage;
    disable-fpc;
}
```

Hierarchy Level

For MX Series routers, T4000 routers, and EX9200 switches:

```
[edit system ddos-protection protocols protocol-group (aggregate | packet-type)]
```

For PTX Series routers and QFX Series switches:

```
[edit system ddos-protection protocols protocol-group (aggregate | packet-type)]
```

Description

Modify DDoS protection aggregate or packet-type policer default values on the specified line card.

This configuration statement is supported on MX Series routers with MPCs, T4000 routers with FPC5s, PTX Series routers, EX9200 switches, and QFX Series switches.

Options

slot-number—Slot number of the card. On fixed form-factor devices, specify the line card as FPC 0.

- **Range:** Depends on the router or switch model

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

```

Hierarchy Level

```
[edit chassis]
```

Description

Configure properties for the DPC or MPC and corresponding Packet Forwarding Engines to create tunnel interfaces.

(MX Series Virtual Chassis only) When you configure chassis properties for MPCs installed in a Virtual Chassis member router, statements included at the `[edit chassis member` *`member-id`* `fpc slot` *`slot-number`*`]` hierarchy level apply to the MPC in the specified slot number only on the specified member router in the Virtual Chassis. Statements included at the `[edit chassis fpc slot` *`slot-number`*`]` hierarchy level apply to the MPCs in the specified slot number on *each* member router in the Virtual Chassis.

BEST PRACTICE: To ensure that the statement you use to configure MPC chassis properties in an MX Series Virtual Chassis applies to the intended member router and MPC, we recommend that you always include the `member` *`member-ID`* option before the `fpc` statement, where *`member-id`* is 0 or 1 for a two-member MX Series Virtual Chassis.

Options

`fpc` *`slot-number`*—Specify the slot number of the DPC.

- **Range:** 0 through 11

`pic` *`number`*—Specify the number of the Packet Forwarding Engine. Each DPC includes four Packet Forwarding Engines.

- **Range:** 0 through 4

`port-mirror-instance` *`port-mirroring-instance-name-fpc-level`*—Associate a port-mirroring instance with the DPC and its corresponding PICs. The port-mirroring instance is configured under the `[edit forwarding-options port-mirroring]` hierarchy level.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.2.

`port-mirror-instance` option added in Junos OS Release 9.3.

`ipv6-extended-attrib` option added in Junos OS Release 14.2 for MX Series routers.

`exception-reporting` option added in Junos OS Release 21.2R1.

fpc (Notification Control)

IN THIS SECTION

- Syntax | 7872
- Hierarchy Level | 7872
- Description | 7872
- Default | 7872
- Options | 7872
- Required Privilege Level | 7873
- Release Information | 7873

Syntax

```
fpc slot-number {
    disable;
}
```

Hierarchy Level

```
[edit poe notification-control]
```

Description

Enable the specified PoE controller to generate PoE traps.

Default

PoE traps are disabled by default.

Options

slot-number—Indicates the PoE controller by FPC slot number, where ***slot-number*** is:

- **0**—On an EX2200, EX3200, standalone EX3300, standalone EX4200, or standalone EX4300 switch
- Member ID—On an EX3300, EX4200, or EX4300 switch in a Virtual Chassis
- Line card slot number—On an EX6200 or EX8200 switch

The remaining statement is explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

fpc (PTX Series Devices)

IN THIS SECTION

- Syntax (PTX Series Devices) | 7874
- Hierarchy Level | 7874
- Description | 7874
- Options | 7874
- Required Privilege Level | 7875
- Release Information | 7875

Syntax (PTX Series Devices)

```
fpc slot-number {
    error
    pfe
    pic
    sampling-instance instance_string;
    traffic-manager {
        (enhanced-priority-mode | no-enhanced-priority-mode)
        }
    optical-options
}
```

Hierarchy Level

```
[edit chassis]
```

Description

Configure properties for the PICs in individual Flexible PIC Concentrators (FPCs). Configure FPC Restart, offline and online (PTX10003 devices only).

Options

slot-number—Slot number in which the FPC is installed.

- **Range:** From 0 to maximum slot number based on the product type.

  For example:

  - For PTX1000 and PTX10001-36MR devices, the FPC slot number is always 0.
  - For PTX10008 device, the slot number range is 0 to 7.
  - For PTX10016 device, the range is 0 to 15,
  - For PTX10003 device, FPC Restart, offline and online options are available.
  - For PTX3000 devices, alternate slot numbers 0, 2, 4, 6, 8, 10, 12, 14).

`pfe`—Slot number in which the PFE is installed. If FPC power off is set along with PFE power ON, then PFE power ON is not initiated.

`sampling-instance` *`instance_string`*— You can configure active sampling using a sampling instance and associate that sampling instance to a Flexible Port Concentrator (FPC), Modular Port Concentrator (MPC), or Dense Port Concentrator (DPC). In addition, you can define multiple sampling instances associated with multiple destinations and protocol families per sampling instance destination.

Sampling-instances are defined under the `[edit forwarding-options]` hierarchy.

`traffic-manager`— You can configure traffic manager attributes for the FPC. Available options are `enhanced-priority-mode` and `no-enhanced-priority-mode`.

The remaining statements are explained separately, for example ,"error " on page 6733.

> **NOTE**: The `fpc <fpc-slot> pfe <pfe-inst> power-off` configuration is added to power-off specific PFE instances when an FPC is brought online or to power-off a PFE during runtime.

> **NOTE**: Click on the highlighted links in the *Syntax* section to view details of other available configuration options. Using the configuration command for error levels, you can isolate PFE errors, thereby reducing the need for a field replacement of FPCs. For feature details and PTX platforms supported, see FPC self-healing.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

- Release Information | 7877

Syntax

```
fpc slot {
    auto-speed-detection disable;
    pic pic-number{
        tunnel-port port-number tunnel-services;
        port port-number{
            channel-speed (speed|disable-auto-speed-detection) ;
        }
        port-range port-range-low port-range-high {
            channel-speed (speed|disable-auto-speed-detection);
        }
    }
}
```

Hierarchy Level

```
[edit chassis]
```

Description

Configure the FPC slot number. For QFX3500 switches, the slot is a line card slot.

For generic routing encapsulation (GRE) tunneling, use the `tunnel-port` statement to specify the port that you want to convert to a GRE tunnel port.

Options

`slot`—Number of the FPC slot. For QFX3500, QFX3600, QFX5200, and OCX Series devices, the slot number is always `0`.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

fpc error

IN THIS SECTION

- Syntax | 7881
- Hierarchy Level | 7881
- Description | 7882
- Options | 7882
- Required Privilege Level | 7883
- Release Information | 7883

Syntax

```
fpc slot number {
    error {
        (fatal | major | minor) {
        threshold threshold-value;
        action (alarm | disable-pfe | offline-pic | log | get-state |offline | reset);
        }
    }
}
```

Hierarchy Level

```
[edit chassis]
```

Description

Configure the threshold at which FPC errors will take the action you configure to be performed by the device.

Some devices include an internal framework for detecting and correcting FPC errors that can have the potential to affect services. For each FPC on the device, you can classify errors according to severity, set an automatic recovery action for each severity, and set a threshold (the number of times the error must occur before the action is triggered).

Options

- `fatal`—Fatal error on the FPC. An error that results in the blockage of a considerable amount of traffic across modules is a fatal error.
- `major`—Major error on the FPC. An error that results in continuing loss of packet traffic but does not affect other modules is a major error.
- `minor`—Minor error on the FPC. An error that results in the loss of a small number of packets but is fully recoverable is a minor error.
- `threshold` *`threshold-value`*—Configure the threshold value at which to take action. If the severity level of the error is fatal, the action is carried out only once when the total number of errors exceeds the threshold value. If the severity level of the error is major, the action is carried out once after the occurrence exceeds the threshold. If the severity level is minor, the action is carried out as many times as the value specified by the threshold. For example, when the severity level is minor, and you have configured the threshold value as 10, the action is carried out after the tenth occurrence.

  > **NOTE**: You can set the threshold value to 0 for errors with a severity level of minor. This implies that no action is taken for that error. You cannot set the threshold value to 0 for errors with a severity level of major or fatal.

  Default: The error count for fatal and major actions is 1. The default error count for minor actions is 10.

  Range: 0—429,496,729

The available detection and recovery actions are as follows:

- `alarm`—Raise an alarm.
- `disable-pfe`—Disable the Packet Forwarding Engine interfaces on the FPC.
- `get-state`—Get the current state of the FPC.

- `log`—Generate a log for the event.
- `offline`—Take the FPC offline.
- `offline-pic`—Take the PIC (installed in the FPC) offline.
- `reset`—Reset the FPC.

Required Privilege Level

routing—To view this in the configuration.

routing-control—To add this to the configuration.

fpc-slice

IN THIS SECTION

- Syntax | 7890
- Hierarchy Level | 7890
- Description | 7891
- Options | 7891
- Required Privilege Level | 7892
- Release Information | 7892

Syntax

```
fpc-slice fpc fpc-slot {
    slc slc-id {
        pfe-id-list pfe-id-list;
        cores number-of-cores;
        dram dram-value;
        }
    }
```

Hierarchy Level

```
[edit chassis network-slices guest-network-functions gnf gnf-id]
```

Description

Configure smaller logical partitions or sub line cards (SLC) of a line card, allocate resources to the SLCs, and assign each SLC to a guest network function (GNF).

This feature is applicable only to the MPC11E line card. An MPC11E line card supports two sub line cards (SLCs). You can assign each GNF with an SLC, which functions like an independent line card.

NOTE:

- You must configure all the SLCs supported by a line card, assign the required resources such as core, DRAM, and Packet forwarding Engines the SLCs before committing the configuration. You must allocate all the Packet forwarding Engines on the line card to the SLCs.

Options

fpc-slot The slot number of the line card on which you want to configure SLCs.

slc *slc-id* Specify the sub line card (SLC) ID which you want to assign to the selected GNF.

NOTE: Do not assign:

- two or more SLCs of the same line card to the same GNF.
- the same SLC of a line card to more than one GNF.

pfe-id-list *pfe-id-list* Specify the Packet Forwarding Engine IDs to be allocated to the SLC. You must allocate all the Packet Forwarding Engines on a line card to the SLCs.

cores *number-of-cores* Specify the number of cores to be allocated to the SLC. Currently, number of cores supported is 4.

dram *dram-value* Specify the DRAM to be allocated to the SLC. The MPC11E line card supports the following combinations:

SLC1 DRAM (GB)	SLC2 DRAM (GB)	Sub Total (GB)
13	13	26

(Continued)

SLC1 DRAM (GB)	SLC2 DRAM (GB)	Sub Total (GB)
9	17	26

fpcs (NSSU Upgrade Groups)

IN THIS SECTION

- Syntax | 7894
- Hierarchy Level | 7894
- Description | 7894
- Options | 7895
- Required Privilege Level | 7895
- Release Information | 7895

Syntax

```
fpcs (slot-number | [list-of-slot-numbers]);
```

Hierarchy Level

```
[edit chassis nssu upgrade-group group-name],
[edit chassis nssu upgrade-group group-name member member-id]
```

Description

Configure switch line cards, Virtual Chassis member switches, or Virtual Chassis Fabric (VCF) member switches as part of an NSSU upgrade group.

To reduce the time an NSSU takes, you can configure line-card upgrade groups for an EX6200 or EX8200 switch with redundant Routing Engines; an EX8200 Virtual Chassis; an EX4650 Virtual Chassis with more than three member switches; QFX3500, QFX3600, and QFX5100 Virtual Chassis; or a

QFX5100 Virtual Chassis Fabric (VCF). NSSU upgrades the devices in the order in which you configure the upgrade groups, so you can also use upgrade groups to control the upgrade sequence.

For switches that have separate line cards, use this statement to assign one or more line cards to an NSSU upgrade group based on their line-card slot numbers.

For Virtual Chassis or VCF member switches that do not have separate line cards, use this statement to assign one or more Virtual Chassis or VCF members to an NSSU upgrade group by specifying their member IDs.

> **NOTE**: For a Virtual Chassis or VCF, you do not use this statement with the `member` option. When to use the `member` statement hierarchy is explained next.

To configure an upgrade group that includes line cards on switches that support multiple line cards and comprise a Virtual Chassis, use this statement with the `member` option to specify the Virtual Chassis member ID and the desired line card slot number or numbers on that member switch to include in the upgrade group. Use multiple statements to add line cards from different Virtual Chassis members to the upgrade group.

Options

list-of-slot-numbers	A list of slot numbers of multiple line cards or member IDs of Virtual Chassis or VCF members to be included in the upgrade group. Separate multiple slot numbers or member IDs with spaces and enclose the list in square brackets—for example: [3 4 7].
slot-number	The slot number of a single line card or member ID of a Virtual Chassis or VCF member to be included in the upgrade group.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.4.

- Required Privilege Level | 7899
- Release Information | 7899

Syntax

```
fragment-threshold bytes;
```

Hierarchy Level

```
[edit class-of-service fragmentation-maps forwarding-class class-name]
```

Description

For link services IQ (`lsq`) interfaces only, set the fragmentation threshold for an individual forwarding class.

Default

If you do not include this statement, the fragmentation threshold you set at the `[edit interfaces interface-name unit logical-unit-number]` or `[edit interfaces interface-name mlfr-uni-nni-bundle-options]` hierarchy level is the default for all forwarding classes. If you do not set a maximum fragment size anywhere in the configuration, packets are fragmented if they exceed the smallest maximum transmission unit (MTU) of all the links in the bundle.

Options

bytes—Maximum size, in bytes, for multilink packet fragments. Any nonzero value must be a multiple of 64 bytes.

- **Range:** 128 through 16,320 bytes

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

options],
[edit logical-systems logical-system-name interfaces (ls-fpc/pic/port| ml-fpc/pic/port) unit
logical-unit-number]
```

Description

For multilink and link services interfaces only, set the fragmentation threshold, in bytes.

Options

bytes—Maximum size, in bytes, for multilink packet fragments. Any nonzero value must be a multiple of 64 bytes.

- **Range:** 128 through 16,320 bytes
- **Default:** 0 bytes (no fragmentation)

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

RELATED DOCUMENTATION

- Release Information | 7904

Syntax

```
fragmentation-map map-name;
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
```

Description

For AS PIC link services IQ (`lsq`) and virtual LSQ redundancy (`rlsq`) interfaces, associate a fragmentation map with a multilink PPP interface or MLFR FRF.16 DLCI.

Default

If you do not include this statement, traffic in all forwarding classes is fragmented.

Options

map-name—Name of the fragmentation map.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Syntax

```
fragmentation-maps {
    map-name {
        forwarding-class class-name {
            drop-timeout milliseconds;
            fragment-threshold bytes;
            multilink-class number;
            no-fragmentation;
        }
    }
}
```

Hierarchy Level

```
[edit class-of-service]
```

Description

For Multiservices and Services PIC link services IQ (`lsq`) and virtual LSQ redundancy (`rlsq`) interfaces, define fragmentation properties for individual forwarding classes.

Default

If you do not include this statement, traffic in all forwarding classes is fragmented.

Options

map-name—Name of the fragmentation map.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

frame-error

IN THIS SECTION

- Syntax | 7906
- Hierarchy Level | 7907
- Description | 7907
- Options | 7907
- Required Privilege Level | 7907
- Release Information | 7907

Syntax

```
frame-error count;
```

Hierarchy Level

```
[edit protocols oam ethernet link-fault-management action-profile event link-event-rate],
[edit protocols oam link-fault-management interface interface-name event-thresholds]
```

Description

Configure the threshold value for sending frame error events or taking the action specified in the action profile.

Frame errors occur on the underlying physical layer. The threshold is reached when the number of frame errors reaches the configured value.

The window or period during which frame errors are counted is 5 seconds or multiples of it (with a maximum value of 1 minute). This window denotes the duration as intervals of 100 milliseconds, encoded as a 16-bit unsigned integer. This window is not configurable in Junos OS. According to the IEEE 802.3ah standard, the default value of the frame-errors window is 1 second. This window has a lower bound of 1 second and an upper bound of 1 minute.

Options

count—Threshold count for frame error events.

- **Range:** 0 through 100

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4.

frame-mode (Dynamic Traffic Shaping)

IN THIS SECTION

- Syntax | 7908
- Hierarchy Level | 7908
- Description | 7908
- Default | 7908
- Options | 7909
- Required Privilege Level | 7909
- Release Information | 7909

Syntax

```
frame-mode (bytes | $junos-cos-byte-adjust | frame-mode-bytes frame-mode-bytes |$junos-cos-byte-
adjust-frame);
```

Hierarchy Level

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name overhead-
accounting],
[edit class-of-service traffic-control-profiles profile-name overhead-accounting]
```

Description

Configure the mode to shape downstream ATM traffic based as frames.

Default

The default is `frame-mode`.

Options

bytes	Byte adjustment value for the `cell-mode` or `frame-mode` shaping options.
$junos-cos-byte-adjust	Predefined variable for byte adjustment that is replaced with a value obtained from the RADIUS server when a subscriber authenticates over the interface to which the dynamic profile is attached.
frame-mode-bytes *frame-mode-bytes*	Overhead bytes when in frame-mode. Traffic shaping is based on the number of bytes in the frame, without regard to cell encapsulation or padding overhead.
$junos-cos-byte-adjust-frame	Predefined variable for frame mode shaping. This variable can not be used when the `overhead-accounting bytes` *bytes* option is configured. • **Range:** –120 through 124 bytes

BEST PRACTICE: We recommend using the `frame-mode-bytes` *frame-mode-bytes* option rather than the `bytes` option.

NOTE: If you specify a value for the `bytes` *bytes* option, you cannot specify a value for either the `frame-mode-bytes` option.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

Variable *$junos-cos-byte-adjust-frame* introduced in Junos OS Release 13.1.

- Required Privilege Level | **7911**
- Release Information | **7911**

Syntax

```
frame-period count;
```

Hierarchy Level

```
[edit protocols oam ethernet link-fault-management action-profile event link-event-rate],
[edit protocols oam link-fault-management interface interface-name event-thresholds]
```

Description

Configure the number of frame errors within the last N frames that has exceeded a threshold. Threshold for sending frame period error events or taking the action specified in the action profile.

A frame error is any frame error on the underlying physical layer. The frame period threshold is reached when the number of frame errors reaches the configured value within the period window. The default period window is the number of minimum-size frames that can be transmitted on the underlying physical layer in 1 second. The window is not configurable.

Currently, Junos does not generate `frame-period` event.

Options

count—Threshold count for frame period error events.

- **Range:** 0 through 100

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4.

```
frame-period-summary count;
```

Hierarchy Level

```
[edit protocols oam ethernet link-fault-management action-profile event link-event-rate],
[edit protocols oam link-fault-management interface interface-name event-thresholds]
```

Description

Configure the threshold value for sending frame period summary error events or taking the action specified in the action profile.

An errored frame second is any 1-second period that has at least one errored frame. This event is generated if the number of errored frame seconds is equal to or greater than the specified threshold for that period window. The default window is 60 seconds. The window is not configurable.

Options

count—Threshold count for frame period summary error events.

- **Range:** 0 through 100

Required Privilege Level

```

Hierarchy Level

```
[edit class-of-service interfaces interface-name unit logical-unit-number loss-priority-maps],
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
```

Description

Assign the loss priority map or the rewrite rule to a logical interface.

Options

- `default`—Apply default loss priority map or default rewrite rule. The default loss priority map contains the following settings:

```
loss-priority low code-point 0;
loss-priority high code-point 1;
```

- The default rewrite rule contains the following settings:

```
loss-priority low code-point 0;
loss-priority medium-low code-point 0;
loss-priority medium-high code-point 1;
loss-priority high code-point 1;
```

- *name*—Name of loss priority map or rewrite rule to be applied.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Release 8.5 of Junos OS.

frame-relay-de (CoS Loss Priority)

IN THIS SECTION

- Syntax | 7915

Point-to-Point Protocol (PPP)

framing (10-Gigabit Ethernet Interfaces)

IN THIS SECTION

- Syntax | 7925
- Hierarchy Level | 7925
- Description | 7925
- Default | 7926
- Options | 7926
- Required Privilege Level | 7926
- Release Information | 7926

Syntax

```
framing (lan-phy | wan-phy);
precise-bandwidth;
```

Hierarchy Level

```
[edit interfaces xe-fpc/pic/port],
[edit interfaces et-fpc/pic/port]
```

Description

For routers supporting the 10-Gigabit Ethernet interface, configure the framing format. WAN PHY mode is supported on MX240, MX480, MX960, T640, T1600,T4000, and PTX Series Packet Transport Routers routers only.

NOTE:

- The T4000 Core Router supports only LAN PHY mode in Junos OS Release 12.1R1. Starting with Junos OS Release 12.1R2, WAN PHY mode is supported on the T4000 routers with the 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP). Starting with Junos OS Release 12.2, WAN PHY mode is supported on the T4000 routers with the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-24XGE-SFPP).
- On PTX Series routers, WAN PHY mode is supported only on the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ .
- When the PHY mode changes, interface traffic is disrupted because of port reinitialization.
- In Junos OS Releases 17.4R2, 17.4R3, and later, on the following MPCs or routers, you cannot configure `wan-phy` mode at 10-Gbps, 40-Gbps, and 100-Gbps on a per-port basis:
  - MPC7E-10G, MPC7E-MRATE, MX2K-MPC8E, and MX2K-MPC9E

- MPC10003
- MX204 router
- JNP10K-LC2101 MPC

- WAN PHY mode is not supported on MPC10E-10C-MRATE and MPC10E-15C-MRATE MPCs.

Default

Operates in LAN PHY mode.

Options

`lan-phy`—10GBASE-R interface framing format that bypasses the WIS sublayer to directly stream block-encoded Ethernet frames on a 10-Gigabit Ethernet serial interface.

`wan-phy`—10GBASE-W interface framing format that allows 10-Gigabit Ethernet wide area links to use fiber-optic cables and SONET devices.

`precise-bandwidth`—Enables precise bandwidth for WAN-PHY interface framing format.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.0.

The option `precise-bandwidth` introduced in Junos OS Release 19.3R1 for MX Series Routers.

Release Information

Statement introduced in Junos OS Release 15.1.

free-nh-memory-watermark (Resource Monitor)

IN THIS SECTION

- Syntax | 7935
- Hierarchy Level | 7935
- Description | 7936
- Options | 7936
- Required Privilege Level | 7936
- Release Information | 7936

Syntax

```
free-nh-memory-watermark number;
```

Hierarchy Level

```
[edit system services resource-monitor]
```

Description

Configure the percentage of free memory space used for next-hops to be monitored with a watermark value. The default value and the configured value of the watermark value for the percentage of free next-hop memory also applies to encapsulation memory. You can configure the resource-monitoring capability on MX80, MX104, MX240, MX480, MX960, MX2010, and MX2020 routers with I-chip-based DPCs and Trio-based FPCs.

Options

number Percentage of free memory space used for next-hops to be monitored with a watermark value. The NH memory watermark is applicable only for encapsulation memory (output WAN static RAM memory). When the configured watermark is exceeded, error logs are triggered. The default watermark values for the percentage of free ukernel or heap memory, next-hop memory, and firewall filter memory are 20.

- **Range:** 1 through 100

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1.

frequency-lock-threshold

IN THIS SECTION

- Syntax | 7937
- Hierarchy Level | 7937
- Description | 7937
- Options | 7937

Required Privilege Level | 7937
Release Information | 7938

Syntax

```
frequency-lock-threshold frequency-offset
```

Hierarchy Level

```
[edit protocols ptp]
```

Description

The frequency lock threshold option controls the frequency offset in parts per billion (ppb) that the servo will lock with. Locking with a higher frequency lock threshold allows a quicker frequency lock, although at the expense of a higher phase offset per window in the phase aligned state. This option can be used for PTP applications that do not demand strict requirements that are typically needed with telecom applications.

Options

frequency-offset The frequency offset value in parts per billion (ppb).

- Range: 1 ppb through 15 ppb
- Default: 1 ppb

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 23.4R1 for MX10008.

Supported on ACX7100-32C, ACX7100-48L, and ACX7024 in Junos OS Evolved Release 24.2R1.

IN THIS SECTION

- Syntax | 7938
- Hierarchy Level | 7939
- Description | 7939
- Options | 7939
- Required Privilege Level | 7939
- Release Information | 7939

Syntax

```
from {
    application-group-any;
    application-groups [ application-group-names ];
    application-unknown;
    applications [ application-names ];
    destination-address address <any-unicast>;
    destination-address-range low minimum-value high maximum-value;
```

```
    destination-prefix-list list-name;
    nested-application-unknown;
    source-address address <any-unicast>;
    source-address-range low minimum-value high maximum-value;
    source-prefix-list list-name;
}
```

Hierarchy Level

```
[edit services aacl rule rule-name term term-name]
```

Description

Specify match conditions for the AACL term.

Options

For information on match conditions, see the description of firewall filter match conditions in the Routing Policies, Firewall Filters, and Traffic Policers User Guide.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 9.5.

RELATED DOCUMENTATION

Configuring AACL Rules

from (Captive Portal Content Delivery Tags)

IN THIS SECTION

- Syntax | 7940
- Hierarchy Level | 7940
- Description | 7940
- Options | 7940
- Required Privilege Level | 7941
- Release Information | 7941

Syntax

```
from {
    destination-address address <except>;
}
```

Hierarchy Level

```
[edit services captive-portal-content-delivery rule rule-name term term-name]
```

Description

Specify one or more addresses in a CPCD rule term to identify traffic that can have header tags inserted into GET messages. Tag insertion is supported only for Routing-Engine-based, static CPCD.

Options

address Destination IPv4 or IPv6 address for traffic to be tagged.

except (Optional) Exclude the specified address from rule matching.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.1R1.

RELATED DOCUMENTATION

Configuring Routing Engine-Based, Static HTTP Redirect Services

from (Firewall)

IN THIS SECTION

- Syntax | 7941
- Hierarchy Level | 7942
- Description | 7942
- Options | 7942
- Required Privilege Level | 7942
- Release Information | 7942

Syntax

```
from {
    match-conditions;
    egress-to-ingress;
}
```

Hierarchy Level

```
[edit firewall family family-name filter                filter-name term term-name]
```

Description

Match packet fields to values specified in a match condition. If the `from` statement is not included in a firewall filter configuration, all packets are considered to match and the actions and action modifiers in the `then` statement are implemented.

Options

match-conditions—Conditions that define the values or fields that the incoming or outgoing packets must contain for a match. You can specify one or more match conditions. If you specify more than one, they all must match for a match to occur and for the action in the `then` statement to be implemented.

egress-to-ingress—Include this option to increase the number of egress VLAN firewall filter terms from 1024 to 2048.

Required Privilege Level

firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1.

Option *egress-to-ingress* introduced in Junos OS Release 19.1R1 for the QFX5110.

from (HTTP Header Enrichment)

IN THIS SECTION

- Syntax | 7943
- Hierarchy Level | 7943
- Description | 7944
- Required Privilege Level | 7944
- Release Information | 7944

Syntax

```
from {
    destination-address {
        (any-ipv4 | any-ipv4 except);
        (any-ipv6 | any-ipv6 except);
        (any-unicast | any-unicast except);
        (prefix | prefix except);
    }
    destination-address-range {
        high address low address <except>;
    }
    destination-port-range {
        high port-number low port-number;
    }
    destination-ports value;
    destination-prefix-list {
        (prefix-name | prefix-name except);
    }
}
```

Hierarchy Level

```
[edit services hcm tag-rule rule-name term term-number]
```

Description

Specify the match criteria for the term in the tag rule. If all the conditions specified in the match criteria are met, then the HTTP header enrichment actions specified in the `then` statement are applied.

If you want the HTTP header enrichment actions specified in the `then` statement to be applied to all HTTP requests, do not include any matching conditions with the `from` statement.

NOTE: You must include a `from` statement in a tag rule.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

RELATED DOCUMENTATION

from (IDS MS-DPC)

IN THIS SECTION

- Syntax | **7945**
- Hierarchy Level | **7945**
- Description | **7945**
- Options | **7945**

Required Privilege Level | 7945
Release Information | 7946

Syntax

```
from {
    application-sets set-name;
    applications [ application-names ];
    destination-address (address | any-unicast) <except>;
    destination-address-range low minimum-value high maximum-value <except>;
    source-address (address | any-unicast) <except>;
    source-address-range low minimum-value high maximum-value <except>;
}
```

Hierarchy Level

```
[edit services ids rule rule-name term term-name]
```

Description

Specify input conditions for the IDS term when using the MS-DPC.

Options

For information on match conditions, see the description of firewall filter match conditions in the Routing Policies, Firewall Filters, and Traffic Policers User Guide.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

RELATED DOCUMENTATION

Configuring Match Conditions in IDS Rules

from (PCC Rules)

IN THIS SECTION

- Syntax | 7946
- Hierarchy Level | 7946
- Description | 7947
- Required Privilege Level | 7947
- Release Information | 7947

Syntax

```
from {
    <application-groups [application-group-name]>;
    <applications [application-name]>;
    flows ([flow-identifier] | any);
}
```

Hierarchy Level

```
[edit unified-edge pcef pcc-rules rule-name],
[edit services pcef pcc-rules rule-name]
```

Description

Specify the match criteria for the policy and charging control (PCC) rules. Any referenced SDF filter, application, or application group in the `from` statement must be configured.

If you are using Junos OS Subscriber Aware, specify the match criteria at the [`edit unified-edge pcef pcc-rules` *`rule-name`*] hierarchy level.

If you are using Junos OS Broadband Subscriber Management, specify the match criteria at the [`edit services pcef pcc-rules` *`rule-name`*] hierarchy level.

> **NOTE**: You must include the `flows` statement. If you do not want to filter subscriber traffic based on service data flow (SDF) filters, use `flows any`.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

For Junos OS Subscriber Aware:

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

For Junos OS Broadband Subscriber Management:

services—To view this statement in the configuration.

services–control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Support at the [`edit services pcef pcc-rules` *`rule-name`*] hierarchy level introduced for Junos OS Broadband Subscriber Management in Junos OS Release 17.2 on MX Series.

Support for Next Gen Services for Junos OS Broadband Subscriber Management introduced in Junos OS Release 19.3R2 on MX Series.

RELATED DOCUMENTATION

Configuring Policy and Charging Control Rules

from (PCP)

IN THIS SECTION

- Syntax | 7948
- Hierarchy Level | 7948
- Description | 7948
- Required Privilege Level | 7949
- Release Information | 7949

Syntax

```
from {
    application-sets set-name;
    applications [ application-name ];
    destination-address address <except>;
    destination-address-range high maximum-value low minimum-value <except>;
    destination-port  high maximum-value low minimum-value;
    destination-prefix-list list-name <except>;
    source-address address <except>;
    source-address-range high maximum-value low minimum-value <except>;
    source-prefix-list list-name <except>;
}
```

Hierarchy Level

```
[edit services pcp rule rule-name term term-name]
```

Description

Specify the match conditions for a PCP rule term. A PCP rule assigns the PCP server that handles selected traffic.

PCP is supported on the MS-DPC, MS-100, MS-400, and MS-500 MultiServices PICS. Starting in Junos OS Release 17.4R1, PCP is also supported on the MS-MPC and MS-MIC.

The remaining statements are explained separately.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2R1.

RELATED DOCUMENTATION

Configuring Port Control Protocol

from (Protocols MPLS)

IN THIS SECTION

- Syntax | 7949
- Hierarchy Level | 7950
- Description | 7950
- Default | 7950
- Options | 7950
- Required Privilege Level | 7950
- Release Information | 7950

Syntax

```
from address;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name]
```

Description

Specify the source address to use for the LSP.

The address you specify does not affect the outgoing interface used by the LSP.

Default

If you do not include this statement, the software automatically selects the loopback interface as the address.

Options

address—IP address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

RELATED DOCUMENTATION

Configuring the Ingress Router Address for LSPs

from (Security NAT)

IN THIS SECTION

- Syntax | 7951
- Hierarchy Level | 7951
- Description | 7951
- Options | 7951
- Required Privilege Level | 7952

Syntax

```
from {
    interface [interface-name];
    routing-instance [routing-instance-name];
    zone [zone-name];
}
```

Hierarchy Level

```
[edit security nat destination rule-set rule-set-name]
[edit security nat source rule-set rule-set-name]
[edit security nat static rule-set rule-set-name]
```

Description

Specify the source of the packet among the routing instance, interface, or zone.

Options

- `interface [interface-name]` —Name of the interface.
- `routing-instance [routing-instance-name]` —Name of the routing instance.

- `zone [zone-name]` —Name of the zone.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.3.

}
```

Hierarchy Level

```
[edit security policies]
```

Description

Specify a source zone and destination zone to be associated with the security policy.

Options

- `from-zone` *`zone-name`*—Name of the source zone.
- `to-zone` *`zone-name`*—Name of the destination zone.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5. Support for the `services-offload` option added in Junos OS Release 11.4. Support for the `source-identity` option added in Junos OS Release 12.1. Support for the `description` option added in Junos OS Release 12.1. Support for the `ssl-termination-profile` and `web-redirect-to-https` options added in Junos OS Release 12.1X44-D10. Support for the `user-firewall` option added in Junos OS Release 12.1X45-D10. Support for the `initial-tcp-mss` and `reverse-tcp-mss` options added in Junos OS Release 12.3X48-D20. Support for the `dynamic-application` and `deny` options added in Junos OS Release 18.2R1.

fru-poweron-sequence

IN THIS SECTION

- Syntax | 7970
- Hierarchy Level | 7970
- Description | 7970
- Options | 7970
- Required Privilege Level | 7971
- Release Information | 7971

Syntax

```
fru-poweron-sequence fru-poweron-sequence;
```

Hierarchy Level

```
[edit chassis]
```

Description

(MX Series 5G Universal Routing Platforms, SRX5xxx Series Platforms) Configure the power-on sequence for the DPCs in the chassis for routers with the enhanced AC Power Entry Module (PEM).

(T640 routers, T1600 routers, T4000 routers, MX2020 routers, and PTX Series packet transport routers) Configure the power-on sequence for Flexible PIC Concentrators (FPCs) installed in the chassis.

Options

(MX Series 5G Universal Routing Platforms only) *fru-poweron-sequence*—Power-on sequence for the DPCs in the chassis. The numbers indicate the slot number of the DPCs.

> **NOTE**: If the power-on sequence is not configured by including the `fru-poweron-sequence` statement, Junos OS uses the `/var/log/fpc_poweron_seq.log` file to determine the power-on sequence for the last power-on operation for the DPCs and the same sequence is used. If the `/var/log/boot_seq.log` file, is not available, Junos OS uses the ascending order of the slot numbers of the DPCs as the sequence to power on the DPCs.

(T640 routers, T1600 routers, T4000 routers, MX2020 routers, and PTX Series packet transport routers) *`fru-poweron-sequence`*—Power-on sequence for the FPCs in the chassis. The numbers indicate the slot number of the FPCs.

> **NOTE**:
>
> - If the configured sequence contains invalid numbers, Junos OS considers only the valid numbers in the sequence. The invalid numbers are silently discarded.
> - If the power-on sequence is not configured by including the `fru-poweron-sequence` statement, Junos OS uses the ascending order of the slot numbers of the FPCs as the sequence to power on the FPCs.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.0.

Redistribute the Available Power by Configuring Power-On Sequence

fte (Port)

IN THIS SECTION

- Syntax | 7972
- Hierarchy Level | 7972
- Description | 7972
- Options | 7973
- Required Privilege Level | 7973
- Release Information | 7973

Syntax

```
fte {
    (port port-number | port-range port-range-low port-range-high);
}
```

Hierarchy Level

```
[edit chassis fpc slot pic pic-number]
```

Description

Configure a specific port or a range of ports to operate as 40-Gigabit Ethernet data plane uplink (*fte*) type ports.

CAUTION: The Packet Forwarding Engine on the switch is restarted when you commit the port type configuration changes. As a result, you might experience packet loss on the switch.

Options

port-number Port number on which you want to configure the port type. Valid values are 2 through 7.

port-range-low Lowest-numbered port in the range of ports. The lowest possible value is 2.

port-range-high Highest-numbered port in the range of ports. The highest possible value is 7.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2X52-D10.

ftp (Flow Collector Files)

IN THIS SECTION

- Syntax | 7978
- Hierarchy Level | 7978
- Description | 7978
- Options | 7978
- Required Privilege Level | 7979
- Release Information | 7979

Syntax

```
ftp:url;
```

Hierarchy Level

```
[edit services flow-collector destination]
```

Description

Specify the primary and secondary destination FTP server addresses.

Options

url—FTP server address. The URL can include the following macros, typed in braces:

- `{%D}`—Date
- `{%T)`—Time when the file is created
- `{%I}`–Description string for the logical interface configured using the `collector` *`interface-name`* statement at the `[edit services flow-collector interface-map]` hierarchy
- `{%N}`—Unique, sequential number for each new file created

- {am_pm}—AM or PM
- {date}—Current date using the {year} {month} {day} macros
- {day}—From 01 through 31
- {day_abbr}—Sun through Sat
- {day_full}—Sunday through Saturday
- {generation number}—Unique, sequential number for each new file created
- {hour_12}—From 01 through 12
- {hour_24}—From 00 through 23
- {ifalias}—Description string for the logical interface configured using the collector statement at the [edit services flow-collector interface-map] hierarchy
- {minute}—From 00 through 59
- {month}—From 01 through 12
- {month_abbr}—Jan through Dec
- {month_full}—January through December
- {num_zone}—From -2359 to +2359; this macro is not supported
- {second}—From 00 through 60
- {time}—Time the file is created, using the {hour_24} {minute} {second} macros
- {time_zone}—Time zone code name of the locale; for example, gmt (this macro is not supported).
- {year}—In the format YYYY; for example, 1970
- {year_abbr}—From 00 through 99

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Configuring Destination FTP Servers for Flow Records

ftp (Security ALG)

IN THIS SECTION

- Syntax | 7980
- Hierarchy Level | 7981
- Description | 7981
- Options | 7981
- Required Privilege Level | 7982
- Release Information | 7982

Syntax

```
ftp {
    allow-mismatch-ip-address;
    disable;
    ftps-extension;
    line-break-extension;
    traceoptions {
        flag {
            all {
                extensive
            }
        }
    }
}
```

Hierarchy Level

```
[edit logical-systems name security alg],
[edit logical-systems name tenants name security alg],
[edit security alg],
[edit services alg],
[edit tenants name security alg]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure the ftp function to Specify the File Transfer Protocol (FTP) Application Layer Gateway (ALG) on the device.

Options

- `allow-mismatch-ip-address`—Control commands in FTP, such as PORT and EPRT, contain IP addresses internally. If the IP address does not match the source IP at Packet Layer 3, which is the client's IP, the packets are discarded. However, when the allow-mismatch-ip-address option is enabled, these packets are accepted.
- `disable`—Disable the FTP ALG. By default, the FTP ALG is enabled. You can enable or disable FTP ALG for both IPV4 and IPV6 mode.
- `ftps-extension`—Enable secure FTP and FTP SSL protocols.
- `line-break-extension`—Enable line-break-extension. This option will enable the FTP ALG to recognize the LF as line break in addition to the standard CR+LF (carriage return, followed by line feed).
- `traceoptions`—Configure FTP ALG tracing options. To specify more than one trace operation, include multiple flag statements.
  - `flag`—Trace operation to perform.
    - `all`—Trace all events.

- `extensive`—(Optional) Display extensive amount of data.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 11.4.

The `tenant` option is introduced in Junos OS Release 18.3R1.

ftp (Services CoS Next Gen Services)

IN THIS SECTION

- Syntax | 7982
- Hierarchy Level | 7983
- Description | 7983
- Options | 7983
- Required Privilege Level | 7983
- Release Information | 7983

Syntax

```
ftp {
    data {
        dscp (alias | bits);
```

```
        forwarding-class class-name;
    }
}
```

Hierarchy Level

```
[edit services cos application-profile profile-name]
```

Description

Configure CoS actions for FTP traffic in an application profile. The application profile can then be used in CoS rule actions.

Options

dscp (*alias* | *bits*) Either a code point alias or a DSCP bit value to apply to the FTP packets.

forwarding-class *class-name* Forwarding class name to apply to the FTP packets. The choices are:

- assured-forwarding
- best-effort
- expedited-forwarding
- network-control

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.3R2.

Configuring Transfer Logs

ftp

IN THIS SECTION

- Syntax | 7987
- Hierarchy Level | 7987
- Description | 7987
- Options | 7987

Required Privilege Level | 7988
Release Information | 7988

Syntax

```
ftp {
    authentication-order [authentication-methods];
    connection-limit limit;
    rate-limit limit;
    enable-anonymous-login;
}
```

Hierarchy Level

```
[edit system services]
```

Description

Allow FTP requests from remote systems to the local device.

Options

authentication-order [*authentication-methods*]

Configure the order in which the software tries different user authentication methods when attempting to authenticate a user. For each login attempt, the software tries the authentication methods in order, starting with the first one, until the password matches.

- **Values:** Specify one or more of the following authentication methods listed in the order in which they must be tried:
  - `ldaps`—Use LDAP authentication services.
  - `password`—Use the password configured for the user with the `authentication` statement at the `[edit system login user]` hierarchy level.

- `radius`—Use RADIUS authentication services.
- `tacplus`—Use TACACS+ authentication services.

- **Default:** If you do not include the `authentication-order` statement, users are verified based on their configured passwords.

connection-limit *limit*

Configure the maximum number of connections sessions for the ftp service per protocol (either IPv6 or IPv4).

> **NOTE**: The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured `connection-limit` value if the system resources are limited.

- **Range:** 1 through 250 connections
- **Default:** 75 connections

rate-limit *limit*

Configure the maximum number of connections attempts per minute, per protocol (either IPv6 or IPv4) on an access service. For example, a rate limit of 10 allows 10 IPv6 ftp session connection attempts per minute and 10 IPv4 ftp session connection attempts per minute.

- **Range:** 1 through 250 connections
- **Default:** 150 connections

enable-anonymous-login

Enable anonymous FTP access. Guests can login and send FTP requests without a password by using the `ftp` username.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Option `ldaps` introduced in Junos OS Release 20.2R1.

Option `enable-anonymous-login` introduced in Junos OS Release 23.2R2.

function (Diameter Network Element)

IN THIS SECTION

- Syntax | 7991
- Hierarchy Level | 7991
- Description | 7991
- Default | 7991
- Options | 7991
- Required Privilege Level | 7992
- Release Information | 7992

Syntax

```
function [function-name];
```

Hierarchy Level

```
[edit diameter network-element element-name]
```

Description

Specify one or more applications (function) associated with a Diameter network element.

Default

By default, all functions are associated with (supported by) the network element.

Options

function-name—Application (function) associated with the route. You can list multiple functions with the element.

- `gx-plus`—Associate the Gx-Plus application with the network element.
- `jsrc`—Associate the JSRC application with the network element.
- `nasreq`—Associate the NASREQ application with the network element.
- `packet-triggered-subscribers`—Associate the packet-triggered subscribers application with the network element.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

Support for PTSP introduced in Junos OS Release 10.2.

Support for Gx-Plus introduced in Junos OS Release 11.2.

Support for PTSP discontinued in Junos OS Release 13.1.

Support for NASREQ added in Junos OS Release 16.1.

function (Diameter Route)

IN THIS SECTION

Syntax | 7993
Hierarchy Level | 7993
Description | 7993

- Default | 7993
- Options | 7993
- Required Privilege Level | 7993
- Release Information | 7994

Syntax

```
function function-name <partition partition-name>;
```

Hierarchy Level

```
[edit diameter network-element element-name forwarding route dne-route-name]
```

Description

Specify the application (function) associated with a destination and metric. Together, these three elements define a route reachable through a Diameter network element.

Default

All functions are associated with the route.

Options

function-name—Application (function) associated with the route. Gx-Plus, JSRC, NASREQ, and packet-triggered-subscribers are the applications currently supported.

partition *partition-name*—(Optional) Partition associated with the application (function).

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6.

Support for PTSP introduced in Junos OS Release 10.2.

Support for Gx-Plus introduced in Junos OS Release 11.2.

Support for PTSP discontinued in Junos OS Release 13.1.

Support for NASREQ added in Junos OS Release 16.1.

g-duplicates-dropped-periodicity

IN THIS SECTION

- Syntax | 8002
- Hierarchy Level | 8002
- Description | 8002
- Default | 8002
- Options | 8002
- Required Privilege Level | 8002
- Release Information | 8002

Syntax

```
g-duplicates-dropped-periodicity seconds;
```

Hierarchy Level

```
[edit services dynamic-flow-capture]
```

Description

Specify the frequency for sending notifications to affected control sources when transmission of duplicate sets of data is restricted because the `g-max-duplicates` threshold has been reached. This setting is applied globally; the `duplicates-dropped-periodicity` setting applied at the `capture-group` level overrides the global setting.

Default

The default period for sending notifications is 30 seconds.

Options

seconds—Period for sending DuplicatesDropped notifications.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

RELATED DOCUMENTATION

duplicates-dropped-periodicity | 6340

Limiting the Number of Duplicates of a Packet

g-max-duplicates

IN THIS SECTION

- Syntax | 8003
- Hierarchy Level | 8003
- Description | 8003
- Default | 8003
- Options | 8003
- Required Privilege Level | 8004
- Release Information | 8004

Syntax

```
g-max-duplicates number;
```

Hierarchy Level

```
[edit services dynamic-flow-capture]
```

Description

Specify the maximum number of content destinations to which DFC PICs can send data from a single input set of packets. Limiting the number of duplicates reduces the load on the PIC. This setting is applied globally; the `max-duplicates` setting applied at the `capture-group` level overrides the global setting.

Default

If no value is configured, a default setting of 3 is used.

Options

number—Maximum number of content destinations.

- **Range:** 1 through 64

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

RELATED DOCUMENTATION

max-duplicates | 10874

Limiting the Number of Duplicates of a Packet

garp-na-enable

IN THIS SECTION

- Syntax | 8004
- Hierarchy Level | 8005
- Description | 8005
- Required Privilege Level | 8005
- Release Information | 8005

Syntax

```
garp-na-enable;
```

Hierarchy Level

```
[edit protocols l2-learning]
```

Description

Enable sending unsolicited GARP or NA messages.

When learning a new MAC-IP binding on a local PE device, or learning a MAC-IP binding on a remote PE device via EVPN, an unsolicited GARP or NA message is sent to all connected access CE devices. This message enables the connected CE devices to update their ARP or ND caches.

Required Privilege Level

[none specified]

Release Information

Statement introduced in Junos OS Release 23.4R1.

gate-status

IN THIS SECTION

- Syntax | 8006
- Hierarchy Level | 8006
- Description | 8006
- Default | 8006
- Options | 8006
- Required Privilege Level | 8006
- Release Information | 8007

Syntax

```
gate-status (uplink | downlink | uplink-downlink | disable-both);
```

Hierarchy Level

```
[edit unified-edge pcef pcc-action-profiles profile-name],
[edit services pcef pcc-action-profiles profile-name]
```

Description

Configure the gate status in a PCC action profile to enable or disable the forwarding of service flow packets. The gate status determines whether the uplink and downlink gates are opened or closed.

If you are using Junos OS Subscriber Aware, configure the gate status at the `[edit unified-edge pcef pcc-action-profiles profile-name]` hierarchy level.

If you are using Junos OS Broadband Subscriber Management, configure the gate status at the `[edit services pcef pcc-action-profiles profile-name]` hierarchy level.

Default

By default, if this statement is not configured, forwarding of service data flow packets is enabled in both the uplink and downlink directions.

Options

disable-both Disable forwarding of service data flow packets in the uplink and downlink directions.

downlink Enable forwarding of service data flow packets in the downlink direction.

uplink-downlink Enable forwarding of service data flow packets in the uplink and downlink directions.

uplink Enable forwarding of service data flow packets in the uplink direction.

Required Privilege Level

For Junos OS Subscriber Aware:

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

For Junos OS Broadband Subscriber Management:

services—To view this statement in the configuration.

services–control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Support at the `[edit services pcef pcc-action-profiles profile-name]` hierarchy level introduced for Junos OS Broadband Subscriber Management in Junos OS Release 17.2 on MX Series.

Support for Next Gen Services for Junos OS Broadband Subscriber Management introduced in Junos OS Release 19.3R2 on MX Series.

gate-timeout

IN THIS SECTION

- Syntax | **8008**
- Hierarchy Level | **8008**
- Description | **8008**
- Options | **8008**
- Required Privilege Level | **8008**
- Release Information | **8008**

Syntax

```
gate-timeout seconds;
```

Hierarchy Level

```
[edit applications application ike-esp-nat]
```

Description

For an IKE ALG application, configure the length of time that can pass after IKE establishes the security association between the IPsec client and server and before the ESP traffic starts in both directions. If the ESP traffic has not started before this timeout value, the ESP gates are deleted and the ESP traffic is blocked.

The IKE ALG enables the passing of IKEv1 and IPsec packets through NAPT-44 and NAT64 rules between IPsec peers that are not NAT-T compliant.

Options

seconds

Number of seconds.

- **Default:** 120 seconds

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

[edit security alg h323 application-screen message-flood],
[edit services alg h323 application-screen message-flood],
[edit tenants name security alg h323 application-screen message-flood]
```

Description

Configure the gatekeeper parameter to limit the rate of requests processed from remote access server (RAS) to the gatekeeper. Messages exceeding the threshold are dropped.

Options

`threshold` *rate*—Threshold measured in messages per second.

- **Range:** 1 through 50,000
- **Default:** 1000

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

gateway (Security Group VPN Member IKE)

IN THIS SECTION

- Syntax | 8011
- Hierarchy Level | 8011
- Description | 8011
- Options | 8011
- Required Privilege Level | 8012
- Release Information | 8012

Syntax

```
gateway gateway-name {
    ike-policy policy-name;
    local address ip-address;
    local-identity {
        (hostname hostname | inet ip-address | inet6 ipv6-address | user-at-hostname e-mail-
address);
    }
    remote-identity {
        (hostname hostname | inet ip-address | user-at-hostname e-mail-address);
    }
    routing-instance routing-instance;
    server-address ip-address;
}
```

Hierarchy Level

```
[edit security group-vpn member ike]
```

Description

Configure IKE gateway for group VPN member. An IKE gateway initiates and terminates network connections between a firewall and a security device.

Options

gateway *gateway-name*	Name of the gateway.
ike-policy *policy-name*	Name of the IKE policy.
local address *ip-address*	Configure the IPv4 address the member uses when accessing the group server.
local-identity *local-identity*	Specify the local IKE identity to send in the exchange with the destination peer to establish communication.
remote-identity *remote-identity*	Specify the name of a routing instance. If this is not specified, the default inet.0 routing instance is used.

routing-instance *routing-instance*

Specify the name of a routing instance. If this is not specified, the default inet.0 routing instance is used.

server-address *ip-address*

Specify the group server IPv4 address that this member registers through a `groupkey-pull` exchange. Up to four server IP addresses can be configured. The group member attempts to register with the first configured server. If registration with a configured server is not successful, the group member tries to register with the next configured server.

We recommend that group members only register with sub-servers in a server cluster and not the root-server.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2. Support for the `routing-instance` option added in Junos OS Release 15.1X49-D30 for vSRX Virtual Firewall.

gateway (Security Group VPN Server IKE)

IN THIS SECTION

- Syntax | 8013
- Hierarchy Level | 8013
- Description | 8013
- Options | 8013
- Required Privilege Level | 8014

Release Information | 8015

Syntax

```
gateway gateway-name {
    address ip-address;
    dead-peer-detection {
        always-send;
        interval seconds;
        threshold number;
    }
    dynamic {
        (hostname hostname | inet ip-address | user-at-hostname e-mail-address);
    }
    ike-policy policy-name;
    local-address ip-address;
    local-identity {
        (hostname hostname | inet ip-address | user-at-hostname e-mail-address);
    }
    remote-identity {
        (hostname hostname | inet ip-address | user-at-hostname e-mail-address);
    }
    routing-instance routing-instance;
}
```

Hierarchy Level

```
[edit security group-vpn server ike]
```

Description

Configure IKE gateway for group VPN server.

Options

`gateway` *`gateway-name`* —Name of the gateway.

`address` *`ip-address`* —Specify the IP address of the peer.

`dead-peer-detection` —Enable DPD between group server cluster servers.

`dynamic`—Specify the identifier for the remote gateway with a dynamic IPv4 address. Use this statement to set up a VPN with a gateway that has an unspecified IPv4 address.

- `hostname` *`domain-name`* —Specify a fully qualified domain name.
- `inet` *`ip-address`* —Specify an IPv4 address to identify the dynamic peer.
- `user-at-hostname` *`e-mail-address`* —Specify an e-mail address.

Configuring `mode main` for group VPN servers or members is not supported when the remote gateway has a dynamic address and the authentication method is `pre-shared-keys`.`ike-policy` *`policy-name`* —Specify the name of the IKE policy.

`local-address` *`ip-address`* —Configure the source IP address the group VPN server uses when communicating with a group member or a root-server. This statement is normally used when there are multiple IP addresses bound to an interface.

`local-identity`—Specify the local IKE identity to send in the exchange with the destination peer to establish communication. If you do not configure a local-identity, the device uses the IPv4 corresponding to the local endpoint by default.

- `hostname` *`hostname`*—Specify identity as a fully qualified domain name (FQDN).
- `inet` *`ip-address`*—Specify identity as an IPv4 address.
- `user-at-hostname` *`e-mail-address`*—Specify identity as an e-mail address.

`remote-identity`—Specify the remote IKE identity of the destination peer. If you do not configure a remote identity, the device uses, by default, the IPv4 address that corresponds to the destination peer.

- `hostname` *`hostname`*—Specify identity as a fully qualified domain name (FQDN).
- `inet` *`ip-address`*—Specify identity as an IPv4 address.
- `user-at-hostname` *`e-mail-address`*—Specify identity as an e-mail address.

`routing-instance` *`routing-instance`*—Configure the routing instance that the group VPN server uses when communicating with a group server. This statement is used when the IKE gateway is not configured in the default routing instance.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

Support for the Group VPN server added in Junos OS Release 15.1X49-D30 for vSRX Virtual Firewall.

[edit security ike]
```

Description

Configure an IKE gateway.

Options

gateway-name Name of the gateway.

address Specify either the IPv4 or IPv6 addresses or the hostnames of the primary Internet Key Exchange (IKE) gateway (peer) and up to four backup gateways.

Consider the following points before configuring multiple peer addresses with IPsec VPN running iked process:

- The option supports one primary address and up to a maximum of 4 backup addresses, all belonging to the same inet family.
- You must configure DPD before configuring multiple peer addresses.
- Only site-to-site VPN configuration supports multiple peer addresses.
- HA configuration doesn't support multiple peer addresses.

> **CAUTION**: Exercise caution when modifying the peer address:
>
> - If you delete an active peer address, the peer address list is updated and the next available peer address is considered active. This is a catastrophic operation and the VPN tunnel is torn down and a new tunnel is negotiated as per the peer address list.
> - If you delete an inactive peer address, the peer address list is updated but does not cause any catastrophic event as there is no impact on the tunnel.
> - If you add a new peer address, it will be appended to the end of the list, and there is no impact on the tunnel.

- Values:
  - address—IPv4 or IPv6 addresses or hostnames of an IKE gateway.

    This is a list of values. Priority of the peer addresses is based on the order of addresses in the list.
- Range:
  - Supports up to 5 peer addresses which includes an active peer address and up to 4 backup peer addresses.

aaa

Specify that extended authentication is performed in addition to IKE Phase 1 authentication for remote users trying to access a VPN tunnel.

advpn

Enable Auto Discovery VPN (ADVPN) protocol on the specified gateway. ADVPN dynamically establishes VPN tunnels between spokes to avoid routing traffic through the Hub.

dead-peer-detection

Enable the device to use dead peer detection (DPD).

dynamic

Specify the identifier for the remote gateway with a dynamic IPv4 or IPv6 address. Use this statement to set up a VPN with a gateway that has an unspecified IPv4 or IPv6 address.

external-interface

Name of the interface to be used to send traffic to the IPsec VPN. Specify the outgoing interface for IKE SAs. This interface is associated with a zone that acts as its carrier, providing firewall security for it.

fragmentation

Disable IKEv2 packet fragmentation and, optionally, configure the maximum size of an IKEv2 message before the message is split into fragments that are individually encrypted and authenticated.

disable

Disables IKEv2 fragmentation. IKEv2 fragmentation is enabled by default.

size *bytes*

Maximum size, in bytes, of an IKEv2 message before it is split into fragments. The size applies to both IPv4 and IPv6 messages.

- **Range:** 500 to 1300 bytes
- **Default:** 576 bytes for IPv4 messages and 1280 bytes for IPv6 messages

general-ikeid

Accept peer IKE-ID in general.

ike-policy

Specify the IKE policy to be used for the gateway.

local-address

Local IP address for IKE negotiations. Specify the local gateway address. Multiple addresses in the same address family can be configured on an external physical interface to a VPN peer. If this is the case, we recommend that `local-address` be configured. If there is only one address configured (IPv4 or IPv6) on an external physical interface, `local-address` configuration is not necessary.

The `local-address` value must be an IP address that is configured on an interface on the SRX Series Firewall. We recommend that `local-address` belong to the external interface of the IKE gateway. If local-address does not belong to the external interface of the IKE gateway, the interface must be in the same zone as the external interface of the IKE gateway and an intra-zone security policy must be configured to permit traffic. The `local-address` value and the remote IKE gateway address must be in the same address family, either IPv4 or IPv6.

local-identity

Specify the local IKE identity to send in the exchange with the destination peer to establish communication.

nat-keepalive

Specify the interval at which NAT keepalive packets (seconds) can be sent so that NAT translation continues. Default value changed from 5 seconds to 20 seconds in Junos OS Release 12.1X46-D10.

- **Default:** 20
- **Range:** 1 through 300

node-local

Mark an IPsec VPN tunnel between Multinode High Availability nodes and a VPN peer device as a node-local tunnel. Node-local tunnels support dynamic routing

protocols that facilitate the device to add the routes dynamically. These routes remain local to a node and are not bound to any services redundancy group (SRG). Use this option only for Multinode High Availability.

no-nat-traversal Disable IPSec NAT traversal. Disables UDP encapsulation of IPsec Encapsulating Security Payload (ESP) packets, otherwise known as Network Address Translation Traversal (NAT-T). NAT-T is enabled by default.

tcp-encap-profile Specify the TCP encapsulation profile to be used for TCP connections for remote access clients.

version Specify the IKE version to use to initiate the connection.

- Values:
  - v1-only—The connection must be initiated using IKE version 1. This is the default.
  - v2-only—The connection must be initiated using IKE version 2

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5. Support for IPv6 addresses added in Junos OS Release 11.1. The `inet6` option added in Junos OS Release 11.1. Support for the `advpn` option added in Junos OS Release 12.3X48-D10.

Option `fragmentation` is introduced in Junos OS Release 15.1X49-D80.

Option `tcp-encap-profile` is introduced in Junos OS Release 15.1X49-D80.

`general-ikeid` option under `[edit security ike gateway` *`gateway-name`* `dynamic]` hierarchy is introduced in Junos OS Release 21.1R1.

Option `node-local` is introduced in Junos OS Release 23.2R1.

Support for multiple peer addresses in the `address` option for IPsec VPN running iked process is introduced in Junos OS Release 23.4R1.

gateway-name (LNS Local Gateway)

IN THIS SECTION

- Syntax | **8021**
- Hierarchy Level | **8021**
- Description | **8021**
- Options | **8022**
- Required Privilege Level | **8022**
- Release Information | **8022**

Syntax

```
gateway-name gateway-name;
```

Hierarchy Level

```
[edit services l2tp tunnel-group group-name local-gateway]
```

Description

Specify the gateway name for the LNS, which the LNS returns to the LAC in response to the LAC's SCCRQ message. This name must match the remote gateway name configured on the LAC, or the tunnel cannot be established.

Options

gateway-name—Name of the LNS.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

- Description | 8025
- Options | 8025
- Required Privilege Level | 8026
- Release Information | 8026

Syntax

```
gbp-pure-l2-profile;
```

Hierarchy Level

```
[edit chassis forwarding-options]
```

Description

Configure your device to run Group-Based Policy (GBP) in a pure layer 2 environment. A pure layer 2 device does not run EVPN-VXLAN or contain VTEPs.

This setting tells the switch to allocate a share of its resources for L2 group-based policies, whereas otherwise the resources would remain committed for use by all other flows. Note that for switches in a virtual chassis, each switch must be rebooted for this setting to apply; for stand-alone switches, the packet forwarding engine (PFE) will be restarted.

Options

None

Required Privilege Level

general-ikeid

IN THIS SECTION

- Syntax | 8026
- Hierarchy Level | 8026
- Description | 8027
- Required Privilege Level | 8027
- Release Information | 8027

Syntax

```
general-ikeid;
```

Hierarchy Level

```
[edit security ike gateway gateway_name dynamic]
```

Description

During IKE Phase 1 negotiation, when negotiation request is received, there are two identity checks.

1. IKE-ID validation from ID payload.
2. Phase 1 authentication by pre-shared key or RSA/DSA certificate.

Configure `remote-identity` to lookup the certificate of the peer for certificate authentication. This `remote-identity` should match the corresponding field in the `SubjectAltname` extension of the peer certificate for successful detection of peer certificate and authentication.

The identity check with the same IKE-ID is repeated, that is, the IKE-ID validation with remote-identity and the certificate authentication. To avoid this, during authentication of remote peer, use the `general-ikeid` under the`set security ike gateway` *`gateway_name`* `dynamic` hierarchy level to bypass the validation process.

If you enable this option, then during authentication of remote peer, the device accepts all ike-id types like, hostname, user@hostname, and so on.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

    timestamp;
    user-name;
    vlan-id;
}
```

Hierarchy Level

```
[edit accounting-options flat-file-profile profile-name fields]
```

Description

Specify general, nonstatistical interface parameters that are displayed as part of the header for the accounting file.

Options

all-fields Display all available nonstatistical fields. Many fields are available for both logical interfaces and physical interfaces, but some fields are available for only one interface type.

accounting-type (Logical interfaces only) Display the accounting status type.

descr Display the description of the interface as configured.

line-id (Logical interfaces only) Display the access line identifier.

logical-interface (Logical interfaces only) Display the name of the logical interface.

nas-port-id (Logical interfaces only) Display the NAS port ID.

physical-interface (Physical interfaces only) Display the name of the physical interface.

routing-instance Display the name of the routing instance to which the interface belongs.

timestamp Display the timestamp of the accounting record.

user-name Display the name of the subscriber.

vlan-id (Logical interfaces only) Display the VLAN identifier.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1R4.

`user-name` option added in Junos OS Release 17.1.

[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options rib routing-table-name],
```

```
[edit routing-options],
[edit routing-options rib routing-table-name]
```

Description

Configure generated routes, which are used as routes of last resort.

Options

defaults—(Optional) Specify global generated route options. These options only set default attributes inherited by all newly created generated routes. These are treated as global defaults and apply to all the generated routes you configure in the `generate` statement.

generate-options—Additional information about generated routes, which is included with the route when it is installed in the routing table. Specify zero or more of the following options in ***generate-options***. Each option is explained separately.

- **(active | passive);**
- **as-path <*as-path*> <origin (egp | igp | incomplete)> <atomic-aggregate> <aggregator *as-number in-address*>;**
- **(brief | full);**
- **community [*community-ids*];**
- **discard;**
- **(metric | metric2 | metric3 | metric4) *value* <type *type*>;**
- **(preference | preference2 | color | color2) *preference* <type *type*>;**
- **tag *metric* type *number*;**

route *destination-prefix*—Configure a non-default generated route:

- **default**—For the default route to the destination. This is equivalent to specifying an IP address of **0.0.0.0/0**.
- ***destination-prefix/ prefix-length***—/ ***destination-prefix*** is the network portion of the IP address, and ***prefix-length*** is the destination prefix length.

The `policy` statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

generate-event

IN THIS SECTION

- Syntax | 8032
- Hierarchy Level | 8032
- Description | 8033
- Options | 8033
- Required Privilege Level | 8034
- Release Information | 8034

Syntax

```
generate-event {
    event-name (time-interval seconds <start-time start-time> | time-of-day time) <no-drift>;
}
```

Hierarchy Level

```
[edit event-options]
```

Description

Generate an internal event based on a time interval or the time of day. You can configure up to 10 internal events.

Configure `time-interval` to specify the frequency at which to generate an event, or configure `time-of-day` to specify the time at which to generate a daily event.

Options

event-name Name of an internally generated event.

no-drift Do not propagate the delay caused in triggering an event to the triggering of the next event.

start-time *start-time* (Optional) Date and time at which to start generating an interval-based event, which is an event configured using the `time-interval` option.

The start time is relative to the local device time and is configured using 24-hour time format *yyyy-mm-dd.hh:mm*. You can optionally include a UTC offset to specify a time relative to UTC (Coordinated Universal Time) by appending `(+|-)`*hhmm* to the time, where the sign is plus (+) for east of UTC and minus (-) for west of UTC, for example, 2020-09-14.11:00-0800. Even if you specify a UTC offset, the `start-time` configuration always displays the time and UTC offset for the device's local time zone.

- **Syntax:** *yyyy-mm-dd.hh:mm*`(+|-)`*hhmm*

time-interval *seconds* Frequency in seconds at which to generate an interval-based internal event.

You can optionally configure the `start-time` option to specify the date and time at which to start generating the events. If you do not specify a start time, Junos OS generates the first event at approximately one time interval after you commit the configuration.

- **Range:** 60 through 2,592,000 seconds

time-of-day *time* Time of day at which to generate a daily internal event.

The time is relative to the local device time and is configured using 24-hour time format *hh:mm:ss*. You can optionally include a UTC offset to specify a time relative to UTC by appending `(+|-)`*hhmm* to the time, where the sign is plus (+) for east of UTC and minus (-) for west of UTC, for example, 11:00:00-0800. Even if you specify a UTC offset, the `time-of-day` configuration always displays the time and UTC offset for the device's local time zone.

- **Syntax:** *hh:mm:ss*`(+|-)`*hhmm*

Required Privilege Level

maintenance—To view or add this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 7.5.

`no-drift` option added in Junos OS Release 14.1R1.

`start-time` option added in Junos OS Release 20.4R1.

Hierarchy Level

```
[edit interfaces interface-name]
```

Description

Configure Gigabit Ethernet specific interface properties.

In Junos OS Evolved, when you configure `set interfaces interface gigether-options 802.3ad ae name` at the same time as you apply a second configuration to the same interface at the `[edit interfaces interface]` hierarchy, the second configuration will not take effect until the interface joins the aggregated Ethernet interface *ae name*.

Table 58 on page 8048 shows the supported and unsupported platforms.

Table 58: Supported Platform Information

Supported Platforms for gigether-options	Supported Platforms for ether-options	Notes
ACX Series Routers (Junos OS) • ACX500 • ACX710 • ACX1000 • ACX1100 • ACX2100 • ACX2200 • ACX4000 • ACX5448 • ACX5048 • ACX5096	ACX Series Routers (Junos OS) • ACX5048 • ACX5096	To configure storm control on the ACX Series routers, use `ether-options`.

Table 58: Supported Platform Information *(Continued)*

Supported Platforms for gigether-options	Supported Platforms for ether-options	Notes
EX Series Switches (Junos OS) • EX4300 Multigigabit • EX4400 • EX4600 • EX4650 • EX9200 • EX9250	EX Series Switches (Junos OS) • EX2300 • EX2300 Multigigabit • EX2300-C • EX3400 • EX4300 • EX4300 Multigigabit • EX4400 • EX4600 • EX4650 • EX9200 • EX9250	EX Series Switches (Junos OS) EX Series switches support both `ether-options` and `gigether-options`. To configure Ethernet configuration options such as aggregated Ethernet, loopback, flow-control, auto-negotiation etc., use `ether-options`. To configure Forward Error Correction (FEC), use `gigether-options`.

Table 58: Supported Platform Information *(Continued)*

Supported Platforms for gigether-options	Supported Platforms for ether-options	Notes
MX Series Routers (Junos OS) • MX5 • MX10 • MX40 • MX80 • MX104 • MX150 • MX204 • MX240 • MX480 • MX960 • MX20008 • MX2010 • MX2020 • MX10003 • MX10008 and MX10016	Not Supported	None

Table 58: Supported Platform Information *(Continued)*

Supported Platforms for gigether-options	Supported Platforms for ether-options	Notes
PTX Series Routers (Junos OS) • PTX1000 • PTX3000 • PTX5000 • PTX10002 • PTX10008 and PTX10016	PTX Series Routers (Junos OS) • PTX1000 • PTX10002 • PTX10008 and PTX10016	PTX Series Routers (Junos OS) In Junos OS Release 17.3R3S7, PTX1000 Series routers support both `ether-options` and `gigether-options`. In Junos OS Releases 17.3R1, 17.4R1, and 17.4R2, PTX10000 Series routers support both `ether-options` and `gigether-options`. In Junos OS Release 18.1R1 and later, PTX Series routers support only `gigether-options` for your configuration and do not support `ether-options`. Before Junos OS Release 18.1R1, PTX Series support `ether-options`. See TSB17864 for additional information. **NOTE**: In Junos OS Release 19.4R2, PTX10002-60C supports `ether-options`.
PTX Series routers (Junos OS Evolved) • PTX10003	PTX Series routers (Junos OS Evolved) • PTX10001-36MR • PTX10003 • PTX10004 • PTX10008 • PTX10016	PTX Series routers (Junos OS Evolved) Starting in Junos OS Evolved Release 20.1R1, PTX Series routers support `ether-options` only. Before Junos OS Evolved Release 20.1R1, PTX Series routers supported `gigether-options` only.

Table 58: Supported Platform Information *(Continued)*

Supported Platforms for gigether-options	Supported Platforms for ether-options	Notes
QFX Series Switches (Junos OS) • QFX5100 (48S) • QFX5100 (48T) • QFX5100 (24Q) • QFX5100 (96S) • QFX5110 (48S) • QFX5110 (32Q) • QFX5120 (48Y) • QFX5120 (48T) • QFX5120 (48ym) • QFX5120 (32C) • QFX5200 (48Y) • QFX5200 (32C) • QFX5210 (64C) • QFX5210 (64C-S) • QFX5220 (32CD) • QFX5220 (128C) • QFX10002 • QFX10008 and QFX10016	QFX Series Switches (Junos OS) • QFX5100 (48S) • QFX5100 (48T) • QFX5100 (24Q) • QFX5100 (96S) • QFX5110 (48S) • QFX5110 (32Q) • QFX5120 (48Y) • QFX5120 (32C) • QFX5200 (48Y) • QFX5120 (48T) • QFX5120 (48ym) • QFX5200 (32C) • QFX5210 (64C) • QFX5210 (64C-S) • QFX5220 (32CD) • QFX5220 (128C) • QFX10002 • QFX10008 and QFX10016	QFX Series Switches (Junos OS) QFX Series switches support both `ether-options` and `gigether-options`. To configure Ethernet configuration options such as loopback, flow-control, auto-negotiation etc., use `ether-options`. To configure Forward Error Correction (FEC), use `gigether-options`.

Table 58: Supported Platform Information *(Continued)*

Supported Platforms for gigether-options	Supported Platforms for ether-options	Notes
Not Supported	QFX Series Switches (Junos OS Evolved) • QFX5200-32C-L • QFX5220-32CD • QFX5220-128C	To configure auto-negotiation on management interfaces (`re0:mgmt-0`), use `ether-options`.
SRX Series (Junos OS) • SRX300 • SRX550 • SRX1500 • SRX4100 and SRX4200 • SRX4600 • SRX5400 • SRX5600	SRX Series (Junos OS) • SRX300 • SRX550 • SRX1500 • SRX4100 and SRX4200 • SRX4600 • SRX5400 • SRX5600	SRX Series (Junos OS) To configure gigabit-Ethernet interfaces (ge-), use `gigether-options`. To configure ethernet interfaces (et-) and fast ethernet interfaces (fe-), use `ether-options`.

Syntax

```
global {
    service-context-id service-context ;
}
```

Hierarchy Level

```
[edit access ocs]
```

Description

Configure global attributes and data elements of the 3rd Generation Partnership Project (3GPP) Diameter credit control service charging system for the Online Charging System (OCS), which interacts with the Policy and Charging Enforcement Function (PCEF). The PCEF optionally reports usage and receives additional authorizations from the OCS using the 3GPP Gy protocol. Broadband PCEF (BPCEF) interactions with the OCS use online session charging with centralized unit determination and centralized rating.

Global Policy Overview

global-advertisements-threshold

IN THIS SECTION

- Syntax | 8065
- Hierarchy Level | 8065
- Description | 8065
- Options | 8066
- Required Privilege Level | 8066
- Release Information | 8066

Syntax

```
global-advertisements-threshold advertisement-value;
```

Hierarchy Level

```
[edit protocols vrrp]
```

Description

Configure the number of fast advertisements that can be missed by a backup router before the primary router is declared as down.

NOTE:

- The advertisement value configured using the `global-advertisements-threshold` statement is applicable to all the Virtual Router Redundancy Protocol (VRRP) groups in the system.
- Setting the advertisement value of the **global-advertisements-threshold** configuration to **1** is not recommended for a scaled configuration with an aggressive advertisement interval. For example, if you have 1000 VRRP groups with an advertisement interval of 100 ms, then do not set the **global-advertisements-threshold** value to 1.
- Changing the advertisement value of the **global-advertisements-threshold** configuration during runtime can result in unpredictable behavior by the VRRP state machine. For example, momentary ownership change from the primary router to the backup router and vice versa. Therefore, avoid changing the advertisement value of the `global-advertisements-threshold` statement during runtime.

Options

advertisement-value—Number of VRRP advertisements missed before the primary router is declared as down.

- **Range:** 1 through 15
- **Default:** 3

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

global-arp-prefix-limit (Host Fast Reroute)

IN THIS SECTION

- Syntax | 8067
- Hierarchy Level | 8067
- Description | 8067
- Default | 8068
- Options | 8068
- Required Privilege Level | 8068
- Release Information | 8069

Syntax

```
global-arp-prefix-limit number;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options host-fast-reroute],
[edit routing-options host-fast-reroute]
```

Description

Set the ARP prefix limit for all host fast-reroute (HFRR) profiles on the routing device.

When you configure HFRR, an optional ARP prefix limit sets a maximum for the number of ARP routes and, therefore FRR routes created for each HFRR profile in the routing table. This limit prevents ARP attacks from exhausting the virtual memory on the routing devices.

There are two configuration statements (`global-arp-prefix-limit` and `arp-prefix-limit`) that set the ARP prefix limit, one at the global `[edit routing-options host-fast-reroute]` hierarchy level and the other at the `[edit routing-instances instance-name routing-options interface interface-name]` hierarchy level, respectively. The global `global-arp-prefix-limit` statement sets a default ARP prefix limit for all HFRR profiles

configured on the routing device. The `arp-prefix-limit` statement overrides the `global-arp-prefix-limit` for that HFRR profile for that protected interface.

Warning system log messages begin when the ARP routes in an HFRR profile reaches 80% of the configured limit. When the number crosses the 100% threshold, the HFRR profile is deactivated. When this happens, all ARP/FRR routes are deleted from the routing table. FRR routes are deleted from forwarding table as well.

After the HFRR profile is deactivated, a blackout timer is started. The timeout value of this timer is the ARP cache timeout (kernel timeout) + the supplementary blackout timer.

There are global and per-HFRR CLI statements (`global-supplementary-blackout-timer` and `supplementary-blackout-timer`) to configure the supplementary blackout timer. The global value is at the `[edit routing-options host-fast-reroute]` hierarchy level and applies to all HFRR profiles on the routing device. The value for the routing-instance interface is at the `[edit routing-instances` *`instance-name`* `routing-options interface` *`interface-name`*`]` hierarchy level, and overrides the global value for that HFRR profile only.

When the blackout timer expires, the HFRR profile is reactivated, and the Junos OS relearns the ARP routes and re-creates the HFRR routes. If the ARP prefix limit is not exceeded again, the HFRR routes will be up.

If an HFRR profile is in the deactivated state, a reevaluation of the ARP state is preformed during every commit operation or whenever the routing process (rpd) is restarted with the `restart routing` command.

Default

If you omit the-`arp-prefix-limit` statement, the `global-arp-prefix-limit` takes effect for all HFRR profiles on the device. If you omit both of these statements, there is no ARP prefix limit for host fast reroute.

Options

number Maximum number of ARP HFRR routes allowed.

- **Range:** 1 through 10,000 HFRR routes

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

global-config (Services)

IN THIS SECTION

- Syntax | 8069
- Hierarchy Level | 8070
- Description | 8070
- Options | 8070
- Required Privilege Level | 8071
- Release Information | 8071

Syntax

```
global-config {
cache-usage-enforcement-threshold cache-usage-enforcement-threshold;
certificate-cache-timeout seconds;
disable-cert-cache;
disable-deferred-profile-selection;
invalidate-cache-on-crl-update;
non-ssl-detection-threshold {
    byte-threshold byte-threshold;
    packet-threshold packet-threshold;
}
```

```
    session-cache-timeout seconds;
    }
```

Hierarchy Level

```
[edit services ssl proxy]
```

Description

Specify the global proxy configuration. When SSL proxy is configured at a global level (within “services ssl proxy”), it is visible across the system configurations on the device.

Options

cache-usage-enforcement-threshold *cache-usage-enforcement-threshold*

Percentage of total cache size after which per logical system limits will be enforced.

- **Range:** 1 through 100

certificate-cache-timeout *seconds*

Regulates the certificate cache timeout.

- **Default:** 600 seconds

disable-cert-cache

Disable the certificate cache. By default certificate cache is enabled.

disable-deferred-profile-selection

Disable the deferred profile selection mechanism. In the defered profile selection mechanism, the SSL proxy module defers SSL profile selection until the dynamic application is detected in a client hello message based on the Server Name Indication (SNI). After detecting dynamic application, SSL proxy module does a firewall rule lookup based on the identified application and selects an appropriate SSL proxy profile.

invalidate-cache-on-crl-update

Invalidate the existing certificate cache. By default, this option is disabled.

non-ssl-detection-threshold

Set limit that allows you to decide how long to wait before ignoring the the session if StartTLS is not received from the client.

- byte-threshold *byte-threshold*—Minimum bytes required to ignore the session. SSL proxy allows the configured number of bytes of plain (unencrypted) SMTP.

After reaching the limit, it ignores the session if StartTLS is not received from the client.

- **Default:** 200
- **Range:** 1 through 600

- packet-threshold *packet-threshold*—Number of plain (unencrypted) packets in client-to-server direction. SSL proxy allows the configured number of packets of plain (unencrypted) SMTP. After reaching the limit, it ignores the session if StartTLS is not received from the client.
  - **Default:** 5
  - **Range:** 1 through 15

> **NOTE**: Starting in Junos OS Release 23.4R1, we've renamed the `mail-threshold` statement to `non-ssl-detection-threshold`.

> **NOTE**: In case your firewall is processing FTP or SMTP traffic and has unified policy (dynamic-application) and ssl-proxy configured, we recommend the following configuration:
>
> ```
> [edit]
> user@host# set services ssl proxy global-config non-ssl-detection-threshold
> ```

session-cache-timeout *seconds*

Specify the session cache timeout.

- **Range:** 300 to 3600 seconds

Required Privilege Level

services—To view this statement in the configuration.

services-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1X44-D10. `disable-cert-cache`, `certificate-cache-timeout`, and `Invalidate-cache-on-crl-update` options are introduced in Junos OS Release 18.1R1.

[edit logical-systems name tenants name routing-instances name protocols bgp],
[edit protocols bgp],
[edit routing-instances name protocols bgp],
```

```
[edit tenants name routing-instances name protocols bgp]
```

Description

Enable global load balancing (GLB). Global load balancing is hashing a route with multiple ECMP links onto several links for load balancing. BGP sends next-next-hop node (NNHN) capability for the route it advertises and monitors the link qualities of all local links with EBGP sessions and floods them to all direct neighbors. On receiving link qualities from neighboring nodes, BGP uses the combined link quality of the next-hops and next-next-hops to make load balancing decisions.

> **NOTE**: You can optionally configure `no-global-load-balancing` on some of the BGP groups or peers to disable GLB on a subset of BGP neighbors. If GLB is disabled on a peer, BGP will neither monitor the link quality, nor send link quality messages over that link. Also, BGP will not send or receive next-next-hop over that peer.

GLB is disabled by default. When you do not configure the options, the node works as both load-balancer and helper.

Options

helper-only (Optional) The node works as a helper and monitors the link quality.

load-balancer-only (Optional) The node works as a load balancer. GLB only receives link qualities from neighboring nodes and uses the combined link quality of next-hops and next-next-hops to make load balancing decisions.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.

    threshold-count count;
    threshold-time seconds;
      /;
}
```

Hierarchy Level

```
[edit protocols l2-learning]
```

Description

Set parameters for media access control (MAC) address move reporting.

Default

By default, MAC moves notify every second, with a threshold time of 1 second and a threshold count of 50.

Options

cooloff-time—Cooloff-time is the time interval during which no additional interface is disabled by the PE (Provider Edge) router after a MAC move is detected.

disable-action—(MX Series routers only) Disable the MAC move action feature globally. MAC move detection configuration does exist, but the action is disabled.

exclusive-mac—List of MACs configured as exclusive MACs are not tracked and counted for mac move related features. Also, these MACs do not get pinned when mac-pinning feature is configured. It excludes MAC addresses from the MAC move limit algorithm.

interface-recovery-time—Interface-recovery-time is the time interval, in seconds, after which a disabled interface is automatically re-enabled following a VPLS MAC move detection.

log—When a MAC has moved rapid enough to cross the threshold count number within the threshold duration configured, a SYSLOG/ERRMSG is generated if log is configured.

notification-time—(MX Series routers only) Configure the notification time value for MAC move reports that a MAC address moves before counting against the threshold values.

reopen-time—(MX Series routers only) Configure the value for the reopen timer.

statistical-approach-wait-time—It is the time interval, in seconds, during which MAC moves are monitored to collect statistics.

threshold-count—(MX Series routers only) Configure the threshold count value for MAC move reports.

threshold-time—(MX Series routers only) Configure the threshold time value for MAC move reports when the MAC address moves at least a specified number of times (threshold count) in the configured interval.

Required Privilege Level

view-level—To view this statement in the configuration.

control-level—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.4.

Support for logical systems added in Junos OS Release 9.6.

Support for disable-action and reopen-time added in Junos OS Release 13.2.

Support for exclusive-mac added in Junos OS Release 14.1X53-D45.

Statements `cooloff-time`, `interface-recovery-time`, `statistical-approach-wait-time`, and `virtual-mac` moved from vpls-mac-move to global-mac-move hierarchy level in Junos OS Release 17.4.

global-parameters (Easy EVPN LAG Configuration)

IN THIS SECTION

- Syntax | 8095
- Hierarchy Level | 8096
- Description | 8096
- Options | 8096
- Required Privilege Level | 8098
- Release Information | 8098

Syntax

```
global-parameters {
  anycast-mac anycast-mac;
  default-vlan-id vlan-id;
  mtu {
    overlay overlay-mtu;
    underlay underlay-mtu;
  }
  no-irb-address-auto-derive;
  start-aggregate-ethernet-index num;
```

```
  virtual-gateway {
    v4-mac v4-mac;
    v6-mac v6-mac;
  }
  virtual-gateway-mac virtual-gateway-mac;
}
```

Hierarchy Level

```
[edit services evpn]
```

Description

Specify global parameters as part of a generated Ethernet VPN (EVPN) fabric configuration.

You use the statements in the `[edit services evpn]` hierarchy level to simplify configuring an EVPN fabric with Ethernet segment identifier (ESI) link aggregation groups (LAGs) in the topology. The feature you enable with statements in this hierarchy is an easy EVPN LAG configuration feature, also called EZ-LAG.

You only need to configure a few statements to provide the parameters required for an EVPN core fabric with multihomed or single-homed customer edge (CE) devices (or end server devices). When you commit the `[edit services evpn]` configuration statements, the device uses a commit script to generate the corresponding standard EVPN fabric configuration statements.

The statements at the `global-parameters` hierarchy level provide parameters for configuration elements that you want to be common across peer provider edge (PE) devices in the EVPN fabric.

Options

anycast-mac ***anycast-mac-address***

Configure the device to globally use the specified anycast virtual gateway MAC address.

You must configure this statement if you include the `[edit services evpn evpn-vxlan irb name] use-anycast-address` option for any integrated routing and bridging (IRB) instances you configure on the PE device.

default-vlan-id ***vlan-id***

Specify the VLAN ID you want the commit script to use in the configuration as the default VLAN.

- **Range:** 1 through 4094

mtu (overlay *overlay-mtu* | underlay *underlay-mtu*)

Set the specified maximum transmission unit (MTU) in bytes in the generated configuration for the interfaces used in the overlay peering or underlay peering. The MTU size is the largest amount of data the device can forward without fragmentation. You can specify MTU values for either or both the overlay and underlay interfaces.

- **Range:** The default MTU and configurable range vary by platform and type of interface or protocol for which you configure the value.

  See *Media MTU and Protocol MTU* for more on setting MTU sizes.

no-irb-address-auto-derive

Instruct the commit script to not derive IRB interface subnet addresses in the generated configuration.

For simplicity, with this feature you can set the same IRB interface subnet address on connected PE devices using the `subnet-address` option at the `[edit services evpn evpn-vxlan irb irb-instance]` hierarchy level. By default, the commit script derives different device IRB subnet addresses using the `subnet-address` value configured for the peer PE device with peer ID 1, based on the device peer ID where the script is running.

When you set this option, instead of the default behavior, the commit script uses exactly the IPv4 or IPv6 subnet addresses you specify with the `subnet-address` option for each peer ID. If you set the `no-irb-address-auto-derive` option, make sure you explicitly set the IRB `subnet-address` values you want for each IRB instance on each device.

> **NOTE**: This option takes effect globally for all IRB instances you configure with the `irb irb-instance` statement at the `[edit services evpn evpn-vxlan]` hierarchy level.
>
> You can alternatively set the `no-irb-address-auto-derive` option for individual IRB instances at the `[edit services evpn evpn-vxlan irb irb-instance subnet-address]` hierarchy level.

start-aggregate-ethernet-index *num*

Set a global starting index for numbering the aggregate Ethernet interfaces in multihomed server (ESI LAG) aggregated Ethernet interface configurations.

- **Range:** 1 through 255

virtual-gateway (v4-mac *mac-address* | v6-mac *mac-address*)

Configure the device to globally use the specified virtual gateway MAC address. With this option, you can specify different MAC addresses for IPv4 and IPv6 traffic.

> **NOTE**: Specify either this option *OR* the `virtual-gateway-mac` option (next).

If you don't specify these parameters, the commit script uses:

- ipv4-mac—00:00:5e:00:01:01
- ipv6-mac—00:00:5e:00:02:01

virtual-gateway-mac *mac-address*

Configure the device to globally use the specified virtual gateway MAC address. If you specify this option, the commit script uses the same MAC address for both IPv4 and IPv6 traffic.

> **NOTE**: Specify either this option *OR* the `virtual-gateway (v4-mac mac-address | v6-mac mac-address)` options above.

You can also consult CLI Explorer.

global-supplementary-blackout-timer (Host Fast Reroute)

IN THIS SECTION

- Syntax | 8099
- Hierarchy Level | 8099
- Description | 8099
- Default | 8100
- Options | 8100
- Required Privilege Level | 8100
- Release Information | 8101

Syntax

```
global-supplementary-blackout-timer minutes;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options host-fast-reroute],
[edit routing-options host-fast-reroute]
```

Description

Set the blackout timer for all host fast-reroute (HFRR) profiles on the routing device.

When you configure HFRR, an optional ARP prefix limit sets a maximum for the number of ARP routes and, therefore FRR routes created for each HFRR profile in the routing table. This limit prevents ARP attacks from exhausting the virtual memory on the routing devices.

There are two configuration statements (`global-arp-prefix-limit` and `arp-prefix-limit`) that set the ARP prefix limit, one at the global `[edit routing-options host-fast-reroute]` hierarchy level and the other at the `[edit routing-instances instance-name routing-options interface interface-name]` hierarchy level, respectively. The global `global-arp-prefix-limit` statement sets a default ARP prefix limit for all HFRR profiles

configured on the routing device. The `arp-prefix-limit` statement overrides the `global-arp-prefix-limit` for that HFRR profile for that protected interface.

Warning system log messages begin when the ARP routes in an HFRR profile reaches 80% of the configured limit. When the number crosses the 100% threshold, the HFRR profile is deactivated. When this happens, all ARP/FRR routes are deleted from the routing table. FRR routes are deleted from forwarding table as well.

After the HFRR profile is deactivated, a blackout timer is started. The timeout value of this timer is the ARP cache timeout (kernel timeout) + the supplementary blackout timer.

There are global and per-HFRR CLI statements (`global-supplementary-blackout-timer` and `supplementary-blackout-timer`) to configure the supplementary blackout timer. The global value is at the `[edit routing-options host-fast-reroute]` hierarchy level and applies to all HFRR profiles on the routing device. The value for the routing-instance interface is at the `[edit routing-instances` *`instance-name`* `routing-options interface` *`interface-name`*`]` hierarchy level, and overrides the global value for that HFRR profile only.

When the blackout timer expires, the HFRR profile is reactivated, and the Junos OS relearns the ARP routes and re-creates the HFRR routes. If the ARP prefix limit is not exceeded again, the HFRR routes will be up.

If an HFRR profile is in the deactivated state, a reevaluation of the ARP state is preformed during every commit operation or whenever the routing process (rpd) is restarted with the `restart routing` command.

Default

If you omit the-`supplementary-blackout-timer` statement, the `global-supplementary-blackout-timer` takes effect for all HFRR profiles on the device. If you omit both of these statements, the blackout timeout value is set to the ARP cache timeout value, which by default is 20 minutes and is configurable with the `aging-timer` statement at the `[edit system arp]` hierarchy level.

Options

minutes Number of minutes, in addition to the ARP cache timeout value, before all HFRR profiles on the routing device are reactivated after the ARP prefix limit is exceeded.

- **Range:** 1 through 15 minutes

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

global-threshold

IN THIS SECTION

- Syntax | 8101
- Hierarchy Level | 8101
- Description | 8101
- Options | 8102
- Required Privilege Level | 8102
- Release Information | 8102

Syntax

```
global-threshold number;
```

Hierarchy Level

```
[edit chassis cluster redundancy-group group-number ip-monitoring]
```

Description

Define global threshold for IP monitoring. This is the number that needs to be met or exceeded by all of the cumulative weights of the monitored IP addresses to trigger a failover.

When a monitored address is marked as unreachable, the weight value associated with that address is deducted from the the redundancy group IP address monitoring global threshold. If the accumulated monitored address weight values surpass the global-threshold value, that is, when the global threshold reaches 0, the global weight is deducted from the redundancy group threshold. Every redundancy group has a default threshold of 255. If the threshold reaches 0, a failover is triggered

Options

number—Value at which the IP monitoring weight is applied against the redundancy group failover threshold.

- **Range:** 0 through 255
- **Default:** 255

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

global-wait-to-restore

IN THIS SECTION

- Syntax | 8103
- Hierarchy Level | 8103
- Description | 8103
- Options | 8103

Required Privilege Level | 8104
Release Information | 8104

Syntax

```
global-wait-to-restore minutes;
```

Hierarchy Level

```
[edit chassis synchronization]
```

Description

Use this statement to configure the global time to wait before opening the interface to receive ESMC messages.

When an interface's signal transitions out of the signal fail state, it must be fault-free for the global-wait-to-restore time before it is again considered by the clock selection process.

When the ESMC clock's EEC quality level (QL) mode is enabled, it sends a signal failure to the clock selection process during the global wait-to-restore time. After the global wait-to-restore time ends, a new quality level value is sent to the clock selection process.

To override the global wait-to-restore time on a specific interface, include the "wait-to-restore" on page 32207 statement at the `[edit chassis source interfaces (external-a | external-b | interface interface-name)]` hierarchy level.

Options

minutes Set the time for the port signal to be up before the port is opened to receive and transmit ESMC messages.

- **Range:** 0 through 12 minutes
- **Default:** 5 minutes

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

global-weight

IN THIS SECTION

- Syntax | 8104
- Hierarchy Level | 8105
- Description | 8105
- Options | 8105
- Required Privilege Level | 8105
- Release Information | 8105

Syntax

```
global-weight number;
```

Hierarchy Level

```
[edit chassis cluster redundancy-group group-number ip-monitoring]
```

Description

Define global weight for IP monitoring. This is the weight that is subtracted from the redundancy group weight for all of the hosts being monitored. This number specifies the relative importance of IP address monitored objects in the operation of the redundancy group.

Every monitored IP address is assigned a weight. If the monitored address becomes unreachable, the weight of the object is deducted from the global-threshold of IP monitoring objects in its redundancy group. When the global-threshold reaches 0, the global-weight is deducted from the redundancy group. Every redundancy group has a default threshold of 255. If the threshold reaches 0, a failover is triggered. Failover is triggered even if the redundancy group is in manual failover mode and preemption is not enabled.

Options

number —Combined weight assigned to all monitored IP addresses. A higher weight value indicates a greater importance.

- **Range:** 0 through 255
- **Default:** 255

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

gnf

IN THIS SECTION

- Syntax | 8106
- Hierarchy Level | 8106
- Description | 8106
- Options | 8107
- Required Privilege Level | 8107
- Release Information | 8107

Syntax

```
gnf id {
    control-plane-bandwidth-percent percent;
    description description;
    fpcs fpcs;
    af-name ;
    collapsed-forward
}
```

Hierarchy Level

```
[edit chassis network-slices guest-network-functions]
```

Description

Define a GNF by assigning an ID to it.

Junos node slicing enables a single MX Series router to be partitioned to appear as multiple, independent routers. Each partition has its own Junos control plane, which runs as a virtual machine (VM), and a dedicated set of line cards. Each partition is called a guest network function (GNF).

Options

id GNF ID

- **Range:** `1-10`

The remaining statements are explained separately.

Required Privilege Level

view-level—To view this statement in the configuration.

control-level—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.2.

            no-remote-trace;
        }
    }
}
```

Hierarchy Level

```
[edit security]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Use the gprs function to configure all the General Packet Radio Service (GPRS) features.

Use `[edit security gprs]` hierarchy-level only for Junos OS Release 20.3 or previous releases.

From Junos OS Release 20.4R1 onwards, we've removed the term gprs from all the configuration statements and operational commands for GTP and SCTP. As a part of this change:

- We've deprecated the `[edit security gprs]` hierarchy-level and all the configuration options under this hierarchy-level.
- All the configuration statements previously available under the `[edit security gprs gtp]` hierarchy-level are now available under the `[edit security gtp]` hierarchy-level.
- All the configuration statements previously available under the `[edit security gprs sctp]` hierarchy-level are now available under the `[edit security sctp]` hierarchy-level.
- For default applications like junos-gprs-gtp and junos-gprs-sctp, you need not remove the term gprs.

Options

The remaining statements are explained separately. See CLI Explorer.

[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options],
[edit routing-options],
[edit routing-instances routing-instance-name routing-options]
```

Description

You configure the graceful restart routing option globally to enable the feature, but not to enable graceful restart for all routing protocols in a routing instance. To enable graceful restart globally, include the graceful-restart statement under the `[edit routing options]` hierarchy level. This enables graceful restart globally for all routing protocols. You can, optionally, modify the global settings at the individual protocol level.

NOTE:

- For VPNs, the `graceful-restart` statement allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers.
- For BGP, if you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.
- LDP sessions flap when `graceful-restart` configurations change.

Default

Graceful restart is disabled by default.

Options

The remaining statements are explained separately. See CLI Explorer.

[edit protocols bgp group group-name],
[edit protocols bgp group group-name neighbor address]
```

Description

Configure the graceful restart capability for long-lived BGP sessions to enable BGP routing details to be retained for a longer period. It in important to retain BGP data for a longer period when the BGP control plane fails for some reason for slowly-restarting routers for a longer duration. Graceful restart allows a

routing device undergoing a restart to inform its adjacent neighbors and peers of its condition. Graceful restart is disabled by default.

When nonstop routing (NSR) and long-lived graceful restart (LLGR) are configured together, the router negotiates the LLGR capability in the usual, regular manner, including a long-lived stale time to trigger LLGR receiver mode in its peers. However, full LLGR restarter functionality (delaying the transmission of End of RIB (EoR) markers until EoRs are received from all peers) does not function under NSR. During a full system (both Routing Engines) restart, the routing protocol daemon (rpd) does not wait for EoRs from other peers before sending its own EoR. It transmits the EoR as soon as it has transmitted the current RIB contents. This condition can cause transient outages when the network reconverges. NSR is considered to be adequate to handle all single-Routing Engine restart scenarios. The restarter mode restriction effects only scenarios where both Routing Engines (or both copies of rpd) restart simultaneously. Ordinary restarter mode configuration is not enabled with NSR. Long-lived graceful restart receiver mode is enabled by default, unless ordinary graceful restart receiver mode is disabled.

NOTE: If you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.

Configure graceful restart globally at the `[edit routing-options]` or `[edit routing-instances instance-name routing-options]` hierarchy level to enable the feature. You cannot enable graceful restart for specific protocols unless graceful restart is also enabled globally. You can, optionally, modify the global settings at the individual protocol level.

The remaining statements are explained separately. See CLI Explorer.

family (l2vpn | route-target | inet) (labeled-unicast | flow)],
[edit routing-instances routing-instance-name protocols bgp family (l2vpn | route-target | inet)
(labeled-unicast | flow)],
[edit routing-instances routing-instance-name protocols bgp group group-name family (l2vpn |
route-target | inet) (labeled-unicast | flow)],
[edit routing-instances routing-instance-name protocols bgp group group-name neighbor address
family (l2vpn | route-target | inet) (labeled-unicast | flow)]
```

NOTE: Each routing table is identified by the protocol family or address family indicator (AFI) and a subsequent address family identifier (SAFI). The AFI parameter can be one of the `(l2vpn | inet | route-target)` protocols and the SAFI parameter can be either of the `(flow | labeled-unicast)` protocols for inet family and one of the `(auto-discovery-mspw | auto-discovery-only | signaling)` protcols for L2VPN family..

Configuring LLGR does not require that BGP graceful restart also be configured. The long-lived-graceful-restart section is visible only for families l2vpn, inet labeled-unicast, inet flow and route-target. It is prohibited for inet-mvpn, inet6-mvpn and inet-mdt. It is hidden for other families.

Description

Configure the graceful restart capability for long-lived BGP sessions on the restarting router to enable BGP routing details to be retained for a longer period. It in important to retain BGP data for a longer period when the BGP control plane fails for some reason for slowly-restarting routers for a longer duration. You can define the time period for which the stale routes need to be maintained.

You can also configure the BGP long-lived graceful restarter mode negotiation mechanism for a particular address family instead of configuring this capability for all address families in a system, logical system, or routing instance.

When LLGR restarter is enabled or disabled for a family or the stale- time is changed, the session is reset so that the new capability can be sent to the neighbor.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

graceful-restart (Protocols BGP)

IN THIS SECTION

- Syntax | 8129
- Hierarchy Level | 8129
- Description | 8129
- Required Privilege Level | 8130
- Release Information | 8130

Syntax

```
graceful-restart {
    disable;
    restart-time seconds;
    stale-routes-time seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols bgp],
[edit logical-systems logical-system-name protocols bgp group group-name],
[edit logical-systems logical-system-name protocols bgp group group-name neighbor address],
[edit protocols bgp],
[edit protocols bgp group group-name],
[edit protocols bgp group group-name neighbor address]
```

Description

Configure graceful restart for BGP. Graceful restart allows a routing device undergoing a restart to inform its adjacent neighbors and peers of its condition. Graceful restart is disabled by default. However, helper mode, the ability to assist a neighboring router attempting a graceful restart, is enabled by default.

To configure the duration of the BGP graceful restart period, include the `restart-time` statement at the `[edit protocols bgp graceful-restart]` hierarchy level. To set the length of time the router waits to receive messages from restarting neighbors before declaring them down, include the `stale-routes-time` statement at the `[edit protocols bgp graceful-restart]` hierarchy level.

> **NOTE**: If you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.

Enable graceful restart mode for BGP (and other protocols) by configuring graceful-restart at the routing-options level. Note that you cannot enable graceful restart for specific protocols unless graceful restart is also enabled globally.

For example, this configuration is required to enable graceful restart:

```
routing-options {
    graceful-restart
}
```

If you want to disable graceful restart for some protocols, you can do this at the protocol's graceful-restart command. The following configuration along with the configuration above will keep graceful restart for all protocols but BGP.

```
protocols{
    bgp{
    graceful-restart;  {
    disable;
}
```

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

graceful-restart (Protocols IS-IS)

IN THIS SECTION

- Syntax | 8131
- Hierarchy Level | 8131
- Description | 8132
- Options | 8132
- Required Privilege Level | 8132
- Release Information | 8132

Syntax

```
graceful-restart {
    disable;
    helper-disable;
    restart-duration seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols isis],
[edit protocols isis]
```

Description

Configure graceful restart parameters for IS-IS.

Graceful restart allows a routing device to restart with minimal effects to the network, and is enabled for all routing protocols at the `[edit routing-options]` hierarchy level. When graceful restart is enabled, the restarting routing device is not removed from the network topology during the restart period. The adjacencies are reestablished after restart is complete.

On LAN interfaces where IS-IS is configured on a transit router that serves as the designated router (DR), a graceful restart causes:

- The ingress router of the label-switched path (LSP), which passes through the DR, to break the LSP.
- The ingress router to re-signal the LSP.

Options

`disable`—Disable graceful restart for IS-IS.

`helper-disable`—Disable graceful restart helper capability. Helper mode is enabled by default.

`restart-duration` *`seconds`*—Time period for the restart to last, in seconds.

- **Range:** 30 through 300 seconds
- **Default:** 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
(ospf | ospf3)],
[edit protocols (ospf | ospf3)],
[edit routing-instances routing-instance-name protocols ospf]
```

Description

Configure graceful restart for OSPF.

Graceful restart allows a routing device to restart with minimal effects to the network, and is enabled for all routing protocols at the `[edit routing-options]` hierarchy level.

Options

disable

Disable graceful restart for OSPF.

helper-disable (standard | restart-signaling| both)

Disable helper mode for graceful restart. When helper mode is disabled, a device cannot help a neighboring device that is attempting to restart. Beginning with Junos OS Release 11.4, you can configure restart signaling-based helper mode for OSPFv2 graceful restart configurations. The last committed statement takes precedence over the previously configured statement.

- `standard` disables helper mode for standard graceful restart (based on RFC 3623).
- `restart-signaling` disables helper mode for restart signaling-based graceful restart (based on RFC 4811, RFC 4812, and RFC 4813).

- `both` disables helper mode for both standard and restart signaling-based graceful restart.

Helper mode is enabled by default. For OSPFv2, both standard and restart-signaling based helper modes are enabled by default.

no-strict-lsa-checking Disable strict OSPF link-state advertisement (LSA) checking to prevent the termination of graceful restart by a helping router. LSA checking is enabled by default.

> **NOTE**: The `helper-disable` statement and the `no-strict-lsa-checking` statement cannot be configured at the same time. If you attempt to configure both statements at the same time, the routing device displays a warning message when you enter the `show protocols (ospf | ospf3)` command.

notify-duration *seconds* Estimated time needed to send out purged grace LSAs over all the interfaces. Range is 1 through 3600 seconds, and the default is 30 seconds.

restart-duration *seconds* Estimated time needed to reacquire a full OSPF neighbor from each area. Range is 1 through 3600 seconds, and the default is 180 seconds.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support for the `no-strict-lsa-checking` statement introduced in Junos OS Release 8.5.

Support for the helper mode `standard`, `restart-signaling`, and `both` options introduced in Junos OS Release 11.4.

```
[edit logical-systems logical-system-name routing-options],
[edit protocols rsvp],
[edit routing-options]
```

Description

Configure graceful restart on the router. You must configure the `graceful-restart` statement at the `[edit routing-options]` hierarchy level to enable graceful restart on the router.

Options

`disable`—Disable graceful restart on the router or for RSVP.

`helper-disable`—Disable RSVP graceful restart helper mode (this option is only available at the `[edit protocols rsvp]` hierarchy level).

- **Default:** Helper mode is enabled by default.

`maximum-helper-recovery-time` *seconds*—The maximum length of time the router stores the state of neighboring routers when they undergo a graceful restart. The value applies to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

- **Default:** 180 seconds
- **Range:** 1 through 3600 seconds

`maximum-helper-restart-time` *seconds*—The maximum length of time the router waits between when it discovers that a neighboring router has gone down and when it declares the neighbor down. This value is applied to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

- **Default:** 20 seconds
- **Range:** 1 through 1800 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

[edit logical-systems logical-system-name protocols bgp group group-name neighbor address]
```

Description

Configure graceful shutdown feature for BGP. Graceful shutdown migrates traffic from one BGP next-hop to another without interrupting the traffic flow. This feature can be enabled for both IBGP and EBGP. The router on which the graceful shutdown is performed is known as the sender or initiator. The receiver is the router that has a BGP session with the sender router. A device acting as a sender is by default a receiver. In other words, with the sender feature enabled, the receiver feature cannot be disabled on the same device.

NOTE: The BGP neighbor device must support graceful shutdown feature, without any additional configuration.

NOTE: On completion of the maintenance window, disabling graceful shutdown is recommended.

Graceful Shutdown: Sender-Side Functionality

When you configure graceful-shutdown sender on your router, it becomes the sender or initiator. The behavior of the sender changes depending on whether the BGP session is E-BGP or I-BGP.

E-BGP

1. Apply an implicit outbound route policy on the BGP session that you plan to shut down. This policy tags the paths with the `GRACEFUL_SHUTDOWN` community before advertising them. The local-preference value is not advertised over the E-BGP session.

2. Apply an implicit inbound route policy on the same session. Tag the incoming paths with the `GRACEFUL_SHUTDOWN` community and set the `LOCAL_PREF` to a lower value (default is zero, but you can configure it).

3. If you configure an explicit local preference using the graceful-shutdown receiver local-pref <val> command, the inbound policy will apply the configured value to incoming routes instead of the default zero.

4. Ensure that all routes (locally originated, redistributed from other protocols, or learned from peers) are tagged with the `GRACEFUL_SHUTDOWN` community when sent to a peer where you've enabled the sender functionality.

You can control this sender-side functionality using the `graceful-shutdown` configuration statement.

I-BGP or Confederation

1. Apply an implicit outbound route policy to tag the paths with the `GRACEFUL_SHUTDOWN` community before advertising them over the session.

2. The policy changes the local preference of the advertised routes to zero (default) or a value that you configure in RIB-OUT.

3. You don't need to take any additional action for incoming routes over the same session.

Graceful Shutdown: Receiver-Side Functionality

When your router receives routes with the `GRACEFUL_SHUTDOWN` community, it functions as the receiver. The behavior depends on whether the session is E-BGP or I-BGP.

E-BGP

1. Apply an implicit inbound route policy that matches the `GRACEFUL_SHUTDOWN` community and lowers the local preference of the matching paths to the default or a value you configure.

2. By default, the local preference is set to zero. If you prefer to change this value or disable the receiver functionality, you can do so with this configuration statement.

3. The receiving router will store the routes in the local RIB and re-advertise them to peers without stripping the `GRACEFUL_SHUTDOWN` community.

I-BGP or Confederation

No action is needed for routes received with the `GRACEFUL_SHUTDOWN` community. The local preference is typically adjusted at the network edge (ASBR). Modifying it within the AS may lead to suboptimal routing or forwarding loops.

BGP Session Shutdown Functionality

When you configure the BGP session shutdown functionality, it tears down the BGP session and prevents reformation until you remove the configuration statement. While the configuration statement is active, if a peer attempts to establish a BGP session by sending an Open message, your router will send a BGP Cease Notification.

This feature is particularly useful during maintenance windows when your router is in an unstable state. Preventing BGP session formation during this time reduces network churn.

BGP Shutdown Communication Functionality

Instead of relying on offline methods like email or phone calls to inform your peer about a BGP session teardown, you can use the shutdown communication feature to transmit a message as part of a Cease Notification.

This feature supports BGP Cease Notifications with the reasons Administrative Shutdown or Administrative Reset. You can include a UTF-8 encoded string in the notification, at your discretion, explaining why the session is being reset. This is in accordance with RFC 8203.

Default

The graceful shutdown receiver feature is enabled by default.

The graceful shutdown sender feature is disabled by default.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.1.

graceful-switchover (Chassis)

IN THIS SECTION

- Syntax | 8147
- Hierarchy Level | 8147
- Description | 8147
- Required Privilege Level | 8148
- Release Information | 8148

Syntax

```
graceful-switchover;
```

Hierarchy Level

```
[edit chassis redundancy]
```

Description

For devices with more than one Routing Engine, including those in a Virtual Chassis or a Virtual Chassis Fabric, configure the primary Routing Engine to switch over gracefully to a backup Routing Engine without interruption to packet forwarding.

NOTE: The `graceful-switchover` statement at the `[edit chassis redundancy]` hierarchy level is not supported for Junos OS Evolved. Graceful switchover is enabled on the Junos OS Evolved system by default.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Syntax

```
gratuitous-arp-count number;
```

Hierarchy Level

```
[edit chassis cluster redundancy-group group-number]
```

Description

Specify the number of gratuitous Address Resolution Protocol (ARP) requests to send on an active interface after failover.

You can configure this option to specify the number of gratuitous ARP requests that an interface can send to notify other network devices of its presence after the redundancy group it belongs to has failed over.

By default, the SRX Series Firewall sends four GARPs per reth on a failover. You can modify the number of GARPs sent per-redundancy-group basis.

Options

number—Number of gratuitous ARP requests that a newly elected primary device in a chassis cluster sends out to announce its presence to the other network devices.

- **Range:** 1 through 16
- **Default:** 4

Required Privilege Level

interface—To view this statement in the configuration.

Syntax

```
group group-name {
    (default-context-prefix | context-prefix context-prefiix){
        security-model (any | usm | v1 | v2c) {
            security-level (authentication | none | privacy) {
                notify-view view-name;
                read-view view-name;
                write-view view-name;
            }
        }
    }
}
```

Hierarchy Level

```
[edit snmp v3 vacm access]
```

Description

Assign the security name to a group, and specify the SNMPv3 context applicable to the group. The `default-context-prefix` statement, when included, adds all the contexts configured on the device to the group, whereas the `context-prefix` *`context-prefix`* statement enables you to specify a context and to add that particular context to the group.

(Not applicable to the QFX Series and OCX Series.) When the context prefix is specified as default (for example, `context-prefix default`), the context associated with the master routing instance is added to the group. To specify a routing instance that is part of a logical system, specify it as `logical system/routing instance`. For example, to specify routing instance ri1 in logical system ls1, include `context-prefix ls1/ri1`.

The remaining statements under this hierarchy are explained separately.

Options

`group-name`—SNMPv3 group name created for the SNMPv3 group.

Required Privilege Level

snmp—To view this statement in the configuration.

snmp-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Description

CAUTION: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure a group of interfaces that have a common configuration, such as authentication parameters. A group must contain at least one interface.

Options

group-name	Name of the group.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

`interface-tag` option introduced in Junos OS Release 23.2R1

IN THIS SECTION

Syntax | 8182

- Hierarchy Level | 8182
- Description | 8182
- Required Privilege Level | 8182
- Release Information | 8182

Syntax

```
group group-name {
    interface interface-name;
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name bridge-domains bridge-domain-name forwarding-options
dhcp-relay],
[edit routing-instances routing-instance-name forwarding-options dhcp-relay]
```

Description

Configure Dynamic Host Configuration Protocol (DHCP) snooping on the router. When acting as a snooping agent, the MX Series router typically is located between the client and the DHCP relay agent. It creates filters by “snooping” DHCP messages and binding DHCP-issued IP addresses with the MAC address of the client. These filters help prevent DHCP spoofing.

Configure DHCP snooping by including the appropriate interfaces under the `group` statement.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.4 (MX Series routers only).

- Syntax | 8185
- Hierarchy Level | 8185
- Description | 8185
- Options | 8185
- Required Privilege Level | 8185
- Release Information | 8186

Syntax

For group configuration with a source, use the following syntax:

```
group ip-address {
    source ip-address;
}
```

For group configuration without a source, use the following syntax:

```
group group;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name protocols igmp interface interface-name static]
```

Description

When configuring with a source address, configure the IGMP multicast group address that receives data on an interface and a source address for certain packets. For configuration without a source address, configure only the IGMP multicast group address that receives data on an interface.

Options

ip-address—Group IP address.

group—Name of group.

NOTE: You must specify a unique address for each group.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

[edit routing-options validation]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure the number of concurrent sessions for each group.

Caches are organized in groups. The Junos OS implementation supports up to 63 sessions per group and both IPv4 and IPv6 address families.

If the number of sessions in a group exceeds the `max-sessions` value, the connections are established in order by the`preference` value. A numerically higher preference results in a higher probability for session establishment. The order of session establishment is random among sessions with equal preferences.

Options

group-name Name of the validation group.

max-sessions *number* Configure the number of concurrent sessions for each group. If the number of sessions in a group exceeds the `max-sessions` value, the connections are established in order by the `preference` value. A numerically higher preference results in a higher probability for session

establishment. The order of session establishment is random among sessions with equal preferences.

- **Range:** 1 through 63 sessions
- **Default:** 2 sessions

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

Description

CAUTION: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the

debug information, immediately disable tracing to minimize risk and restore normal system performance.

Define a BGP peer group. BGP peer groups share a common type, peer autonomous system (AS) number, and cluster ID, if present. To configure multiple BGP groups, include multiple `group` statements.

By default, the group's options are identical to the global BGP options. To override the global options, include group-specific options within the `group` statement.

The `group` statement is one of the statements you must include in the configuration to run BGP on the routing device.

Each group must contain at least one peer and can establish up to 2048 peers. Before establishing a BGP session, RPD checks for established peer count for the group. If the peer count is more than 2048 then the BGP session fails.

Options

group-name	Name of the BGP group
link-bandwith auto-sense	Enable this option to automatically detect the bandwidth towards the peer and attach the link-bandwith value to the interface speed over which the BGP route was received. This prevents a policy churn when there is a change in the link-bandwidth of an interface. Make sure that you also include the `auto-sense` statement in the import policy to enable this feature.
send-non-transitive-link-bandwidth	Enable this option to send non-transitive-link-bandwidth-extended-community towards EBGP neighbors only for link-bandwidth communities. All non-transitive link bandwith community values are advertised including originated or received and readvertised link-bw community.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`link-bandwith auto-sense`, and `send-non-transitive-link-bandwidth` options introduced in Junos OS Release 24.2R1.

- Description | 8211
- Options | 8211
- Required Privilege Level | 8211
- Release Information | 8212

Syntax

```
group name {
    interface interface-name <primary>;
        interface interface-name;
    preempt-cutover-timer seconds;
}
```

Hierarchy Level

For platforms with ELS:

```
[edit switch-options redundant-trunk-group]
```

For platforms without ELS:

```
[edit ethernet-switching-options redundant-trunk-group]
```

Description

Create a redundant trunk group.

Options

name—The name of the redundant trunk group.

- For platforms with ELS:

  The group name must be a string “rtg*n*” where *n* is a number from 0 through 15, such as “rtg2” or “rtg10”.

- For platforms without ELS:

  The group name must start with a letter and can consist of letters, numbers, dashes, and underscores.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system–control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

Hierarchy level `[edit switch-options]` introduced in Junos OS Release 13.2X50-D10 (ELS). (See *Using the Enhanced Layer 2 Software CLI* for information about ELS.)

            static-lsp lsp-name;
        }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name provider-
tunnel selective],
[edit routing-instances routing-instance-name provider-tunnel selective]
```

Description

Specify the IP address for the multicast group configured for point-to-multipoint label-switched paths (LSPs) and PIM-SSM GRE selective provider tunnels.

Options

address—Specify the IP address for the multicast group. This address must be a valid multicast group address.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

The `inter-region-segmented` statement added in Junos OS Release 15.1.

        communication-type (unicast);
        encryption-algorithm (aes-128-cbc | aes-192-cbc | aes-256-cbc);
        lifetime-seconds seconds;
        number-of-retransmission number;
        retransmission-period seconds;
        sig-hash-algorithm (sha-256 | sha-384);
    }
}
```

Hierarchy Level

```
[edit security group-vpn server]
```

Description

Configure group VPN on the group server. Group VPNv2 is supported on SRX300, SRX320, SRX340, SRX345, SRX550HM, SRX1500, SRX4100, SRX4200, and SRX4600 devices and vSRX Virtual Firewall instances.

Options

name—Name of the group.

- `anti-replay-time-window` *milliseconds*—Configure antireplay time in milliseconds. Specify a value from 1 to 60,000.

  We recommend that NTP be configured on Group VPNv2 devices to ensure proper antireplay operation.

  Group members that are running on vSRX Virtual Firewall instances on a host machine where the hypervisor is running under a heavy load may experience issues that can be corrected by reconfiguring the `anti-replay-time-window` value. If data that matches the IPsec policy on the group member is not being transferred, check the `show security group-vpn member ipsec statistics` output for D3P errors. Make sure that NTP is operating correctly. If there are errors, adjust the `anti-replay-time-window` value.

- `description` *description*—Description of the group.

- `group-id` *`number`*—Identifier for this group VPN. Specify a value from 1 to 4,294,967,295.
- `ike-gateway` *`gateway-name`*—Define the group member for Phase 1 negotiation. There can be multiple instances of this option configured. When a group member sends its registration request to the server, the server checks to see that the member is configured for the group.
- `ipsec-sa` *`name`*—Configure the group SAs to be downloaded to members. There can be multiple group SAs downloaded to group members.
- `member-threshold` *`number`*—Specify the maximum number of group VPN members that can be accepted in the group. The same `member-threshold` value must be configured on the root-server and all sub-servers in a group server cluster.

  The maximum number you can configure for a group is dependent upon the group server platform. Also, the sum of the `member-threshold` numbers for all groups configured on the group server must not exceed the capacity of the group server platform.
- `server-cluster`—Configure the Group Domain of Interpretation (GDOI) group controller/key server (GCKS) cluster for the specified group. All servers in a group VPN server cluster must be SRX Series Firewalls.
- `server-member-communication`—Enable and configure server to member communication. When these options are configured, group members receive new keys before current keys expire.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2

`member-threshold` option introduced in Junos OS Release 15.1X49-D30 for vSRX Virtual Firewall.

group (Traffic Load Balancer)

IN THIS SECTION

- Syntax | 8225
- Hierarchy Level | 8225
- Description | 8225
- Options | 8226
- Required Privilege Level | 8226
- Release Information | 8226

Syntax

```
group group-name {
    control-interface control-interface-name;
    health-check-interface-subunit health-check-interface-subunit;
    network-monitoring-profile [profile-name1, <profile-name2>];
    real-service-rejoin-options no-auto-rejoin;
    real-services [server-list];
    <routing-instance routing-instance>;
}
```

Hierarchy Level

```
[edit services traffic-load-balance instance instance-name]
```

Description

Configure a group of servers as a pool for next-hop session distribution.

Options

group-name	Use the specified string identifier for a group of servers to which sessions are distributed using the server distribution table in conjunction with the session distribution API.
control-interface *control-interface-name*	Use the specified service offloading interface name for session offloading functionality.
group health-check-interface-subunit *health-check-interface-subunit*	Use the specified subunit of the ms- interface used for health checking.
network-monitoring-profile *profile-name1*	Name of the network monitoring profile used to monitor the health of servers in the group.
network-monitoring-profile *profile-name2*	(Optional) Name of a second network monitoring profile used to monitor the health of servers in the group.
real-services *server-list*	Use the specified list of individual servers to which sessions are distributed using the server distribution table in conjunction with the session distribution API.
real-services-rejoin-options no-auto-rejoin	Disable the default behavior that allows a server to rejoin the group automatically when it comes up.
routing-instance *routing-instance*	(Optional) Use the specified routing instance if the default `inet.0` is not used.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

Support added in Junos OS Release 19.3R2 for Next Gen Services on MX Series routers MX240, MX480 and MX960 with the MX-SPC3 services card.

Support added for `control-interface` option for Connected Security Distributed Services (CSDS) in Junos OS Release 25.4R1.

group-address (Routing Instances Tunnel Group)

IN THIS SECTION

- Syntax | 8230
- Hierarchy Level | 8230
- Description | 8230
- Required Privilege Level | 8230
- Release Information | 8230

Syntax

```
group-address address;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name provider-
tunnel family inet / inet6 pim-ssm],
[edit routing-instances routing-instance-name provider-tunnel family inet / inet6 pim-ssm]
```

Description

Configure the PIM-ASM (Rosen 6) or PIM-SSM (Rosen 7) provider tunnel group address. Each MDT is linked to a group address in the provider space.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.4.

In Junos OS Release 17.3R1, the `pim-ssm` hierarchy was moved from `provider-tunnel` to the `provider-tunnel family inet` and `provider-tunnel family inet6` hierarchies as part of an upgrade to add IPv6 support for default multicast distribution tree (MDT) in Rosen 7, and data MDT for Rosen 6 and Rosen 7.

[edit routing-instances routing-instance-name provider-tunnel pim-ssm family inet],
[edit routing-instances routing-instance-name provider-tunnel pim-ssm family inet6]
```

Description

Specify a group address on which to encapsulate multicast traffic from a virtual private network (VPN) instance.

NOTE: IPv6 provider tunnels are not currently supported for draft-rosen MVPNs. They are supported for MBGP MVPNs.

Options

address—For IPv4, IP address whose high-order bits are 1110, giving an address range from 224.0.0.0 through 239.255.255.255, or simply 224.0.0.0/4. For IPv6, IP address whose high-order bits are FF00 (FF00::/8).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Starting with Junos OS Release 11.4, to provide consistency with draft-rosen 7 and next-generation BGP-based multicast VPNs, configure the provider tunnels for draft-rosen 6 anysource multicast VPNs at the `[edit routing-instances routing-instance-name provider-tunnel]` hierarchy level. The `mdt`, `vpn-tunnel-source`, and `vpn-group-address` statements are deprecated at the `[edit routing-instances routing-instance-name protocols pim]` hierarchy level. Use `group-address` in place of `vpn-group-address`.

group-count (Protocols MLD)

IN THIS SECTION

- Syntax | 8236
- Hierarchy Level | 8236
- Description | 8236
- Options | 8236
- Required Privilege Level | 8237
- Release Information | 8237

Syntax

```
group-count number;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mld interface interface-name static group
multicast-group-address],
[edit protocols mld interface interface-name static group multicast-group-address]
```

Description

Configure the number of static groups to be created.

Options

number—Number of static groups.

- **Default:** 1
- **Range:** 1 through 512

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6.

RELATED DOCUMENTATION

Enabling MLD Static Group Membership

group-increment (Dynamic MLD Interface)

IN THIS SECTION

- Syntax | 8237
- Hierarchy Level | 8238
- Description | 8238
- Options | 8238
- Required Privilege Level | 8238
- Release Information | 8238

Syntax

```
group-increment increment;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name protocols mld interface interface-name static group multicast-group-address source]
```

Description

Configure the number of times the address should be incremented for each static group created on a dynamic interface. The increment is specified in a format similar to an IPv6 address.

Options

increment—Number of times the address should be incremented.

- **Default:** ::1
- **Range:** ::1 through ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff:

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

        primary-dns IP address;
        primary-wins IP address;
        secondary-dns IP address;
        secondary-dns IP address;
    }
}
```

Hierarchy Level

```
[edit access]
```

Description

Configure a group profile to define Point-to-Point Protocol (PPP) and L2TP attributes. Any client referencing the configured group profile inherits all the group profile attributes.

Options

- `ppp`—Configure Point-to-Point Protocol (PPP) attributes.
- `cell-overhead`—Configure the session to use Asynchronous Transfer Mode (ATM)-aware egress shaping.
- `framed-pool` *`pool-name`*—Configure a framed-pool.
- `idle-timeout`—Configure the idle timeout for a user.
- `interface-id`—Configure the interface identifier.
- `keep-alive`—Configure the keepalive interval for an L2TP tunnel.

- `primary-dns`—Specify the primary-dns IP address.
- `secondary-dns`—Specify the secondary-dns IP address.
- `primary-wins`—Specify the primary-wins IP address.
- `secondary-wins`—Specify the secondary-wins IP address.

Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

group-range (Data MDTs)

IN THIS SECTION

Syntax | 8262

- Hierarchy Level | 8262
- Description | 8262
- Options | 8262
- Required Privilege Level | 8262
- Release Information | 8263

Syntax

```
group-range multicast-prefix;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name provider-
tunnel family inet / inet6 mdt],
[edit routing-instances routing-instance-name provider-tunnel family inet / inet6 mdt]
```

Description

Establish the group range to use for data MDTs created in this VRF instance. Only IPv4 address are valid for group range. This address range cannot overlap the default MDT addresses of any other VPNs on the router, nor can the group range specified under the `inet` and `inet6` hierarchies overlap. If you configure overlapping group ranges, the configuration commit fails. Up to 8000 MDT group ranges are supported for IPv4 and IPv6.

Options

multicast-prefix—Multicast address range to identify data MDTs.

- **Range:** Any valid, nonreserved multicast address range
- **Default:** None (No data MDTs are created for this VRF instance.)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4. In Junos OS Release 17.3R1, the `mdt` hierarchy was moved from `provider-tunnel` to the `provider-tunnel family inet` and `provider-tunnel family inet6` hierarchies as part of an upgrade to add IPv6 support for default MDT in Rosen 7, and data MDT for Rosen 6 and Rosen 7. The `provider-tunnel mdt` hierarchy is now hidden for backward compatibility with existing scripts.

group-rp-mapping

IN THIS SECTION

- Syntax | 8267
- Hierarchy Level | 8267
- Description | 8268
- Options | 8268
- Required Privilege Level | 8268
- Release Information | 8268

Syntax

```
group-rp-mapping {
    family (inet | inet6) {
        log-interval seconds;
        maximum limit;
        threshold value;
    }
    log-interval seconds;
    maximum limit;
    threshold value;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim rp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols pim
rp],
[edit protocols pim rp],
[edit routing-instances routing-instance-name protocols pim rp]
```

Description

Configure a limit for the number of incoming group-to-RP mappings.

> **NOTE**: The maximum limit settings that you configure with the `maximum` and the `family (inet | inet6) maximum` statements are mutually exclusive. For example, if you configure a global maximum group-to-RP mapping limit, you cannot configure a limit at the family level for IPv4 or IPv6. If you attempt to configure a limit at both the global level and the family level, the device will not accept the configuration.

Options

`family (inet | inet6)`—(Optional) Specify either IPv4 or IPv6 messages to be counted towards the configured group-to-RP mapping limit.

- **Default:** Both IPv4 and IPv6 messages are counted towards the configured group-to-RP limit.

The remaining statements are described separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

Syntax

```
group-threshold value;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols igmp interface interface-name],
[edit protocols igmp interface interface-name]
```

Description

Specify the threshold at which a warning message is logged for the multicast groups received on a logical interface. The threshold is a percentage of the maximum number of multicast groups allowed on a logical interface.

For example, if you configure a maximum number of 1,000 incoming multicast groups, and you configure a threshold value of 90 percent, warning messages are logged in the system log when the interface receives 900 groups.

To confirm the configured group threshold on the interface, use the `show igmp interface` command.

Default

By default, there is no configured threshold value.

Options

value—Percentage of the maximum number of multicast groups allowed on the interface that starts triggering the warning. You configure a percentage of the **group-limit** value that starts triggering the warnings. You must explicitly configure the **group-limit** to configure a threshold value.

- **Range:** 1 through 100

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

        ipsec {
            proposal proposal-name;
        }
        traceoptions (Security Group VPN);
    }
}
```

Hierarchy Level

```
[edit security]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure Group VPNs in Group VPNv2. Group VPNv2 extends IPsec architecture to support SAs that are shared by a group of security devices. With Group VPNv2, any-to-any connectivity is achieved by preserving the original source and destination IP addresses in the outer header.

Options

member Configure group VPN member.

ike	Configure IPsec group VPN on the group member.
policy	Configure an IKE policy.
proposal	Define an IKE proposal. You can configure one or more IKE proposals. Each proposal is a list of IKE attributes to protect the IKE connection between the IKE host and its peer.
traceoptions	Configure group VPN tracing options to aid in troubleshooting the IKE or server issues.
ipsec	Configure IPsec for Phase 2 exchange on the group member.
vpn	Configure IPsec VPN for Phase 2 exchange on the group member.
server	Configure group VPN server.
group	Configure group VPN on the group server.
anti-replay-time-window	Configure antireplay time in milliseconds. Specify a value from 1 to 60,000. Each IPsec packet contains a timestamp. The group member checks whether the packet's timestamp falls within the configured `anti-replay-time-window` value. A packet is dropped if the timestamp exceeds the value.
description	Description of the group.
group-id *number*	Identifier for this group VPN. Specify a value from 1 to 4,294,967,295.
ike-gateway *gateway-name*	Define the group member for Phase 1 negotiation. There can be multiple instances of this option configured. When a group member sends its registration request to the server, the server checks to see that the member is configured for the group.
ipsec-sa	Configure the group SAs to be downloaded to members. There can be multiple group SAs downloaded to group members.
member-threshold	Specify the maximum number of group VPN members that can be accepted in the group. There is no default number.
server-cluster	Configure the Group Domain of Interpretation (GDOI) group controller/key server (GCKS) cluster for the specified group. All servers in a group VPN server cluster must be SRX Series Firewalls.
server-member-communication	Enable and configure server to member communication. When these options are configured, group members receive new keys before current keys expire.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

Group VPNv2 Overview

grouped-ie-profile

IN THIS SECTION

- Syntax | 8277
- Hierarchy Level | 8278
- Description | 8278
- Options | 8278
- Required Privilege Level | 8278
- Release Information | 8278

Syntax

```
grouped-ie-profile name {
    ie ie-number {
        instance inst-number {
            grouped-ie-profile grpie-prf-name;
        }
```

```
    }
}
```

Hierarchy Level

```
[edit security gtp]
```

Description

Specify a GTP grouped IE filter profile. A grouped IE is a group of IEs or a group of grouped IEs. A grouped-ie-profile is defined and linked to the IE when a Must-IE check is expected to go deep into a grouped IE.

From Junos OS Release 20.4R1 onwards, the `[edit security gprs gtp]` hierarchy level is replaced by `[edit security gtp]`.

Options

name Name of the GTP grouped IE filter profile.

ie-number IE number.

- **Range:** 1 to 255

inst-number instance number.

- **Range:** 0 to 11
- **Default:** 0

grpie-prf-name GTP grouped IE filter profile.

Required Privilege Level

security—To view this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 20.2R1.

        configuration-data;
    }
    lccn-re1 {
        configuration-data;
```

```
    }
}
```

Hierarchy Level

```
[edit]
```

Description

Create a configuration group.

> **NOTE**: Junos OS does not support configuring statements corresponding to third-party YANG data models, for example, OpenConfig or custom data models, under the `[edit groups]` hierarchy.

Options

group-name Name of the configuration group. To configure multiple groups, specify more than one group name.

configuration-data The configuration statements that are to be applied elsewhere in the configuration with the `apply-groups` statement, to have the target configuration inherit the statements in the group.

when Define conditions under which the configuration group should be applied. Conditions include the type of chassis, model, or Routing Engine, virtual chassis member, cluster node, and start and optional end time of day. If you specify multiple conditions in a single configuration group, all conditions must be met before the configuration group is applied.

- `chassis` *chassis-id*—Specify the chassis type of the router. Valid types include SCC0, SCC1, LCC0, LCC1 ... LCC3.
- `member` *member-id*—Specify the name of the member of the virtual chassis.
- `model` *model-id*—Specify the model name of the router, such as m7i or tx100.
- `node` *node-id*—Specify the cluster node.

- `peers` *names-of-peers*—Specify the names of the MC-LAG peers participating in commit synchronization.
- `routing-engine` *routing-engine-id*—Specify the type of Routing Engine, re0 or re1.
- `time` *start-time* `[to` *end-time*`]`—Specify the start time or time duration for this configuration group to be applied. If only the start time is specified, the configuration group is applied at the specified time and remains in effect until the time is changed. If the end time is specified, then on each day, the applied configuration group is started and stopped at the specified times. The syntax for specifying the time uses the format yyyy-mm-dd.hh:mm, hh:mm, or hh.

conditional-data Option introduced in Junos 11.3. The conditional statements that are to be applied when this configuration group is applied. On routers that support multiple Routing Engines, you can also specify two special group names:

- `re0`—Configuration statements that are to be applied to the Routing Engine in slot 0.
- `re1`—Configuration statements that are to be applied to the Routing Engine in slot 1.

On routers that support multiple Routing Engines, you can also specify two special group names:

The configuration specified in group `re0` is applied only if the current Routing Engine is in slot 0; likewise, the configuration specified in group `re1` is applied only if the current Routing Engine is in slot 1. Therefore, both Routing Engines can use the same configuration file, each using only the configuration statements that apply to it. Each `re0` or `re1` group contains at a minimum the configuration for the hostname and the management interface (`fxp0`). If each Routing Engine uses a different management interface, the group also should contain the configuration for the backup router and static routes.

(Routing matrix only) The TX Matrix router supports group names for the Routing Engines in each connected T640 router in the following formats:

> **NOTE**: The management Ethernet interface used for the TX Matrix Plus router, T1600 routers in a routing matrix, and PTX Series Packet Transport Routers, is `em0`. Junos OS automatically creates the router's management Ethernet interface, `em0`.

- `lcc`*n*`-re0`—Configuration statements applied to the Routing Engine in slot 0 of the specified T640 router that is connected to a TX Matrix router.
- `lcc`*n*`-re1`—Configuration statements applied to the specified to the Routing Engine in slot 1 of the specified T640 router that is connected to a TX Matrix router.

  n identifies the T640 router and can be from 0 through 3.

Required Privilege Level

configure—To enter configuration mode.

grpc-replay

IN THIS SECTION

- Syntax | 8284
- Hierarchy Level | 8284
- Description | 8284
- Options | 8285
- Required Privilege Level | 8285
- Release Information | 8285

Syntax

```
grpc-replay <last minute|facility facility|priority priority>
```

Hierarchy Level

```
[edit system syslog]
```

Description

Configure this configuration statement to replay the events.

Options

- `last` *`minute`*–Use this configuration to replay the events. Specify the time in minutes. Once you configure this configuration statement, eventd starts storing the syslog events. Eventd streams up to one million events. Once the replaying of the old data is over, eventd starts streaming the live events. While eventd is replaying the old data as initial sync and any live event takes place, the system immediately streams the live event.

- `facility` *`facility`*–Use this option to filter the events as per facility. You can use this option to filter the live and replay events. This configuration has no relationship with the existing syslog configuration for writing and sending events to file and remote host. Choose facility from the available options under this configuration.

- `priority` *`priority`*–Use this configuration to filter the events as per priority. You can use this configuration to filter the live and replay events. This configuration has no relationship with the existing syslog configuration for writing and sending events to file and remote host. Choose the priority from the available options under this configuration.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 21.2R1.

- Options | 8287

Required Privilege Level | 8288
Release Information | 8288

Syntax

```
grpc-tunnel {
    servers {
        retry-interval interval;
        server server-name {
            address ip-address;
            port port-number;
            credentials {
                tls {
                    certificate-id local-certificate in pki
                    ca-profiles [ specific ca-profiles in pki ];
                }
            }
            targets [ ssh | netconf-ssh | gnmi-gnoi];
            routing-instance routing-instance;
            source-address ip-address;
        }
    }
    target-string-option {
        pattern [ hostname | vendor | model | version | custom ];
        custom-string custom-string;
        delimiter delimiter-string;
    }
}
```

Hierarchy Level

```
[edit system services]
```

Description

Configure gRPC tunnel settings.

Options

retry-interval Optional. Specify the time after which the target retries to connect again if the tunnel-server is not reachable. There is no limit on the number of times the target retries to connect to the server.

- Range: 10-300
- Default: 30 seconds

server Specify the tunnel server name. A maximum of 10 tunnel servers can be configured at a time.

address Specify the IPv4 or IPv6 address or hostname of the tunnel server.

port Specify the port number through which the tunnel server listens.

credentials Configure options for TLS-based authentication.

tls Configure TLS certificate related options.

certificate-id Optional. Specify the local tunnel client certificate-id loaded in the PKI hierarchy.

Mandatory in cases where mutual authentication is required and the client must present the certificate to the server.

ca-profiles Optional. Specify the list of certificate authority (CA)s to validate the certificate of the tunnel server. If not specified, the gRPC tunnel utilizes the loaded CAs through PKI hierarchy to validate the server certificate.

targets Specify the list of target applications that are to be made available. It may contain one or more target types.

- Values: `ssh`, `netconf-ssh`, `gnmi-gnoi`

routing-instance Optional. Specify the name of the routing instance through which the target can reach the tunnel server.

source-address Optional. Specify the IPv4 or IPv6 source address that can connect with the tunnel server.

target-string-option Optional. Configure to modify the target string that gets registered with the tunnel server.

pattern Optional. Specify the list of supported options. You can use this statement to select the string to be created using the options.

- Default: hostname
- Values: `hostname`, `vendor`, `model`, `version`, `custom`

custom-string Specify the string to be used when **pattern** contains **custom** as one of the options.

delimiter Specify a character to act as the delimiter.

- Default: `|` (pipe character)

Required Privilege Level

system— To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS and Junos OS Evolved Release 22.4R1.

`routing-instance` *`routing-instance`* and `source-address` *`ip-address`* options introduced in Junos OS and Junos OS Evolved Release 23.2R1.

gsmp-syn-timeout (ANCP)

IN THIS SECTION

- Syntax | 8290
- Hierarchy Level | 8290
- Description | 8291
- Options | 8291
- Required Privilege Level | 8291
- Release Information | 8291

Syntax

```
gsmp-syn-timeout seconds;
```

Hierarchy Level

```
[edit protocols ancp]
```

Description

Configure the maximum period that the ANCP agent waits before sending a SYN message to an ANCP neighbor to negotiate the adjacency. If the neighbor sends a SYN message during this period, the ANCP agent uses the partition information in the neighbor's message when generating its own initial SYN message to the neighbor. The agent does not wait for the period to expire if it receives a SYN message from the neighbor.

Options

seconds—Number of seconds the ANCP agent waits.

- **Range:** 1 through 60 seconds
- **Default:** 60 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.3.

gsmp-syn-wait (ANCP)

IN THIS SECTION

Syntax | 8292

Hierarchy Level | 8292

- Description | 8292
- Default | 8292
- Required Privilege Level | 8292
- Release Information | 8293

Syntax

```
gsmp-syn-wait;
```

Hierarchy Level

```
[edit protocols ancp]
```

Description

Enable the ANCP agent to learn partition ID information from neighbors, in support of nonzero ANCP partition IDs. This statement forces the ANCP agent to delay sending a SYN message during adjacency negotiation for a configurable period. When the neighbor sends a SYN message to the ANCP agent during that period, the agent learns the partition ID information from the neighbor and uses that information when it sends its own SYN message. If the agent does not receive the message during the period, then it sends a SYN message to the neighbor when the period times out.

Default

This statement is disabled. The ANCP agent does not wait before sending the initial SYN message and does not support nonzero partition IDs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.3

```

Description

CAUTION: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the

debug information, immediately disable tracing to minimize risk and restore normal system performance.

Use the GTP commands to enable the GTP service, configure GTP objects, set traceoptions, remove GTP inspection object configurations, and obtain configuration information.

From Junos OS Release 20.4R1 onwards, the `[edit security gprs]` hierarchy level is replaced by `[edit security gtp]`.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.0. The `restart-path` option added in Junos OS Release 11.4. New GPRS tunneling protocol (GTP) message types added in Junos OS Release 11.4. Support for GTPv2 added in Junos OS Release 11.4. Statement modified in Junos OS Release 15.1X49-D40. Support for `handover-default` and `handover-group` options added in Junos OS Release 17.4R1.

gtp-header-offset

IN THIS SECTION

- Syntax | 8299
- Hierarchy Level (QFX5000 line of switches) | 8299
- Description | 8299
- Required Privilege Level | 8300
- Release Information | 8300

Syntax

```
gtp-header-offset  offset-value
```

Hierarchy Level (QFX5000 line of switches)

```
[edit forwarding-options enhanced-hash-key hash-mode]
```

Description

You must only provide a decimal value for *gtp-header-offset* command. As per standards, 0x32 is the default header offset value. But, due to some special patterns in the header, offset may vary like, 0x30, 0x28, and so on. In this case, you need to convert it to a proper offset value as follows:

For Example:

- If the offset value is 0x32, the equivalent decimal value is calculated as (16*3+2) which is equal to 50.
- If the offset value is 0x30, the equivalent decimal value is calculated as (16*3+0) which is equal to 48.

After setting *gtp-header-offset* to a proper offset value, run *gtp-tunnel-endpoint-identifier* command to enable GTP hashing. Refer "gtp-tunnel-endpoint-identifier" on page 8301 for more details. For example:

- If the IPv6 traffic has *0x32* as offset value, then use `set forwarding-options enhanced-hash-key family inet` *`gtp-tunnel-endpoint-identifier`* command directly.

- If the IPv6 traffic has *0x30* as offset value, then you must set proper offset value after enabling GTP hashing as follows:

  ```
  set forwarding-options enhanced-hash-key family inet gtp-tunnel-endpoint-identifier
  ```

  ```
  set forwarding-options enhanced-hash-key hash-mode gtp-header-offset 48
  ```

- If the IPv4 traffic has *0x32* as offset value, then use `set forwarding-options enhanced-hash-key family inet gtp-tunnel-endpoint-identifier` command directly.

- If the IPv4 traffic has *0x30* as offset value, then you must set proper offset value after enabling GTP hashing as follows:

  ```
  set forwarding-options enhanced-hash-key family inet gtp-tunnel-endpoint-identifier
  ```

  ```
  set forwarding-options enhanced-hash-key hash-mode gtp-header-offset 48
  ```

> **NOTE**: Both IPv4 and IPv6 share same GTP header offset value. If there are two different traffic streams, that is, if IPv4 has value X as offset value and IPv6 has Y as offset value, then hashing will be successful only for one of the traffic stream.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Hierarchy Level (QFX10000 line of switches)

```
[edit forwarding-options enhanced-hash-key family inet],
```

```
[edit forwarding-options enhanced-hash-key family inet6]
```

Description

When you configure `gtp-tunnel-endpoint-identifier`, the hash calculation of IPv4 or IPv6 packets are included in the GPRS tunneling protocol–tunnel endpoint ID (GTP-TEID) field hash calculations.

> **NOTE**: The `gtp-tunnel-endpoint-identifier` configuration statement is supported on PTX Series routers only when network services is set to `enhanced-mode`. For more information, see `enhanced-mode`.

On the QFX5000 and QFX10000 lines of switches, if the `gtp-tunnel-endpoint-identifier` statement is configured, the default Layer 4 port 2152 (and 2123 as well on QFX5000) is set to use along with the default first byte 0x32.

(On the QFX5000 line of switches only) In most cases, configuring the `gtp-tunnel-endpoint-identifier` statement on QFX5000 switches is sufficient for enabling GTP hashing. After you have enabled GTP hashing, if GTP hashing does not work, we recommend that you capture the packets using relevant tools and identify the offset value. As per standards, 0x32 is the default header offset value. But, due to some special patterns in the header, offset may vary to say 0x30, 0x28, and so on. In these cases, use the `gtp-header-offset` statement to set a proper offset value. Once the header offset value is resolved, run the `gtp-tunnel-endpoint-identifier` command for enabling GTP hashing successfully. Refer to "gtp-header-offset" on page 8299 for more details.

guaranteed-rate (Dynamic Traffic Shaping)

IN THIS SECTION

- Syntax | 8303
- Hierarchy Level | 8303
- Description | 8303
- Default | 8304
- Options | 8304
- Required Privilege Level | 8304
- Release Information | 8304

Syntax

```
guaranteed-rate (rate | $junos-cos-guaranteed-rate) <burst-size [ bytes | $junos-cos-guaranteed-
rate-burst]>;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]
```

Description

Configure a guaranteed minimum rate for a logical interface and optionally a burst size for the guaranteed rate.

NOTE: The guaranteed-rate burst size must not exceed the shaping-rate burst size.

Default

If you do not include this statement and you do not include the `delay-buffer-rate` statement, the logical interface receives a minimal delay-buffer rate and minimal bandwidth equal to 2 MTU-sized packets.

Options

rate—Guaranteed rate in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 1000 through 6,400,000,000,000 bps

`$junos-cos-guaranteed-rate`—Junos predefined variable that is replaced with the guaranteed rate obtained from the RADIUS server when a subscriber authenticates over the interface to which the dynamic profile is attached.

`burst-size` *bytes*—(Optional) Maximum burst size, in bytes.

- **Range:** 0 through 1,000,000,000

`$junos-cos-guaranteed-rate-burst`—(Optional) Variable for the burst-size that is specified for the guaranteed rate. Use this variable at the [`edit dynamic-profiles` *profile-name* `class-of-service traffic-control-profile`] hierarchy level.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

The `$junos-cos-guaranteed-rate` variable introduced in Junos OS Release 9.4.

Option `burst-size` introduced in Junos OS Release 11.4.

output-traffic-control-profile (Dynamic CoS Definition) | **12513**

guaranteed-rate (Traffic Control Profiles)

IN THIS SECTION

- Syntax | **8305**
- Hierarchy Level | **8305**
- Description | **8305**
- Default | **8306**
- Options | **8306**
- Required Privilege Level | **8307**
- Release Information | **8307**

Syntax

```
guaranteed-rate (percent percentage | rate) <burst-size bytes>;
```

Hierarchy Level

```
[edit class-of-service traffic-control-profiles profile-name]
```

Description

Configure a guaranteed minimum rate of transmission for a traffic control profile. The sum of the guaranteed rates of all of the forwarding class sets (priority groups) on a port should not exceed the total port bandwidth. The guaranteed rate also determines the amount of excess (extra) port bandwidth that

the priority group (forwarding class set) can share. Extra port bandwidth is allocated among the priority groups on a port in proportion to the guaranteed rate of each priority group.

> **NOTE**: You cannot configure a guaranteed rate for a forwarding class set (priority group) that includes strict-high priority queues. If the traffic control profile is for a forwarding class set that contains strict-high priority queues, do not configure a guaranteed rate.

On supported platforms, you can also configure an optional burst size for a logical interface. This can help to ensure that higher priority services do not starve lower priority services.

Default

If you do not include this statement and you do not include the `delay-buffer-rate` statement, the logical interface receives a minimal delay-buffer rate and minimal bandwidth equal to 2 MTU-sized packets.

If you do not specify a guaranteed rate, the guaranteed rate is zero (0) and there is no minimum guaranteed bandwidth.

> **NOTE**: If you do not configure a guaranteed rate for a traffic control profile, the queues that belong to any forwarding class set (priority group) that uses that traffic control profile cannot have a configured transmit rate. The result is that there is no minimum guaranteed bandwidth for those queues and that those queues can be starved during periods of congestion.

Options

`percent` *`percentage`*

Minimum percentage of transmission capacity allocated to the forwarding class set or logical interface.

- **Range:** 1 through 100 percent

`rate`

Minimum transmission rate allocated to the forwarding class set or logical interface, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 1000 through 6,400,000,000,000 bps

`burst-size` *`bytes`*

(Optional) Maximum burst size, in bytes.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

Option `burst-size` introduced in Junos OS Release 9.4.

Syntax

```
gw-interface interface-name.logical-unit-number;
```

Hierarchy Level

```
[edit services service-set service-set-name ipsec-vpn-options local-gateway address]
```

Description

Enable the cleanup of IKE triggers and IKE and IPsec SAs when an IPsec tunnel's local gateway IP address goes down or the MS-MIC or MS-MPC being used in the tunnel's service set goes down. If the local gateway IP address for an IPsec tunnel's service set goes down or the MS-MIC or MS-MPC that is being used in the service set goes down, the service set no longer sends IKE triggers. In addition, when the local gateway IP address goes down, the IKE and IPsec SAs are cleared for next-hop service sets, and go to the Not Installed state for interface-style service sets. The SAs that have the Not Installed state are deleted when the local gateway IP address comes back up.

If the local gateway IP address that goes down is for the responder peer, then you need to manually clear the IKE and IPsec SAs on the initiator peer so that the IPsec tunnel comes back up once the local gateway IP address comes back up (see "clear services ipsec-vpn ike security-associations" on page 4320 and "clear services ipsec-vpn ipsec security-associations" on page 4322).

Options

interface-name	Name of the interface of the IPsec local gateway.
logical-unit-numer	Number of the logical unit of the IPsec local gateway interface. You must include the logical unit number.

Required Privilege Level

        }
    }
}
```

Hierarchy Level

```
[edit unified-edge diameter-profiles]
```

Description

Configure the Diameter profile used for Gx applications.

Options

profile-name	Name of the Diameter profile.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

- Hierarchy Level | **8324**
- Description | **8324**
- Options | **8325**
- Required Privilege Level | **8325**
- Release Information | **8325**

Syntax

```
h323 {
    application-screen {
        message-flood {
            gatekeeper {
                threshold rate;
            }
        }
        unknown-message {
            permit-nat-applied;
            permit-routed;
        }
    }
    disable;
    dscp-rewrite {
        code-point string;
    }
    endpoint-registration-timeout value-in-seconds;
    media-source-port-any;
    traceoptions {
        flag flag <detail | extensive | terse>;
    }
}
```

Hierarchy Level

```
[edit security alg]
[edit tenants tenant-name security alg]
```

Description

CAUTION: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Specify the H.323 Application Layer Gateway (ALG) on the device. H.323 is a control-signaling protocol used to exchange messages between H.323 endpoints.

Options

`disable`—Disable the H.323 ALG. By default, H.323 ALG is enabled.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

The `tenant` option is introduced in Junos OS Release 18.3R1.

halt-on-prefix-down (RFC 2544 Benchmarking)

IN THIS SECTION

- Syntax | 8326
- Hierarchy Level (Junos OS) | 8326
- Hierarchy Level (Junos OS Evolved) | 8326
- Description | 8326
- Required Privilege Level | 8326
- Release Information | 8326

Syntax

```
halt-on-prefix-down;
```

Hierarchy Level (Junos OS)

```
[edit services rpm rfc2544-benchmarking tests test-name test-name]
```

Hierarchy Level (Junos OS Evolved)

```
[edit services monitoring rfc2544 tests test-name test-name]
```

Description

By default, the RFC 2544-based benchmarking test ignores a prefix-down event (when the prefix associated with the test goes down) and continues to run. If you configure this parameter, a prefix that moves to the down state causes the corresponding tests to be stopped. The `show` command output for the test displays that the test was terminated due to the prefix going down.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3X53.

Statement introduced in Junos OS Evolved Release 23.4R1.

handover-default

IN THIS SECTION

- Syntax | 8327
- Hierarchy Level | 8327
- Description | 8327
- Options | 8328
- Required Privilege Level | 8328
- Release Information | 8328

Syntax

```
handover-default {
    deny;
}
```

Hierarchy Level

```
[edit security gtp]
```

Description

A GPRS tunneling protocol (GTP) handover group is a set of SGSNs or serving gateway (SGW) with a common address-book library. You can configure the handover group using the “handover-group” command. If there is no handover group defined in the GTP profile, and if the traffic reaches the policy configured with this profile, handover between all GTPs matching this policy is permitted by default. Therefore, if you configure handover-default deny command, then handover is denied.

From Junos OS Release 20.4R1 onwards, the `[edit security gprs gtp]` hierarchy level is replaced by `[edit security gtp]`.

Options

deny To deny default handover.

Required Privilege Level

security—To view this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 17.4R1.

handover-group

IN THIS SECTION

- Syntax | 8328
- Hierarchy Level | 8329
- Description | 8329
- Options | 8329
- Required Privilege Level | 8329
- Release Information | 8329

Syntax

```
handover-group group-name;
```

Hierarchy Level

```
[edit security gtp profile profile-name]
```

Description

A GPRS tunneling protocol (GTP) handover group is a set of SGSNs or serving gateway (SGW) with a common address-book library. You can configure a GTP profile and associate an GTP handover group to the GTP profile. When a GTP handover group name is referenced by a GTP profile, the device checks to see if the current SGSN/SGW address and the proposed SGSN/SGW address are both contained within the same GTP handover group. If both SGSN/SGW addresses are contained within the same GTP handover group, then the handover is allowed. If both the current and proposed SGSN/SGW addresses are not within the same GTP handover group, then the profile for the default handover group is used.

From Junos OS Release 20.4R1 onwards, the `[edit security gprs gtp profile profile-name]` hierarchy level is replaced by `[edit security gtp profile profile-name]`.

Options

name To specify the handover group on the GTP profile.

address-book To specify the common address-book name.

address-set To specify the address set for the handover group.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 17.4R1.

handshake-timeout

IN THIS SECTION

- Syntax | 8330
- Hierarchy Level | 8330
- Description | 8330
- Options | 8330
- Required Privilege Level | 8331
- Release Information | 8331

Syntax

```
handshake-timeout time-in-seconds;
```

Hierarchy Level

```
[edit security sctp profile profile-name]
```

Description

Use the handshake-timeout function to set the handshake time for Stream Control Transmission Protocol (SCTP).

From Junos OS Release 20.4R1 onwards, the `[edit security gprs sctp profile profile-name]` hierarchy level is replaced by `[edit security sctp profile profile-name]`.

Options

time-in-seconds—Number of seconds of handshake time that elapse before the session is terminated.

- **Range:** 10 to 30 seconds.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

hardware-assisted-keepalives

IN THIS SECTION

- Syntax | 8334
- Hierarchy Level | 8334
- Description | 8334
- Default | 8335
- Options | 8335
- Required Privilege Level | 8335
- Release Information | 8335

Syntax

```
hardware-assisted-keepalives [enable | disable];
```

Hierarchy Level

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring]
```

Description

For Ethernet interfaces on Modular Port Concentrators (MPCs) in MX Series routers only, delegate the transmission of the continuity check messages (CCMs) to the forwarding ASIC (that is, to the hardware) by enabling inline transmission of CCMs. Inline transmission of CCMs is also known as Inline-KA.

By default, CCMs are transmitted by the CPU of the MPC and not by the hardware. If the duration between transmissions of CCMs is low or if the CCMs for a specific line card scale, we recommend that you enable delegation of the transmission of CCMs to the hardware. By enabling inline transmission of CCMs, you can achieve maximum scaling of CCMs.

> **NOTE**: Starting in Junos OS Release 16.1R1, the inline support for 1s interval is supported on MPC1 to MPC7 (except MPC3 and MPC4) line cards.

Default

Inline transmission is disabled by default.

Options

enable Enable inline transmission of CCMs.

> **NOTE**: Inline transmission of CCMs is not enabled when there is a CFM session already established. To enable inline transmission, you must first deactivate the CFM session using the `deactivate` command and then reactivate the CFM session using the `activate` command.

disable Disable inline transmission of CCMs.

> **NOTE**: After disabling inline transmission of CCMs, you must reboot the router for the changes to take effect.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2R1.

hardware-assisted-timestamping

IN THIS SECTION

- Syntax | 8336
- Hierarchy Level | 8336
- Description | 8336
- Required Privilege Level | 8336
- Release Information | 8337

Syntax

```
hardware-assisted-timestamping;
```

Hierarchy Level

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring]
```

Description

For Ethernet interfaces on Enhanced and Enhanced Queuing Dense Port Concentrators (DPCs) in MX Series routers only, enable hardware-assisted timestamping support for Ethernet frame delay measurement.

By default, the ETH-DM feature calculates frame delays using software-based timestamping of the ETH-DM PDU frames sent and received by the MEPs in the session. As an option that can increase the accuracy of ETH-DM calculations when the DPC is loaded with heavy traffic in the receive direction, you can enable hardware-assisted timestamping of session frames in the receive direction.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

Hierarchy Level

```
[edit dynamic-profiles name protocols pim],
[edit logical-systems name protocols pim],
[edit logical-systems name routing-instances name protocols pim],
[edit protocols pim],
[edit routing-instances name protocols pim]
```

Description

Configure PIM hash-based RPF selection to ensure that multicast traffic for a specific source and group (S,G) is routed consistently through the same upstream node.

On enabling this feature, the (S,G) pair's RPF is updated with the output of the hashing algorithm. This update of the RPF happens in Make-before-break (MBB) fashion and therefore, enabling or disabling this configuration does not result in a loss of traffic.

Use the `show pim join` command to view the winner RPF upstream neighbor for the given (S, G).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 25.4R1.

[edit chassis fpc slot-number pic pic-number]
```

Description

(MX Series 5G Universal Routing Platforms only) Configure data used in a hash key for a PIC for symmetrical load balancing on an 802.3ad Link Aggregation Group.

Options

family—Configure data used in a hash key for a protocol family. This statement has the following suboptions:

- **inet**—Configure data used in a hash key for the **inet** protocol family.
- **multiservice**—Configure data used in a hash key for the **multiservice** protocol family.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6.

- Hierarchy Level | 8346
- Description | 8347
- Default | 8347
- Options | 8347
- Required Privilege Level | 8347
- Release Information | 8347

Syntax

```
hash-key (layer-3 | layer-4);
```

Hierarchy Level

```
[edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-
provider data-flow-affinity]
```

Description

Set the hashing distribution of flow affinity. This is an optional setting. Once the `data-flow-affinity` statement is enabled, you may need to choose the hashing distribution. Modifying this statement causes the PIC to reboot.

Default

If you do not configure the `hash-key` statement, the hashing distribution is 5-tuple hashing, or `layer-4`.

Options

`layer-3`—3-tuple hashing (source IP address, destination IP address, and IP protocol).

`layer-4`—5-tuple hashing (3-tuple plus source and destination TCP or UDP ports).

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

}
```

Hierarchy Level

```
[edit forwarding-options]
[edit chassis fpc slot-number pic pic-number]
```

Description

Select which packet header data to use for per-flow load balancing.

The options are explained separately.

NOTE: You can configure either Layer 3 or Layer 4 load balancing, or both at the same time

NOTE: On I chip platforms, an unknown Layer 4 header is excluded from load-balance hashing to avoid undesired packet reordering.

NOTE: To modify the default hashing mechanism on Modular Port Concentrators (MPCs) and Type 5 FPCs, you need to configure the statements at the `[edit forwarding-options enhanced-hash-key]` hierarchy level. Statements at the `[edit forwarding-options hash-key]` hierarchy level do not support MPCs and Type 5 FPCs.

NOTE: The following statements are not supported on T Series routers:

- The `symmetric-hash` and the `session-id` statements at the `[edit forwarding-options hash-key family inet]` hierarchy level and all statements at the `[edit forwarding-options hash-key family multiservice]` hierarchy level.
- The `label-1` and `label-2` statements, and the IP configuration at the `[edit forwarding-options hash-key family multiservice]` hierarchy level.

NOTE: The following statements are not supported on QFX Series switches:

- The `symmetric-hash` and the `session-id` statements at the `[edit forwarding-options hash-key family inet]` hierarchy level.

NOTE: QFX 5000 Series switches with an EVPN Type 5 overlay must configure `overlay-ecmp` at the `[edit forwarding-options vxlan-routing` hierarchy.

NOTE: QFX 10000 Series switches in an EVPN-VXLAN environment should configure the `layer2` option with appropriate sub-option at the `[edit forwarding-options enhanced-hash-key]` hierarchy. This applies to the overlay fabric.

Addtionally, you should configure the `family` option with appropriate sub-option at the `[edit forwarding-options enhanced-hash-key` hierarchy. This applies to both EVPN-VXLAN underlay and overlay fabrics.

NOTE: On PTX platforms, *family inet/inet6 layer-3 traffic-class (dscp-v4/dscp-v6)* is disabled by default.

PTX platforms running Junos OS Evolved require the `enhanced-hash-key family` setting for EVPN-VXLAN underlay and overlay fabrics.

NOTE: EVPN-VXLAN configuration is required for underlay ECMP to work in ACX platforms on Junos EVO.

NOTE: On ACX 7000 Series of routers, the following statements are not supported:

- `label-1`, `label-2`, and `payload` statements at the `[edit forwarding-options hash-key family multiservice]` hierarchy level
- `bottom-label-1`, `bottom-label-2`, `bottom-label-3`, `label-1`, `label-2`, `label-3`, `no-labels`, and `no-label-1-exp` at the `[edit forwarding-options hash-key family mpls]` hierarchy level
- `disable` and `port-data` statements at the `[edit forwarding-options hash-key family mpls payload ip]` hierarchy level
- `destination-address`, `incoming-interface-index`, `next-header`, `source-address`, `traffic-class` at the `[edit forwarding-options hash-key family inet6 layer-3]` hierarchy level
- `destination-port` and `source-port` at the `[edit forwarding-options hash-key family inet6 layer-4]` hierarchy level

> **NOTE**: On ACX Series routers, configure the `family (inet|inet6)` option with appropriate sub-option at the `[edit forwarding-options enhanced-hash-key` hierarchy. This applies to both EVPN-VXLAN underlay and overlay fabrics.

Options

- *inet*-IPv4 protocol family.
- *mpls*-MPLS protocol family.
- *layer-3*-Incorporate Layer 3 data into the hash key.
- *layer-4*-Incorporate Layer 4 data into the hash key.
- *session-id*-Incorporate session ID data into the hash key (SRX3000 and SRX5000 lines only). The session ID data has higher precedence than the Layer 3 or 4 information.
- *label-1*-Incorporate the first MPLS label into the hash key.
- *label-2*-Incorporate the second MPLS label into the hash key.
- *label-3*-Incorporate the third MPLS label into the hash key.
- *no-labels*-Include no MPLS labels into the hash key.
- *payload*-Incorporate payload data into the hash key.
- *ip*-Include the IP address of the IPv4 or IPv6 payload into the hash key.
- *layer-3–only*-Include only Layer 3 IP information.
- *port-data*-Include the source and destination port field information.
- *source-msb*-Include the most significant byte of the source port.
- *source-lsb*-Include the least significant byte of the source port.
- *destination-msb*-Include the most significant byte of the destination port.
- *destination-lsb*-Include the least significant byte of the destination port.
- *source-mac*-Include source MAC address in hash key.
- *destination-mac*-Include destination MAC address in hash key.
- *outer-vlan-id*—Include outer VLAN ID information in the hash key.

- *inner-vlan-id*—Include inner VLAN ID information in the hash key.s

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`family multiservice` and `no-label-1-exp` options introduced in Junos OS Release 8.0.

`label-3` and `no-labels` options introduced in Junos OS Release 8.1.

`ether-pseudowire` statement introduced in Junos OS Release 9.1 (M320 and T Series routers only); support extended to M120 and MX Series routers in Junos OS Release 9.4.

`ip`, `label-1`, `label-2`, `layer-3-only`, and `payload` options for the `family multiservice` statement introduced in Junos OS Release 9.4 (M120 and M320 routers only). For MX Series routers, only the `ip` and `payload` statements apply.

`layer-3`, `source-ip-only`, `destination-ip-only`, and `layer-4` statements introduced for the `family multiservice` statement in Junos OS Release 9.5. (MX Series routers only).

`all-labels` and `payload ip disable` statements introduced for the `family mpls` statement in Junos OS Release 12.1X48R2 PTX Series Packet Transport Routers only.

`bottom-label` statement introduced for the `family mpls` statement in Junos OS Release 14.1 for MX Series routers with DPCs (excluding M7i, M10i, and M120.)

`zero-control-word` option for the `ether-pseudowire` statement introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

hash-keys (Aggregated Multiservices)

IN THIS SECTION

- Syntax | 8356
- Hierarchy Level | 8356
- Description | 8356
- Options | 8358
- Required Privilege Level | 8359
- Release Information | 8359

Syntax

```
hash-keys {
    egress-key (destination-ip | source-ip);
    ingress-key (destination-ip | source-ip);
}
```

Hierarchy Level

```
[edit services service-set service-set-name interface-service load-balancing-options]
```

Description

Configure the hash keys used for load balancing in aggregated multiservices (AMS) for service applications (Network Address Translation [NAT], stateful firewall, application-level gateway [ALG], HTTP header enrichment, and mobility). The hash keys supported in the ingress and egress direction are the source IP address and destination IP address.

Hash keys are used to define the load-balancing behavior among the various members in the AMS group. For example, if **hash-keys** is configured as **source-ip**, then the hashing would be performed based on the source IP address of the packet. Therefore, all packets with the same source IP address land on the same member. Hash keys must be configured with respect to the traffic direction: ingress or egress. For example, if **hash-keys** is configured as **source-ip** in the ingress direction, then it should be configured as **destination-ip** in the egress direction. This is required to ensure that the packets of the same flow reach the same member of the AMS group.

The configuration of the ingress and egress hash keys is mandatory if you are using AMS for NAT. This configuration is not mandatory if you are using AMS for stateful firewall; if the hash keys are not configured, then the defaults are chosen. Refer to Table 59 on page 8357 for the supported hash keys.

The resource-triggered option enables anchor session PICs to use the load or resource information from the anchor services PICs to select the AMS member will anchor the services for the subscriber for load balancing among AMS members. In addition, for mobile subscriber-aware services (such as HTTP header enrichment), you must configure the `resource-triggered` statement, which means that the load balancing is not done using the ingress and egress keys.

Table 59: Hash Keys Supported for AMS for Service Applications

	Service Set at Ingress Interface		Service Set at Egress Interface	
Hash Keys for NAT				
NAT Type	Ingress hash key	Egress hash key	Ingress hash key	Egress hash key
source static	Destination IP address	Source IP address	Source IP address	Destination IP address
source dynamic	Source IP address	Destination IP address	Destination IP address	Source IP address
Network Address Port Translation (NAPT)	Source IP address	Destination IP address	Destination IP address	Source IP address
destination static	Source IP address	Destination IP address	Destination IP address	Source IP address
Hash Keys for Stateful Firewall				

Stateful Firewall	Destination IP address	Source IP address	Destination IP address	Source IP address
Stateful Firewall	Source IP address	Destination IP address	Source IP address	Destination IP address

NOTE: If NAT is used in the service set (along with stateful firewall and ALG), then the hash keys should be based on the NAT type; otherwise, the hash keys of the stateful firewall should be used.

Options

NOTE: The `egress-keys` option is hidden and is deprecated in Junos OS Release 15.1 and later, and is only maintained for backward compatibility. It might be removed completely in a future software release. Load-balancing or steering of traffic occurs, based on the hash keys in the forward direction. Load-balancing of traffic also occurs, based on the hash keys in the reverse direction except in dynamic NAT scenarios (dynamic NAT, NAT64, and NAPT44). For interface-style services, the ingress hash-key is used for the forward direction and the egress hash-key is used for the reverse direction. These hash-keys are configured within the service-set definition by using the `ingress-key` and `egress-key` statements at the `[edit services service-set` *`service-set-name`* `interface-service load-balancing-options]` hierarchy level. For next-hop style services, the ingress hash-key on the inside-domain next-hop is used in the forward direction and the ingress hash-key (not the egress hash-key) on outside-domain next-hop is used for the reverse direction. These hash-keys are configured at the logical AMS interface level by using the `ingress-key` and `egress-key` statements at the `[edit interfaces ams`*`N`* `unit` *`logical-unit-number`* `load-balancing-options hash-keys]` hierarchy level.

ingress-key destination-ip
Use the destination IP address of the flow to compute the hash used in load balancing in the ingress flow direction.

ingress-key source-ip
Use the source IP address of the flow to compute the hash used in load balancing in the ingress flow direction.

egress-key destination-ip
Use the destination IP address of the flow to compute the hash used in load balancing. Configure the hash keys to be used in the egress flow direction. The configuration is mandatory if you are using AMS for Network Address Translation

(NAT). This configuration is not mandatory if you are using AMS for stateful firewall; if the hash keys are not configured, then the defaults are chosen.

egress-key source-ip Use the source IP address of the flow to compute the hash used in load balancing. Configure the hash keys to be used in the egress flow direction.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

    ipv6-source-prefix-length ipv6-source-prefix-length;
}
```

Hierarchy Level

```
[edit interfaces unit unit-name load-balancing-options]
```

Description

Configure the hash keys used for load balancing in aggregated multiservices (AMS) for next-hop style services. The hash keys supported in the ingress and egress direction are the source IP address and destination IP address.

Hash keys are used to define the load-balancing behavior among the various members in the AMS. For example, if `hash-keys` is configured as `source-ip`, then the hashing is performed based on the source IP address of the packet, so that all packets with the same source IP address land on the same member. When you use `ingress-key` and `egress-key`, you must configure hash keys to take the traffic direction into consideration. For example, if you configure `hash-keys` as `source-ip` in the ingress direction, then you must configure `hash-keys` as `destination-ip` in the egress direction. This is required to ensure that the packets of the same flow reach the same member of the AMS group.

If you are configuring an AMS interface used in a service set for DS-Lite,

The remaining statements are explained separately. See CLI Explorer.

Options

egress-key destination-ip	Use the destination IP address of the flow to compute the hash used in load balancing. Configure the hash keys to be used in the egress flow direction.
egress-key source-ip	Use the source IP address of the flow to compute the hash used in load balancing. Configure the hash keys to be used in the egress flow direction.
ingress-key destination-ip	Use the destination IP address of the flow to compute the hash used in load balancing. Configure the hash keys to be used in the ingress flow direction.

ingress-key source-ip Use the source IP address of the flow to compute the hash used in load balancing. Configure the hash keys to be used in the ingress flow direction.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

`ipv6-source-prefix-length` option introduced in Junos OS Release 18.2R1.

Support added in Junos OS Release 19.3R2 for Next Gen Services on MX Series routers MX240, MX480 and MX960 with the MX-SPC3 services card. The `ipv6-source-prefix-length` option is not supported for Next Gen Services.

Configuring Load Balancing on AMS Infrastructure

hash-mode

IN THIS SECTION

- Syntax | 8362
- Hierarchy Level | 8362
- Description | 8362
- Default | 8363
- Options | 8363
- Required Privilege Level | 8363
- Release Information | 8363

Syntax

```
hash-mode {
    layer2-header;
    layer2-payload;
    gtp-header-offset offset-value;
}
```

Hierarchy Level

```
[edit forwarding-options enhanced-hash-key]
```

Description

Select the mode for the hashing algorithm.

The hashing algorithm is used to make traffic-forwarding decisions for traffic entering a LAG bundle or for traffic exiting a switch when ECMP is enabled.

For LAG bundles, the hashing algorithm determines how traffic entering a LAG bundle is placed onto the bundle's member links. The hashing algorithm tries to manage bandwidth by evenly load-balancing all incoming traffic across the member links in the bundle.

When ECMP is enabled, the hashing algorithm determines how incoming traffic is forwarded to the next-hop device.

The hash mode that is set using this statement determines which fields are inspected by the hashing algorithm. You must set the hash mode to `layer2-payload` if you want the hashing algorithm to inspect fields in the Layer 2 payload when making hashing decisions. You must set the hash mode to `layer2-header` if you want the hashing algorithm to inspect fields in the Layer 2 header when making hashing decisions.

If the hash mode is set to `layer2-payload`, you can set the fields used by the hashing algorithm to hash IPv4 traffic using the `set forwarding-options enhanced-hash-key inet` statement. You can set the fields used by the hashing algorithm to hash IPv6 traffic using the `set forwarding-options enhanced-hash-key inet6` statement.

If the hash mode is set to `layer2-header`, you can set the fields that the hashing algorithm inspects in the Layer 2 header using the `set forwarding-options enhanced-hash-key layer2` statement.

Default

layer2-payload

Options

`layer-2-payload`	Set the hashing algorithm to use fields in the Layer 2 payload to make hashing decisions.
`layer-2-header`	Set the hashing algorithm to use fields in the Layer 2 header to make hashing decisions.
`gtp-header-offset`	Set proper offset value for the header based on the different patterns.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2X51-D15.

Statement is not supported on QFX10002 and QFX 10008 switches.

Hash mode option *gtp-header-offset* introduced in Junos OS Release 17.3R3 for QFX5000 line of switches.

hash-seed (profile)

IN THIS SECTION

- Syntax | 8366
- Hierarchy Level | 8366
- Description | 8366
- Options | 8366
- Required Privilege Level | 8366
- Release Information | 8367

Syntax

```
hash-seed seed-value
```

Hierarchy Level

```
[edit forwarding-options enhanced-hash-key profile1/profile2]
```

Description

Configure a hash seed for load-balancing functions for the given load balancing profile (profile1 or profile2).

Options

hash-seed *seed-value* - A hash seed value, in the range from 0 to 4294967295

Required Privilege Level

- interface—To view this statement in the configuration.
- interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 23.2

hash-seed

IN THIS SECTION

- Syntax | 8367
- Hierarchy Level | 8367
- Description | 8367
- Options | 8368
- Required Privilege Level | 8368
- Release Information | 8368

Syntax

```
hash-seed seed-value;
```

Hierarchy Level

```
[edit forwarding-options enhanced-hash-key ]
```

Description

Configure a hash seed for load-balancing functions.

By default, the QFX10002, QFX10008, QFX5220, QFX5130, and QFX5700 switches use the system MAC address to generate a hash seed value. You can configure the hash seed value using the **hash-seed** statement at the [`edit forwarding-options enhanced-hash-key`] hierarchy. Set a value between 0 and 4294967295. If you do not configure a hash seed value, the system will generate a hash seed value based on the system MAC address.

> **NOTE**: The `fabric-load-balance` and `user-defined-fields` statements are not supported at the [`edit forwarding-options enhanced-hash-key`] hierarchy level.

Options

hash-seed*seed-value* A hash seed value, in the range from 0 to 4294967295.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

- Release Information | 8377

Syntax

```
header-integrity-check {
    enable-all;
}
```

Hierarchy Level

```
[edit services service-set service-set service-set-options]
```

Description

Configure Junos OS to verify the packet header for anomalies in IP, TCP, UDP, and ICMP information and to flag such anomalies and errors.

Starting in Junos OS release 17.1R1, the header integrity check on the MS-MPC or MS-MIC drops any packets with header anomalies and includes the following checks:

- ICMP ping of death
- IP unknown protocol
- TCP no flag
- TCP SYN FIN
- TCP FIN no ACK

> **NOTE**: The `header-integrity-check` option that is supported on MS-MICs and MS-MPCs to verify the packet header for anomalies in IP, TCP, UDP, and ICMP information and flag such anomalies and errors has a functionality that is opposite to the functionality caused by passive mode tunneling. If you configure both the `header-integrity-check` statement and the `passive-mode tunneling` statement on MS-MICs and MS-MPCs, and attempt to commit such a configuration, an error is displayed during commit.
>
> The passive mode tunneling functionality (by including the `passive-mode-tunnelin` statement at the `[edit services service-set` *`service-set-name`* `ipsec-vpn-options]` hierarchy level) is a superset of the capability to disable IPsec tunnel endpoint in the traceroute output (by including `no-ipsec-tunnel-in-traceroute` statement at the `[edit services ipsec-vpn]` hierarchy level). Passive mode tunneling also bypasses the active IP checks and tunnel MTU check in addition to not treating an IPsec tunnel as a next-hop as configured by the `no-ipsec-tunnel-in-traceroute` statement.

Required Privilege Level

health-monitor (KHMS)

IN THIS SECTION

- Syntax | 8381
- Hierarchy Level | 8381
- Description | 8381
- Options | 8382
- Required Privilege Level | 8382
- Release Information | 8383

Syntax

```
health-monitor {
    ifstate-clients {
        (peer-stuck | non-peer-stuck | all-clients-stuck);
    }
    threshold-level {
        (low | medium | high);
    }
    action {
        (alarm | alarm-with-cores | restart);
    }
}
```

Hierarchy Level

```
[edit system]
```

Description

Configure the kernel health monitoring system (KHMS). The KHMS is used to detect and take action on stuck ifstate clients. Stuck ifstate clients can affect system performance. With this configuration statement you can configure a time interval in which the system can detect a stuck ifstate client. You also can configure the action the system takes when it finds a stuck ifstate client.

The ifstate clients receive states from the kernel. There are two kinds of ifstate clients:

- non-peer clients (for example, some daemons, or processes, on the Routing Engine)—ifstate non-peer clients open connections between programs and read states from or write states to the kernel.
- peer clients (for example, FPCs)—ifstate peer clients read peer messages and send updates to the peers.

An ifstate client is stuck if the kernel sends a message and the ifstate client does not send back an ACK. A rt_pfe_veto condition is a log message that indicates that states are sent but no ACK comes back. However, the system won't take the configured action until the configured time interval times outs, in case the ACK comes late.

Options

ifstate-clients

Configure which ifstate clients you want to monitor and manage. There are three options:

- `peer-stuck`—Monitor and manage stuck peers.
- `non-peer-stuck`—Monitor and manage stuck processes.
- `all-clients-stuck`—Monitor and manage both stuck peers and stuck processes.

threshold-level

Configure the time interval in which to detect if a given ifstate client is stuck:

- `high`—540 seconds
- `medium`—360 seconds; this is the default.
- `low`—180 seconds

action

Configure the action to be taken on the stuck ifstate client once the configured time interval times out.

- `alarm`—Only an alarm will be raised about the stuck ifstate client; this is the default.
- `alarm-with-cores`—An alarm will be raised about the stuck ifstate client after collecting live cores from the primary Routing Engine kernel and the stuck peer.

  CAUTION: In the case of a stuck peer, collecting lives cores might result in the component being restarted or rebooted.

- `restart`—The stuck ifstate client will be disconnected after collecting live cores from the primary Routing Engine kernel and the stuck peer (depending on supportability).

  CAUTION: When choosing this action, be aware of the implications of restarting an ifstate client. For example, some FPCs don't simply restart; they reboot.

heartbeat-address (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | 8385
- Hierarchy Level | 8385
- Description | 8385
- Options | 8385
- Required Privilege Level | 8385
- Release Information | 8385

Syntax

```
heartbeat-address (ip-address | ipv6-address);
```

Hierarchy Level

```
[edit virtual-chassis]
```

Description

Configure an IPv4 address or IPv6 address used to create an IP-based packet connection, known as a *heartbeat connection*, between the primary router and backup router in an MX Series Virtual Chassis. To ensure consistent access to the primary Routing Engine in the Virtual Chassis primary router (VC-Pp) regardless of which Routing Engine is active, you must configure the address for the management Ethernet interface (`fxp0`) with the `master-only` statement at the `[edit groups]` hierarchy level.

> **NOTE**: The `heartbeat-address` statement and the `no-split-detection` statement at the `[edit virtual-chassis]` hierarchy level are mutually exclusive. As a result, the software prevents you from configuring both `heartbeat-address` and `no-split-detection` at the same time. If you attempt to do so, the software displays an error message and causes the `commit` operation to fail.

Options

ip-address	IPv4 `master-only` address for the `fxp0` management interface.
ipv6-address	IPv6 `master-only` address for the `fxp0` management interface.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1.

heartbeat-interval

IN THIS SECTION

- Syntax | 8386
- Hierarchy Level | 8386
- Description | 8386
- Options | 8387
- Required Privilege Level | 8387
- Release Information | 8387

Syntax

```
heartbeat-interval milliseconds;
```

Hierarchy Level

```
[edit chassis cluster]
```

Description

Set the interval between the periodic signals broadcast to the devices in a chassis cluster to indicate that the active node is operational.

The `heartbeat-interval` option works in combination with the `heartbeat-threshold` option to define the wait time before failover is triggered in a chassis cluster. The default values of these options produce a wait

time of 3 seconds. In a large configuration approaching full capacity on an SRX5400 or SRX5600 or SRX5800 device, however, we recommend that you increase the failover wait time to 5 seconds.

For example, a `heartbeat-threshold` of 3 and a `heartbeat-interval` of 1000 milliseconds result in a total wait of 3 seconds before failover is triggered. To increase this wait to 5 seconds, you could increase the `heartbeat-threshold`, the `heartbeat-interval`, or both. A `heartbeat-threshold` of 5 and a `heartbeat-interval` of 1000 milliseconds would yield a wait time of 5 seconds. Setting the `heartbeat-threshold` to 4 and the `heartbeat-interval` to 1250 milliseconds would also yield a wait time of 5 seconds.

> **NOTE**: In a chassis cluster scaling environment, the `heartbeat-threshold` must always be set to 8.

Options

`milliseconds`—Time interval between any two heartbeat messages.

- **Range:** 1000 through 2000 milliseconds
- **Default:** 1000 milliseconds

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

heartbeat-timeout (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | 8390
- Hierarchy Level | 8390
- Description | 8390
- Options | 8390
- Required Privilege Level | 8390
- Release Information | 8391

Syntax

```
heartbeat-timeout seconds;
```

Hierarchy Level

```
[edit virtual-chassis]
```

Description

Configure the maximum time period within which a Virtual Chassis member router must respond to a heartbeat packet sent by the other member router. When an adjacency disruption or split is detected in the Virtual Chassis configuration, each member router sends a single heartbeat packet to the other member router to determine whether that router is still operating and able to respond. If the other member router responds to the heartbeat packet within the configured or default timeout period, the heartbeat connection helps prevent the member routers from changing primary role roles, which can cause undesirable results.

> **NOTE**: Both member routers forming the heartbeat connection must be assigned the `routing-engine` role in the preprovisioned Virtual Chassis configuration. The `routing-engine` role makes the router eligible to function as either the primary router or backup router of the Virtual Chassis.

Options

seconds—Number of seconds within which a Virtual Chassis member router must respond to a heartbeat packet.

- **Range:** 1 through 60 seconds
- **Default:** 2 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1.

heartbeat-tos (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | 8391
- Hierarchy Level | 8391
- Description | 8392
- Options | 8392
- Required Privilege Level | 8393
- Release Information | 8393

Syntax

```
heartbeat-tos value;
```

Hierarchy Level

```
[edit virtual-chassis]
```

Description

Configure a network-specific value for the header field that defines either the type of service (ToS), traffic class (TC), or differential services (DS) octet that is transmitted in the header of a heartbeat packet.. This field is a single octet that ensures preferential delivery of heartbeat packets between Virtual Chassis member routers in a congested network. You can set the IP precedence portion of the ToS header field or the differentiated services code point (DSCP) in the DS header field in accordance with your network. When you configure a `heartbeat-tos` value, the software uses this octet value in the IP header for all generated Virtual Chassis heartbeat packets.

Configuring the `heartbeat-tos` Virtual Chassis heartbeat packets is particularly useful in congested networks or in networks with high bandwidth demands. For example, setting the appropriate `heartbeat-tos` value for your network design enables you to prioritize the traffic flows that transmit Virtual Chassis heartbeat packets at a higher service level than the traffic flows for traditional IP applications such as e-mail or Web browsing. During periods of network congestion, configuring the appropriate value can ensure reliable delivery of the heartbeat packets and decrease the likelihood of packet loss.

BEST PRACTICE: To properly prioritize the traffic flows for heartbeat packets based on the network load, make sure you are using a value that is consistent with the protocol standard that was implemented in your network.

Options

`value`—Network-specific value of the ToS, TC, or DS octet transmitted in Virtual Chassis heartbeat packets. Depending on your network design and protocol family implementation, the value you specify must conform to the following RFC standards:

- IPv4 ToS as defined in RFC 791, *INTERNET PROTOCOL - DARPA INTERNET PROGRAM PROTOCOL SPECIFICATION*
- IPv6 traffic class (TC) as defined in RFC 2460, *Internet Protocol, Version 6 (IPv6) Specification*
- IPv4 and IPv6 Differentiated Services as defined in RFC 2474, *Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers*
- Assured forwarding per-hop behavior (PHB) as defined in RFC 2597, *Assured Forwarding PHB Group*
- RFC 3260, *New Terminology and Clarifications for Diffserv*
- **Range:** 0 through 255
- **Default:** 0 (`heartbeat-tos` not set)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

- Syntax | 8393
- Hierarchy Level | 8394
- Description | 8394
- Default | 8394
- Required Privilege Level | 8394
- Release Information | 8394

Syntax

```
hello-acknowledgements;
```

Hierarchy Level

```
[edit logical-systems logical-systems-name protocols rsvp],
[edit protocols rsvp]
```

Description

Enable hello messages from nonsession neighbors to be acknowledged with a hello acknowledgment message. Once hello acknowledgments are enabled, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or the configuration is changed by an administrator.

Default

Hello acknowledgments are disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

RELATED DOCUMENTATION

hello-dead-interval

IN THIS SECTION

Syntax | 8395

- Hierarchy Level | 8395
- Description | 8395
- Options | 8395
- Required Privilege Level | 8395
- Release Information | 8396

Syntax

```
hello-dead-interval milliseconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols link-management peer peer-name lmp-protocol],
[edit protocols link-management peer peer-name lmp-protocol]
```

Description

Specify how long the Link Management Protocol (LMP) waits before declaring the control channel to be dead. This is an interval during which the router receives no LMP hello packets from the neighbor on a control that is active or up.

Options

milliseconds—Interval to wait before declaring the control channel to be dead.

- **Range:** 500 through 300,000
- **Default:** 500 milliseconds (three times the hello interval)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.0.

RELATED DOCUMENTATION

- Required Privilege Level | 8397
- Release Information | 8397

Syntax

```
hello-interval seconds;
```

Hierarchy Level

```
[edit services l2tp tunnel-group name]
```

Description

Specify the keepalive timer for L2TP tunnels.

Options

seconds—Interval, in seconds, after which the server sends a hello message if no messages are received. A value of `0` means that no hello messages are sent.

- **Range:** 0 through 3600
- **Default:** 60 seconds

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Description

Control the LDP timer that regulates how often hello messages are sent. You can control the rate both link hello messages and targeted hello messages are sent depending on the hierarchy level at which you configure the `hello-interval` statement.

Options

seconds—Length of time between transmission of hello packets.

- **Range:** 1 through 65,535 seconds
- **Default:** 5 seconds for link hello messages, 15 seconds for targeted hello messages

> **NOTE**: The default hello intervals on EX 9200 switches are not sufficient to avoid protocol flapping during an ISSU Linux upgrade. To avoid protocol flapping during the upgrade, configure the hello intervals for 35 seconds or more.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support for LDP targeted hellos added in Junos OS Release 9.5.

hello-message (NETCONF)

IN THIS SECTION

- Syntax | **8404**
- Hierarchy Level | **8404**

- Description | 8404
- Default | 8404
- Options | 8405
- Required Privilege Level | 8405
- Release Information | 8405

Syntax

```
hello-message {
    yang-module-capabilities {
        advertise-native-yang-modules;
        advertise-custom-yang-modules;
        advertise-standard-yang-modules;
    }
}
```

Hierarchy Level

```
[edit system services netconf]
```

Description

Configure the NETCONF server to advertise additional capabilities in the NETCONF capabilities exchange. The NETCONF server emits the `<hello>` element and the `<capabilities>` child element with the list of capabilities at the start of the NETCONF session.

Default

If you do not include the `hello-message` statement, the NETCONF server does not advertise any additional capabilities beyond the default capabilities in the NETCONF capabilities exchange.

Options

yang-module-capabilities Configure the YANG modules that the NETCONF server advertises in the NETCONF capabilities exchange. The following statements are supported:

- `advertise-custom-yang-modules`—Advertise third-party YANG modules installed on the device.
- `advertise-native-yang-modules`—Advertise Junos OS native YANG modules.
- `advertise-standard-yang-modules`—Advertise standard YANG modules supported by the device, for example, OpenConfig modules.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 21.1R1 and Junos OS Evolved Release 21.1R1.

Syntax

```
help < (apropos string | reference statement-name| syslog syslog-tag| tip cli number | topic
word)>
```

Description

Display help about available operational commands, configuration statements, or general information about getting help. Entering the `help` command without an option provides introductory information about how to use the `help` and `?` commands.

Options

`apropos` *string*—(Optional) Display command names and help text that matches the string specified. If the string contains spaces, enclose it in quotation marks (" "). You can also specify a regular expression for the string, using standard UNIX-style regular expression syntax.

`reference` *statement-name*—(Optional) Display summary information for a configuration statement. This information is based on summary descriptions that appear in the Junos configuration guides.

`syslog` *syslog-tag*—(Optional) Display information about system log messages.

`tip cli` *number*—(Optional) Display a tip about using the CLI. Specify the number of the tip you want to view.

`topic` *word*—(Optional) Display usage guidelines for a topic or configuration statement. This information is based on subjects that appear in the Junos configuration guides.

Required Privilege Level

None

Release Information

Command introduced before Junos OS Release 7.4.

The `apropos` option was added in Junos OS Release 8.0.

    }
}
```

Hierarchy Level

```
[edit forwarding-options]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Enable TFTP or DNS request packet forwarding, or configure the router, switch, or interface to act as a DHCP/BOOTP relay agent. Use only one server address per interface or global configuration.

You can also use the helpers `port` statement to enable forwarding LAN broadcast traffic on custom UDP ports to particular servers as unicast traffic. Configure the UDP port number and optionally an interface

on which to listen for broadcast traffic, and the destination server address to receive that traffic, as shown in either of the following sample configurations:

```
user@ host# show forwarding-options
helpers {
    port 1200 {
        server 10.20.30.40;
        }
    }
```

```
user@ host# show forwarding-options
helpers {
    port 3000 {
        interface {
            fe-0/0/1.0 {
                server 192.0.2.2;
            }
        }
    }
    port 3001 {
        interface {
            fe-0/0/0.0 {
                server 192.0.2.2;
            }
        }
    }
}
```

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

        then {
            discard;
        }
    }
}
```

Hierarchy Level

```
[edit dynamic-profiles profile-name firewall],
[edit firewall]
```

Description

Use a hierarchical policer to rate-limit ingress Layer 2 traffic at a physical or logical interface and apply different policing actions based on whether the packets are classified as `premium` for expedited forwarding (EF) or `aggregate` for a lower priority. The two policers defined within the hierarchical policer are `aggregate` and `premium`.

Hierarchical policers are supported on Enhanced Intelligent Queuing (IQE) PICs and SONET interfaces hosted on the M120 and M320 with incoming Flexible PIC Concentrators (FPCs) as SFPC and outgoing FPCs as FFPC; on MPCs hosted on MX Series routers; on the T320, T640, and T1600 with Enhanced Intelligent Queuing (IQE) PICs; and on the T4000 with Type 5 FPC and Enhanced Scaling Type 4 FPC.

NOTE:

- The `if-exceeding-pps` statement is only supported on MX Series routers with MPCs.
- The `if-exceeding` and `if-exceeding-pps` statements are mutually exclusive and, therefore, cannot be applied at the same time.

You can configure the policer in static firewall filters or dynamic firewall filters in a dynamic client profile or a dynamic service profile.

Options

hierarchical-policer-name—Name that identifies the policer. The name can contain letters, numbers, and hyphens (-), and can be up to 255 characters long. To include spaces in the name, enclose the name in quotation marks (“ ”).

uid—When you configure a hierarchical policer at the `[edit dynamic-profiles profile name firewall]` hierarchy level, you must assign a variable UID as the policer name.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

Support at the `[edit dynamic-profiles` *`profile-name`* `firewall]` hierarchy level introduced in Junos OS Release 11.4.

Support for `if-exceeding-pps` statement on MX Series routers with MPCs introduced in Junos OS Release 15.2.

hierarchical-policer

IN THIS SECTION

- Syntax | 8423
- Hierarchy Level | 8424
- Description | 8424
- Options | 8424
- Required Privilege Level | 8424
- Release Information | 8424

Syntax

```
hierarchical-policer name {

aggregate {
    if-exceeding {
        bandwidth-limit bandwidth;
        burst-size-limit burst;
    }
    then {
        discard;
    }
}
premium {
    if-exceeding {
        bandwidth-limit bandwidth;
        burst-size-limit burst;
    }
    then {
        discard;
    }
}
```

Hierarchy Level

```
[edit firewall]
```

Description

For M40e, M120, and M320 (with FFPC and SFPC) edge routers and T320, T640, and T1600 core routers with Enhanced Intelligent Queuing (IQE) PICs, specify a hierarchical policer.

Options

Options are described separately.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

hierarchical-scheduler (Subscriber Interfaces on MX Series Routers)

IN THIS SECTION

- Syntax | 8425
- Hierarchy Level | 8425

- Description | 8425
- Options | 8426
- Required Privilege Level | 8426
- Release Information | 8426

Syntax

```
hierarchical-scheduler {
    implicit-hierarchy;
    maximum-hierarchy-levels number;
}
```

Hierarchy Level

```
[edit interfaces interface-name]
```

Description

Configure hierarchical scheduling options on the interface.

The statement is supported on the following interfaces:

- MIC and MPC interfaces in MX Series routers
- GRE tunnel interfaces configured on physical interfaces hosted on MIC or MPC line cards in MX Series routers

To enable hierarchical scheduling on MX Series routers, configure the `hierarchical-scheduler` statement at each member physical interface level of a particular aggregated Ethernet interface as well as at that aggregated Ethernet interface level. On other routing platforms, it is enough if you include this statement at the aggregated Ethernet interface level.

Options

implicit-hierarchy Configure four-level hierarchical scheduling. When you include the `implicit-hierarchy` option, a hierarchical relationship is formed between the CoS scheduler nodes at level 1, level 2, level 3, and level 4. The `implicit-hierarchy` option is supported only on MPC/MIC subscriber interfaces and interface sets on MX Series routers.

maximum-hierarchy-levels *number* Specify the maximum number of hierarchical scheduling levels allowed for node scaling, from 2 through 4 levels. The default number of levels is 3. The `maximum-hierarchy-levels` option is supported on MPC/MIC or EQ DPC subscriber interfaces and interface sets on MX Series routers.

- If you set `maximum-hierarchy-levels` to `2`, interface sets are not allowed. In this case, if you configure a level 2 interface set, you generate Packet Forwarding Engine errors.
- If you do not include the `maximum-hierarchy-levels` option, keeping the default number of hierarchy levels at 3, interface sets can be at either level 2 or level 3, depending on whether the member logical interfaces within the interface set have a traffic control profile. If any member logical interface has a traffic control profile, then the interface set is a level 2 CoS scheduler node. If no member logical interface has a traffic control profile, the interface set is at level 3.

> **CAUTION**: MPC3E, 32x10GE MPC4E, and 2x100GE + 8x10GE MPC4E MPCs support only two levels of scheduling hierarchy. When enabling hierarchical scheduling on these cards, you must explicitly set `maximum-hierarchy-levels` to `2`.

Required Privilege Level

view-level—To view this statement in the configuration.

control-level—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

`implicit-hierarchy` option added in Junos OS Release 13.1.

Support on GRE tunnel interfaces configured on physical interfaces on MICs or MPCs in MX Series routers added in Junos OS Release 13.3.

Support for up to four hierarchy levels added in Junos OS Release 16.1.

hierarchical-scheduler

IN THIS SECTION

- Syntax | 8427
- Hierarchy Level | 8427
- Description | 8428
- Options | 8428
- Required Privilege Level | 8428
- Release Information | 8428

Syntax

```
hierarchical-scheduler {
    implicit-hierarchy;
    maximum-hierarchy-levels number;
}
```

Hierarchy Level

```
[edit interfaces]
[edit dynamic-profiles name interfaces],
```

```
[edit dynamic-profiles name logical-systems name interfaces]
```

Description

Enable the use of hierarchical schedulers. If you do not include this statement, the interfaces on the router cannot use hierarchical interfaces.

NOTE: When configuring hierarchical scheduling for network slices on an interface, you do not need to enable vlan-tagging on that interface.

NOTE: To enable hierarchical scheduling on MX80 and MX104 routers, configure the `hierarchical-scheduler` statement at each member physical interface level of a particular aggregated Ethernet interface as well as at that aggregated Ethernet interface level. On other routing platforms, it is enough if you include this statement at the aggregated Ethernet interface level.

Options

implicit-hierarchy For MPC/MIC subscriber interfaces and interface sets running over aggregated Ethernet on MX Series routers, form a hierarchical relationship between the CoS scheduler nodes at level 1, level 2, and level 3.

maximum-hierarchy-levels *number* Set the maximum number of hierarchy levels.

- **Range:** 2 through 4
- **Default:** 3

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Configure Multinode High Availability options on SRX Series Firewalls.

Options

grid-id Grid identifier number.

- **Range**:1 through 15

hardware-upgrade Enable hardware upgrade state.

"local-domain-id" on page 10358 Local domain identifier for four-Node multinode high availability setup.

"local-id" on page 10367 Define local node identifier.

"peer-id" on page 12880	Define peer node related information.
"peer-domain-id" on page 12870	Peer domain identifier for 4-Node multinode high availability setup.
"services-redundancy-group" on page 17407	Define the services redundancy group details.
"software-upgrade" on page 29184	Enable software upgrade mode.
"traceoptions" on page 30705	Define high availability traceoptions.

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

high-availability-options (Aggregated Multiservices)

IN THIS SECTION

- Syntax | 8439
- Hierarchy Level | 8439

- Description | 8439
- Required Privilege Level | 8440
- Release Information | 8440

Syntax

```
high-availability-options {
    (many-to-one | one-to-one) {
        preferred-backup preferred-backup;
    }
}
```

Hierarchy Level

```
[edit interfaces interface-name load-balancing-options]
```

Description

Configure the high availability options for the aggregated multiservices (AMS) interface. For service applications, if only the load-balancing feature is being used, then this configuration is optional.

For many-to-one (N:1) high availability support for service applications like Network Address Translation (NAT), the preferred backup services PIC, in hot standby mode, backs up one or more (N) active services PICs.

> **NOTE**: In both cases, if one of the active services PICs goes down, then the backup replaces it as the active PIC. When the failed PIC comes back up, it becomes the new backup. This is called *floating backup*.

One-to-one (1:1) high availability support associates a single backup interface with a single active interface. 1:1 configuration is supported only on the MS-MPC and MX-SPC3. In 1:1 (stateful) configurations, synchronization causes the active and back up PICs to synchronize traffic states and data structures, preventing data loss during a failover event. Stateful synchronization is required for IPsec high availability support. For IPsec connections, AMS supports 1:1 configuration only.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

Support added in Junos OS Release 19.3R2 for Next Gen Services on MX Series routers MX240, MX480 and MX960 with the MX-SPC3 services card.

high-cos-queue-threshold

IN THIS SECTION

- Syntax | **8440**
- Hierarchy Level | **8441**
- Description | **8441**
- Options | **8441**
- Required Privilege Level | **8441**
- Release Information | **8442**

Syntax

```
high-cos-queue-threshold number;
```

Hierarchy Level

```
[edit system services resource-monitor]
```

Description

Configure the class-of-service (CoS) queue threshold by percentage.

> **NOTE**: This feature is only available when you enable subscriber management. For more information on enabling subscriber management, see *Configuring Junos OS Enhanced Subscriber Management*.

This CoS resource monitoring feature bases admission decisions only on queues. Other CoS resources are not part of this criteria. This feature does not support throttling for subscribers arriving on pseudo-wire, logical tunnel, or redundant logical tunnel devices. The feature is supported on the following hardware:

- MX240, MX480, and MX960 routers
- MPC2E legacy, MPC2E-NG, MPC3E-NG, MPC5E, and MPC7E line cards

Options

number High-threshold percentage for CoS queue utilization per scheduler. When CoS queue utilization on a given FPC reaches that FPC's configured threshold level, further subscriber logins on that FPC are not allowed. This resource monitoring mechanism provides adjustable safety margins to proactively avoid completely exhausting each FPC's available CoS queue resources. Starting in Junos OS Release 19.4R1, you can specify a value of 0, which means that no subscribers are throttled based on CoS queue throttling.

- **Range:** 0 through 90
- **Default:** 100

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

- Required Privilege Level | 8444
- Release Information | 8444

Syntax

```
high-power;
```

Hierarchy Level

```
[edit poe interface (all | interface-name)]
```

Description

Configure a four-pair PoE port to deliver up to 60 W of power. The four-pair PoE standard allows for power to be delivered over all four pairs of wires in a standard CAT5/6 RJ-45 Ethernet cable.

When you configure the four-pair PoE port with the `high-power` option, the port provides up to 60 W of power, even if the powered device does not consume that amount of power.

Default

By default the PoE port operates in two-pair mode and provides power up to 30 W in accordance with the IEEE 802.3at PoE+ standard.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

high-threshold (Resource Monitor)

IN THIS SECTION

Syntax | 8445

- Hierarchy Level | 8445
- Description | 8445
- Options | 8445
- Required Privilege Level | 8445
- Release Information | 8446

Syntax

```
high-threshold number;
```

Hierarchy Level

```
[edit system services resource-monitor]
```

Description

Configure the high threshold value, exceeding which warnings or error logs are generated, for all the regions of memory, such as heap or ukernel, next-hop and encapsulation, and firewall filter memory. You can configure the resource-monitoring capability on MX80, MX104, MX240, MX480, MX960, MX2010, and MX2020 routers with I-chip-based DPCs and Trio-based FPCs.

Options

number High threshold percentage for memory resource utilization

- **Range:** 1 through 100

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1.

high-watermark

IN THIS SECTION

- Syntax | 8446
- Hierarchy Level | 8446

hint

IN THIS SECTION

- Syntax | 8447
- Hierarchy Level | 8448
- Description | 8448
- Default | 8448
- Options | 8448
- Required Privilege Level | 8448
- Release Information | 8448

Syntax

```
hint [ hint-strings ];
```

Hierarchy Level

```
[edit services nat pool nat-pool-name pgcp]
```

Description

Configure a hint that enables the border gateway function (BGF) to choose a NAT pool by direction rather than by virtual interface. The BGF matches the configured hint with a termination hint located in the Direction field of a nonstandard termination ID.

Default

When no hint is configured, the BGF can choose any NAT pool associated with the virtual interface.

Options

hint-string—Alphanumeric string of up to three characters that the BGF uses to match with a termination hint located in the Direction field of a nonstandard termination ID. You can also include underscores (_) and hyphens (-) within the string. To specify a list of hints, use the format: **[hint *xx* hint *yy*]**.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

history

    bucket-size number;
    interface interface-name;
    interval seconds;
    owner owner-name;
}
```

Hierarchy Level

```
[edit snmp rmon]
```

Description

Configure RMON history group entries. This RMON feature can be used with the Simple Network Management Protocol (SNMP) agent in the switch to monitor all the traffic flowing among switches on all connected LAN segments. The RMON history feature collects statistics in accordance with user-configurable parameters.

The history group controls the periodic statistical sampling of data from various types of networks. This group contains configuration entries that specify an interface, polling period, and other parameters. If you use the `history` statement, you must also configure the "interface" on page 9380 *`interface-name`* statement.

Default

Not configured.

Options

history-index—Tag the history entries with a number.

- **Range:** 1 through 655535 (integer)

Required Privilege Level

snmp—To view this statement in the configuration.
snmp-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

hold-down

IN THIS SECTION

- Syntax | 8454
- Hierarchy Level | 8454
- Description | 8454
- Options | 8454
- Required Privilege Level | 8455
- Release Information | 8455

Syntax

```
hold-down {
    seconds;
    flaps number;
    period seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options bmp],
[edit logical-systems logical-system-name routing-options bmp station station-name],
[edit routing-options bmp],
[edit routing-options bmp station station-name]
```

Description

If the connection to a BMP station flaps and the `hold-down` statement is configured, the station is prevented from reconnecting to the device for the specified period of time. A flap is when the TCP session unexpectedly switches from established to non-established. If you alter the configuration of the `hold-down` statement, the hold down timer and flap counter are reset.

You can effectively disable the `hold-down` statement by setting the `flaps` option to 10 and the `period` option to 30 seconds.

Options

seconds Specify the time in seconds to wait before allowing the BMP station to reconnect to the device.

- **Default:** 600 seconds
- **Range:** 30 through 65,535 seconds

flaps ***number*** Specify the number of BMP station flaps allowed before terminating the connection to the BMP station and triggering the hold down timer.

- **Default:** 3 flaps
- **Range:** 2 to 10 flaps

period *seconds*

Specify the time in seconds for the BGP station flaps (specified using the `flaps` option) to occur before triggering the hold down timer. Every time a flap occurs, the number of flaps in the last time period is checked to see if the criteria is met.

For example, if you defined the `period` as 60 seconds and the `flaps` as 4 and the BGP station flaps just 2 times in a 60 second period, the hold down timer would not be triggered. However, if the BGP station flaps 4 times in a 60 second period, the hold down timer would be triggered.

- **Default:** 300 seconds
- **Range:** 30 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

hold-down-interval

IN THIS SECTION

- Syntax | 8456
- Hierarchy Level | 8456
- Description | 8456
- Options | 8456
- Required Privilege Level | 8456

Release Information | 8457

Syntax

```
hold-down-interval number;
```

Hierarchy Level

```
[edit chassis cluster redundancy-group group-number]
```

Description

Set the minimum interval to be allowed between back-to-back failovers for the specified redundancy group (affects manual failovers, as well as automatic failovers associated with monitoring failures).

For redundancy group 0, this setting prevents back-to-back failovers from occurring less than 5 minutes (300 seconds) apart. Note that a redundancy group 0 failover implies a Routing Engine failure.

For some configurations, such as ones with a large number of routes or logical interfaces, the default or specified interval for redundancy group 0 might not be sufficient. In such cases, the system automatically extends the dampening time in increments of 60 seconds until the system is ready for failover.

Options

number—Number of seconds specified for the interval.

- **Range:** For redundancy group 0, 300 through 1800 seconds; for redundancy group 1 through 128, 0 through 1800 seconds.
- **Default:** For redundancy group 0, 300 seconds; for redundancy group 1 through 128, 1 second.

Required Privilege Level

interface—To view this statement in the configuration.

- Release Information | 8467

Syntax

```
hold-time up milliseconds down milliseconds;
```

Hierarchy Level

```
[edit interfaces interface-name],
[edit interfaces interface-range interface-range-name]
```

Hierarchy Level (ae- interfaces) (PTX5000, PTX1000, PTX10002, PTX10008, PTX10016, and MX Series routers)

```
[edit interfaces ae{x}]
```

Description

Specify the `hold-time` value to use to damp shorter interface transitions milliseconds. The hold timer enables interface damping by not advertising interface transitions until the hold timer duration has passed. When a hold-down timer is configured and the interface goes from up to down, the down hold-time timer is triggered. Every interface transition that occurs during the hold-time is ignored. When the timer expires and the interface state is still down, then the router begins to advertise the interface as being down. Similarly, when a hold-up timer is configured and an interface goes from down to up, the up hold-time timer is triggered. Every interface transition that occurs during the hold-time is ignored. When the timer expires and the interface state is still up, then the router begins to advertise the interface as being up.

The attribute “up” and “down” is mandatory when we configure the knob “hold-time”. Failing to configure either one, will result in a commit error.

We recommend you to configure sub-second down hold timer value as 500 milliseconds on:

- MX204 router
- MX routers with MPC7E, MPC8E, MPC9E, MPC10E, and MX10003-LC2103 MPCs

The sub-second down hold timer is not supported on the interfaces created on MX routers with MPC3E, MPC4E, MPC5E, MPC5EQ, MPC6E, and MPC11E MPCs. The sub-second hold timer is a configuration of hold timer less than a second.

Starting from Junos OS release 21.4R1, you can specify the `hold-time` value on aggregated ethernet interfaces. When you configure hold-timer for `ae-` interfaces, we recommend not to configure the hold-time for member links.

NOTE:

- We recommend that you configure the `hold-time` value after determining an appropriate value by performing repeated tests in the actual hardware environment. This is because the appropriate value for `hold-time` depends on the hardware (XFP, SFP, SR, ER, or LR) used in the networking environment.
- The `hold-time` option is not available for controller interfaces.

NOTE: On MX Series routers with MPC3E and MPC4E, we recommend that you do not configure the hold-down timer to be less than 1 second. On MX Series routers with MPC5EQ-100G10G (MPC5EQ) or MPC6E (MX2K-MPC6E) with 100-Gigabit Ethernet MIC with CFP2 OTN interfaces, we recommend that you do not configure the hold-down timer to be less than 3 seconds.

Default

Interface transitions are not damped.

Options

`down` *`milliseconds`*—Hold time to use when an interface transitions from up to down. Junos OS advertises the transition within 100 milliseconds of the time value you specify.

- **Range:** 0 through 4,294,967,295
- **Default:** 0 (interface transitions are not damped)

`up` *`milliseconds`*—Hold time to use when an interface transitions from down to up. Junos OS advertises the transition within 100 milliseconds of the time value you specify.

- **Range:** 0 through 4,294,967,295
- **Default:** 0 (interface transitions are not damped)

```

Description

Specify the hold-time value to use when negotiating a connection with the peer. The hold time is three times the interval at which keepalive messages are sent. For the default hold time of 90 seconds, the keepalive interval is 30 seconds. If a BGP speaker does not receive a keepalive, update, or notification message from its peer within the hold time, it declares the peer down. The keepalive messages are sent at regular intervals (the keepalive interval) to ensure that the connection between the BGP peers remains active.

The hold-time value is advertised in open packets and indicates to the peer the length of time that it should consider the sender valid. If the peer does not receive a keepalive, update, or notification message within the specified hold time, the BGP connection to the peer is closed and routing devices through that peer become unavailable.

The hold time is three times the interval at which keepalive messages are sent.

BGP on the local routing device uses the smaller of either the local hold-time value or the peer's hold-time value received in the open message as the hold time for the BGP connection between the two peers.

Starting in Junos OS Release 12.3, the BGP hold-time value can be zero (0). This implies that the speaker does not expect keepalive messages from its peer to maintain the BGP session. When negotiating between two peers, if one side requests a nonzero hold time and the other requests a zero hold time, the negotiation settles on the nonzero value and keepalive intervals are determined accordingly. Both sides must be set to zero for keepalive messages to stop being sent.

Starting in Junos OS Evolved Release 24.2R1, you can configure up to 400 BGP sessions with highly sensitive hold-times of 10 seconds or less, and up to 8000 total BGP sessions on PTX Series devices that support this feature. When configuring BGP sessions at scale, we recommend using the default hold-time value of 90 seconds for the majority of BGP sessions.

Options

seconds—Hold time.

- **Range:** 3 through 65,535 seconds (or 0 for infinite hold time)
- **Range:** 10 through 65,535 seconds for EX Series switches.
- **Default:** 90 seconds

TIP: When you set a hold-time value of 3 through 19 seconds, we recommend that you also configure the BGP `precision-timers` statement. The `precision-timers` statement ensures that if scheduler slip messages occur, the routing device continues to send keepalive

messages. When the `precision-timers` statement is included, keepalive message generation is performed in a dedicated kernel thread, which helps to prevent BGP session flaps.

Starting in Junos OS Release 17.3R1, the `precision-timers` statement is supported on QFX Series switches.

Required Privilege Level

routing—To view this statement in the configuration.

hold-time (Protocols IS-IS)

IN THIS SECTION

- Syntax | 8473
- Hierarchy Level | 8473
- Description | 8474
- Options | 8474
- Required Privilege Level | 8475
- Release Information | 8475

Syntax

```
hold-time seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols isis interface interface-name level level-number],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols isis interface interface-name level level-number],
[edit protocols isis interface interface-name level level-number],
[edit routing-instances routing-instance-name protocols isis interface interface-name level level-number]
```

Description

Set the length of time a neighbor considers this router to be operative (up) after receiving a hello packet. If the neighbor does not receive another hello packet within the specified time, it marks this routing device as inoperative (down). The hold time itself is advertised in the hello packets.

The hold time specifies how long a neighbor should consider this routing device to be operative without receiving another hello packet. If the neighbor does not receive a hello packet from this routing device within the hold time, it marks the routing device as being unavailable.

For systems configured with graceful routing switchover (GRES) with Graceful Restart, the hold time for Primary and Backup Routing Engines should be set to a value higher than 40 seconds. This ensures that adjacencies between the Routing Engine and the neighboring peer 'helper' routers do not time out, stopping graceful restart, and all traffic.

Options

seconds—Hold-time value, in seconds.

- **Range:** 3 through 65,535 seconds, or 1 to send out hello packets every 333 milliseconds
- **Default:** 9 seconds (for designated intermediate system [DIS] routers), 27 seconds (for non-DIS routers; three times the default hello interval)

NOTE: When elected as a designated intermediate system [DIS] router on any LAN adjacency, the hello and hold-timer intervals are scaled down by a factor of 3. This means the default values of 9 and 27 seconds of ISIS hello and hold time intervals are scaled down to 3 and 9 seconds for LAN adjacencies. During switchovers, this hold time is too short to form LAN adjacencies. Therefore, you can configure one of the following solutions:

- Set the hello and hold time interval for LAN adjacencies to 30 seconds and 90 seconds respectively on both the DIS router and a neighboring router.
- Convert the LAN interfaces to point-to-point IS-IS interfaces.

BEST PRACTICE: On QFX10000 switches, we strongly recommend that you configure all IS-IS interfaces, including peer interfaces, as point-to-point interfaces. If you do not, you might experience session flaps, that is, IS-IS sessions that go down and then come back up, when IS-IS is configured in virtual routing and forwarding (VRF) instances. When you scale IS-IS in any scenario, you might also experience scaling issues if you do not configure IS-IS interfaces as point-to-point interfaces.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

hold-time (Protocols LDP)

IN THIS SECTION

- Syntax | 8475
- Hierarchy Level | 8476
- Description | 8476
- Options | 8476
- Required Privilege Level | 8476
- Release Information | 8476

Syntax

```
hold-time seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp interface interface-name],
[edit logical-systems logical-system-name protocols ldp targeted-hello],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp
interface interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp
targeted-hello],
[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Description

Specify how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. You can specify times for both link hello messages and targeted hello messages depending on the hierarchy level at which you configure the `hold-time` statement.

Options

seconds—Hold-time value.

- **Range:** 1 through 65,535 seconds
- **Default:** 15 seconds for link hello messages, 45 seconds for targeted hello messages

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support for LDP targeted hellos added in Junos OS Release 9.5.

[edit routing-instances instance-name protocols msdp],
```

```
[edit routing-instances instance-name protocols msdp group group-name peer address]
[edit routing-instances instance-name protocols msdp peer address]
```

Description

Specify the hold-time period to use when maintaining a connection with the MSDP peer. If a keepalive message is not received for the hold-time period, the MSDP peer connection is terminated. According to the RFC 3618, *Multicast Source Discovery Protocol (MSDP)*, the recommended value for the hold-time period is 75 seconds.

The hold-time period must be longer than the keepalive interval.

You might want to change the hold-time period and keepalive timer for consistency in a multi-vendor environment.

Default

In Junos OS, the default hold-time period is 75 seconds, and the default keepalive interval is 60 seconds.

Options

seconds—Hold time.

- **Range:** 15 through 150 seconds
- **Default:** 75 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

hold-time (Redundant Ethernet Interfaces)

IN THIS SECTION

- Syntax | 8481
- Hierarchy Level | 8481
- Description | 8481
- Options | 8481
- Required Privilege Level | 8481
- Release Information | 8482

Syntax

```
hold-time (up | down) timer
```

Hierarchy Level

```
[edit interfaces interface-name ]
```

Description

The hold timer enables interface damping by not advertising interface transitions until the hold timer duration has passed. When a hold-down timer is configured for a parent RETH interface and the primary child interface goes from up to down, the down hold-time timer is triggered. Every interface transition that occurs during the down hold-time is ignored. When the timer expires and the primary child interface state is still down, then the router begins to advertise the parent RETH interface as being down. Similarly, when a hold-up timer is configured for a parent RETH interface and the primary child interface goes from down to up, the up hold-time timer is triggered. Every interface transition that occurs during the up hold-time is ignored. When the timer expires and the primary child interface state is still up, then the router begins to advertise the parent RETH interface as being up.

The hold timer (both up and down) improves the flexibility and resilience of SRX Series Firewalls. Specify the *timer* value in seconds to reduce unnecessary loss of traffic and downtime.

> **NOTE**: Starting in Junos OS release 18.4R1, all SRX Series Firewalls have default delay timer of 11 seconds for both up hold-time and down hold-time.

Options

`down` *seconds*—Hold time to use when an interface transitions from up to down.

`up` *seconds*—Hold time to use when an interface transitions from down to up.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.4R1.

hold-time up

IN THIS SECTION

- Syntax | 8484
- Hierarchy Level | 8484
- Description | 8484
- Options | 8485
- Required Privilege Level | 8485
- Release Information | 8485

Syntax

```
hold-time up timer-value;
```

Hierarchy Level

```
[edit interfaces aex aggregated-ether-options lacp]
```

Description

Specifies the time period for which the Link Aggregation Control Protocol (LACP) maintains the state of a child (member) link as expired or default.

When a child link goes from the current state to the expired state, the LACP monitors the reception of protocol data units (PDUs) on the child link for the configured hold-up time interval and does not allow the child link to transition back to the current state. This configuration thus prevents excessive flapping of a child link on an aggregated Ethernet interface.

The configured hold-up timer value is applicable to all the child links within a link aggregated (LAG) interface. By default, this feature is disabled.

Options

timer-value—Hold-up interval in seconds.

- **Range:** 1 to 6000 seconds

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

```

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

- **Range:** 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)
- **Default:** 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Hierarchy Level

```
[edit services l2tp tunnel-group group-name syslog]
```

Description

Specify the hostname for the system logging utility.

Options

hostname—Name of the system logging utility host machine. This can be the local Routing Engine or an external server address.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

host (Security IDP Sensor Configuration)

IN THIS SECTION

- Syntax | 8510
- Hierarchy Level | 8510
- Description | 8510
- Options | 8510
- Required Privilege Level | 8510
- Release Information | 8510

Syntax

```
host ip-address <port number>;
```

Hierarchy Level

```
[edit security idp sensor-configuration packet-log]
```

Description

Configure the IP address and port number of the server where the packet capture object will be sent.

Options

- `host` *`ip-address`*—The IP address of the server where the packet capture object will be sent.
- `port` *`number`*—The port number of the server where the packet capture object will be sent.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

host (Security Log)

IN THIS SECTION

- Syntax | 8511
- Hierarchy Level | 8511

- Description | 8511
- Options | 8511
- Required Privilege Level | 8512
- Release Information | 8512

Syntax

```
host {
    ip-address;
    port port-number;
    routing-instance instance-name;
}
```

Hierarchy Level

```
[edit security log stream stream-name]
[edit logical-systems name security log stream stream-name]
[edit tenants tenant-name security log stream stream-name]
```

Description

You can specify the IP address of the server to which the security logs are streamed.

Options

- *ip-address*—Specify IP address of the host.
- `port` *port-number*—Specify host port number.
  - **Default:** The default destination port is the system log port. For UDP or TCP, the default port is 514. For TLS, the default port is 6514.
- `routing-instance` *instance name* —Specify the routing instance name that is used to send security logs to the specified host. This configuration allows you to direct log traffic through a specific routing table.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

The [edit `logical-systems` *name* security log stream *stream-name*] hierarchy level introduced in Junos OS Release 18.2R1.

The [edit `tenants` *tenant-name* security log stream *stream-name*] hierarchy levels introduced in Junos OS Release 18.3R1.

The `routing-instance` option introduced in Junos OS Release 18.2R1 for tenant systems and Junos OS Release 18.3R1 for tenant systems.

host (Security Web Filtering)

IN THIS SECTION

- Syntax | 8513
- Hierarchy Level | 8513
- Description | 8513
- Required Privilege Level | 8513
- Release Information | 8513

Syntax

```
host host-name;
```

Hierarchy Level

```
[edit security utm default-configuration]
[edit security utm feature-profile web-filtering surf-control-integrated server]
[edit security utm feature-profile web-filtering websense-redirect profile profile-name server]
[edit security utm feature-profile web-filtering juniper-enhanced profile profile-name server]
```

Description

Set server host parameters by entering the server name or IP address.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

The Surf-Control feature is not supported from Junos OS Release 15.1X49-D10 onwards. For previous releases, statement introduced in Junos OS Release 9.5.

Statement introduced in Junos OS Release 11.4 .

The `[edit security utm default-configuration]` hierarchy level is introduced in Junos OS Release 18.2R1.

host (service-set)

IN THIS SECTION

Syntax | 8514

- Hierarchy Level | 8514
- Description | 8514
- Options | 8515
- Required Privilege Level | 8515
- Release Information | 8515

Syntax

```
host hostname {
    class {
        alg-logs;
        deterministic-nat-configuration-log;
        ids-logs;
        nat-logs;
        packet-logs;
        pcp-logurlf-logs;
        session-logs <open | close>;
        stateful-firewall-logs;
        urlf-logs;
    }
    facility-override facility-name;
    interface-service prefix-value;
    log-prefix prefix-value;
    port port-number;
    services severity-level;
    source-address source-address;
}
```

Hierarchy Level

```
[edit services service-set service-set-name syslog]
```

Description

Specify the hostname for the system logging utility.

Starting in Junos OS Release 17.4R1, you can configure up to a maximum of four system log servers (combination of local system log hosts and remote system log collectors) for each service set at the `[edit services service-set service-set-name]` hierarchy level.

> **NOTE**: Starting with Junos OS release 14.1X55, 14.2R5, 15.1R3, and 16.1R1, for multiservices (ms-) interfaces, you cannot configure system logging for PCP and ALGs by including the pcp-logs and alg-logs statements at the `[edit services service-set service-set-name syslog host hostname class]` hierarchy level. An error message is displayed if you attempt to commit a configuration that contains the pcp-logs and alg-logs options to define system logging for PCP and ALGs for ms- interfaces.

Options

hostname—Name of the system logging utility host machine.

From Junos OS Release 17.4R1, you can configure up to four system log hosts.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`class` option introduced in Junos OS Release 13.2.

You can configure multiple system log hosts from Junos OS Release 17.4R1 onwards.

    port;
    source-address source-address
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name system syslog],
[edit system syslog]
```

Description

Configure the logging of system messages to a remote destination.

Options

facility—Class of messages to log. To specify multiple classes, include multiple *facility severity* statements. For a list of the facilities, see *Junos OS System Logging Facilities*.

hostname—IPv4 address, IPv6 address, or fully qualified hostname of the remote machine to which to direct messages. To direct messages to multiple remote machines, include a `host` statement for each one.

`other-routing-engine`—Direct messages to the other Routing Engine on a router or switch with two Routing Engines installed and operational.

> **NOTE**: The `other-routing-engine` option is not applicable to the QFX Series and OCX Series.

`port`—Port number of the remote syslog server that can be modified.

`scc-master`—(TX Matrix routers only) On a T640 router that is part of a routing matrix, direct messages to the TX Matrix router.

severity—Severity of the messages that belong to the facility specified by the paired *facility* name. Messages with severities of the specified level and higher are logged. For a list of the severities, see *System Log Message Severity Levels*.

`sfc0-master`—(TX Matrix Plus routers only) On a T1600 or T4000 router that is part of a routing matrix, direct messages to the TX Matrix Plus router.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

host-address-base (Source NAT Next Gen Services)

IN THIS SECTION

- Syntax | 8519
- Hierarchy Level | 8519
- Description | 8519
- Options | 8520
- Required Privilege Level | 8520
- Release Information | 8520

Syntax

```
host-address-base ip-address;
```

Hierarchy Level

```
[edit services nat source pool nat-pool-name]
```

Description

Configure static mapping of the source address.

For static NAT that is performed on the services card, configure a one-to-one static shifting of a range of original source addresses to the range of addresses in the source pool by specifying the base address of the original source address range.

For example, if the host address base is 198.51.100.30 and the NAT pool uses the range 203.0.113.10 to 203.0.113.20, then 198.51.100.30 translates to 203.0.113.10, 198.51.100.31 translates to 203.0.113.11, and so on.

Options

host-address-base *ip-address*	The IP address used as the host address base.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.3R2.

host-address-base

host-name (DHCP Relay Agent)

IN THIS SECTION

- Syntax | 8524
- Hierarchy Level | 8525
- Description | 8525
- Required Privilege Level | 8525
- Release Information | 8525

Syntax

```
host-name name;
```

Hierarchy Level

```
[edit forwarding-options dhcp-relay relay-option-82],
[edit forwarding-options dhcp-relay group group-name relay-option-82]
```

Description

Supports the addition of vendor-specific hostname in the option 82, suboption 9 field of DHCPv4 control messages on server-facing interfaces. The hostname can be a string of characters such as **Juniper-AB-1**.

Junos OS automatically adds the remaining vendor-specific information as per RFC 4243, *Vendor-Specific Information Suboption for the Dynamic Host Configuration Protocol (DHCP) Relay Agent Option*. The Juniper Networks enterprise ID is 2636. The hostname is option-data 1 (the location is option-data 2). The DHCPv4 relay strips the suboption data from replies from the server before it relays the packets out the client facing interface.

This feature can be useful, in conjunction with operator-developed tools, for troubleshooting DHCP servers and providing service assurances. For example, a central DHCP server can log the information, and operators can query the hostname to track and troubleshoot subscriber IP information and network attachment points.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Command introduced in Junos OS Release 16.2.

host-name (DHCPv6 Relay Agent)

IN THIS SECTION

Syntax | 8526

- Hierarchy Level | 8526
- Description | 8526
- Required Privilege Level | 8526
- Release Information | 8527

Syntax

```
host-name name;
```

Hierarchy Level

```
[edit forwarding-options dhcp-relay dhcpv6 relay-option-vendor-specific],
[edit forwarding-options dhcp-relaygroup group-name dhcpv6 relay-option-vendor-specific]
```

Description

Supports the addition of vendor-specific hostname in the vendor-specific option (17) of DHCPv6 control messages on server-facing interfaces. The hostname can be a string of characters such as **Juniper-AB-1**.

Junos automatically adds the remaining vendor-specific information as per RFC 4243, *Vendor-Specific Information Suboption for the Dynamic Host Configuration Protocol (DHCP) Relay Agent Option*. The Juniper Networks enterprise ID is 2636. The hostname is option-data 1 (the location is option-data 2). The DHCPv6 relay strips the suboption data from replies from the server before it relays the packets out the client facing interface.

This feature can be useful, in conjunction with operator-developed tools, for troubleshooting DHCP servers and providing service assurances. For example, a central DHCP server can log the information, and operators can query the hostname to track and troubleshoot subscriber IP information and network attachment points.

host-name (System)

IN THIS SECTION

- Syntax | 8527
- Hierarchy Level | 8527
- Description | 8527
- Options | 8528
- Required Privilege Level | 8528
- Release Information | 8528

Syntax

```
host-name hostname;
```

Hierarchy Level

```
[edit system]
```

Description

Set the hostname of the router or switch.

On Junos OS Evolved, when you specify the `host-name` statement, the Routing Engine name where the configuration is committed is appended to the hostname you specify. For example, on Routing Engine 0, `set system host-name my-host` sets the hostname to `my-host-re0`. You can also use the `%s` character to designate where to substitute the Routing Engine name. For example, on Routing Engine 1, `set system host-name %s_my_host` sets the hostname to `re1_my-host`.

Options

hostname	Name of the router or switch.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

- Syntax | 8534
- Hierarchy Level | 8535
- Description | 8535
- Options | 8535
- Required Privilege Level | 8535
- Release Information | 8535

Syntax

```
host-outbound-traffic {
    forwarding-class class-name;
    dscp-code-point code-point;
}
```

Hierarchy Level

```
[edit class-of-service]
```

Description

Allow queue selection for traffic generated by the Routing Engine (host). The selected queue must be configured properly. You can also configure specific DSCP code point bits for the type of service (ToS) field of the generated packets. This configuration does not affect transit packets or incoming packets. This is a global configuration that only affects packets originating on the Routing Engine. If you do not configure an output queue for host outbound traffic, the switch uses the default queue mapping.

Options

`forwarding-class` *`class-name`*—Set the forwarding class name for outbound host traffic (traffic generated by the Routing Engine).

`dscp-code-point` *`code-point`*—Set the six-bit DSCP code point value in the type of service (ToS) field of the packet generated by the Routing Engine (host).

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.3.

```

Description

(MPC5 and MPC6 cards) Improve datapath performance by allowing only DHCPv4 subscribers that negotiate a 32-bit prefix to come up on the underlying VLAN interface. All DHCP subscribers on the underlying interface must negotiate a 32-bit prefix. Subscribers that negotiate a subnet prefix are not brought up. You can configure this statement for static or dynamic subscribers.

NOTE: You must add or remove this statement before subscribers become active. The configuration fails if you attempt to configure the statement while subscribers are active.

NOTE: You must also configure `demux-source inet` for the logical interface. Only `inet` is supported. A commit error occurs if you specify `demux-source inet6` or `demux-source [inet inet6]`.

hostkey-algorithm

IN THIS SECTION

- Syntax (Prior to Junos OS Release 22.3R1) | 8546
- Syntax (Starting in Junos OS Release 22.3R1) | 8546
- Hierarchy Level | 8546
- Description | 8547
- Options | 8547
- Required Privilege Level | 8548
- Release Information | 8548

Syntax (Prior to Junos OS Release 22.3R1)

```
hostkey-algorithm {
    (no-ssh-dss | ssh-dss);
    (no-ssh-rsa | ssh-rsa);
    (no-ssh-ecdsa | ssh-ecdsa);
    (no-ssh-ed25519 | ssh-ed25519);
}
```

Syntax (Starting in Junos OS Release 22.3R1)

```
hostkey-algorithm-list (ecdsa-sha2-nistp256 | ecdsa-sha2-nistp384 | ecdsa-sha2-nistp521 |
ed25519 | rsa)
```

Hierarchy Level

```
[edit system services ssh]
```

Description

Allow or disallow a host-key algorithm to authenticate another host through the SSH protocol. The host-key uses RSA, ECDSA, ED25519, and DSS algorithms.

The following are the behaviors when the `hostkey-algorithm` option is configured with SSH client and SSH server:

- On the SSH client, the host-key algorithms that are supported when talking to a server are:
  1. RSA: Equal or greater-than to 1024 bit
  2. ECDSA: 256, 384, or 521 bit
  3. ED25519: 256 bit
  4. DSS: 1024 bit
- On the SSH server, the host-key algorithms that are generated and stored are:
  1. RSA: 2048 bit
  2. ECDSA: 256 bit (Prior to Junos OS Release 22.3R1).

     ECDSA: 256, 384, or 521 bit (Starting in Junos OS Release 22.3R1).
  3. ED25519: 256 bit
  4. DSS: 1024 bit

Starting in Junos OS Release 22.3R1, we've introduced the `hostkey-algorithm-list` statement at the [`edit system services ssh`] hierarchy level. This enhancement enables you to configure only the specified SSH hostkey algorithms. The system automatically disables the remaining unspecified hostkey algorithms. In earlier releases, you need to disable the hostkey algorithms explicitly. All the hostkey algorithms at this hierarchy enabled by default. The DSS algorithm is no longer available at this new hierarchy. In addition, we've deprecated the `hostkey-algorithm` statement at the [`edit system services ssh`] hierarchy level.

Starting in Junos OS Release 24.2R1, the `hostkey-algorithm` statement at the [`edit system services ssh`] hierarchy level is removed and can no longer be used.

Options

ecdsa-sha2-nistp256	Allow generation of ECDSA host-key with NIST P-256 curve.
ecdsa-sha2-nistp384	Allow generation of ECDSA host-key with NIST P-384 curve.

ecdsa-sha2-nistp521 Allow generation of ECDSA host-key with NIST P-521 curve

ed25519 Allow generation of EdDSA host-key with curve25519.

rsa Allow generation of 2048-bit RSA host-key

ssh-ecdsa Allow generation of an ECDSA host-key. Key pair sizes of 256, 384, or 521 bits are compatible with ECDSA.

ssh-dss Allow generation of a 1024-bit DSA host-key.

> **NOTE**: DSA keys are not supported in FIPS, so the `ssh-dss` option is not available on systems operating in FIPS mode.

ssh-rsa Allow generation of RSA host-key. Key pair sizes greater than or equal to 1024 are compatible with RSA.

no-ssh-dss Do not allow generation of a 1024-bit Digital Signature Algorithm (DSA) host-key.

no-ssh-ecdsa Do not allow generation of an Elliptic Curve Digital Signature Algorithm (ECDSA) host-key.

no-ssh-rsa Do not allow generation of an RSA host-key.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

`hostkey-algorithm-list` option added in Junos OS Release 22.3R1.

`hostkey-algorithm` option removed in Junos OS Release 24.2R1.

hot-root-standby (MBGP MVPN)

IN THIS SECTION

- Syntax | 8551
- Hierarchy Level | 8551
- Description | 8551
- Required Privilege Level | 8552
- Release Information | 8553

Syntax

```
hot-root-standby {
    min-rate <rate>;
    source-tree;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
mvpn],
[edit routing-instances routing-instance-name protocols mvpn]
```

Description

In a BGP multicast VPN (MVPN) with either RSVP-TE point-to-multipoint or MLDP point-to-multipoint provider tunnels, configure hot-root standby, as defined in *Multicast VPN fast upstream failover*, draft-morin-l3vpn-mvpn-fast-failover-05.

Starting in Junos OS Release 21.1R1, you can configure MLDP point-to-multipoint provider tunnel on MX Series router.

Hot-root standby enables an egress PE router to select two upstream PE routers for an (S,G) and send C-multicast joins to both the PE routers. Multiple ingress PE routers then receive traffic from the source

and forward into the core. The egress PE router uses sender-based RPF to forward the one stream received by the primary upstream PE router.

When `hot-root-standby` is configured, based on local policy, as soon as the PE router receives this standby BGP customer multicast route, the PE can install the VRF PIM state corresponding to this BGP source-tree join route. The result is that join messages are sent to the CE device toward the customer source (C-S0, and the PE router receives (C-S,C-G) traffic. Also, based on local policy, as soon as the PE router receives this standby BGP customer multicast route, the PE router can forward (C-S, C-G) traffic to other PE routers through a P-tunnel independently of the reachability of the C-S through some other PE router.

The receivers must join the source tree (SPT) to establish a hot-root standby. Customer multicast join messages continue to be sent to a single upstream provider edge (PE) router for shared-tree state, and duplicate data does not flow through the core in this case.

In case there are more than two PE routers multihomed to the source, backup UMH selection is based on the same algorithm used to select the primary UMH.

There is no limitation in Junos OS on which upstream multicast hop (UMH) selection method is used. For example, you can use `static-umh (MBGP MVPN)` or `unicast-umh-election` .

PIM dense mode as the customer multicast protocol is not supported.

Hot-root standby is supported for RSVP point-to-multipoint and mLDP point-to-multipoint provider tunnels. Other provider tunnels are not supported. A commit error results if `hot-root-standby` is configured and the provider-tunnel is not either RSVP point-to-multipoint or mLDP point-to-multipoint.

Fast failover (sub 50ms) is supported for C-multicast streams within NG-MVPNs in a hot-standby mode. The threshold to trigger fast failover must be set. See "min-rate" on page 11165 for information on fast failover.

When you configure `hot-root-standby` on MPC10 or MPC11 linecards, the failover process takes up to 150 milliseconds.

Cold-root standby and warm-root standby, as specified in draft Morin, are not supported.

The backup attribute is not sent in the customer multicast routes, as this is only needed for warm and cold-root standby.

Internet multicast is not supported with hot-root standby.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

Support for MLDP point-to-multipoint provider tunnel is introduced in Junos OS Release 21.1R1 for MX Series router.

neighbor address backup-neighbor address],
[edit protocols l2circuit neighbor address interface interface-name backup-neighbor address],
[edit routing-instances routing-instance-name protocols vpls neighbor address backup-neighbor
address]
```

Description

Configure the pseudowire to the specified backup neighbor as the hot-standby. When you configure this statement, traffic flows over both the active and hot-standby pseudowires to the backup device (either a CE device or PE router). The backup device drops the traffic from the hot-standby pseudowire, unless the active pseudowire fails. If the active pseudowire fails, the backup device automatically switches to the hot-standby pseudowire.

Configure the `hot-standby` statement on routers that have both active and standby virtual circuits. Generally, these are access routers. On provider edge routers, configure the `hot-standby-vc-on`' statement to indicate that a hot-standby pseudowire is desired upon arrival of a PW_FWD_STDBY status-TLV.

address pseudowire-status-tlv]
```

Description

On provider edge (PE) aggregation routers, configure the `hot-standby-vc-on` statement to indicate that a hot-standby pseudowire is desired upon arrival of a PW_FWD_STDBY status-tlv. This flag indicates the standby state. Configure in conjunction with the `hot-standby` statement on routers that have both active and standby virtual circuits. Generally, these are access routers.

The goal of the `hot-standby` statement is to reduce the amount of traffic being discarded during primary-to-backup transition periods. This statement enables the possibility of keeping both the active and standby paths open within the Layer 2 domain. By having both the active and standby VCs able to send and receive traffic, traffic loops could potentially occur within the Layer 2 domain. In consequence, Layer 2 VCs are kept open only in the PE-to-access direction. In other words, aggregation PE devices can send traffic toward access devices, but access devices send traffic exclusively through the active VC.

In this regard, the `hot-standby` statement is quite similar to the `standby` statement. The `hot-standby` statement allows for a faster forwarding-path switchover during transition periods, as compared to what is allowed by the `standby` statement.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2.

Support for VPLS routing instances added in Junos OS Release 15.1R2.

http (Web API)

IN THIS SECTION

- Syntax | 8565
- Hierarchy Level | 8565
- Description | 8565
- Options | 8566
- Required Privilege Level | 8566
- Release Information | 8566

Syntax

```
http {
    port port;
}
```

Hierarchy Level

```
[edit system services webapi]
```

Description

Specify HTTP as the communication protocol for the Web API function of the SRX Series integrated ClearPass authentication and enforcement feature.

The SRX Series Firewall exposes to the ClearPass Policy Manager (CPPM) the Web API for it to use to initiate a connection and then use that connection to send to the SRX Series Firewall user authentication and identity information.

This statement also specifies the port number to use for the HTTP connection. The port number is optional.

If you deploy HTTP along with a Web management application, you must ensure that they run on different service ports.

Options

port Port for HTTP to use for the Web API function.

- **Default:** 8080
- **Range:** 1 through 65535

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3X48-D30.

http (Web Management)

IN THIS SECTION

- Syntax | 8567
- Hierarchy Level | 8567
- Description | 8567
- Options | 8567
- Required Privilege Level | 8567
- Release Information | 8567

Syntax

```
http {
    interface [ interface-names ];
    port port;
}
```

Hierarchy Level

```
[edit system services web-management]
```

Description

Configure the port and interfaces for the HTTP service, which is unencrypted.

Options

interface [*interface-names*] Specify the name of one or more interfaces on which to accept access through the HTTP service. By default, HTTP access is allowed through built-in Fast Ethernet or Gigabit Ethernet interfaces only.

port *port-number* Configure the TCP port number on which to connect the HTTP service.

- **Range:** 1 through 65,535

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 8.5 for SRX Series.

vSRX Virtual Firewall 3.0 on Hyper-V does not support the web management https configuration.

http-log-multiple-transactions (LRF Profile)

IN THIS SECTION

- Syntax | 8568
- Hierarchy Level | 8568
- Description | 8568
- Required Privilege Level | 8569
- Release Information | 8569

Syntax

```
http-log-multiple-transactions;
```

Hierarchy Level

```
[edit services lrf profile profile-name]
```

Description

Configure HTTP transaction logging to generate and send HTTP metadata for each transaction of a data session. This option is only relevant if the template specified in an LRF rule includes `http` in the `template-type`.

By default, HTTP transaction logging is disabled, and the HTTP transaction records for a TCP session are sent together as one group of records.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Support for Next Gen Services introduced in Junos OS Release 19.3R1 on MX Series.

http-persist

IN THIS SECTION

- Syntax | 8569
- Hierarchy Level | 8570
- Description | 8570
- Required Privilege Level | 8570
- Release Information | 8570

Syntax

```
http-persist;
```

Hierarchy Level

```
[edit security utm default-configuration web-filtering]
[edit security utm feature-profile web-filtering]
```

Description

Checks all HTTP requests in a connection. By default, Web filtering first checks the HTTP request method (for example, GET or PUT) in the same session. If there are multiple HTTP request methods in the subsequent HTTP request of the same session, then Web filtering checks are not performed on these methods. If `http-persist` command is enabled for clear text HTTP traffic, then Web filtering checks every HTTP request packet in the same session.

Required Privilege Level

Web Filtering Overview

http-reassemble

IN THIS SECTION

- Syntax | 8574
- Hierarchy Level | 8575
- Description | 8575
- Required Privilege Level | 8575
- Release Information | 8575

Syntax

```
http-reassemble;
```

Hierarchy Level

```
[edit security utm default-configuration web-filtering]
[edit security utm feature-profile web-filtering]
```

Description

Reassembles HTTP requests segments. When the `http-reassemble` option is enabled the requested fragment is reassembled. By default, Web filtering checks only HTTP requests in the first HTTP request packet. If HTTP request methods and URLs are fragmented in different packets, then these URLs are not checked. If `http-reassemble` option is enabled for clear text HTTP traffic, then Enhanced Web Filtering (EWF) reassembles the fragmented HTTP request to avoid evasion instead of packet-based inspection.

When a new URL is matched against the active Web Filtering profile and the profile dictates that the URL should be dropped, the entire HTTP session will be blocked by the device.

Required Privilege Level

view

https (Web API)

IN THIS SECTION

- Syntax | 8577
- Hierarchy Level | 8577
- Description | 8578
- Options | 8579
- Required Privilege Level | 8579
- Release Information | 8579

Syntax

```
https {
    certificate certificate;
    certificate-key certificate-key;
    default-certificate;
    pki-local-certificate pki-local-certificate;
    port port;
}
```

Hierarchy Level

```
[edit system services webapi]
```

Description

Specify HTTPS as the communication protocol for the Web API function of the SRX Series integrated ClearPass authentication and enforcement feature. When you configure HTTPS, you specify the service certificate and certificate key. You can also specify the port to be used.

The Web API process, acting as an HTTPS server, allows the ClearPass Policy Manager (CPPM), acting as the client, to send POST request messages to HTTPS server. The CPPM, which is the authentication source for this feature, sends to the SRX Series Firewall user authentication and identity information.

If you deploy HTTPS with a Web management application, ensure that they run on different service ports.

certificate- Configures a custom certificate to be used for the Integrated ClearPass Authentication and Enforcement feature Web API (webapi) configuration when the HTTPS protocol is configured.

When you configure the Web API (webapi) function to use HTTPS, you can use the default certificate, a custom one, or a certificate generated by the PKI local store.

If you configure a custom certificate, you must configure a certificate key with it. Here is an example of how to configure a certificate and certificate key:

```
set system services webapi https certificate /var/tmp/certificate.crt
set system services webapi https certificate-key /var/tmp/certificate.key
```

The Web API supports only the Privacy-Enhanced Mail (PEM) format for the custom certificate and certificate key.

certificate-key- Configures the filename of the certificate key to use with the specified custom certificate for the Web API (webapi) HTTPS configuration. A certificate key is required if a custom certificate file is used.

The Integrated ClearPass Authentication and Enforcement feature Web API supports only the PEM format for the custom certificate and certificate key.

default-certificate- Specify that the default certificate is to be used for the integrated ClearPass authentication and enforcement Web API process (webapi) HTTPS configuration. To ensure security, the Junos OS default certificate key size is 2084 bits.

pki-local-certificate- Configure the Web API process to use the local X.509 PKI certificate for HTTPS when HTTPS is specified as the communication protocol. The SRX Series integrated ClearPass authentication and enforcement feature exposes the Web API to the ClearPass Policy Mananger (CPPM) to allow the CPPM to initiate a connection to the SRX Series Firewall. For this feature, ClearPass acts as the authentication source. The CPPM uses the HTTPS connection to send user authentication and identity information to the SRX Series Firewall.

port- Specify the SRX Series Firewall TCP port to use for incoming HTTP or HTTPS connection requests initiated by the ClearPass Policy Manager (CPPM). The SRX Series Firewall integrated ClearPass authentication and enforcement feature exposes its Web API (webapi) to the CPPM. The CPPM uses the Web API to establish a connection to the SRX Series Firewall and send user authentication and identity information to it.

Options

`certificate`	Configures the Web API process to use the specified, custom certificate file.
`certificate-key`	Configures the Web API process service certificate key. This parameter is required if a custom service certificate file is configured.
`default-certificate`	Configures the Web API process (webapi) to use the default HTTPS certificate.
`pki-local-certificate`	Configures the Web API process to use the local X.509 PKI certificate.
`port`	Configures the HTTPS service port. • **Range:** For port number, 1 through 65,535. • **Default:** For port, 8443.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

- Description | 8580
- Options | 8580
- Required Privilege Level | 8581
- Release Information | 8581

Syntax

```
https {
    interface [ interface-names ];
    ( local-certificate name | pki-local-certificate name | system-generated-certificate );
    port port;
    virtual-domain virtual-domain-name {
        pki-local-certificate pki-local-certificate-name;;
}
}
```

Hierarchy Level

```
[edit system services web-management]
```

Description

Configure the secure version of the HTTP service, HTTPS, which is encrypted.

Options

interface [*interface-names*]

Specify the name of one or more interfaces on which to accept access through the HTTPS service. By default, HTTPS access is allowed through any ingress interface, but HTTP access is allowed through built-in Fast Ethernet or Gigabit Ethernet interfaces only.

(local-certificate *name* | pki-local-certificate *name* |

Specify the X.509 certificate type for a Secure Sockets Layer (SSL) connection.

system-generated-certificate)

- **Values:** Specify one of the following:
  - local-certificate *name*—Specify the name of the X.509 certificate. You configure the local certificate at the `[edit security certificates local]` hierarchy level.
  - pki-local-certificate *name*—(EX, QFX, and SRX Series only) Specify the name of the X.509 certificate that is generated by the public key infrastructure (PKI) and authenticated by a certificate authority (CA).
  - system-generated-certificate—(EX, QFX, and SRX Series only) Automatically generate a self-signed X.509 certificate for enabling the HTTPS service.

port *port-number*

Configure the TCP port number on which to connect the HTTPS service.

- **Range:** 1 through 65,535

virtual-domain [*virtual-domain-name*]

Specify the virtual-domain name for certificate mapping. Name of the virtual-domain in FQDN format (*host.example.com*).

- Alphabets, numerical, dashes, dot, and underscores are allowed but not exceed 249 characters.
- Only DNS or Server hostnames are supported as virtual domain names but not IP addresses.
- Duplicate entries are not allowed.
- Maximum number of allowed virtual domains is 50.

pki-local-certificate [*pki-local-certificate-name*]

Specify the name of the X.509 certificate that is generated to use from the PKI local store for certificate mapping.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`pki-local-certificate` introduced in Junos OS Release 9.1 for SRX Series.

`system-generated-certificate` introduced in Junos OS Release 11.1 for EX Series.

Statement introduced on the SRX5400, SRX5600, and SRX5800 devices starting from Junos OS Release 12.1X44-D10 and on vSRX Virtual Firewall, SRX300, SRX320, SRX340, SRX345, SRX380, SRX550M, and SRX1500 Services Gateways starting from Junos OS Release 15.1X49-D40.

`virtual-domain` statement is introduced in Junos OS Release 23.1R1

hw-db-profile

IN THIS SECTION

- Syntax | 8585
- Syntax (ACX7024) | 8585
- Hierarchy Level | 8586
- Description | 8586
- Options | 8586
- Usage scenarios for modular database (MDB) profile | 8587
- Upgrade and Downgrade Scenarios | 8588
- Release Information | 8589

Syntax

```
hw-db-profile
     {
          (lean-edge | bng | carrier-ethernet | cloud-metro);
      }
```

Syntax (ACX7024)

```
hw-db-profile
     {
          (lean-edge | cloud-metro);
      }
```

Hierarchy Level

```
[edit system packet-forwarding-options]
```

Description

Use this configuration to configure various database profiles to allocate tables with different sizes in the hardware. PFE restarts automatically once you change the configuration and commit. Profiles under this configuration support the below databases:

- Large Exact Match (LEM)—This table stores Mac table entries, LSR entries, and IPv4 host entries
- Longest Prefix Match (LPM)—This table stores IPv4 and IPv6 route entries

Options

lean-edge Configures lean-edge profile for Border Network Gateways (BNGs).

bng Selects BNG DB profile and restarts PFE

carrier-ethernet Selects carrier Ethernet high scale MAC DB profile and restarts PFE. Allocation for LPM is less and LEM is more in carrier-ethernet profile.

cloud-metro Selects Cloud-Metro DB profile, restarts PFE

Default profile lean-edge.

Please find the change in profile naming and default as follows:

New MDB Profile	Corresponding old profile
lean-edge (default)	l3-xl
cloud-metro	balanced (default)
carrier-ethernet	l2-xl
bng	balanced-exem

NOTE: For features such as EVPN-VXLAN, if there is a requirement for a higher Layer 2 MAC scale, then it is recommended to migrate to “cloud-metro” profile.

ACX7024 devices support lean-edge and cloud-metro options only.

NOTE: ACX7100-32C, ACX7100-48L, and ACX7509 support FIB compression by default. ACX7024 platform does not support FIB compression.

NOTE: In ACX series routes on Junos OS Evolved, only BNG profile supports multiple groups for VRRP-VPLS.

Usage scenarios for modular database (MDB) profile

Below are the recommended steps to retain an MDB profile which corresponds to the older MDB profile.

Example 1:

To retain the existing default old profile: “balanced” after upgrading to the new software image:

- After the image upgrade to the new software the new default MDB profile is changed to “lean-edge” which corresponds to the old profile l3-xl.
  - Explicitly configure the “cloud-metro” MDB profile by executing the below command:
  - ```
    user@root# set system packet-forwarding-options hw-db-profile cloud-metro
    ```

Example 2: To retain the corresponding MDB profile after upgrading to the newer software:

- The older configured MDB profile, if configured on any network device, is considered and after the upgrade, the corresponding new MDB profile gets activated.
  - If you have configured old profile "balanced-exem", after the upgrade, the corresponding new MDB profile, “bng” is activated.
    ```

- It is recommended that the user explicitly configures the new MDB profile and deletes the older configuration. Use the following commands:

```
user@root# set system packet-forwarding-options hw-db-profile bng
```

```
user@root# delete system packet-forwarding-options hw-db-profile balanced-exem
```

Upgrade and Downgrade Scenarios

The below table summarises the expected behaviour during the upgrade and downgrade scenarios with Junos Evolved release 23.4R1.

Scenario	Behaviour
Upgrade to new software when there are no explicit MDB profile configurations present then the default profile is used.	The upgrade will be successful. Default profile will be configured to "lean-edge".
Upgrade to new software when there are existing profile configurations.	MDB profiles are mapped internally with the corresponding new profile.
Downgrade/ rollback to older image from new image if new CLI is present	Downgrade to the older image displays error if new commands are present and upgrade is not completed. In order to successfully downgrade to older version, the new MDB configurations must be removed. If there are no explicit new MDB profile configurations, downgrade to older software is successful. The system runs with the old default profile: "balanced" .
LPM distribution configuration	If lpm-distribution option was configured in the older version software using `set system packet-forwarding-options hw-db-profile lpm-distribution (1|2|3|4|200)` command, upgrade to new software is successful, but LPM distribution configuration is not applied.

Release Information

Statement introduced in Junos OS Evolved Release 23.4R1 for ACX7024, ACX7024X, ACX7100-32C, ACX7100-48L, ACX7348, and ACX7509 routers.

hw-profile

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Evolved Release 25.3R1 for ACX7100-32C, ACX7100-48L, ACX7332, ACX7348, ACX7509, ACX7024, and ACX7024X

hw-profiles

IN THIS SECTION

- Syntax | 8591
- Hierarchy Level | 8591
- Description | 8591
- Options | 8591
- Required Privilege Level | 8592
- Release Information | 8592

Syntax

```
system {
packet-forwarding-options {
    custom-profiles {
        hw-profiles <hw-profile-name> {
            counter-profile <counter-profile>
        }
     }
   }
}
```

Hierarchy Level

```
[edit system packet-forwarding-option custom-profiles hw-profiles hw-profile-name]
```

Description

A custom hardware profile is a grouping of multiple custom profiles. You can create tailored custom hardware profiles based on application needs. This approach allows dynamic allocation of resources rather than allocating resources statically. For example, you can create a custom counter profile and then group them under a custom hardware profile. If required, you can create multiple custom hardware profiles. Then you select one of the custom hardware profiles as the active custom hardware profile by using the below configuration statement:

`set system packet-forwarding-options hw-profile <hw-profile-name>`

NOTE: Activation triggers commit validation and PFE restart

Options

- counter-profile <*counter-profile*> — Specify the name of the custom counter profile if you want to include it in this custom hardware profile.

Required Privilege Level

- Required Privilege Level | 8594
- Release Information | 8595

Syntax

```
(hyper-mode | no-hyper-mode);
```

Hierarchy Level

```
[edit forwarding-options]
```

Description

Configure the hyper mode feature to increase the rate at which a data packet is processed. This configuration results in the optimization of the lifetime of a data packet, which further enables the network device (a router or a switch) to provide better performance and throughput. This feature is supported on enhanced MPCs such as MPC3E, MPC4E, MPC5E, and MPC6E.

Configure the `no-hyper-mode` statement when you want to turn off hyper mode and have the device operate in normal mode.

> **NOTE**: The hyper mode feature is configured at the global level and requires a system reboot to turn it on or off. You can enable the feature only if the network-service mode on the device is configured as either `enhanced-ip` or `enhanced-ethernet`.

Understanding the Hyper Mode Feature on Enhanced MPCs for MX Series Routers and EX9200 Switches contains a list of features that are not supported in hyper mode.

Release Information

Statement introduced in Junos OS Release 13.3R4.

RELATED DOCUMENTATION

Configuring Hyper Mode on Enhanced MPCs to Speed Up Packet Processing

Understanding the Hyper Mode Feature on Enhanced MPCs for MX Series Routers and EX9200 Switches

show forwarding-options hyper-mode | **21011**

[edit logical-systems logical-system-name services],
[edit tenants tenants_name services]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure the ICAP redirection service.

The SRX Series Firewall acts as an SSL proxy, decrypts HTTP or HTTPS traffic, and redirects the HTTP message to a third-party, on-premise DLP server through the Internet Content Adaptation Protocol (ICAP) channel. To enable ICAP redirection service, you must configure an ICAP redirect profile.

The ICAP server profile allows the ICAP server to process request messages, response messages, fallback options, and so on, to the permitted traffic. This profile is applied as an application service in the security policy.

Starting in Junos OS Release 20.1R1, you can enable ICAP redirect service at the tenant system level, and you can view/clear the ICAP redirect services status and statistics at the tenant systems level. The ICAP service redirect configuration for tenant system is implemented under profile and the ICAP redirect profile capacity is 64 globally. All tenant systems need to share this profile capacity. If 64 tenant systems used the maximum tenants profile capacity, the remaining tenant systems will not be not able to configure the ICAP redirect profile. Tenant systems can reserve the required or the maximum ICAP redirect profile capacity in their security-profiles using the following CLI commands respectively:

- `edit system security-profile security-profile-name icap-redirect-profile reserved quota`
- `edit system security-profile security-profile-name icap-redirect-profile maximum quota`

In addition, we’ve introduced the `X-Client-IP`, `X-Server-IP`, `X-Authenticated-User`, and `X-Authenticated-Groups` header extensions in an ICAP message to provide information about the source of the encapsulated HTTP message.

Options

The statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.1 R1.

Support at the `[edit logical-system logical-system-name services]` hierarchy level introduced in Junos OS Release 18.3R1.

Support at the `[edit tenants tenants_name services]` hierarchy level introduced in Junos OS Release 20.1R1.

        liveness-detection;
    }
}
```

Hierarchy Level

```
[edit protocols iccp]
[edit logical-systems logical-system-name protocols iccp]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure Interchassis Control Protocol (ICCP) between the multichassis link aggregation group (MC-LAG) peers. ICCP replicates forwarding information, validates configurations, and propagates the operational state of the MC-LAG members.

Default

If you do not include this statement, no ICCP protocol tracing operations are performed.

Options

`traceoptions`—Set Interchassis Control Protocol (ICCP) tracing options.

`local-ip-address`—Specify the source address where the ICCP packet is routed.

`session-establishment-hold-time`—Specify if the chassis takes over as the primary at the ICCP session.

`authentication-key` —Specify TCP Message Digest 5 (MD5) option for an ICCP TCP session.

`peer ip-address`—Specify the IP address of the peer that hosts an MC-LAG. You must configure ICCP for both peers that host the MC-LAG.

`redundancy-group-id-list`—Specify the redundancy groups between two ICCP peers. The value you assign to this option must match the value you assign to the `redundancy-group-id` option that you configure on the MC-AE interface. If the value differs, when you commit the changes, the system reports a commit check error.

`liveness-detection`—Specify Bidirectional Forwarding Detection (BFD) protocol options.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.0.

Support for logical systems introduced in Junos OS Release 14.1.

icl-down-delay

IN THIS SECTION

- Syntax | 8624
- Hierarchy Level | 8624
- Release Information | 8624
- Description | 8624
- Options | 8625
- Required Privilege Level | 8625

Syntax

```
icl-down-delay seconds;
```

Hierarchy Level

```
[edit interfaces name multi-chassis-protection IP address of MC-LAG peer]
```

```
[edit multi-chassis multi-chassis-protection IP address of MC-LAG peer]
```

Release Information

Statement introduced in Junos OS Release 19.4R3.

Description

The number of seconds that elapse between when the interchassis link (ICL) goes down and the multichassis aggregated Ethernet interfaces (MCAEs) change to standby mode. Configuring the icl-

down-delay time results in better convergence during a MC-LAG peer reboot when the status control of the peer is active.

Options

`icl-down-delay` *seconds*—The number of seconds that elapse between when the interchassis link (ICL) goes down and the multichassis aggregated Ethernet interfaces (MCAEs) change to standby mode.

- **Range:** 1 through 6000

Required Privilege Level

interface

icmp (Error Message Rate Limit)

IN THIS SECTION

- Syntax | 8625
- Hierarchy Level | 8626
- Description | 8626
- Options | 8626
- Required Privilege Level | 8626
- Release Information | 8626

Syntax

```
icmp {
    rate-limit rate-limit;
}
```

Hierarchy Level

```
[edit chassis]
```

Description

Configure the rate at which ICMP messages are generated for IPv4 packet errors for non-ttl-expired packets. Although you configure the rate limit at the `[edit chassis]` hierarchy level, it is not a chassis-wide limit. Instead, the rate limit applies per interface family. This means, for example, that multiple physical interfaces configured with `family inet` can simultaneously generate the ICMP error messages at the configured rate.

> **NOTE**: This rate limit takes effect only for traffic that lasts 10 seconds or longer. The rate limit is not applied to traffic with a shorter duration, such as 5 seconds or 9 seconds.

> **NOTE**: This statement does not apply to ICMP messages for ttl-expired packets; for these errors, the rate is fixed at 500 pps.

Options

`rate-limit` *`rate-limit`*—Rate in packets per second (pps). Starting in Junos OS Release 18.4R1, the maximum rate is 1000 pps. In earlier releases, the maximum rate is 50 pps.

- **Range:** 1 through 1000
- **Default:** 1

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

```

Description

Configure the rate at which ICMP messages are generated for IPv6 packet errors for non-ttl-expired packets. Although you configure the rate limit at the `[edit chassis]` hierarchy level, it is not a chassis-wide limit. Instead, the rate limit applies per interface family. This means, for example, that multiple physical interfaces configured with `family inet` can simultaneously generate the ICMP error messages at the configured rate.

> **NOTE**: This rate limit takes effect only for traffic that lasts 10 seconds or longer. The rate limit is not applied to traffic with a shorter duration, such as 5 seconds or 9 seconds.

> **NOTE**: This statement does not apply to ICMP messages for ttl-expired packets; for these errors, the rate is fixed at 500 pps.

Options

`rate-limit` *`rate-limit`*—Rate in packets per second (pps). Starting in Junos OS Release 18.4R1, the maximum rate is 1000 pps. In earlier releases, the maximum rate is 50 pps.

- **Range:** 1 through 1000
- **Default:** 1

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

- Release Information | 8658

Syntax

```
id-components {
    use-class;
    use-imsi;
    use-msisdn;
    use-nai;
    use-nas-port;
    use-nas-port-id;
    use-realm;
    use-username;
}
```

Hierarchy Level

```
[edit unified-edge gateways tdf gateway-name domains domain-name ip-subscriber subscription-id
subscription-id-options entry-name]
```

Description

Specify a method for constructing the Subscription-Id for the Diameter credit control request (CCR) message that is sent from the TDF to the PCRF for IP-based subscribers belonging to the TDF domain. You may specify more than one option, and the order of preference matches the order in which the options appear.

Options

use-class Subscription-Id-Type is configurable and the Subscription-Id-Data is the entire Class attribute value by default. You can configure a regular expression to parse the Class attribute contents, specify characters to insert between the resulting regular expression groups, and specify the subscription ID type with the `use-class` options under the `[edit unified-edge gateways tdf gateway-name domains domain-name subscription-id]` hierarchy.

use-imsi Subscription-Id-Type is END_USER_IMSI and the Subscription-Id-Data is the 3GPP-IMSI.

use-msisdn Subscription-Id-Type is END_USER_E164 and the Subscription-Id-Data is the Calling-Station-Id.

use-nai Subscription-Id-Type is END_USER_NAI and the Subscription-Id-Data is the entire User-Name.

use-nas-port Subscription-Id-Type is END_USER_PRIVATE and the Subscription-Id-Data is the NAS-Port.

use-nas-port-id Subscription-Id-Type is END_USER_PRIVATE and the Subscription-Id-Data is the NAS-Port-Id.

use-realm Subscription-Id-Type is END_USER_PRIVATE and the Subscription-Id-Data is the realm portion of User-Name in NAI format.

use-username Subscription-Id-Type is END_USER_PRIVATE and the Subscription-Id-Data is the user name portion of User-Name in NAI format.

Required Privilege Level

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

identifier (VPLS Multihoming for FEC 129)

IN THIS SECTION

- Syntax | 8661
- Hierarchy Level | 8661
- Description | 8661
- Options | 8662
- Required Privilege Level | 8662
- Release Information | 8662

Syntax

```
identifier identifier;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances instance-name protocols vpls multi-
homing site site-name],
[edit routing-instances instance-name protocols vpls multi-homing site site-name]
```

Description

Configure a Layer 2 VPN or VPLS multihoming identifier (MHID). An identifier needs to be configured for each multihomed site. Multihoming site identifiers are specific to a VPLS domain. They need not be unique on a provider edge (PE) router when multiple VPLS instances are present. The network layer reachability information (NLRI) advertisements sent to a CE device are identified as candidates for designated forwarder selection because the advertisements have the same multihoming identifier. Thus, you should assign the same identifier on all VPLS PE routers that are multihomed to the same customer site.

NOTE: The route distinguisher must be unique among PE routers participating in a multihomed site, so that the RD:MHID combination is unique across multiple VPLS domains. For example, one PE router might have a route distinguisher of 192.0.2.4:1, and another PE router in the same site might have a route distinguisher of 192.0.2.:1. The first number can be, for example, the loopback interface address that identifies the PE router. The second number is the multihoming identifier.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Options

identifier Number that identifies the multihomed site.

- **Range:** 1 through 65535

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

            }
            attribute device-vendor {
                  string string-value;
```

```
            }
        }
}
```

Hierarchy Level

```
[edit services user-identification device-information]
```

Description

Specify the name of the device identity profile, also referred to as the `identity-context-profile`, and either one or more of its attributes or the name of the Active Directory domain to which the device belongs.

The device identity profile is a key component of the SRX Series firewall identity feature, which enables you to control access to network resources based on the identity of the user's device, not the identity of the user of the device. The device identity profile includes the domain name and a collection of attributes that characterize the device.

Options

profile-name ***profile-name***	Name of the device identity profile; for example, marketing-west-coast. The profile is specified in the `destination-identity-context-profile` field of a security policy.
domain ***domain-name***	Name of the domain to which the device belongs; for example, domain1.
attribute device-category ***string***	Category of the device, for example, laptop.
attribute device-identity ***string***	Name given to the device, for example, my-device1.
attribute device-os ***string***	Operating system running on the device, for example, Windows.
attribute device-os-version ***string***	Version of the operating system that is running on the device, for example, 10.1.
attribute device-type ***string***	Type of device, for example, ThinkPad.
attribute device-vendor ***string***	Name of the manufacturer of the device, for example, Lenovo.

Required Privilege Level

services—To view this statement in the configuration.

services-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 23.4R1.

    }
}
```

Hierarchy Level

```
[edit services user-identification]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure identity management to collect identity information. The SRX Series or NFX Series device relies on JIMS to obtain user identity information much in the same way that it does LDAP. By configuring the `identity-management`, the device can query JIMS for identity information, populate identity management authentication table with the information that is obtained from JIMS and use the populated identity management authentication table to authenticate a user or a device requesting access to a protected resource.

Options

authentication-entry-timeout

Authentication entry timeout number (0, 10-1440) (minutes)

- **Default:** 60

invalid-authentication-entry-timeout

Invalid authentication entry timeout number (0, 10-1440) (minutes)

- **Default:** 30

file Configure the trace file options.

- *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory `/var/log`. By default, the name of the file is the name of the process being traced.

- `files` *number*—Maximum number of trace files. When a trace file named *`trace-file`* its maximum size, it is renamed to *`trace-file`*`.0`, then *`trace-file`*`.1`, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.

  If you specify a maximum number of files, you also must specify a maximum file size with the `size` option and a filename.

  Range: 2 through 1000 files

  Default: 10 files

- `match` *`regular-expression`*—Refine the output to include lines that contain the regular expression.

- `size` *`maximum-file-size`*—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named *`trace-file`* reaches this size, it is renamed *`trace-file`*`.0`. When the `trace-file` again reaches its maximum size, *`trace-file`*`.0` is renamed *`trace-file`*`.1` and *`trace-file`* is renamed *`trace-file`*`.0`. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

  If you specify a maximum file size, you also must specify a maximum number of trace files with the `files` option and a filename.

  Syntax: *`x`* `K` to specify KB, *`x`* `m` to specify MB, or *`x`* `g` to specify GB

  Range: 10 KB through 1 GB

  Default: 128 KB

- `world-readable` | `no-world-readable`—By default, log files can be accessed only by the user who configures the tracing operation. The `world-readable` option enables any user to read the file. To explicitly set the default behavior, use the `no-world-readable` option.

flag —Trace operation to perform.

level -Level of debugging output.

- `all` —Match all levels.
- `error` —Match error conditions.
- `info` —Match informational messages.
- `notice` —Match conditions that should be handled specially.
- `verbose` —Match verbose messages.
- `warning` —Match warning messages.

no-remote-trace —Set remote tracing as disabled.

The remaining statements are explained separately. See CLI Explorer.

idle-after-switch-over

IN THIS SECTION

- Syntax | 8677
- Hierarchy Level | 8677
- Description | 8677
- Options | 8677
- Required Privilege Level | 8677

Release Information | 8678

Syntax

```
idle-after-switch-over (forever | seconds);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols bgp],
[edit logical-systems logical-system-name protocols bgp group group-name],
[edit logical-systems logical-system-name protocols bgp group group-name neighbor address],
[edit protocols bgp],
[edit protocols bgp group group-name],
[edit protocols bgp group group-name neighbor address]
```

Description

Configure the routing device so that it does not automatically reestablish BGP peer sessions after a nonstop active routing (NSR) switchover. This feature is particularly useful if you are using dynamic routing policies because the dynamic database is not synchronized with the backup Routing Engine when NSR is enabled.

Options

forever—Do not reestablish a BGP peer session after an non-stop routing switchover until the `clear bgp neighbor` command is issued.

seconds—Do not reestablish a BGP peer session after an non-stop routing switchover until after the specified period.

- **Range:** 1 through 4,294,967,295 (2^{32} – 1)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

idle-timeout (Access)

IN THIS SECTION

- Syntax | 8680
- Hierarchy Level | 8680
- Description | 8680
- Options | 8681
- Required Privilege Level | 8681
- Release Information | 8681

Syntax

```
idle-timeout seconds;
```

Hierarchy Level

```
[edit access group-profile profile-name ppp ppp],
[edit access profile profile-name client client-name ppp]
```

Description

Configure the idle timeout for a user. The router might consider a PPP session to be idle because of the following reasons:

- There is no ingress traffic on the PPP session.
- There is no egress traffic.
- There is neither ingress or egress traffic on the PPP session.
- There is no ingress or egress PPP control traffic. This is applicable only if keepalives are enabled.

Options

seconds—Number of seconds a user can remain idle before the session is terminated.

- **Range:** 0 through 4,294,967,295 seconds
- **Default:** 0

> **NOTE**: The `[edit access]` hierarchy is not available on QFabric systems.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

idle-timeout (L2TP)

IN THIS SECTION

- Syntax | 8682
- Hierarchy Level | 8682
- Description | 8682
- Options | 8682
- Required Privilege Level | 8682
- Release Information | 8682

Syntax

```
idle-timeout seconds;
```

Hierarchy Level

```
[edit services l2tp tunnel]
```

Description

Specify how long a tunnel is active after its last session is terminated. The timer starts when the session is terminated and the tunnel is disconnected when the timer expires.

BEST PRACTICE: Before you downgrade to a Junos OS Release that does not support this statement, unconfigure the statement by issuing `no services l2tp tunnel idle-timeout`.

Options

seconds—Length of the idle timeout. A value of `0` creates a persistent tunnel; that is, the tunnel remains active indefinitely until the remote peer disconnects it or you issue the `clear services l2tp tunnel` command.

- **Range:** 0 through 86,400
- **Default:** 60

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1.

IN THIS SECTION

- Syntax | 8683
- Hierarchy Level | 8683
- Description | 8683
- Options | 8684
- Required Privilege Level | 8684
- Release Information | 8684

Syntax

```
idle-timeout;
```

Hierarchy Level

```
[edit system services web-management session]
```

Description

Configure in minutes the idle-timeout parameter for web-management sessions. The idle-timeout parameter, which applies to all sessions, specifies the length of time a session can be idle before it is terminated. The web-management feature allows you to configure the device using the J-Web interface.

You can also configure the maximum allowed number of concurrent web management sessions using the session-limit parameter.

Options

idle-timeout *minutes*

- **Default:** 30
- **Range:** 1 to 1440

Required Privilege Level

system—To view this in the configuration.

system-control—To add this to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

idle-timeout (System)

IN THIS SECTION

- Syntax | 8685
- Hierarchy Level | 8685
- Description | 8685
- Options | 8685
- Required Privilege Level | 8686
- Release Information | 8686

Syntax

```
idle-timeout idle-timeout;
```

Hierarchy Level

For root users:

```
[edit system login]
```

For non-root users:

```
[edit system login class]
```

Description

Configure the maximum time for which the C shell or CLI session can be idle. The root user is logged out of the CLI session after the expiry of `idle-timeout` and is logged out of the C shell after the expiry of another `idle-timeout`. For instance, if you configure `idle-timeout` as 5 minutes, the root user is logged out of the system after 10 minutes.

> **NOTE**: This config knob is applicable only for root user. To enable `idle-timeout` for non-root user, refer to Configure the Timeout Value for Idle Login Sessions.

The `set system login idle-timeout` is a global setting that applies to the default class and the custom class. If an ideal-timeout is configured for any custom class, it would override the global setting of its user.

Options

idle-timeout

Maximum idle time for root users before logout.

- **Range:** 1 through 60 minutes

> **NOTE**: Although you can set the idle-timeout to 1 minute, it is recommended to set it to 2 minutes or more for proper operation.

Maximum idle time out for non-root users before logout.

- **Range:** Any configured minutes

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

idle-timeout (Unified Edge)

IN THIS SECTION

- Syntax | 8686
- Hierarchy Level | 8686
- Description | 8687
- Options | 8687
- Required Privilege Level | 8687
- Release Information | 8687

Syntax

```
idle-timeout idle-timeout;
```

Hierarchy Level

```
[edit unified-edge gateways tdf gateway-name domains domain-name ip-subscriber]
```

Description

Configure the idle timeout for the TDF IP-based subscriber session. The idle timeout is the duration that the subscriber session waits to receive a data packet before timing out. After the idle timeout expires, the TDF takes down the session. Setting the idle timeout ensures that if no data is being sent for the duration specified, then the session can be taken down, and the TDF's resources can be freed.

Options

idle-timeout Number of minutes after which the TDF subscriber session times out.

- **Range:** 0 through 300.

Required Privilege Level

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure Intrusion Detection and Prevention (IDP) to selectively enforce various IDP attack detection and prevention techniques on the network.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.3. The `expression` option added in Junos OS Release 11.4.

Starting in Junos OS Release 18.3R1, when an SRX Series Firewall is configured with unified policies, you can configure multiple IDP policies and set one of those policies as the default IDP policy. If multiple IDP policies are configured for a session and when policy conflict occurs, the device applies the default IDP policy for that session and thus resolves any policy conflicts.

NOTE: If you have configured two or more IDP policies in a unified security policy, then you must configure the default IDP policy.

idp-policy (Application Services)

IN THIS SECTION

- Syntax | 8707
- Hierarchy Level | 8708
- Description | 8708
- Required Privilege Level | 8708
- Release Information | 8708

Syntax

```
idp-policy idp-policy;
```

Hierarchy Level

```
[edit security policies from-zone zone-name to-zone zone-name policy policy-name then permit
application-services]
```

Description

Specify IDP policy name.

When you configure a unified policy with a dynamic application as one of the matching condition, the configuration eliminates the additional steps involved in IDP policy configuration. IDP policy configurations are simplified within a unified policy. Configuring source or destination address, source and destination-except, from and to zone, or application is not required with unified policy, as the match happens in the security policy itself.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.2R1

Starting in Junos OS Release 18.2R1, IDP policy is available within unified security policy.

Unified policies are supported on SRX Series Firewalls, allowing granular control and enforcement of Dynamic Layer Applications within the traditional Security Policy. Layer 7 dynamic applications are integrated with security policy match criteria and IDP policy supports Layer 7 application based security policies.

Description

Configure a security IDP policy.

Options

policy-name—Name of the IDP policy.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

Starting with Junos OS Release 18.2R1, IDP policy is directly assigned in the security policy rule. This is to simplify IDP policy usage and to provide flexibility to have multiple policies active at the same time. As a part of the session interest check, IDP is enabled if an IDP policy is present in any of the matched rules. An IDP policy is activated in security policies by permitting the IDP policy within the application services using the `set security policies from-zone zone-name to-zone zone-name policy policy-name then permit application-services idp-policy idp-policy-name` command. Because the IDP policy name is directly used in the security policy rule, the `[edit security idp active-policy policy-name]` statement is deprecated.

Additional tags under filters of dynamic attack groups (CVSS score, age-of-attack, file-type, vulnerability-type) are added in Junos OS Release 18.2R1 for dynamic attacks grouping of IDP signatures. The Product and Vendor tags are already supported under existing filter products. The CLI interface for configuring these tags is now more user friendly, with more options available for configuration in Junos OS Release 18.2R1.

Starting in Junos OS Release 18.3R1, with unified policies configured on an SRX Series Firewall, you can configure multiple IDP policies and set one of those policies as the default IDP policy.

> **NOTE**: If you have configured two or more IDP policies in a unified security policy, then you must configure the default IDP policy.

        }
    }
}
```

Hierarchy Level

```
[edit security screen],
[edit tenants tenant-name security screen]
```

Description

Define screens for the intrusion detection service (IDS). An `ids-option` can be used for enabling the screen protection on the SRX Series Firewalls. One `ids-option` can be associated with several zones. However each zone can be linked with only one `ids-option`.

Options

`description` *`text`*—Descriptive text about a screen.

`alarm-without-drop`—Direct the device to generate an alarm when detecting an attack but not block the attack.

`icmp`—Configure the ICMP ids options.

`ip`—Configure the IP layer ids options.

`limit-session`—Limit the number of concurrent sessions the device can initiate from a single source IP address or the number of sessions it can direct to a single destination IP address.

`tcp`—Configure the TCP Layer ids options.

`udp`—Configure the UDP Layer ids options.

`loose-source-route-option`—The device detects packets where the IP option is 3 (Loose Source Routing) and records the event in the screen counters list for the ingress interface. This option specifies a partial route list for a packet to take on its journey from source to destination. The packet must proceed in the order of addresses specified, but it is allowed to pass through other devices in between those specified.

`source-route-option`—Enable this option to block all IP traffic that employs the loose or strict source route option. Source route options can allow an attacker to enter a network with a false IP address.

`strict-source-route-option`—The device detects packets where the IP option is 9 (Strict Source Routing) and records the event in the screen counters list for the ingress interface. This option specifies the complete route list for a packet to take on its journey from source to destination. The last address in the list replaces the address in the destination field. Currently, this screen option is applicable to IPv4 only.

> **NOTE**: Loose source route option and strict source route option will only alarm and will not be dropped when there is overflow of traffic. When only IP source option is configured, the attacked packets are dropped.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

Support for the `description` option added in Junos OS Release 12.1.

UDP supports `port-scan` option starting from Junos OS Release 12.1X47-D10.

The `tenant` option is introduced in Junos OS Release 18.3R1.

ieee-802.1 (Classifier on Physical Interface)

IN THIS SECTION

- Syntax | 8728
- Hierarchy Level | 8728
- Description | 8728
- Options | 8729
- Required Privilege Level | 8729
- Release Information | 8729

Syntax

```
ieee-802.1 (classifier-name | default) vlan-tag (inner | outer );
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name classifiers]
```

Description

For ACX Series Universal Metro routers and EX Series switches, map the ieee-802.1p field of the incoming packet to the forwarding class and packet loss priority based on the specified 802.1p classifier. In the case of double tagged packets, you can configure whether to use the 802.1p of the outer or inner VLAN tag.

Options

vlan-tag inner In the case of double tagged packets, classify based on the 802.1p of the inner VLAN tag.

vlan-tag outer Classify based on the 802.1p of the outermost VLAN tag.

classifier-name Name of the previously defined ieee-802.1p behavior aggregate classifier.

default Default ieee-802.1p behavior aggregate classifier.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

ieee-802.1 (Fibre Channel Interfaces)

IN THIS SECTION

- Syntax | 8734
- Hierarchy Level | 8734
- Description | 8734
- Required Privilege Level | 8735

Syntax

```
ieee-802.1 {
    code-point code-point-bits;
}
```

Hierarchy Level

```
[edit class-of-service interfaces fibre-channel-interface-name rewrite-value input]
```

Description

Configure the IEEE 802.1p code point value to which all traffic received from the Fibre Channel (FC) network on the specified FC interface is rewritten. After the code point value is rewritten, the interface forwards the traffic to the Ethernet (FCoE) network. This works in conjunction with configuring a fixed classifier on the FC interface. The fixed classifier maps all traffic from the FC network into one lossless forwarding class (the lossless forwarding class must be mapped to the code point specified in the rewrite value). Traffic mapped to the lossless forwarding class uses the IEEE 802.1p priority specified by the code point bits in the rewrite value.

FCoE networks typically use priority 3 (IEEE code point 011) for FCoE traffic. The QFX Series default configuration uses IEEE 802.1p priority 3 for FCoE traffic. Rewriting the code point value enables you to change the IEEE 802.1p priority of the FCoE traffic if the Ethernet network uses a different priority than priority 3 (code point 011).

The system supports only one IEEE 802.1p code point value per FC interface. You cannot configure more than one IEEE 802.1p rewrite value per FC interface. In addition, you can specify only one rewrite value per local FCoE-FC gateway fabric; all interfaces in the local fabric must use the same rewrite value. Attempting to configure FC interfaces in the same local fabric with different rewrite values generates a commit error. You can specify different rewrite values for interfaces that belong to different local FCoE-FC gateway fabrics.

The statement is described separately.

Required Privilege Level

interfaces—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

```

Description

Configure rate limits in packets per second for a single-rate two-color policer when policing is desired on a packets-per-second basis rather than a bits-per-second basis. This can help protect against distributed denial of service (DDoS) attacks.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

ifl-subscriber

IN THIS SECTION

- Syntax | 8758
- Hierarchy Level | 8758
- Description | 8758
- Options | 8759
- Required Privilege Level | 8759
- Release Information | 8759

Syntax

```
ifl-subscriber [subscriber-name] {
    access-interfaces [interface-name];
    apply-groups [group-names];
    apply-groups-except [group-names];
}
```

Hierarchy Level

```
[edit unified-edge gateways tdf gateway-name domains domain-name]
```

Description

Specify the name of the IFL-based subscriber for traffic that is carried on a particular interface or interfaces. You can configure up to 32 IFL-based subscribers in a TDF domain.

To configure a subscriber name, you must have set the `subscriber-type` to **ifl** at the `[edit unified-edge gateway tdf gateway-name domains domain-name]` hierarchy.

Options

subscriber-name Name of the subscriber. You can configure up to 32 IFL-based subscribers in a TDF domain.

- **Range:** Up to 63 bytes.

The remaining statements are described separately.

Required Privilege Level

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Enabling IGMP

igmp-querier (QFabric Systems only)

IN THIS SECTION

- Syntax | 8764
- Hierarchy Level | 8764
- Description | 8764
- Options | 8765
- Required Privilege Level | 8765
- Release Information | 8765

Syntax

```
igmp-querier {
    source-address source address;
}
```

Hierarchy Level

```
[edit protocols igmp-snooping vlan vlan-name]
```

Description

Configure a QFabric Node device to be an IGMP querier. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is lower (a smaller number) than the IP addresses for those routers on the network. This ensures that Node is always the IGMP querier on the network.

Options

source-address *source address* — The address that the switch uses as the source address in the IGMP queries that it sends.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1X53-D15.

```

Description

Configure IGMP snooping, which constrains multicast traffic to only the ports that have receivers attached.

IGMP snooping enables the device to selectively send out multicast packets on only the ports that need them. Without IGMP snooping, the device floods the packets on every port. The device listens for the exchange of IGMP messages by the device and the end hosts. In this way, the device builds an IGMP snooping table that has a list of all the ports that have requested a particular multicast group.

You can also configure IGMP proxy, IGMP querier, and multicast VLAN registration (MVR) functions on VLANs at this hierarchy level.

> **NOTE**: IGMP snooping must be disabled on the device before running an ISSU operation.

Default

For most devices, IGMP snooping is disabled on the device by default, and you must configure IGMP snooping parameters in this statement hierarchy to enable it on one or more VLANs.

On legacy switches that do not support the Enhanced Layer 2 Software (ELS) configuration style, IGMP snooping is enabled by default on all VLANs, and the `vlan` statement includes a `disable` option if you want to disable IGMP snooping selectively on some VLANs or disable it on all VLANs.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

ignore (Event Policy)

IN THIS SECTION

- Syntax | 8773
- Hierarchy Level | 8773

- Description | 8773
- Required Privilege Level | 8773
- Release Information | 8773

Syntax

```
ignore;
```

Hierarchy Level

```
[edit event-options policy policy-name then]
```

Description

Define a policy that ignores particular events. If one or more of the listed events occur, a system log message for the event is not generated, and no further policies associated with this event are processed. If you include the `ignore` statement in a policy configuration, you cannot configure any other actions in the policy.

Required Privilege Level

maintenance—To view or add this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 7.5.

```
[edit logical-systems logical-system-name protocols isis],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
isis],
[edit protocols isis],
[edit routing-instances routing-instance-name protocols isis]
```

Description

Ignore the attached bit on IS-IS Level 1 routers. Configuring this statement enables the routing device to ignore the attached bit on incoming Level 1 link-state PDUs. If the attached bit is ignored, no default route, which points to the routing device which has set the attached bit, is installed.

There might be times, such as during a denial-of-service (DoS) attack, that you do not want a Level 1 router to be able to forward traffic based on a default route.

To prevent a routing device from being able to reach interarea destinations, you can prevent the routing device from installing the default route without affecting the status of its IS-IS adjacencies. The `ignore-attached-bit` statement is used to tell the routing device to ignore the presence of the attached bit in Level 1 link-state PDUs, which blocks the installation of the IS-IS default route.

Default

The `ignore-attached-bit` statement is disabled by default.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Syntax

```
ignore-lsp-metrics;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ospf traffic-engineering shortcuts],
[edit protocols ospf traffic-engineering shortcuts]
```

Description

Cause OSPF to ignore the RSVP LSP metric.

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This can cause interoperability problems when you configure LDP tunneling over RSVP LSPs in heterogeneous networks.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.5.

ignore-magic-number-mismatch (Access Group Profile)

IN THIS SECTION

- Syntax | 8784
- Hierarchy Level | 8784
- Description | 8784
- Required Privilege Level | 8785

Release Information | 8785

Syntax

```
ignore-magic-number-mismatch;
```

Hierarchy Level

```
[edit access group-profile name ppp ppp-options]
```

Description

Prevent the Packet Forwarding Engine from performing a validation check for magic numbers received in LCP keepalive (Echo-Request/Echo-Reply) exchanges for a group of tunneled PPP subscribers at the LNS.

A mismatch occurs when the PPP magic number received from a remote peer in the keepalive exchange does not match the value agreed upon during LCP negotiation. Disabling the validation check prevents PPP from terminating the session when an unexpected number is received. Configuring this statement has no effect on LCP magic number negotiation or on the exchange of keepalives when the remote peer magic number is the expected negotiated number.

NOTE: Because magic number validation is not performed, the Packet Forwarding Engine does not detect whether the remote peer sends the local peer's magic number, which would indicate a loopback or other network issue. This is considered to be an unlikely situation, because LCP negotiation completed successfully, meaning no loopback was present at that time.

NOTE: You can also configure this behavior in a dynamic PPP profile. When PPP options are configured in both a group profile and a dynamic profile, the dynamic profile configuration takes complete precedence over the group profile when the dynamic profile includes one or more of the PPP options that can be configured in the group profile. Complete precedence means that there is no merging of options between the

profiles. The group profile is applied to the subscriber only when the dynamic profile does not include any PPP option available in the group profile.

This means that `ignore-magic-number-mismatch` configured in a group profile is not applied when the dynamic profile includes any PPP option, even when the dynamic profile does not include `ignore-magic-number-mismatch` statement.

NOTE: This statement is not supported on static interfaces.

Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.1R1.

[edit dynamic-profiles profile-name interfaces pp0 unit $junos-interface-unit ppp-options],
[edit dynamic-profiles profile-name interfaces $junos-interface-ifd-name unit $junos-interface-
unit ppp-options]
```

Description

Prevent the Packet Forwarding Engine from performing a validation check for magic numbers received in LCP keepalive (Echo-Request/Echo-Reply) exchanges for dynamic PPP subscriber connections terminated at the router or for dynamic tunneled PPP subscribers on LNS inline service interfaces.

A mismatch occurs when the PPP magic number received from a remote peer in the keepalive exchange does not match the value agreed upon during LCP negotiation. Disabling the validation check prevents PPP from terminating the session when an unexpected number is received. Configuring this statement has no effect on LCP magic number negotiation or on the exchange of keepalives when the remote peer magic number is the expected negotiated number.

For dynamic PPP subscriber connections terminated at the router, configure the statement at the `[edit dynamic-profiles profile-name interfaces pp0 unit “$junos-interface-unit” ppp-options]` hierarchy level.

For dynamic tunneled PPP subscribers on LNS inline service interfaces, configure the statement at the `[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name" unit “$junos-interface-unit” ppp-options]` hierarchy level.

NOTE: Because magic number validation is not performed, the Packet Forwarding Engine does not detect whether the remote peer sends the local peer’s magic number, which would indicate a loopback or other network issue. This is considered to be an unlikely situation, because LCP negotiation completed successfully, meaning no loopback was present at that time.

NOTE: You can also configure this behavior in an L2TP group profile that applies to tunneled PPP subscribers at the LNS. When PPP options are configured in both a group profile and a dynamic profile, the dynamic profile configuration takes complete

precedence over the group profile when the dynamic profile includes one or more of the PPP options that can be configured in the group profile. Complete precedence means that there is no merging of options between the profiles. The group profile is applied to the subscriber only when the dynamic profile does not include any PPP option available in the group profile.

This means that "ignore-magic-number-mismatch" on page 8783 configured in a group profile is not applied when the dynamic profile includes any PPP option, even when the dynamic profile does not include "ignore-magic-number-mismatch" on page 8785.

NOTE: This statement is not supported on static interfaces.

ignore-reassembly-memory-overflow | no-ignore-reassembly-memory-overflow

IN THIS SECTION

- Syntax | 8790
- Hierarchy Level | 8790
- Description | 8791
- Required Privilege Level | 8791
- Release Information | 8791

Syntax

```
(ignore-reassembly-memory-overflow | no-ignore-reassembly-memory-overflow);
```

Hierarchy Level

```
[edit security idp sensor-configuration re-assembler]
```

Description

Reassembly memory overflow occurs when the memory allocated for the reassembly of TCP fragments is exceeded. When the reassembly of TCP fragments exceeds the memory limit, defined with `max-packet-mem-ratio`, you can define the system behavior to ignore or drop the offending packets. If the `ignore-reassembly-memory-overflow` command is enabled on the SRX device, IDP will ignore and permit packets from sessions which trigger a reassembly memory overflow. If you enable the `no-ignore-reassembly-memory-overflow` command when reassembly memory overflow occurs, packets of that session are dropped by the device. By default, the `ignore-reassembly-memory-overflow` command is enabled.

Required Privilege Level

security—To view this statement in the configuration.

```

Hierarchy Level

```
[edit access profile profile-name client client-name]
```

Description

Configure an IKE access profile.

The remaining statements are explained below.

> **NOTE**: This statement is not supported on MX Series routers.

Options

allowed-proxy-pair

Specify the network address of the local and remote peer associated with an IKE access profile.

- Values:
  - local *local-proxy-address*—Network address of the local peer. Default: 0.0.0.0
  - remote *remote-proxy-address*—Network address of the remote peer. Default: 0.0.0.0

ike-policy *policy-name*

Specify the IKE policy used to authenticate dynamic peers during IKE negotiation.

- Values:
  - *policy-name*—The name of an IKE policy configured at the `[edit services ipsec-vpn ike policy policy-name]` hierarchy level. The IKE policy defines either the local digital certificate or the pre-shared key used for IKE authentication with dynamic peers.

initiate-dead-peer-detection

Detect inactive peers on dynamic IPsec tunnels.

pre-shared-key (ascii-text *character-string* | hexadecimal *hexadecimal-digits*);

Configure the key used to authenticate a dynamic peer during IKE phase 1 negotiation. Specify the key in either ASCII or hexadecimal format.

- Values:
  - ascii-text *character-string*—Authentication key in ASCII format.
  - hexadecimal *hexadecimal-digits*—Authentication key in hexadecimal format.

reverse-route

Configure a reverse route for dynamic endpoint IPsec tunnels.

- **Values:** preference *metric-value*

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

    }
}
```

Hierarchy Level

```
[edit security ipsec vpn vpn-name]
```

Description

Define an IKE-keyed IPsec VPN.

Options

anti-replay-window-size

To enable the `anti-replay-window-size` option, you first need to configure the option for each VPN object or at the global level. You can configure the anti-replay window size in the range of 64 to 8192 (power of 2). If the anti-replay window size is not configured, the window size is 64 by default. If `anti-replay-window-size` command is configured at both the global and VPN object levels, the configuration on VPN object takes precedence over global configuration.

`anti-replay-window-size` is supported only on SRX5000 line with SRX5K-SPC3 card installed.

gateway-name

Name of the remote IKE gateway.

idle-time

Specify the maximum amount of idle time to delete a security association (SA) when there is no traffic flow.

- **Default:** Disabled
- **Range:** 60 through 999,999 seconds

install-interval

Specify the maximum number of seconds to allow the installation of a rekeyed outbound security association (SA) on the device.

- **Default:**
  - 1 second, prior to Junos OS Release 23.4R1 (without iked process)
  - Starting Junos OS Release 23.4R1 with iked process:
    - 3 seconds, for IKEv1 initiator and IKEv2 responder.
    - 0 seconds, for rest of the scenarios
- **Range:** 0 through 10 seconds.

  You can configure 0-10 seconds from CLI, and it takes effect in data plane only for IKEv1 initiator or IKEv2 responder. CLI configured value takes precedence over the default value.

ipsec-policy

Specify the IPsec policy name.

no-anti-replay

Disable the antireplay checking feature of IPsec. Antireplay is an IPsec feature that can detect when a packet is intercepted and then replayed by attackers. By default, antireplay checking is enabled.

proxy-identity Optionally specify the IPsec proxy ID to use in negotiations. The default is the identity based on the IKE gateway. If the IKE gateway is an IPv6 site-to-site gateway, the default proxy ID is ::/0. If the IKE gateway is an IPv4 gateway or a dynamic endpoint or dialup gateway, the default proxy ID is 0.0.0.0/0.

- `local`—Specify the local IPv4 or IPv6 address and subnet mask for the proxy identity.
- `remote`—Specify the remote IPv4 or IPv6 address and subnet mask for the proxy identity.
- `service`—Specify the service (port and protocol combination) to protect. Name of the service is as defined with `system-services` (`Interface Host-Inbound Traffic`) and `system-services` (`Zone Host-Inbound Traffic`).

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5. Support.

Statement `anti-replay-window-size` is introduced in Junos OS Release 19.2R1.

Support for `idle-time` and `install-interval` options with IPsec VPN running iked process is added in Junos OS Release 23.4R1.

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Define Internet Key Exchange (IKE) configuration. IKE is a key management protocol that creates dynamic SAs; it negotiates SAs for IPsec. An IKE configuration defines the algorithms and keys used to establish a secure connection with a peer security gateway.

Options

`respond-bad-spi` *`max-responses`*—(Optional) Number of times to respond to invalid SPI values per gateway. Enable response to invalid IPsec Security Parameter Index (SPI) values. If the security associations (SAs) between two peers of an IPsec VPN become unsynchronized, the device resets the state of a peer so that the two peers are synchronized.

- **Range:** 1 through 30
- **Default:** 5

`traceoptions`—Configure IKE tracing options to aid in troubleshooting the IKE issues. This helps troubleshoot one or multiple tunnels negotiation by standard tracefile configuration. IKE tracing allows the user to view the detailed packet exchange and the negotiation information in Phase 1 and Phase 2. IKE tracing is not enabled by default. By default , all IKE or IPsec negotiations are logged into /var/log/kmd. But user can also specify customized file name while configuring the IKE traceoptions.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 8.5.

Support for IPv6 addresses added in Junos OS Release 11.1.

Support for `inet6` option added in Junos OS Release 11.1.

Support for `group15`, `group16`, `group21`, `ecdsa-signatures-521`, and `sha-512` options added in Junos OS Release 19.1R1 on SRX5000 line with `junos-ike` package installed.

Starting in Junos OS Release 20.2R1, we've changed the help text description as `NOT RECOMMENDED` for the CLI options `md5` and `sha1` for devices running IKED with `junos-ike` package installed.

Support for `group15`, `group16`, and `group21` options added in Junos OS Release 20.3R1 on vSRX Virtual Firewall instances with `junos-ike` package installed.

Support for `group15`, `group16`, and `group21` options added in Junos OS Release 21.1R1 on vSRX Virtual Firewall 3.0 instances with `junos-ike` package installed.

`level` option introduced in Junos OS Release 21.1R1.

Support for `seeded-pre-shared-key` option added in Junos OS Release 21.1R1.

Support for `session` and `blocklists` option added in Junos OS Release 23.4R1

We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure Application Layer Gateway (ALG) for Internet Key Exchange (IKE) and Encapsulating Security Payload (ESP) traffic with Network Address Translation (NAT).

Options

- `Enable` —Enable the IKE-ESP ALG.
- `esp-gate-timeout` *seconds*—Set the timeout for the ESP gates created after an IKE Phase 2 exchange has completed.

  Range: 2 through 30 seconds.

  Default: 5 seconds.
- `esp-session-timeout` *seconds*—Set the idle timeout for the ESP sessions created from the IPsec gates.

  Range: 60 through 2400 seconds.

  Default: 1800 seconds.
- `state-timeout` *seconds*—Set the timeout for the ALG state information.

  Range: 180 through 86,400 seconds.

Default: 14,400 seconds.

- `traceoptions`—Set the IKE-ESP ALG trace options.
  - `flag` —Specify which tracing operation to perform.
    - `all`—Trace all operations.
      - `extensive`—Set trace verbosity level to extensive.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Syntax

```
ike-log {
    filename filename;
    level level;
}
```

Hierarchy Level

```
[edit security host-vpn]
```

Description

Configure IKE logging details.

Options

filename *filename*

Specify the filename for logging—for example, **/var/log/*filename*.log**.

- **Default: /var/log/charon.log**

level *level*

Specify the logging level (how much detail is included) of the IKE daemon's log messages. Following are the levels of logging available:

- 0: Very basic auditing logs (for example SA up/SA down).
- 1: Generic control flow with errors. This is the default.
- 2: More detailed debugging control flow.
- 3: Including RAW (unprocessed) data dumps in hex.
- **Range:** 0 (minimal logging) through 3
- **Default:** 1

Required Privilege Level

        id id;
        secret (ascii-text ascii-text | hexadecimal hexadecimal);
    }
}
```

Hierarchy Level

```
[edit security host-vpn]
```

Description

Configure IKE shared secret details. If the shared secret passed between devices does not match, a session is not set up.

> **NOTE**: To configure a host-to-host VPN connection, you must configure the `ike-secrets` statement.

Options

ike-secret	Specify the name of the IKE secret.
id *id*	Specify the identity that the secret belongs to—for example, an IP address, a domain name, or an e-mail address. This identity matches local and remote identities as exchanged in the IKE security association (SA) negotiation at the `[edit security host-vpn connections` hierarchy level.
secret (ascii-text *ascii-text* **| hexadecimal** *hexadecimal***)**	Define the preshared private key associated with the identity in either ASCII or hexadecimal format.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Description

Configure the optical ILA IP address for optical supervisory channel communications across the amplifier chain and threshold crossing alerts for the optical ILA performance monitors.

> **NOTE**: To configure any other optical ILA options, you must log in to the optical ILA CLI, see Optical Inline Amplifier Hardware Guide.

You configure and manage optical ILAs through the associated anchor IPLC module in the PTX3000 integrated photonic line system. All communication to the optical ILA is through the anchor IPLC.

Default

Options

ila-ipv4-address *ila-ipv4-address*

Specify the IPv4 address of the optical ILA in the format: w.x.y.z/a. To enable OSC communication to and from the specified optical ILA, you must configure the IP address of the optical ILA.

> **TIP**: All communication to and from an optical ILA is through the anchor IPLC in the PTX3000 integrated photonic line system, therefore when you set the IP address of an optical ILA, you must also specify the FPC slot in which the anchor IPLC resides. In addition, be sure to specify an IP address on the same subnet as the anchor IPLC.

> **NOTE**: All IP addresses associated with the OSC in the optical amplifier chain must be on the same subnet.

tca-xxx-xxx.....—Specify the threshold crossing alerts values for the optical ILA EDFAs, OSC, and VOAs. Table 1, Table 2, and Table 3describe the TCAs you can configure for the optical ILA.

Table 60: Optical ILA EDFA Threshold Crossing Alerts

EDFA Threshold Crossing Alerts	
Threshold Crossing Alert Name	**Description**

                    writethrough;
                    }
    image-type [qcow2 | raw];
}
```

Hierarchy Level

```
[edit virtual-network-functions]
```

Description

Specify the VNF image source file. VNF image is virtual hard disk, which contains the bootable file-system for the VNF.

Options

file-path Path of the image source file

image-type Format of the image. Default value is qcow2.

bus-type Type of the system bus. Default value is virtio.

driver-cache Type of the driver cache mode. Default mode is default-cache

- default-cache—Default mode when you do not specify any driver cache mode.
- directsync—Enables the hypervisor to interact with the disk image file or block device with both `O_DSYNC` and `O_DIRECT` semantics. The hypervisor reports that the writes are completed only when the data is committed to the storage device, and when it is also desirable to bypass the host page cache.
- none—Enables the hypervisor to interact with the disk image file or block device with `O_DIRECT` semantics. The hypervisor bypasses the host page cache and I/O happens directly between the hypervisor user space buffers and the storage device. y.
- unsafe—Ignores all flush commands from the guests. Using this mode implies that the user has accepted the trade-off of performance over risk of data loss in case of a host failure.
- writeback—Enables the hypervisor to interact with the disk image file or block device with neither `O_DSYNC` nor `O_DIRECT` semantics. The hypervisor uses the host page cache and reports the writes to the guest as completed when the writes are in the host page cache.
- writethrough—Enables the hypervisor to interact with the disk image file or block device with `O_DSYNC` semantics. The hypervisor reports the writes as completed only when the data is committed to the storage device.

Syntax

```
immediate-leave;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name protocols mld interface interface-name]
```

Description

The immediate leave setting is useful for minimizing the leave latency of MLD memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows MLD to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending MLD group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the MLD leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both MLD version 1 and MLD version 2.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Description

Enable host tracking to allow the device to track the hosts that send membership reports, determine when the last host sends a leave message for the multicast group, and immediately stop forwarding traffic for the multicast group after the last host leaves the group. This setting helps to minimize IGMP or MLD membership leave latency—it reduces the amount of time it takes for the switch to stop sending multicast traffic to an interface when the last host leaves the group.

> **NOTE**: EVPN-VXLAN multicast uses special IGMP group leave processing to handle multihomed sources and receivers, so we don't support the `immediate-leave` option in EVPN-VXLAN networks.

IGMPv2, IGMPv3, MLDv1, and MLDv2 all have immediate leave disabled by default. In this state, the device does not track host memberships. When the device receives a leave report from a host, it sends out a group-specific query to all hosts. If no receiver responds with a membership report within a set interval, the device removes all hosts on the interface from the multicast group and stops forwarding multicast traffic to the interface.

With immediate leave enabled, the device removes an interface from the forwarding-table entry immediately without first sending IGMP group-specific queries out of the interface and waiting for a response. The device prunes the interface from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are active simultaneously.

Immediate leave is supported for IGMPv2, IGMPv3, MLDv1 and MLDv2 on devices that support these protocols.

> **NOTE**: We recommend that you configure immediate leave with IGMPv2 and MLDv1 only when there is only one host on an interface. With IGMPv2 and MLDv1, only one host on a interface sends a membership report in response to a general query—any other interested hosts suppress their reports. Report suppression avoids a flood of reports for the same group, but it also interferes with host tracking because the device knows only about one interested host on the interface at any given time.

Default

Immediate leave is disabled.

```

Description

Apply one or more routing policies to routes being imported into the Junos OS routing table from BGP.

If you specify more than one policy, they are evaluated in the order specified, from left to right, and the first matching filter is applied to the route. If no match is found, BGP places into the routing table only those routes that were learned from BGP routing devices. The policy framework software evaluates the routing policies in a chain sequentially. If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies. For example, if the action specified in the first policy of a chain sets a route's metric to 500, this route matches the criterion of `metric 500` defined in the next policy.

It is also important to understand that in Junos OS, although an import policy (inbound route filter) might reject a route, not use it for traffic forwarding, and not include it in an advertisement to other peers, the router retains these routes as hidden routes. These hidden routes are not available for policy or routing purposes. However, they do occupy memory space on the router. A service provider filtering routes to

control the amount of information being kept in memory and processed by a router might want the router to entirely drop the routes being rejected by the import policy.

Hidden routes can be viewed by using the `show route receive-protocol bgp` *`neighbor-address`* `hidden` command. The hidden routes can then be retained or dropped from the routing table by configuring the `keep all | none` statement at the `[edit protocols bgp]` or `[edit protocols bgp group` *`group-name`*`]` hierarchy level.

The rules of BGP route retention are as follows:

- By default, all routes learned from BGP are retained, except those where the AS path is looped. (The AS path includes the local AS.)
- By configuring the `keep all` statement, all routes learned from BGP are retained, even those with the local AS in the AS path.
- By configuring the `keep none` statement, all routes received are discarded. When this statement is configured and the inbound policy changes, Junos OS re-advertises all the routes advertised by the peer.

```
[edit logical-systems logical-system-name protocols mpls traffic-engineering database],
[edit protocols mpls traffic-engineering database]
```

Description

Configure the traffic engineering database import parameters.

Options

bgp-ls-identifier *domain-identifier*	BGP-TE domain identifier.
identifier *identifier*	BGP-TE identifier. • **Range:** 2 through 18446744073709551615
ipv6	Enable import of IPv6 addresses into the traffic engineering database (TED).
l3-unicast-topology	Download L3-Unicast topology into RIB.
policy *policy-name*	Name of the import policy.
igp-topology	Download IGP topology information into the traffic engineering database (TED). In Junos OS, the IGPs install topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. The IGP routes are installed by the traffic engineering database on behalf of the corresponding IGP into a user-visible routing table called lsdist.0, subject to route policies.
bgp-link-state	Export IGP topology information into BGP-Link State (BGP-LS) from the lsdist.0 routing table. The lsdist.0 routing table stores the network topology information from the traffic engineering database. The BGP-LS reads IGP entries from lsdist.0 and advertises the information to BGP peers.

Required Privilege Level

routing—To view this statement in the configuration.

import (Protocols LDP)

IN THIS SECTION

- Syntax | 8860
- Hierarchy Level | 8860
- Description | 8860
- Options | 8860
- Required Privilege Level | 8861
- Release Information | 8861

Syntax

```
import [ policy-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Description

Apply policy filters to received LDP label bindings. Filters are applied to all label bindings from all neighbors.

Options

policy-names—Name of one or more routing policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

- Description | 8874
- Options | 8874
- Required Privilege Level | 8874
- Release Information | 8874

Syntax

```
import-labeled-routes [ routing-instance-name ]
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
vpls],
[edit routing-instances routing-instance-name protocols vpls ]
```

Description

(MX Series routers with MPCs and MIC interfaces only) Specify one or more routing instances where MPLS paths (pseudowire labeled routes) are leaked from the mpls.0 routing table in the primary routing instance to the local *routing-instance-name*.mpls.0 routing table.

This capability is useful in an L2VPN/VPLS configuration when the remote PE router is learned from the IGP in a nondefault routing instance, because L2VPN/VPLS installs ingress-labeled routes only in the primary mpls.0 table.

When L2VPN/VPLS traffic is received on the core-facing interface in a nondefault routing instance, the router performs a lookup in the table that corresponds to that interface, *routing-instance-name*.mpls.0. Because the routes are not leaked by default, no routes are found in the *routing-instance-name*.mpls.0 routing table and all the incoming traffic is dropped.

Options

routing-instance-name	Name of a nondefault routing instance where you want routes leaked from the primary MPLS routing table.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

RELATED DOCUMENTATION

import-policy

IN THIS SECTION

- Syntax | 8875
- Hierarchy Level | 8875
- Description | 8875
- Options | 8876
- Required Privilege Level | 8876
- Release Information | 8876

Syntax

```
import-policy [ policy-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options rib-groups group-name],
[edit logical-systems logical-system-name routing-options rib-groups group-name],
[edit routing-instances routing-instance-name routing-options rib-groups group-name],
[edit routing-options rib-groups group-name]
```

Description

Apply one or more policies to routes imported into the routing table group. The `import-policy` statement complements the `import-rib` statement and cannot be used unless you first specify the routing tables to which routes are being imported.

> **NOTE**: On EX Series switches, only dynamically learned routes can be imported from one routing table group to another.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

export-rib | **6993**

passive (Routing Options) | **12717**

import-rib

IN THIS SECTION

- Syntax | **8877**
- Hierarchy Level | **8877**
- Description | **8877**
- Options | **8877**
- Required Privilege Level | **8877**
- Release Information | **8878**

Syntax

```
import-rib [ routing-table-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options rib-groups group-name],

[edit logical-systems logical-system-name routing-options rib-groups group-name],
[edit routing-instances routing-instance-name routing-options rib-groups group-name],
[edit routing-options rib-groups group-name]
```

Description

Specify the name of the routing table into which Junos OS should import routing information. The first routing table name you enter is the primary routing table. Any additional names you enter identify secondary routing tables. When a protocol imports routes, it imports them into the primary and any secondary routing tables. If the primary route is deleted, the secondary route also is deleted. For IPv4 import routing tables, the primary routing table must be **inet.0** or **routing-instance-name.inet.0**. For IPv6 import routing tables, the primary routing table must be **inet6.0**.

In Junos OS Release 9.5 and later, you can configure an IPv4 import routing table that includes both IPv4 and IPv6 routing tables. Including both types of routing tables permits you, for example, to populate an IPv6 routing table with IPv6 addresses that are compatible with IPv4. In releases prior to Junos OS Release 9.5, you could configure an import routing table with only either IPv4 or IPv6 routing tables.

NOTE: On EX Series switches, only dynamically learned routes can be imported from one routing table group to another.

Options

routing-table-names—Name of one or more routing tables.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

```
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols mvpn
route-target],
[edit routing-instances routing-instance-name protocols mvpn route-target]
```

Description

Enable you to override the Layer 3 VPN import and export route targets used for importing and exporting routes for the MBGP MVPN NLRI.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4.

imsi-prefix

IN THIS SECTION

- Syntax | 8880
- Hierarchy Level | 8880

- Description | 8880
- Options | 8880
- Required Privilege Level | 8881
- Release Information | 8881

Syntax

```
imsi-prefix imsi-prefix-digits {
    action (APN GTP) {
        drop;
        pass;
        selection (ms|net|vrf);
    }
}
```

Hierarchy Level

```
[edit security gtp profile profile-name apn pattern-string]
```

Description

Use the imsi-prefix option to specify an International Mobile Station Identity (IMSI) prefix for filtering GTP packets. You can also filter GTP packets based on the combination of an IMSI prefix and an access point name (APN).

From Junos OS Release 20.4R1 onwards, the `[edit security gprs gtp profile profile-name apn pattern-string]` hierarchy level is replaced by `[edit security gtp profile profile-name apn pattern-string]`.

Options

imsi-prefix-digits—To specify an IMSI prefix.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.0. Support.

Hierarchy Level (Junos OS)

```
[edit services rpm rfc2544-benchmarking tests test-name test-name]
```

Hierarchy Level (Junos OS Evolved)

```
[edit services monitoring rfc2544 tests test-name test-name]
```

Description

Runs the test in the `in-service` mode. In this mode, while the test is running, the rest of the data traffic sent to and from the UNI port under test on the service are not interrupted. Control protocol packets and control protocol peering are not interrupted.

If this mode is not configured, the test runs in the default `out-of-service` mode. In the `out-of-service` mode, while the test is running, all the data traffic sent to and from the UNI port under test on the service is interrupted. Control protocol peering is not interrupted whereas control protocol packets such as CFM sessions are interrupted.

Default

The default service mode for the reflecting egress interface for an E-LAN service is `out-of-service` mode.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

inactivity-interval (Fabric Load Balance)

IN THIS SECTION

- Syntax | 8891
- Hierarchy Level | 8891
- Description | 8891
- Default | 8891
- Options | 8892
- Required Privilege Level | 8892
- Release Information | 8892

Syntax

```
inactivity-interval interval;
```

Hierarchy Level

```
[edit forwarding-options enhanced-hash-key fabric-load-balance flowlet]
```

Description

Set the inactivity interval for adaptive load balancing (ALB) using flowlets within a VCF.

> **NOTE**: Starting in Junos OS Release 14.1X53-D46, 15.1R7, 16.1R6, 17.1R3, 17.2R2, 17.3R2, and 17.4R1, the ALB feature is deprecated. If `fabric-load-balance` is enabled in the configuration and `inactivity-interval` is set, delete these configuration items upon upgrading Junos OS.

The inactivity interval is the amount of time that occurs between packet bursts on a sending interface before a traffic flow is spliced into smaller traffic flows—flowlets—when ALB is implemented using flowlets. The flowlets are then individually forwarded across the VCF to the same destination device over different paths.

You should configure the inactivity interval to ensure in-order packet delivery, so that overall performance is not negatively impacted by the packet re-ordering process at the receiving device. To ensure in-order packet delivery, the inactivity interval should be larger than the largest latency skew among all the paths in the VCF from any node to any other node.

Default

ALB is disabled, by default.

If ALB is enabled without specifying a mode, ALB is enabled using flowlet mode with an inactivity interval of 16 microseconds.

If ALB is enabled using flowlet mode without specifying an inactivity interval, the inactivity interval is set to 16 microseconds.

Options

interval The amount of time that occurs between packet bursts on a sending interface before a traffic flow is spliced into flowets.

- **Range:** 16 microseconds (16us) to 32 milliseconds(32ms).

Required Privilege Level

system—To view this statement in the configuration.

Description

Configure Inband Flow Analyzer 2.0 (IFA 2.0). IFA 2.0 provides insights about complex networks by collecting per-hop flow data on the data plane. IFA uses probe packets to collect network-wide flow data. IFA generates probe packets by sampling the traffic flow of interest. IFA probe packets are representative packets of the original flow and possess the exact same characteristics as the original flow. This means that IFA packets traverse the same path in the network and the same queues in the networking element as the original packet would. Because the IFA probe packets traverse the same network path as the original flow, the packets experience similar latency and congestion.

IFA uses the following processing nodes to monitor and analyze flows:

- IFA initiator node (also known as ingress node)

- IFA transit node
- IFA terminating node (also known as egress node)

Use the `inband-flow-telemetry` configuration options to configure the IFA nodes.

Options

`clock-source (ntp | ptp)`

Configure the clock source protocol to enable more accurate timestamping. The QFX5120-48YM switch supports PTP as well as NTP; all of the other QFX5120 switch models support NTP only.

Default: `ntp`

`device-id (`*`id-number`*` | auto)`

(Mandatory for all IFA nodes) Specify a unique device identifier for each hop within an IFA zone. You must configure this value for all three IFA node types: IFA initiator, IFA transit, and IFA terminating. If you configure `auto`, then the device ID is internally generated from the router ID or the management IP address.

Range: 1-1,048,575 for *id-number*, or specify `auto` to have the software create one.

`flow-type (l3 | vxlan)`

(Mandatory for IFA initiator node and terminating node and optional for transit node) Specify the IFA flow type—`l3` or `vxlan`. If you configure the flow type as `vxlan`, and the incoming traffic is L3, or vice versa, then the IFA nodes do not behave as expected. This is because you cannot initiate IFA probe packets with invalid fields.

You cannot configure both L3 or VXLAN flows on the same device. This restriction is applicable for the IFA initiator and terminating nodes (generally leaf nodes).

You don't need to configure `flow-type` for a transit node (generally spine nodes).

Default: `l3`

`hop-limit `*`value`*

(Optional) Configure the maximum allowed hops in an IFA zone. The initiator node initializes this field. The hop limit is decremented at each hop. If the hop limit of the incoming packets is 0, the current node does not insert the metadata.

You can avoid the metadata insertion at the transit node by using the `hop-limit` configuration.

The IFA terminating node does not perform a hop-limit check. Even if the incoming IFA packet has hop-limit set to 0, the IFA terminating node inserts the metadata and reduces the hop limit by 1. In this case, the `hop-limit` value resets to 255. The `hop-limit` option cannot have a negative value.

- **Range**: 1-250

- **Default**: 250

meta-data-stack-length *value*

(Optional) Configure the maximum allowed length of the metadata stack in multiples of four octets. The initiator node initializes this field. Each node in the path compares the current length with the maximum allowed length. If the current length equals or exceeds the maximum length, the transit node must stop inserting the metadata.

- **Range**: 8-255
- **Default**: 240 (for 30 hops)

mode (live | probe);

Configure a mode for an IFA initiator node to initiate packets or for an IFA terminator node to know how to parse the IFA header in the packet:

- `live`—IFA 2.0 uses the original packets as IFA probe packets. The initiator node inserts IFA headers and metadata into the live packets. The terminator node strips the IFA layer and forwards the modified live packet to its destination.
- `probe`—IFA 2.0 uses copies of the original packets as the IFA probe packets. The initiator node samples the flow and copies that sample to create the probe. This probe packet may be truncated if required. The terminator node drops the packet and sends a mirror copy to the collector.
- **Default:** `probe`

You do not configure this statement option on an IFA transit node. Transit nodes process all the packets in the same way.

no-ipv6-address-match

(Optional) Optimize IFA filter group processing by removing the IPv6 source and destination address match qualifiers from the IFA filter group. IFA cannot be initiated or terminated with these two qualifiers, but you can initiate or terminate IFA with the remaining qualifiers.

Default: off (this statement is not included in the IFA configuration unless you specifically configure it)

profile *ifa-profile-name*

IFA profile
name.

sample-rate *value*

Configure the average number of samples obtained in one second. For example, if you configure the sample rate as 1000, then out of 1000 packets one packet is sampled per second. You cannot have different sample rates for different flows on an IFA initiator node enabled on a port. All flows within a port must have the same sample rate.

Range: 1-16,777,215

collector Configure a collector for IFA 2.0 probe packets. The monitored packets are exported to the collector in IPFIX format. By default, Junos OS supports a maximum packet length of 256 bytes starting with the Ethernet header. An IFA IPFIX packet contains IFA headers (8 bytes), IFA metadata (variable length), and the originally monitored packet (256 bytes).

Configure the following collector-related options:

- `source-address` *`ipv4-address`*—IPv4 source address.
- `destination-address` *`ipv4-address`*—IPv4 destination address.
- `destination-port` *`port-number`*—Destination port value.
  Range: 1-65,535.
- `maximum-clip-length` *`length`*—Number of bytes of the original flow packet that should be exported in the IPFIX packet. Because the maximum MTU is 9000 bytes at the IFA termination node, the maximum clip length for the IPFIX packet is equal to or less than: 9000 bytes - (IFA header length + IFA metadata header length + IFA metadata stack length).

  Range: 64 to 9000 bytes

  Default: 256 bytes
- `mtu` *`size`*—Size in bytes of the maximum transmission unit for IPFIX packets leaving the IFA termination node. Any packet exceeding 9000 bytes in length is dropped.

  Range: 256 to 9000 bytes

  Default: 9000 bytes

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 21.4R1.

`clock-source`, `maximum-clip-length`, `mtu`, and `no-ipv6-address-match` options introduced in Junos OS Release 22.2R1.

Statement introduced in Junos OS Evolved Release 22.4R1.

Inband Flow Analyzer (IFA) 2.0 Probe for Real-Time Performance Monitoring

inband-ztp

IN THIS SECTION

- Syntax | 8908
- Hierarchy Level | 8909
- Description | 8909
- In-band ZTP | 8909
- Options | 8909
- Required Privilege Level | 8909
- Release Information | 8909

Syntax

```
inband-ztp {
    management-vlan-id management-vlan-id;
    name-server [ name-server ... ];

    }
}
```

Hierarchy Level

```
[edit system services]
```

Description

Enable in-band ZTP.

In-band ZTP enables your already-provisioned Day 1 upstream devices in your IP fabric to monitor for newly connected Day 0 downstream devices. In-band ZTP invokes an autonomous Python daemon, which uses Link-Level Discovery Protocol (LLDP) telemetry data, to monitor for any new downstream interfaces. When a Day 1 upstream device detects a downstream interface, the Day 1 upstream device can provide Layer 3 connectivity to the Day 0 downstream device. With Layer 3 connectivity, the Day 0 device can then proceed with ZTP.

In-band ZTP

Options

management-vlan-id Provide the management VLAN ID. The management VLAN enables in-band ZTP for a particular VLAN. An upstream device can belong to multiple VLANs, and the management VLAN enables in-band ZTP to monitor for interfaces in those VLANs.

name-server Provide a list of DNS server addresses.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

None.

interface-id | relay-agent-remote-id)],
[edit routing-instances routing-instance-name forwarding-options dhcp-relay ... relay-option-82
(circuit-id | remote-id)],
[edit vlans vlan-name forwarding-options dhcp-security dhcpv6-options option-18],
[edit vlans vlan-name forwarding-options dhcp-security dhcpv6-options option-37]
```

Description

Include both the integrated routing and bridging (IRB) interface name and Layer 2 interface name in the `circuit-id` or `remote-id` value in the DHCP option 82 information. VLAN tags are global.

For leasequery and bulk leasequery operations that involve integrated routing and bridging (IRB) interfaces, you must configure DHCP relay agent to include the layer 2 interface name along with IRB name in the circuit ID of option 82. DHCP relay agent uses the layer 2 interface name when using leasequery or bulk leasequery to restore the lease database.

When you configure the `include-irb-and-l2` statement without including the `no-vlan-interface` statement, the format is as follows:

- Bridge domain:

```
(fe | ge)-fpc/pic/port.subunit:bridge-domain-name+irb.subunit
```

- VLAN:

```
(fe | ge)-fpc/pic/port.subunit:vlan-name+irb.subunit
```

NOTE: For remote systems, the *subunit* is required and is used to differentiate an interface.

When you configure both the `include-irb-and-l2` statement and the `use-vlan-id` statement, the format is as follows:

```
(fe | ge)-fpc/pic/port.subunit:svlan-id-vlan-id+irb.subunit
```

NOTE: The *svlan-id-vlan-id* represents the VLANs associated with the bridge domain.

When you configure both the `include-irb-and-l2` and `no-vlan-interface-name` statements, the format is as follows:

```
(fe | ge)-fpc/pic/port.subunit+irb.subunit
```

When you configure both the `include-irb-and-l2` and `use-interface-description` statements, the format displays the description for the Layer 2 interface:

```
l2_descr: vlan-name+irb.subunit
```

If you configure both the `include-irb-and-l2` and `use-interface-description` statements, and no description for the Layer 2 interface is found, the format displays the Layer 2 logical interface name:

```
(fe | ge)-fpc/pic/port.subunit: vlan-name+irb.subunit
```

When you configure the `include-irb-and-l2` statement with both the `no-vlan-interface-name` and `use-interface-description` statements, the format displays as follows:

```
l2_descr+irb.subunit
```

If you configure the `include-irb-and-l2` statement with both the `no-vlan-interface-name` and `use-interface-description` statements, and no description is found for the Layer 2 interface, the format displays as follows:

```
(fe | ge)-fpc/pic/port.subunit+irb.subunit
```

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1.

NOTE: The EX Series switches that support the `include-irb-and-l2` statement are the EX4300, EX4600, and EX9200 switches.

include-sci (MACsec for MX Series)

IN THIS SECTION

- Syntax | 8926
- Hierarchy Level | 8926
- Description | 8927
- Default | 8927
- Required Privilege Level | 8927
- Release Information | 8927

Syntax

```
include-sci;
```

Hierarchy Level

```
[edit security macsec connectivity-association connectivity-association-name]
```

Description

Specifies that the SCI tag should be appended to each packet on a link that has enabled MACsec.

This option is used only when connecting a router to a host device that requires SCI tagging. SCI tags are eight octets long, so appending an SCI tag to all traffic on the link adds a significant amount of unneeded overhead.

Default

SCI tagging is not enabled by default.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1.

RELATED DOCUMENTATION

- Description | 8928
- Default | 8928
- Required Privilege Level | 8928
- Release Information | 8928

Syntax

```
include-sci;
```

Hierarchy Level

```
[edit security macsec connectivity-association connectivity-association-name]
```

Description

Specifies that the SCI tag should be appended to each packet on a link that has enabled MACsec.

You must enable SCI tagging on a switch that is enabling MACsec on an Ethernet link connecting to an EX4300 or EX4600 switch.

SCI tags are automatically appended to packets leaving a MACsec-enabled interface on EX4300 or EX4600 switches, so this option is not available on these switches.

You should only use this option when connecting a switch to an EX4300 or EX4600 switch, or to a host device that requires SCI tagging. SCI tags are eight octets long, so appending an SCI tag to all traffic on the link adds a significant amount of unneeded overhead.

Default

SCI tagging is enabled by default on SRX Series Firewalls, EX4300 and EX4600 switches that have enabled MACsec using static connectivity association key (CAK) security mode.

SCI tagging is disabled on all other interfaces, by default.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2X50-D15.

```
[edit dynamic-profiles profile-name interfaces $junos-interface-ifd-name unit $junos-interface-
unit auto-configure line-identity],
[edit interfaces interface-name unit logical-unit-number auto-configure line-identity]
```

Description

Configure the access-line identifier received in DHCP or PPPoE discovery packets that is a trusted option. Trusted options are accepted for dynamically creating a VLAN on a static or dynamic underlying VLAN interface. These VLANs are known as access-line-identifier-based VLANs.

Options

accept-no-ids (Optional) Enables creation of a VLAN in the absence of the ACI and the ARI string in the received DHCP or PPPoE packet. This VLAN serves an a default VLAN to collect all subscribers for which no sub-option is received. For PPPoE subscribers you can configure the `accept-no-ids mac-address` to use a single network-wide unique MAC address assigned to each household or access line to create the ALI based dynamic VLAN when neither ACI nor the ARI is received in the PPPoE control packet.

circuit-id (Optional) Enables creation of the VLAN when the ACI string is received in a DHCP or PPPoE packet.

remote-id (Optional) Enables creation of the VLAN when the ARI string is received in a DHCP or PPPoE packet.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS 17.1.

`mac-address` option introduced in Junos OS 25.2R1.

independent-domain

IN THIS SECTION

- Syntax | 8935
- Hierarchy Level | 8935
- Description | 8935
- Options | 8936
- Required Privilege Level | 8936
- Release Information | 8936

Syntax

```
independent-domain <no-attrset>;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options autonomous-system autonomous-system],
[edit routing-instances routing-instance-name routing-options autonomous-system autonomous-
system]
```

Description

Configure an independent AS domain.

The independent domain uses transitive path attribute 128 (attribute set) messages to tunnel the independent domain's BGP attributes through the internal BGP (IBGP) core.

This improves the transparency of Layer 3 VPN services for customer networks by preventing the IBGP routes that originate within an autonomous system (AS) in the customer network from being sent to a service provider's AS. Similarly, IBGP routes that originate within an AS in the service provider's network are prevented from being sent to a customer AS.

NOTE: In Junos OS Release 10.3 and later, if BGP receives attribute 128 and you have not configured an independent domain in any routing instance, BGP treats the received attribute 128 as an unknown attribute.

NOTE: The `[edit logical-systems]` hierarchy level is not applicable in ACX Series routers.

Options

`no-attrset` (Optional) Disables attribute set messages on the independent AS domain.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`no-attrset` option introduced in Junos OS Release 10.4.

indexed-load-balance

IN THIS SECTION

- Syntax | 8940
- Hierarchy Level | 8940
- Description | 8940
- Default | 8940
- Required Privilege Level | 8940
- Release Information | 8940

Syntax

```
indexed-load-balance;
```

Hierarchy Level

```
[edit forwarding-options load-balance],
[edit logical-systems logical-system-name forwarding-options load-balance],
[edit logical-systems logical-system-name routing-instances routing-instance-name forwarding-
options load-balance],
[edit routing-instances routing-instance-name forwarding-options load-balance]
```

Description

The `indexed-load-balance` statement causes the creation of a nexthop structure that is both a function of the hash, and a function of the low-order bits of the IP address. Include this statement if you notice issues with load-balance distribution for IPv4 or IPv6 traffic to improve load-balance distribution for unicast and aggregated next hops.

For MPC line cards in MX routers, `indexed-load-balance` has been superseded by an internal hash-rotation mechanism to reduce polarization.

CAUTION: Including the `indexed-load-balance` statement causes an increase in memory usage on the device.

Default

Disabled

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Starting with Junos OS Release 12.1, the indexed-next-hop statement has been renamed as the indexed-load-balance statement.

indirect-next-hop

IN THIS SECTION

- Syntax | 8944
- Hierarchy Level | 8944
- Description | 8944
- Default | 8945
- Options | 8945
- Required Privilege Level | 8945
- Release Information | 8945

Syntax

```
(indirect-next-hop | no-indirect-next-hop);
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table],
[edit routing-options forwarding-table]
```

Description

Enable indirectly connected next hops for route convergence. This statement is implemented on the Packet Forward Engine to speed up forwarding information base (FIB) updates. Configuring this statement significantly speeds convergence times. The only downside of configuring this statement is that some additional FIB memory overhead is required. Unless routes have an extremely high number of next hops, this increased memory usage should not be noticeable.

NOTE:

- When virtual private LAN service (VPLS) is configured on the routing device, the `indirect-next-hop` statement is configurable at the `[edit routing-options forwarding-table]` hierarchy level. However, this configuration is not applicable to indirect nexthops specific to VPLS routing instances.
- By default, the Junos Trio Modular Port Concentrator (MPC) chipset on MX Series routers is enabled with indirectly connected next hops, and this cannot be disabled using the `no-indirect-next-hop` statement.
- By default, indirectly connected next hops are enabled on PTX Series routers.

Default

Disabled.

Options

indirect-next-hop—Enable indirectly connected next hops.

no-indirect-next-hop—Explicitly disable indirect next hops.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.2.

indirect-next-hop-change-acknowledgements

IN THIS SECTION

- Syntax | 8946
- Hierarchy Level | 8946
- Description | 8946
- Default | 8947
- Options | 8947
- Required Privilege Level | 8947
- Release Information | 8947

Syntax

```
(indirect-next-hop-change-acknowledgements | no-indirect-next-hop-change-acknowledgements);
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table],
[edit routing-options forwarding-table]
```

Description

Configure the routing protocol process (rpd) to request an acknowledgement when creating a new forwarding next hop.

During an indirect next-hop change sequence, the routing device might create a new forwarding next hop that is referenced by the indirect next hop. If the `indirect-next-hop-change-acknowledgements` statement is configured, the routing protocol process requests an acknowledgement when creating the new forwarding next hop. When the routing protocol process receives the acknowledgement, this indicates that all PFEs have received the new forwarding next hop and it is then safe to change the indirect next hop to reference the new forwarding next hop. This prevents packet loss when changing the indirect next hop by ensuring that all PFEs have consistent state information for the new forwarding next hop.

The routing protocol process is not requesting an acknowledgement for the indirect next hop itself. Rather, the routing protocol process is requesting an acknowledgement for the new forwarding next hop that the indirect next hop is going to reference. In the case when the forwarding next hop is an existing one (meaning that it is already installed in the forwarding table), the routing protocol process does not request an acknowledgement, even if the `indirect-next-hop-change-acknowledgements` statement is configured.

We recommend that the `indirect-next-hop-change-acknowledgements` statement be configured when protection mechanisms are being used. This includes MPLS RSVP protection such as fast reroute (FRR) as well as interior gateway protocol (IGP) loop-free alternate (LFA) link or node protection. If there is no protection mechanism being used in the network, the `indirect-next-hop-change-acknowledgements` statement does not provide any benefit and might increase packet loss.

Default

Disabled by default in all platforms except PTX Series, where it is enabled by default.

Options

indirect-next-hop-change-acknowledgements—Enable acknowledgements.

no-indirect-next-hop-change-acknowledgements—Explicitly disable acknowledgements.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Description

Select the payload fields in IPv4 traffic used by the hashing algorithm to make hashing decisions.

When IPv4 traffic enters a LAG and the hash mode is set to Layer 2 payload, the hashing algorithm checks the fields configured using the `inet` statement and uses the information in the fields to decide how to place traffic onto the LAG bundle's member links or how to forward traffic to the next hop device when ECMP is enabled.

The hashing algorithm, when used to hash LAG bundle traffic, always tries to manage bandwidth by evenly load-balancing all incoming traffic across the member links in the bundle.

The hashing algorithm only inspects the IPv4 fields in the payload to make hashing decisions when the hash mode is set to `layer2-payload`. The hash mode is set to Layer 2 payload by default. You can set the hash mode to Layer 2 payload using the `set forwarding-options enhanced-hash-key hash-mode layer2-payload` statement.

Default

The following fields are used by the hashing algorithm to make hashing decisions for IPv4 traffic:

- IP destination address
- IP source address
- Layer 4 destination port
- Layer 4 source port
- Protocol

Options

`no-ipv4-destination-address`	Exclude the IPv4 destination address field from the hashing algorithm.
`no-ipv4-source-address`	Exclude the IPv4 source address field from the hashing algorithm.
`no-l4-destination-port`	Exclude the Layer 4 destination port field from the hashing algorithm.
`no-l4-source-port`	Exclude the Layer 4 source port field from the hashing algorithm.
`no-protocol`	Exclude the protocol field from the hashing algorithm.
`no-incoming-port`	Exclude the incoming port number from the hashing algorithm.
`vlan-id`	Include the VLAN ID field in the hashing algorithm.

> **NOTE**: The `vlan-id` option is not supported and should not be configured on a Virtual Chassis or Virtual Chassis Fabric (VCF) that contains any of the following switches as members: EX4300, EX4600, QFX3500, QFX3600, QFX5100, or QFX5110 switches.

Required Privilege Level

interface—To view this statement in the configuration.

inet (Port Mirroring)

IN THIS SECTION

- Syntax | 8963
- Hierarchy Level | 8963
- Description | 8963
- Required Privilege Level | 8963
- Release Information | 8964

Syntax

```
inet {
output {
    ip-addressaddress {
    }
    routing-instance instance-name {
        ip-address address {
    }
}
```

Hierarchy Level

```
[edit forwarding-options port-mirroring [instance name] family]
```

Description

Specify that the output interface will be of type `inet`. Use this statement so that you can send the mirrored packets to the IP address of the device running an analyzer application. The device can be on a remote network. When you use this feature, the mirrored packets are GRE-encapsulated. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)

NOTE: An output IP address cannot be in the same subnetwork as any of the switch's management interfaces.

NOTE: If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1X53.

inet (Routing Policy Condition)

inet (Security Static NAT)

IN THIS SECTION

- Syntax | 8966
- Hierarchy Level | 8966
- Description | 8966
- Options | 8966
- Required Privilege Level | 8966
- Release Information | 8966

Syntax

```
inet {
    routing-instance (routing-instance-name| default);
}
```

Hierarchy Level

```
[edit security nat static rule-set rule-set-name rule rule-name then static-nat]
```

Description

Specify the automatic translation of IPv6 addresses to IPv4 addresses (and vice versa).

> **NOTE**: If you use this option, you do not need to use the *prefix* option because with this option, the first 96 most significant bits are automatically stripped from the 128-bit IPv6 address.

Options

- `routing-instance` *`routing-instance-name`* —Use the user-defined static NAT routing-instance to perform static NAT.
- `default`—Use the default routing-instance to perform static NAT. When a `routing-instance-name` is not provided, the default routing-instance primary is used, which refers to the main inet.0 (for IPv4 unicast routes) routing table or inet.6 (for IPv6 unicast routes) routing table.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.6.

inet (Subscriber Secure Policy)

- Description | **8974**

- Default | 8974
- Options | 8974
- Required Privilege Level | 8975
- Release Information | 8975

Syntax (EX Series and QFX5100 Switch)

```
inet6 {
    no-ipv6-destination-address;
    no-ipv6-source-address;
    no-l4-destination-port;
    no-l4-source-port;
    no-next-header;
    vlan-id;
}
```

Syntax (QFX10000 Series Switches)

```
inet6 {
    gtp-tunnel-endpoint-identifier;
    ipv6-flow-label;
    no-ipv6-destination-address;
    no-ipv6-source-address;
    no-l4-destination-port;
    no-l4-source-port;
    no-incoming-port;
}
```

Hierarchy Level

```
[edit forwarding-options enhanced-hash-key family]
```

Description

Select the payload fields in an IPv6 packet used by the hashing algorithm to make hashing decisions.

When IPv6 traffic enters a LAG and the hash mode is set to Layer 2 payload, the hashing algorithm checks the fields configured using this statement and uses the information in the fields to decide how to place traffic onto the LAG bundle's member links or to forward traffic to the next hop device when ECMP is enabled.

The hashing algorithm, when used to hash LAG traffic, always tries to manage bandwidth by evenly load-balancing all incoming traffic across the member links in the bundle.

The hashing algorithm only inspects the IPv6 fields in the payload to make hashing decisions when the hash mode is set to Layer 2 payload. The hash mode is set to Layer 2 payload by default. You can set the hash mode to Layer 2 payload using the `set forwarding-options enhanced-hash-key hash-mode layer2-payload` statement.

Default

The data in the following fields are used by the hashing algorithm to make hashing decisions for IPv6 traffic:

- IP destination address
- IP source address
- Layer 4 destination port
- Layer 4 source port
- Next header

Options

no-ipv6-destination-address	Exclude the IPv6 destination address field from the hashing algorithm.
no-ipv6-source-address	Exclude the IPv6 source address field from the hashing algorithm.
no-l4-destination-port	Exclude the Layer 4 destination port field from the hashing algorithm.
no-l4-source-port	Exclude the Layer 4 source port field from the hashing algorithm.
no-incoming-port	Exclude the incoming port number from the hashing algorithm.
no-next-header	Exclude the Next Header field from the hashing algorithm.

`vlan-id` Include the VLAN ID field in the hashing algorithm.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

inet6

IN THIS SECTION

Syntax | 8985

- Hierarchy Level | 8985
- Description | 8985
- Required Privilege Level | 8985
- Release Information | 8985

Syntax

```
inet6;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table chained-composite-
next-hop ingress labeled-bgp],
[edit routing-options forwarding-table chained-composite-next-hop ingress labeled-bgp]
```

Description

Allows you to configure chained composite next hops for IPv6 labeled-unicast routes.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

This statement was introduced in Junos OS Release 12.3.

RELATED DOCUMENTATION

Accepting Route Updates with Unique Inner VPN Labels in Layer 3 VPNs

inet6-advertise-interval (VRRP)

IN THIS SECTION

- Syntax | 8986
- Hierarchy Level | 8986
- Description | 8986
- Options | 8987
- Required Privilege Level | 8987
- Release Information | 8987

Syntax

```
inet6-advertise-interval milliseconds;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family inet6 address address vrrp-inet6-group group-id],
[edit logical-systems logical-system-name  interfaces interface-name unit logical-unit-number family inet6 address address vrrp-inet6-group group-id]
```

Description

Configure the interval between Virtual Router Redundancy Protocol (VRRP) IPv6 advertisement packets.

All routers in the VRRP group must use the same advertisement interval.

NOTE: When VRRPv3 is enabled, the `inet6-advertise-interval` statement cannot be used to configure advertisement intervals. Instead, use the `fast-interval` statement to configure advertisement intervals.

Options

milliseconds—Interval, in milliseconds, between advertisement packets.

- **Range:** 100 to 40,000 milliseconds (ms)
- **Default:** 1 second

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4R2.

Configuring VRRP for IPv6 (CLI Procedure)

version-3 | **31903**

inet6-backup-router

IN THIS SECTION

- Syntax | **8988**
- Hierarchy Level | **8988**
- Description | **8988**
- Options | **8988**
- Required Privilege Level | **8988**
- Release Information | **8988**

Syntax

```
inet6-backup-router address <destination destination-address>;
```

Hierarchy Level

```
[edit system]
```

Description

Set a default router (running IP version 6 [IPv6]) to use while the local router or switch (running IPv6) is booting and if the routing protocol processes fail to start. The Junos OS removes the route to this router or switch as soon as the software starts.

Options

address Address of the default router.

destination *destination-address* (Optional) Destination address that is reachable through the backup router. You can include this option to achieve network reachability while loading, configuring, and recovering the router or switch, but without the risk of installing a default route in the forwarding table.

- **Default:** All hosts (default route) are reachable through the backup router.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

inet6-bgpmcast

IN THIS SECTION

- Syntax | 8989
- Hierarchy Level | 8989
- Description | 8989
- Required Privilege Level | 8989
- Release Information | 8990

Syntax

```
inet6-bgpmcast {
    signaling;
}
```

Hierarchy Level

```
[edit protocols bgp family],
[edit protocols bgp group group-name family],
[edit protocols bgp neighbor neighbor-address family]
```

Description

Enable the `inet6-bgpmcast` address family to advertise BGP multicast NLRI.

IPv4 and IPv6 can be enabled or disabled separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 21.1

- Release Information | 8994

Syntax

```
inet6-options {
    source-address address;
}
```

Hierarchy Level

```
[edit services rpm probe owner test test-name]
```

Description

Specify the source IPv6 address used for probes. If the source IPv6 address is not one of the devices' assigned addresses, the packet uses the outgoing interface's address as its source.

Options

`inet6-options`—Use the specified base IPv6 protocol-related settings to be used for RPM probes

`source-address` *`ipv6-address`*—Specify the base IPv6 address for sending the RPM probes from the client to the server (for example, 2001:db8::a:b:c:d).

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1R4.

RELATED DOCUMENTATION

inet6-precedence (CoS Rewrite Rules)

IN THIS SECTION

- Syntax | 8994
- Hierarchy Level | 8995
- Description | 8995
- Options | 8995
- Required Privilege Level | 8995
- Release Information | 8995

Syntax

```
inet6-precedence rewrite-name {
    protocol mpls;
}
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
```

Description

Apply an IPv6 precedence rule to rewrite the first three bits of the IPv6 DSCP value.

Options

rewrite-name Name of a `rewrite-rules` mapping configured at the `[edit class-of-service rewrite-rules inet6-precedence]` hierarchy level.

`protocol mpls` (Optional for ingress MPLS tunnel nodes) Rewrite the DSCP value for IPv6 packets entering the MPLS tunnel.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.1R1.

inet6-vpn

IN THIS SECTION

- Syntax | 8996
- Hierarchy Level | 8996
- Description | 8996
- Options | 8997
- Required Privilege Level | 8997
- Release Information | 8997

Syntax

```
inet6-vpn (any | multicast | unicast) {
    aggregate-label;
    prefix-limit maximum;
    rib-group rib-group-name;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols bgp family],
[edit logical-systems logical-system-name protocols bgp group group-name family],
[edit protocols bgp family],
[edit protocols bgp group group-name family]
```

Description

Enable IP version 6 (IPv6) on the provider edge (PE) router for the Layer 3 VPN.

NOTE: The `[edit logical-systems]` hierarchy level is not applicable in ACX Series routers.

Options

`any`—Configure the family type to be both multicast and unicast.

`multicast`—Configure the family type to be multicast. This means that the BGP peers are being used only to carry the unicast routes that are being used by multicast for resolving the multicast routes.

`prefix-limit` *`maximum`*—Maximum prefix limit.

- **Range:** 1 through 4,294,967,295
- **Default:** 1

`rib-group` *`rib-group-name`*—The name of the routing table group.

`unicast`—Configure the family type to be unicast. This means that the BGP peers only carry the unicast routes that are being used for unicast forwarding purposes.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

inet-precedence (Classifier on Physical Interface)

IN THIS SECTION

- Syntax | 9006
- Hierarchy Level | 9006
- Description | 9006
- Options | 9007
- Required Privilege Level | 9007
- Release Information | 9007

Syntax

```
inet-precedence (classifier-name | default);
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name  classifiers]
```

Description

On ACX Series Universal Metro routers and EX Series switches, map the inet-precedence field of the incoming packet to the forwarding class and packet loss priority, based on the specified inet-precedence

classifier. When no classifier is configured on the physical interface, the default ipprec-compatibility inet-precedence classifier is applied on the physical interface.

Options

classifier-name	Name of the previously defined inet-precedence behavior aggregate classifier.
default	Default inet-precedence behavior aggregate classifier.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

inet-precedence (CoS Classifiers)

IN THIS SECTION

- Syntax | 9007
- Hierarchy Level | 9008
- Description | 9008
- Options | 9008
- Required Privilege Level | 9008
- Release Information | 9008

Syntax

```
inet-precedence (classifier-name | default) {
    import (classifier-name | default);
```

```
    forwarding-class class-name {
        loss-priority level code-points [ aliases ] [ bit-patterns ]
        }
    }
```

Hierarchy Level

```
[edit class-of-service classifiers]
```

Description

Define an IPv4 classifier.

Options

`default`—The default mapping. By default, IP precedence rewrite rules alter the first three bits on the type of service (ToS) byte while leaving the last three bits unchanged.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

inet-precedence (CoS Rewrite Rules)

IN THIS SECTION

- Syntax | 9009
- Hierarchy Level | 9009
- Description | 9009
- Options | 9009
- Required Privilege Level | 9010
- Release Information | 9010

Syntax

```
inet-precedence (rewrite-name | default) protocol (inet-both | inet-outer | mpls);
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
```

Description

Apply an IPv4 precedence rewrite rule.

Options

rewrite-name Name of a `rewrite-rules` mapping configured at the `[edit class-of-service rewrite-rules inet-precedence]` hierarchy level.

default The default mapping. By default, IP precedence rewrite rules alter the first three bits on the type of service (ToS) byte while leaving the last three bits unchanged.

`protocol inet-both`	Rewrite the inet-precedence CoS value to both the inner and outer header for Unicast/Multicast IPv4 traffic. The first three bits of the CoS value are rewritten and the final six bits are taken from the incoming CoS value.
`protocol inet-outer`	Rewrite the inet-precedence CoS value to the outer header for Unicast/Multicast IPv4 traffic. The first three bits of the CoS value are rewritten and the final six bits are taken from the incoming CoS value.
`protocol mpls`	(Optional for ingress MPLS tunnel nodes) Rewrite the MPLS EXP bits in the MPLS header independently of the IPv4 DSCP value for IPv4 packets entering an MPLS tunnel.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

[edit routing-instances routing-instance-name protocols pim spt-threshold]
```

Description

Apply one or more policies to set the SPT threshold to infinity for a source-group address pair. Use the **infinity** statement to prevent the last-hop routing device from transitioning from the RPT rooted at the RP to an SPT rooted at the source for that source-group address pair.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.0.

    password password;
    port port-number;
    server-certificate-subject subject;
}
```

Hierarchy Level

```
[edit services unified-access-control ]
```

Description

To configure an Infranet Controller, specify the hostname of the IC Series device with which the SRX Series Firewall should communicate. Possible values for this statement range from 1 to 31 characters.

This statement is required when you are configuring the SRX Series Firewall to act as a Junos OS Enforcer in a Unified Access Control (UAC) deployment. When deployed as a Junos OS Enforcer, the SRX Series Firewall enforces the policies that are defined on the UAC's IC Series device.

One or more IC Series devices can be configured as Infranet Controllers on the SRX Series Firewall. There is no maximum number of IC Series devices that can be configured. However, only one IC Series device can be active at any time. The others are failover devices. A round-robin algorithm determines which of the configured IC Series devices is the active Infranet Controller. If the active Infranet Controller becomes inoperative, the algorithm is reapplied to the remaining IC Series devices that are configured to establish the new active Infranet Controller.

Options

The remaining statements are explained separately. See CLI Explorer.

ingress (Buffer Configuration)

IN THIS SECTION

- Syntax | 9021
- Hierarchy Level | 9021
- Description | 9021
- Default | 9022
- Options | 9022
- Required Privilege Level | 9022
- Release Information | 9022

Syntax

```
ingress {
    buffer-partition (lossless | lossless-headroom | lossy) {
        percent percent;
    }
    percent percent;
}
```

Hierarchy Level

```
[edit class-of-service shared-buffer]
```

Description

Configure the global shared buffer pool allocation for ingress traffic. The system allocates the shared buffer pool dynamically across its ports as the ports require memory space. Some buffer space is reserved for buffers such as dedicated buffers (buffers allocated permanently to ports) and headroom buffers (buffers that help prevent packet loss on lossless flows).

The percentage you specify is the percentage of available (user-configurable) buffer space allocated to the global shared ingress buffer pool. If you allocate less than 100 percent of the available buffer space

to the shared buffer pool, the remaining buffer space is added to the dedicated buffer pool. (You cannot directly configure the dedicated buffer pool for each port; dedicated buffers are allocated evenly across all the ports.)

> **CAUTION**: Changing the buffer configuration is a disruptive event. Traffic stops on *all* ports until buffer reprogramming is complete.

You can also partition the shared buffer pool to adjust the ingress buffer allocations for different mixes of network traffic using the `buffer-partition` statement.

Default

The default shared buffer percentage is 100 percent. (All available buffer space is allocated to the shared buffer pool.)

Options

`percent` *percent*—Percentage of available ingress buffer space allocated to the shared buffer pool. If the percentage is less than 100 percent, the remaining buffer space is allocated to the dedicated buffer pool.

The remaining statement is explained separately. See CLI Explorer.

Required Privilege Level

interfaces—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

ingress (Chained Composite Next Hop)

IN THIS SECTION

- Syntax | 9023
- Hierarchy Level | 9023
- Description | 9024
- Default | 9024
- Options | 9024
- Required Privilege Level | 9025
- Release Information | 9025

Syntax

```
ingress {
    (evpn | no-evpn);
    (fec129-vpws | no-fec129-vpws);
    (l2ckt | no-l2ckt);
    (l2vpn | no-l2vpn);
    l3vpn ;
    labeled-bgp;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table chained-composite-next-hop],
[edit routing-options forwarding-table chained-composite-next-hop]
```

Description

Allows you to configure chained composite next hops for devices handling ingress traffic in the network.

NOTE:

- On MX Series routers containing both DPC and MPC FPCs, the chassis must be configured with `enhanced-ip` option for enabling chained composite next hops. Only the "l3vpn" on page 9983 option under the `ingress` statement is supported on DPC and DPCE-based MX Series routers. All other statements and functionality under the `ingress` statement are not supported on MX routers with DPC linecards.
- The `extended-space` statement is not supported in ACX Series routers.
- The `[edit logical-systems]` hierarchy level is not applicable in ACX Series routers.
- On MX series routers with Modular Port Concentrator 9 (MPC9) and the previous models of line cards, only the `labeled-bgp` option and the "l3vpn (ingress)" on page 9983 option are supported under the "ingress (Chained Composite Next Hop)" on page 9023 configuration statement; all other configuration options and functionality are not supported.

Default

This statement is disabled by default.

Options

`evpn | no-evpn`	Enable or disable composite chained next hop for ingress EVPN label-switched paths (LSPs).
`fec129-vpws | no-fec129-vpws`	Enable or disable composite chained next hop for ingress FEC 129 virtual private wire service (VPWS) LSPs.
`l2ckt | no-l2ckt`	Enable or disable composite chained next hop for ingress Layer 2 circuit LSPs.
`l2vpn | no-l2vpn`	Enable or disable composite chained next hop for ingress Layer 2 virtual private network (VPN) LSPs.

The remaining statements are explained separately. See CLI Explorer.

Syntax

```
ingress-node-replication;
```

Hierarchy Level

```
[edit routing-instances routing-instance-name vlans vlan-name vxlan],
[edit vlans vlan-name vxlan]
```

Description

EVPN all-active mode with VXLAN encapsulation is based on the local bias for traffic coming from the access layer (redundant Layer 2 gateway function through a pair of top-of-rack switches). Because the traffic has no MPLS label, the split-horizon filtering rule for multihomed Ethernet segments is modified to be based on the IP address of the EVPN provider edge (PE) device instead of the MPLS ES-label. This is called *local bias* for EVPN-VXLAN.

Each EVPN PE device tracks the IP address of its peer multihomed EVPN PE devices that share the same Ethernet segment. This is the source VTEP IP address (outer SIP) for each VXLAN packet received from other EVPN PE devices. The PE device enforces the local bias filtering rule on both ingress and egress PE devices for the multi-destination traffic. For egress traffic, there is no forwarding of any multi-destination packets to the same multihomed Ethernet segment that an egress PE device shares with its ingress PE, regardless of the egress PE device's DF election status for that Ethernet segment. Ingress traffic is responsible for forwarding multi-destination packets coming from any directly attached access

interfaces to the rest of the multi-homed Ethernet segments associated with it, regardless of the ingress PE device's designated forwarder election status on the connected physical device segment.

> **NOTE**: With this statement configured, the device adds all active VTEP interfaces to every bridge domain (VLAN). However, the default routing behavior without this statement results in an optimal flood list with VTEPs and VLANs associated only based on advertised EVPN Type 3 routes. As a result, in general you don't need to configure this statement on EVPN-VXLAN devices.

If you add or remove this option in an existing VLAN configuration statement and commit the change, the device removes the corresponding VLAN from the forwarding plane and adds it back into the forwarding plane. This causes traffic disruption. As a result, you should plan to make either of those types of changes during a maintenance window.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit vlans vlan-name vxlan]
```

Description

Enable ingress node replication for a specified Virtual Extensible LAN (VXLAN) that is managed by the Open vSwitch Database (OVSDB) management protocol.

With this feature enabled, instead of service nodes, Juniper Networks devices with OVSDB implemented handle incoming broadcast, unknown unicast, or multicast (BUM) traffic. For more information about the scenarios in which you can use ingress node replication and how it works, see *Understanding How Layer 2 BUM and Layer 3 Routed Multicast Traffic Are Handled with OVSDB*.

> **NOTE**: When Juniper Networks devices replicate Layer 2 BUM packets to a large number of remote software VTEPs, the performance of the Juniper Networks devices might be impacted.

Default

If you do not include the `ingress-node-replication` statement, one or more service nodes handle BUM traffic.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

ingress-policer-overhead

IN THIS SECTION

- Syntax | 9036
- Hierarchy Level | 9036
- Description | 9036
- Options | 9037
- Required Privilege Level | 9037
- Release Information | 9037

Syntax

```
ingress-policer-overhead bytes;
```

Hierarchy Level

```
[edit chassis fpc slot-number pic pic-number]
```

Description

Add the configured number of bytes to the length of a packet entering the interface.

Configure a policer overhead to control the rate of traffic received on an interface. Use this feature to help prevent denial-of-service (DoS) attacks or to enforce traffic rates to conform to the service-level agreement (SLA). When you configure a policer overhead, the configured policer overhead value (bytes) is added to the length of the final Ethernet frame. This calculated length of frame is used to determine the policer or the rate-limiting action.

Traffic policing combines the configured policy bandwidth limits and the burst size to determine how to meter the incoming traffic. If you configure a policer overhead on an interface, Junos OS adds those bytes to the length of incoming Ethernet frames. This added overhead fills each frame closer to the burst size, allowing you to control the rate of traffic received on an interface.

You can configure the policer overhead to rate-limit queues and Layer 2 and Layer 3 policers, for standalone (SA) and high-avalability (HA) deployments. The policer overhead and the shaping overhead can be configured simultaneously on an interface.

NOTE: vSRX Virtual Firewall supports policer overhead on Layer 3 policers only.

The policer overhead applies to all interfaces on the PIC. In the following example, Junos OS adds 10 bytes of overhead to all incoming Ethernet frames on ports ge-0/0/0 through ge-0/0/4.

```
set chassis fpc 0 pic 0 ingress-policer-overhead 10
```

NOTE: vSRX Virtual Firewall only supports `fpc 0 pic 0`. When you commit the `ingress-policer-overhead` statement, the vSRX Virtual Firewall takes the PIC offline and then back online.

You need to craft the policer overhead size to match your network traffic. A value that is too low will have minimal impact on traffic bursts. A value that is too high will rate-limit too much of your incoming traffic.

In this example, the policer overhead of 255 bytes is configured for ge-0/0/0 through ge-0/0/4. The firewall policer is configured to discard traffic when the burst size is over 1500 bytes. This policer is applied to ge-0/0/0 and ge 0/0/1. Junos OS adds 255 bytes to every Ethernet frame that comes into the configured ports. If, during a burst of traffic, the combined length of incoming frames and the overhead bytes exceeds 1500 bytes, the policer starts to discard further incoming traffic.

```
set chassis fpc 0 pic 0 ingress-policer-overhead 255
set interfaces ge-0/0/0 unit 0 family inet policer input overhead_policer
set interfaces ge-0/0/0 unit 0 family inet address 10.9.1.2/24
set interfaces ge-0/0/1 unit 0 family inet policer input overhead_policer
set interfaces ge-0/0/1 unit 0 family inet address 10.9.2.2/24
set firewall policer overhead_policer if-exceeding bandwidth-limit 32k
set firewall policer overhead_policer if-exceeding burst-size-limit 1500
set firewall policer overhead_policer then discard
```

Options

bytes—Number of bytes added to a frame entering an interface.

- **Range:** 0–255 bytes
- **Default:** 0

```
[edit chassis fpc 0 pic 0]
user@host# set ingress-policer-overhead 10;
```

[edit routing-instances routing-instance-name provider-tunnel],
[edit routing-instances routing-instance-name provider-tunnel selective group address source
source-address]
```

Description

A provider tunnel type used for passing multicast traffic between routers through the MPLS cloud, or between PE routers when using MVPN. The ingress replication provider tunnel uses MPLS point-to-point LSPs to create the multicast distribution tree.

Optionally, you can specify a label-switched path template. If you configure `ingress-replication label-switched-path` and do not include `label-switched-path-template`, ingress replication works with existing LDP or RSVP tunnels. If you include `label-switched-path-template`, the tunnels must be RSVP.

Options

existing-unicast-tunnel—An existing tunnel to the destination is used for ingress replication. If an existing tunnel is not available, the destination is not added. Default mode if no option is specified.

create-new-ucast-tunnel—When specified, a new unicast tunnel to the destination is created and used for ingress replication. The unicast tunnel is deleted later if the destination is no longer included in the multicast distribution tree.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

    input-packets;
    output-bytes;
    output-packets;
    queue-id;
}
```

Hierarchy Level

```
[edit accounting-options flat-file-profile profile-name fields]
```

Description

Specify ingress queue statistics to be collected for the interface.

Options

all-fields Collect all ingress queue statistics available for the interface context, logical or physical.

drop-packets Collect the number of received packets dropped on the Ingress queue.

input-bytes Collect the number of octets received on the queue for the traffic class indicated by the queue identifier.

input-packets Collect the number of packets received on the queue for the traffic class indicated by the queue identifier.

output-bytes Collect the number of octets forwarded for the traffic class indicated by the queue identifier. Same value as `input-bytes` unless oversubscription is present at the ingress.

output-packets Collect the number of packets forwarded for the traffic class indicated by the queue identifier. Same value as `input-packets` unless oversubscription is present at the ingress.

queue-id Collect the logical identifier for the ingress queue; identifies the traffic class.

Required Privilege Level

init-command-string

IN THIS SECTION

- Syntax | 9049
- Hierarchy Level | 9049
- Description | 9049
- Options | 9050
- Required Privilege Level | 9050
- Release Information | 9050

Syntax

```
init-command-string initialization-command-string;
```

Hierarchy Level

```
[edit interfaces umd0 modem-options]
```

Description

For J Series Services Routers, configure the command string used to initialize the USB modem.

When you connect the USB modem to the USB port on a Services Router, the router applies the modem AT commands configured in the `init-command-string` command to the initialization commands on the modem.

For example, the initialization command string **ATS0 = 2\n** configures the USB modem to pick up a call after 2 rings.

If you do not include the `init-command-string` statement, the router applies the default initialization string to the modem.

Options

initialization-command-string—Specify an initialization command string using the following AT command values:

- **%C0**—Disables data compression.
- **&C1**—Disables reset of the modem when it loses the carrier signal.
- **&Q8**—Enables Microcom Networking Protocol (MNP) error control mode.
- **AT**—Attention. Informs the modem that a command follows.
- **E0**—Disables the display on the local terminal of commands issued to the modem from the local terminal.
- **Q0**—Enables the display of result codes.
- **S0=0**—Disables the auto-answer feature, whereby the modem automatically answers calls.
- **S7=45**—Instructs the modem to wait 45 seconds for a telecommunications service provider (carrier) signal before terminating the call.
- **V1**—Displays result codes as words.
- **Default: AT S7=45 S0=0 V1 X4 &C1 E0 Q0 &Q8 %C0**

initial-tcp-mss

IN THIS SECTION

- Syntax | 9054
- Hierarchy Level | 9054
- Description | 9054
- Required Privilege Level | 9054
- Release Information | 9054

Syntax

```
initial-tcp-mss mss-value;
```

Hierarchy Level

```
[edit security policies from-zone zone-name to-zone zone-name
policy policy-name then permit tcp-options]
```

Description

Configure the TCP maximum segment size (MSS) for packets that arrive at the ingress interface (initial direction), match a specific policy, and for which a session is created. The value you configure overrides the TCP MSS value in the incoming packet when the value in the packet is higher than the one you specify.

The `initial-tcp-mss` value per policy takes precedence over a global `tcp-mss` value (`all-tcp`, `ipsec-vpn`, `gre-in`, `gre-out`), if one is configured. However, when the `syn-flood-protection-mode syn-proxy` statement at the `[edit security flow]` hierarchy level is used to enable SYN proxy defenses against SYN attacks, the TCP MSS value is not overriden.

Because each policy has two directions, you can configure a value for both directions or for just one direction. To configure a TCP MSS value for the reverse session, use the `reverse-tcp-mss` option.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

```

```
unit ppp-options],
[edit interfaces pp0 unit logical-unit-number ppp-options],
[edit interfaces si-fpc/pic/port unit logical-unit-number ppp-options]
```

Description

Configure PPP Network Control Protocol (NCP) negotiation mode (active or passive) for dynamic and static IPv4 and IPv6 PPP subscriber interfaces. You can also configure PPP NCP negotiation mode for the PPP server in an IPv4/IPv6 dual-stack configuration.

Options

dual-stack-passive Enable passive PPP NCP negotiation for the PPP server in an IPv4/IPv6 dual-stack configuration. The `initiate-ncp dual-stack-passive` statement overrides the `initiate-ncp ip` and `initiate-ncp ipv6` statements if they are configured in an IPv4/IPv6 dual-stack configuration.

ip Enable active PPP NCP negotiation for dynamic and static PPP subscriber interfaces configured with the IPv4 (`inet`) protocol address family, and for which IPv4 address attributes are assigned during authorization. By default, dynamic and static IPv4 subscriber interfaces use passive PPP NCP negotiation. In an IPv4/IPv6 dual-stack configuration, use the `initiate-ncp ip` statement to enable active PPP NCP negotiation for the IPv4 subscriber interface.

ipv6 Enable active PPP NCP negotiation for dynamic and static PPP subscriber interfaces configured with the IPv6 (`inet6`) protocol address family, and for which IPv6 address attributes are assigned during authorization. By default, dynamic and static IPv6 subscriber interfaces use passive PPP NCP negotiation. In an IPv4/IPv6 dual-stack configuration, use the `initiate-ncp ipv6` statement to enable active PPP NCP negotiation for the IPv6 subscriber interface.

Required Privilege Level

interface—To view this statement in the configuration.

Syntax

```
inline;
```

Hierarchy Level

```
[edit protocols lacp ppm]
```

Description

(MX Series routers with MPC line cards only) To enable the inline Link Aggregation Control Protocol (LACP) PDU transmission processing.

This statement disables the default distributed periodic packet management (PPM) processing for Link Aggregation Control Protocol (LACP) packets and run all Link Aggregation Control Protocol (LACP) PDU transmission processing inline. The inline option can be used in scenarios where the line card CPU is under heavy load and cannot schedule the PPM processing for LACP packets. PPM, by default,

delegates the transmission of PDUs to the PPMAN process on the PFE/line card. But when the inline option is configured, it delegates the transmission of LCAP PDUs even further away from the line card CPU and into the forwarding chipset.

For example, in a system with both MPCs and DPCs, upon configuration of `[protocols lacp ppm inline]`, the PDUs are sent inline on the MPCs and performed by periodic packet management (PPM) on DPCs.

> **BEST PRACTICE**: We recommend to retain the default and disable distributed PPM or enable inline processing only if Juniper Networks Customer Service advises you to do so. You should disable distributed PPM or enable inline processing only if you have a compelling reason to disable it.

Refer Disabling or Enabling Inline Periodic Packet Management for LACP Packets for more details.

Default

Distributed PPM processing is enabled for all packets that use PPM.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

inline-monitoring

IN THIS SECTION

- Syntax | 9066
- Hierarchy Level | 9067
- Description | 9067
- Options | 9067
- Required Privilege Level | 9068
- Release Information | 9068

Syntax

```
inline-monitoring {
    instance instance-name;
    observation-cloud-id observation-cloud-identifier;
    template template-name;
    traceoptions;
}
```

Hierarchy Level

```
[edit services]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Configure inline monitoring services. When you enable inline monitoring, you can monitor actual IPv4 and IPv6 packets at different sampling rates, and export the actual packet up to the configured clip length. By default, Junos OS supports a maximum packet length of 126 bytes starting with the Ethernet header. The monitored packets are exported to an collector for further processing. The packets are exported in an IPFIX format, which includes information on the original packet size, and incoming or outgoing interface.

Options

instance *instance-name*

Configure parameters for an inline-monitoring instance. See "instance" on page 9149 for more information.

observation-cloud-id *observation-cloud-identifier*

Observation cloud ID—an identifier for a particular observation cloud. An observation cloud is the largest set of observation domains. Per RFC 5101, an observation domain is the largest set of observation points for which flow information can be aggregated by a metering process. For example, a router line card may be an observation domain if it is composed of several interfaces, each of which is an observation point. The observation domain ID is unique per exporting process. Also per RFC 5101, an observation point is a location in the network where IP packets can be observed. Examples include: a line to which a probe is attached, a shared medium, such as an Ethernet-based LAN, a single port of a router, or a set of interfaces (physical or logical) of a router.

- Range: 1 through 255

template *template-name*

Configure templates for inline packet monitoring. See "template" on page 30204 for more information.

traceoptions (Optional) Configure traceoptions for the inline monitoring process. See "traceoptions" on page 30720 for more information.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.4R1.

`observation-cloud-id` option introduced in Junos OS Release 21.2R1.

```
inline-services {
                  service-port;
 bandwidth bandwidth;
}
```

Hierarchy Level

```
[edit chassis fpc slot-number pic number]
```

Description

Enable inline services on PICs residing on MPCs and optionally specify a bandwidth for traffic on the inline service interface. Bandwidth values can be 1g, 10g, 20g, 30g, 40g, 50g, 60g, 70g, 80g, 90g, 100g, 200g, 300g, or 400g.

NOTE: For an MPC, such as MPC2, always configure inline-services at the `[chassis fpc slot-number pic number]` hierarchy level. Do not configure inline services for a service card such as MS-MPC.

For MX304, MX10K-LC9600 and MX10K-LC4800:

The valid bandwidth range is 2Gbps through 400Gbps with increments of 1Gbps. When you configure inline services bandwidth of 1Gbps, the Routing Engine CLI configuration commit does not fail.

If you newly commit an inline tunnel service configuration with the bandwidth of 1Gbps or apply it as part of device reboot, `si-` interfaces are not created. However, no commit error message is displayed. If you change the bandwidth on an existing inline services configuration to 1Gbps, a commit error message will not be displayed. However, the configuration change does not take effect. The previously committed inline services configuration continues to be in effect.

The remaining statement is explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

Support added in Junos OS Release 19.3R2 for Next Gen Services on MX Series routers MX240, MX480 and MX960 with the MX-SPC3 services card.

- Release Information | 9074

Syntax

```
inner-list [vlan-id-vlan-id];
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number]
```

Description

List or a set of VLAN identifiers. `inner-list` is used in double-tagged interfaces and doesn't support Tag Protocol Identifier (TPID) values such as `0x8100`, `0x88a8`, `0x9100`, and `0x9200`. You can configure a maximum of

32 unique ranges for VLAN IDs for each IFD and configure a maximum of 1024 VLAN ID lists at the system level.

Multiple IFLs from the same IFD can use the same inner range or inner VLAN ID but the VLAN IDs cannot overlap. For example: you have 8 IFLs. IFL1 has an outer VLAN D of 400 and inner VLAN ID range of 40 to 50, and IFL2 has an outer VLAN ID of 800 and inner VLAN ID of 10. In this case, the allowed configurations could be:

- IFL3 with an outer VLAN ID of 500 and inner VLAN ID range of 40 to 50
- IFL7 with an outer VLAN ID of 100 and inner VLAN ID range of 60 to 70.

The following configurations won't be allowed:

- IFL4 with an outer VLAN ID of 600 and inner VLAN ID range of 45 to 48. This conflicts with IFL1.
- IFL6 with an outer VLAN ID of 700 and inner VLAN ID range of as 5 to 15. This conflicts with IFL2.

Options

***vlan-id-vlan-id*—The first vlan-id is the lowest VLAN ID in the range the second vlan-id is the highest VLAN ID in the range.**	• Range: 1 through 4094. VLAN ID 0 is reserved for tagging the priority of frames.

Required Privilege Level

interface—To view this statement in the configuration.

Release Information

Statement introduced in Junos OS Evolved Release 24.2R1-EVO for ACX Series Switches.

RELATED DOCUMENTATION

inner-range

IN THIS SECTION

- Syntax | 9075
- Hierarchy Level | 9075
- Description | 9075
- Options | 9075
- Required Privilege Level | 9076
- Release Information | 9076

Syntax

```
inner-range tpid.vlan-id-vlan-id;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number]
```

Description

Specify a TPID and a range of VLAN IDs. inner-range is used in double-tagged interfaces and supports all Tag Protocol Identifier (TPID) values such as `0x8100`, `0x88a8`, `0x9100`, and `0x9200`. You can configure a maximum of 32 unique ranges for VLAN IDs for each IFD and configure a maximum of 1024 VLAN ID lists at the system level.

Options

***tpid*—The global tpid used for the tag.**

***vlan-id*—The first vlan-id is the start of the range and the second vlan-id is the end of the range.**

- Range: 1 through 4094. VLAN ID 0 is reserved for tagging the priority of frames.

Required Privilege Level

interface—To view this statement in the configuration.

Release Information

Statement introduced in Junos OS Evolved Release 25.2R1-EVO for ACX.

inner-tag-protocol-id (Dynamic VLANs)

IN THIS SECTION

- Syntax | 9076
- Hierarchy Level | 9077
- Description | 9077
- Default | 9077
- Options | 9077
- Required Privilege Level | 9077
- Release Information | 9077

Syntax

```
inner-tag-protocol-id tpids;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-numberinput-vlan-map],
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number output-vlan-map]
```

Description

For dynamic VLAN interfaces, configure the IEEE 802.1Q TPID value to rewrite for the inner tag. All TPIDs you include in input and output VLAN maps must be among those you specify at the `[edit interfaces interface-name gigether-options ethernet-switch-profile tag-protocol-id tpids ]` hierarchy level.

Default

If the `inner-tag-protocol-id` statement is not configured, the TPID value is 0x8100.

Options

tpids—TPIDs to be accepted on the VLAN. Specify TPIDs in hexadecimal format.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.4.

Syntax

```
inner-tag-protocol-id tpid;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number input-vlan-map],
[edit interfaces interface-name unit logical-unit-number output-vlan-map],
[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number
input-vlan-map],
[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number
output-vlan-map]
```

Description

Configure the IEEE 802.1Q TPID value to rewrite for the inner tag.

All TPIDs you include in input and output VLAN maps must be among those you specify at the `[edit interfaces interface-name gigether-options ethernet-switch-profile tag-protocol-id [ tpids ]]` hierarchy level.

On MX Series routers, you can use this statement for Gigabit Ethernet IQ, IQ2 and IQ2-E interfaces, and for aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs.

Default

If the `inner-tag-protocol-id` statement is not configured, the TPID value is 0x8100.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Syntax

```
inner-vlan-id number;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number input-vlan-map],
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number output-vlan-map]
```

Description

For dynamic VLAN interfaces, specify the VLAN ID to rewrite for the inner tag of the final packet.

You cannot include the `inner-vlan-id` statement with the `swap` statement, `swap-push` statement, `push-push` statement, or `push-swap` statement and the `inner-vlan-id` statement at the [`edit logical-systems` *`logical-system-name`* `interfaces` *`interface-name`* `unit` *`logical-unit-number`* `output-vlan-map`] hierarchy level. If you include any of those statements in the output VLAN map, the VLAN ID in the outgoing frame is rewritten to the `inner-vlan-id` statement you include at the [`edit interfaces` *`interface-name`* `unit` *`logical-unit-number`*] hierarchy level.

Options

`number`—VLAN ID number. When used for input VLAN maps, you can specify the `$junos-inner-vlan-map-id` predefined variable to dynamically obtain the VLAN identifier.

- **Range:** 0 through 4094

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Syntax

```
inner-vlan-id-swap-ranges low-inner-tag-high-inner-tag;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number]
```

Description

Define core-facing VLAN ID ranges from which an inner VLAN ID tag can be allocated to replace the outer VLAN tag that was appended by the access node on the upstream packets to the BNG in a Layer 2 wholesale network. The tag swap occurs before the subscriber traffic is forwarded to the network service provider (NSP). You can configure up to 32 non-overlapping inner VLAN ID ranges per core-facing physical interface for VLAN-OOB subscribers.

You can add or remove ranges or increase or decrease the size of existing ranges even while Layer 2 wholesale sessions are assigned to the core-facing interface associated with the ranges. You cannot remove a range from which a VLAN ID has already been allocated. You cannot reduce a range if the new range excludes a VLAN ID that has already been allocated.

Options

low-inner-tag Inner (core-facing) VLAN ID tag representing the lower limit of the swap range.

- **Range:** 1 through 4094.

high-inner-tag Inner (core-facing) VLAN ID tag representing the upper limit of the swap range.

- **Range:** 1 through 4094.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.2R1.

```

```
        interface  (all | interface-name);
        routing-instance {
            instance-name {
                bridge-domain bridge-domain-name;
            }
            vlan (vlan-id | vlan-name);
        }
        vlan (vlan-id | vlan-name);
    }
    maximum-packet-length bytes;
    rate number;
}
```

Hierarchy Level

```
[edit forwarding-options analyzer analyzer-name]
```

Description

Define the traffic to be mirrored in a mirroring configuration—the definition can be a combination of:

- Packets entering or exiting a port
- Packets entering or exiting a VLAN
- Packets entering or exiting a bridge domain

The remaining statements are explained separately. See CLI Explorer.

Native analyzer sessions (that is, the `[edit forwarding-options analyzer analyzer-name input]` hierarchy level for MX Series routers) can be configured without specifying input parameters, which would mean that the instance uses default input values: rate = 1 and maximum-packet-length = 0.

Default

No default.

input (Fibre Channel Interfaces)

IN THIS SECTION

- Syntax | 9089
- Hierarchy Level | 9090
- Description | 9090
- Required Privilege Level | 9090

Syntax

```
input {
    ieee-802.1{
```

```
        code-point code-point-bits;
    }
}
```

Hierarchy Level

```
[edit class-of-service interfaces fibre-channel-interface-name rewrite-value]
```

Description

Configure the IEEE 802.1p code point value to which all traffic received from the Fibre Channel (FC) network on the specified FC interface is rewritten. After the code point value is rewritten, the interface forwards the traffic to the Ethernet (FCoE) network. This works in conjunction with configuring a fixed classifier on the FC interface. The fixed classifier maps all traffic from the FC network into one lossless forwarding class (the lossless forwarding class must be mapped to the code point specified in the rewrite value). Traffic mapped to the lossless forwarding class uses the IEEE 802.1p priority specified by the code point bits in the rewrite value.

FCoE networks typically use priority 3 (IEEE code point 011) for FCoE traffic. The QFX Series default configuration uses IEEE 802.1p priority 3 for FCoE traffic. Rewriting the code point value enables you to change the IEEE 802.1p priority of the FCoE traffic if the Ethernet network uses a different priority than priority 3 (code point 011).

The system supports only one IEEE 802.1p code point value per FC interface. You cannot configure more than one IEEE 802.1p rewrite value per FC interface. In addition, you can specify only one rewrite value per local FCoE-FC gateway fabric; all interfaces in the local fabric must use the same rewrite value. Attempting to configure FC interfaces in the same local fabric with different rewrite values generates a commit error. You can specify different rewrite values for interfaces that belong to different local FCoE-FC gateway fabrics.

The statements are described separately.

- Release Information | 9100

Syntax

```
input-chain [ filter-name ]
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family family filter]
```

Description

The `input-chain` command works like the **next** filter term to allow multiple levels of filtering on the interface in both the ingress and egress direction. For example, you can implement a combination of classification and firewall filter rules for evaluation, wherein the first filter performs a generic filter classification and the subsequent filters go on to perform the actual filtering and actions.

To continue on to the next filter, the terminating action in the current filter must be **accept**.

The `input-chain` command is supported on all interfaces except loopback (lo0 and fxp0) and interfaces under logical systems.

Options

[*filter-names*]—Name of each filter in the chain that is to be evaluated when packets are received on the interface. Supports up to 8 ingress and 8 egress filters. Evaluation occurs in the order in which the names appear, from left to right.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Syntax

```
input-hierarchical-policer policer-name;
```

Hierarchy Level

```
[edit interfaces interface-name layer2-policer],
[edit interfaces interface-name unit logical-unit-number layer2-policer]
```

Description

Apply a hierarchical policer to the Layer 2 input traffic for all protocol families at the physical or logical interface.

Options

policer-name—Name of the hierarchical policer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

RELATED DOCUMENTATION

input-native-vlan-push

IN THIS SECTION

- Syntax | 9109
- Hierarchy Level | 9110
- Description | 9110
- Default | 9110
- Options | 9110
- Required Privilege Level | 9110
- Release Information | 9110

Syntax

```
input-native-vlan-push (disable | enable);
```

Hierarchy Level

```
[edit interfaces interface-name]
```

Description

On EX2300, EX3400, EX4300, EX4300-MP, EX4600, EX4650, and the QFX5000 line of switches except QFX5220, QFX5130, QFX5230, QFX5240, and QFX5700, for a Q-in-Q tunneling configuration, enable or disable whether the switch inserts a native VLAN identifier in untagged frames received on the C-VLAN interface when the configuration statement "input-vlan-map" on page 9128 with a `push` operation is configured. QFX5220, QFX5130, QFX5230, QFX5240, and QFX5700 switches do not insert a native VLAN identifier in untagged frames received on the C-VLAN interface when the configuration statement "input-vlan-map" on page 9128 with a `push` operation is configured.

Default

If you do not include the `input-native-vlan-push` statement, the option is enabled.

> **NOTE**: Starting in Junos OS Release 21.4R3-S7, the default on EX4300 switches is `enable`, In earlier releases, the default is `disable`.

Options

disable Disable `input-native-vlan-push`.

enable Enable `input-native-vlan-push`.

Required Privilege Level

interface

Release Information

Statement introduced in Junos OS Release 19.3R1 on EX Series and QFX Series switches.

input-scheduler-map

IN THIS SECTION

- Syntax | 9115
- Hierarchy Level | 9116
- Description | 9116
- Options | 9116
- Required Privilege Level | 9116
- Release Information | 9116

Syntax

```
input-scheduler-map map-name;
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name],
[edit class-of-service interfaces interface-name unit logical-unit-number]
```

Description

Associate a scheduler map with a physical or logical input interface. The `input-scheduler-map` and `input-traffic-control-profile` statements are mutually exclusive at the same hierarchy level.

NOTE: On some devices, CoS queuing and scheduling are enabled on the egress side but disabled on the ingress side by default. To enable ingress CoS, you must configure the `traffic-manager` statement with `ingress-and-egress` mode:

```
[edit chassis fpc slot-number pic pic-number]
traffic-manager mode ingress-and-egress;
```

Options

map-name—Name of scheduler map that you define at the `[edit class-of-service scheduler-maps]` hierarchy level.

`default`—The default scheduler mapping.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

input-shaping-rate (Logical Interface)

IN THIS SECTION

- Syntax | 9117
- Hierarchy Level | 9117
- Description | 9117
- Default | 9118
- Options | 9118
- Required Privilege Level | 9118
- Release Information | 9118

Syntax

```
input-shaping-rate (percent percentage | rate);
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
```

Description

Configure input traffic shaping by specifying the amount of bandwidth to be allocated to the logical interface. You can configure hierarchical shaping, meaning you can apply an input shaping rate to both the physical interface and the logical interface.

Default

If you do not include this statement, logical interfaces share a default scheduler. This scheduler has a committed information rate (CIR) that equals 0. (The CIR is the guaranteed rate.) The default scheduler has a peak information rate (PIR) that equals the physical interface shaping rate.

Options

percent *percentage*
Shaping rate as a percentage of the available interface bandwidth.

- **Range:** 0 through 100 percent

rate
Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 1000 through 6,400,000,000,000 bps

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

        }
    }
    input-ipfix {
        parameters {
            maximum-connections number;
            tcp-port port-number;
            vrf-name name;
        }
    }
    input-jti-ipfix {
        parameters {
            record-group group-name {
                record ipfix-record-name;
                reporting-interval seconds;
            }
        }
```

```
    }
}
```

Hierarchy Level

```
[edit services analytics agent service-agents agent-name]
```

Description

Configure parameters for a Network Telemetry Framework (NTF) service agent input plug-in. For each service agent instance, you can configure more than one input plug-in to push data to the output plug-in.

> **NOTE**: When you modify the input plug-in configuration of a service agent instance, the associated service agent daemon is restarted.

Options

analytics parameters
Configure parameters to collect data from Junos Telemetry Interface (JTI) sensors.

generate-tags *value*
(Optional) Enable tag generation.

- **Default:** Enabled

sample-frequency *value*
Specify the frequency interval (in seconds) at which the JTI sensor generates data to export to the data collector. Range is from 0 to 24 hours.

- **Default:** 5 seconds

sensors *file-path*
Specify the resource string associated with the JTI sensor for collecting JTI data from a specific resource. The format is a file path and must be entered exactly. For a list of available JTI resource string options, see the sensor configuration statement and Guidelines for gRPC and gNMI Sensors (Junos Telemetry Interface) documentation.

input-ipfix parameters
Configure parameters for the IPFIX mediation service agent to gather and consolidate IPFIX records from downstream devices.

> **NOTE**: Any change you make to an existing `input-ipfix` plug-in configuration restarts the IPFIX service agent daemon to apply the changes.

> **NOTE**: Although each of the parameters has a default value, you must configure at least one of the parameters to enable the plug-in. If you configure only one parameter and want to use the default value, you must specify that value.

maximum-connections *number*

(Optional) Maximum number of TCP connections that the IPFIX mediator can support.

- **Range:** 1 through 500
- **Default:** 100

tcp-port *port-number*

(Optional) TCP port on the IPFIX mediator that receives TCP packets; the listening port.

- **Default:** 4739

vrf-name *name*

(Optional) Name of the VRF (routing instance) in which IPFIX packets are accepted.

- **Default:** default

input-jti-ipfix parameters

Configure parameters for the IPFIX mediation service agent to collect and report local sensor data from the BNG configured as an IPFIX mediator. For each group of records, the plug-in subscribes to the specific sensor data sets associated with each record.

When you remove a record group from the configuration, the sensor sets for the member records are unsubscribed. The template IDs for the associated IPFIX records are returned to the pool for re-use.

record *ipfix-record-name*

One of the following individual IPFIX records associated with a nonconfigurable set of local sensor data. See *Telemetry Data Collection on the IPFIX Mediator for Export to an IPFIX Collector* for the sensors collected by each record.

address-pool-utilization	port-statistics

chassis-inventory	resource-utilization
chassis-power	subscriber-statistics
dhcpv4-server-stats	thermal
interface-metadata	uptime
interface-queue-statistics	

BEST PRACTICE: We recommend that you configure the `interface-metadata` record whenever you configure the `interface-queue-statistics` record. The metadata information is essential for understanding details about the subscriber whose queue statistics are being collected.

record-group *group-name*

Name of a group of IPFIX records that subscribes to the sensor data sets associated with the individual records that comprise the record group. You can configure a maximum of 10 record groups.

reporting-interval *seconds*

(Optional) Interval in seconds between reports for the subscribed sensor data. The interval applies to all records (and all sensor sets) in the record group.

- **Range:** 60 through 86,400 seconds
- **Default:** 900 seconds

Required Privilege Level

[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
[edit protocols source-packet-routing source-routing-path lsp-name]
```

Description

Associate one or more prefixes with an LSP. When the LSP is up, all the prefixes are installed as entries into the inet.3 or inet6.3 routing table.

The support of the `install` statement at the `[edit protocols source-packet-routing source-routing-path lsp-name]` is applicable for both colored and non-colored segment routing LSPs.

For static colored LSPs, when the install prefix is configured, a route similar to the tunnel ingress route is installed in the `inetcolor.0` or `inet6color.0` routing table.

On the other hand, for static non-colored LSPs, when the install prefix is configured, a route similar to the tunnel `to` route is installed in `inet.3` or `inet6.3` routing table.

You can use the "show route table" on page 24698 command to view the `install` routes for both colored and non-colored segment routing traffic-engineered LSPs.

NOTE: Take the following into consideration when configuring the `install` *`destination-prefix`* statement at the `[edit protocols source-packet-routing source-routing-path` *`lsp-name`*`]` hierarchy level:

- The install prefixes should be unique in a tunnel, and should not be the same as the tunnel `to` address. A commit check is done to ensure that the prefixes are unique.
- If two install prefixes are same across two different tunnels, then the gateways of the both tunnels are considered only if the segment lists are of the same resolution type. If the first hop resolution types vary, the route is not installed. In such cases, a system log message is generated to record the error.

For example:

```
[edit protocols source-packet-routing]
segment-list path-1 {
    hop-1 ip-address 172.0.12.2;
    hop-2 label 1000012;
    hop-3 label 1000013;
    hop-4 label 1000014;
}
source-routing-path lsp1 {
    to 10.10.10.1;
    install 20.20.20.2;
    install 30.30.30.3;
    primary {
        path-1;
    }
}
```

The `inet.3` routing table has two additional routes (to 20.20.20.2 and 30.30.30.3) with next hops derived from the same segment list path-1 with same attributes as the `to` address route.

Options

active (Optional) Install the route into the inet.0 or inet6.0 routing table. This allows you to issue a `ping` or `traceroute` command on this address.

> **NOTE**: The `install` *`destination-prefix`* `active` statement is not supported on static LSPs. When the `install` *`destination-prefix`* `active` statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

destination-prefix IPv4 or IPv6 address to associate with the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support at the `[edit protocols source-packet-routing source-routing-path lsp-name]` hierarchy level introduced in Junos OS Release 19.1R1.

[edit routing-instances routing-instance-name routing-options static (defaults | route)],
[edit routing-options rib routing-table-name static (defaults | route)],
[edit routing-options static (defaults | route)]
```

Description

Configure whether Junos OS installs all static routes into the forwarding table. Even if you configure a route so it is not installed in the forwarding table, the route is still eligible to be exported from the routing table to other protocols.

Options

install—Explicitly install all static routes into the forwarding table. Include this statement when configuring an individual route in the **route** portion of the `static` statement to override a **no-install** option specified in the **defaults** portion of the statement.

no-install—Do not install the route into the forwarding table, even if it is the route with the lowest preference.

- **Default: install**

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

```

Hierarchy Level

```
[edit logical-systems logical-system-name policy-options policy-statement policy-name term term-
name then],
[edit policy-options policy-statement policy-name term term-name then]
```

Description

Select a specific label-switched path (LSP), or select an LSP from a set of similarly named LSPs as the traffic destination for the configured community. Also can prevent the installation of any matching next hops.

Options

`except`—Prevent the installation of any matching next hops.

`fallback`—Backup option

`lsp` *`lsp-name`*—Configure a specific LSP.

`lsp-regex` *`lsp-regular-expression`*—Configure a range of similarly named LSPs. You can use the following wildcard characters when configuring an LSP regular expression:

- Asterisk (*)—Match any characters.
- Period (.)—Match any single digit.

`non-labelled-nexthop`—Next-hop without tag

`non-lsp-nexthop`—Next-hop with non-lsp

`overlay-vxlan-interfaces`—Next-hop for VXLAN interfaces

`static-lsp`—Next-hop static LSP name

`static-lsp-regex`—Next-hop static LSP name regular expression

`strict`—Do not use any other available next hops

`strict-named-lsp`—Do not use any other non-lsp next hops

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`overlay-vxlan-interfaces` statement introduced in Junos OS Release 22.4R1.

`overlay-vxlan-interfaces` statement introduced in Junos OS Evolved Release 22.4R1.

instance (CASB)

IN THIS SECTION

- Syntax | 9145
- Hierarchy Level | 9145
- Description | 9145
- Options | 9145
- Required Privilege Level | 9146

- Release Information | 9147

Syntax

```
instance instance-name {
 application application-name;
    domain domain-name;
 instance-id instance-id;
 tag tag-value;
 type type;
}
```

Hierarchy Level

```
[edit security casb]
```

Description

Configure Cloud Access Security Broker (CASB) instance.

Configuring the CASB instance with specific parameters such as the application, instance ID, domain, and type allows controlled access by differentiating between corporate and non-corporate usage of cloud applications.

Options

instance *instance-name*	CASB instance name.
application *application-name*	Application name.
domain *domain-name*	An email domain address.

For example, acmecorp07.com is an organization domain. Then, Box, Dropbox, Google Docs, Salesforce, Microsoft OneDrive, SharePoint, Gmail, and Slack uses the same domain for all the users.

instance-id *id*

Each application has a unique web address (URL) to access it. This web address includes a special identifier (such as 'acmecorp07') that points to a specific instance of the application.

- Box—acmecorp07.app.box.com
- Microsoft OneDrive or SharePoint—acmecorp07ms-my.sharepoint.com
- Salesforce URLs—
- • acmecorp07.my.salesforce.com
  - acmecorp07.lightning.force.com
- Slack—acmecorp-zoy8730.slack.com.

Following are generic URLs and instance ID is not applicable.

- Dropbox—dropbox.com
- Google Docs—docs.google.com
- Gmail—mail.google.com

tag

Specify tag value. You can specify one of the following options:

- Sanctioned—Application instances sanctioned by your organization.
- Unsanctioned—Application instances unsanctioned by your organization.

type

Specify type of instance. You can specify one of the following option.

- Work
- Personal

You must configure the type for Dropbox. For other applications, this configuration is optional.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 24.2R1.

instance (Ephemeral Database)

IN THIS SECTION

- Syntax | 9147
- Hierarchy Level | 9147
- Description | 9147
- Options | 9148
- Required Privilege Level | 9149
- Release Information | 9149

Syntax

```
instance instance-name {
    cyclic-version version;
    resize {
        database-size-diff size MB;
        database-size-on-disk size MB;
    }
}
```

Hierarchy Level

```
[edit system configuration-database ephemeral]
```

Description

Enable an instance of the ephemeral configuration database.

The order in which the configuration lists the instances determines their priority when merging conflicting configuration statements from different instances into the configuration. The instances are listed in order from highest to lowest priority. In addition, user-defined instances of the ephemeral configuration database have higher priority than the default ephemeral database instance, which has higher priority than the static configuration database.

> **TIP**: When you configure an ephemeral instance, you can specify its placement in the configuration by using the `insert` command instead of the `set` command.

Table 64 on page 9148 summarizes the maximum number of user-defined ephemeral database instances supported for different Junos OS variants.

Table 64: Maximum Ephemeral Database Instances

Junos OS Variant	Maximum Instances
Junos OS	7
Junos OS Evolved	8

Options

`cyclic-version` *`version`*

Number of versions of the ephemeral instance's database for which the system stores deleted configuration objects. After each commit, the device reclaims the space occupied by objects deleted in the previous database version relative to the current database version as determined by the cyclic version value. You can disable cyclic versioning by setting the value to 0.

Thus, starting with the 11th commit operation, the device, by default, reclaims the space occupied by objects deleted in version 1 of the database. The process continues with each subsequent commit operation.

- **Default:** 10
- **Range:** 0 through 4,294,967,295

instance-name

User-defined name for an instance of the ephemeral configuration database.

The instance name must contain only alphanumeric characters, hyphens, and underscores, and it must not exceed 32 characters. You cannot use `default` as the name.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

maintenance—To view or add this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 16.2R2 and Junos OS Evolved Release 22.1R1.

`cyclic-version` statement introduced in Junos OS Release 23.2R1 and Junos OS Evolved Release 23.2R1.

instance (Inline Monitoring)

IN THIS SECTION

- Syntax (Junos OS) | 9150
- Syntax (Junos OS Evolved) | 9150
- Hierarchy Level | 9150
- Description | 9150
- Options | 9150
- Required Privilege Level | 9151
- Release Information | 9151

Syntax (Junos OS)

```
instance name {
    collector name;
    maximum-clip-length maximum-clip-length;
    template-name template-name;
}
```

Syntax (Junos OS Evolved)

```
instance name {
    collector name;
    controller name;
    export-by-asic;
    maximum-clip-length maximum-clip-length;
    sampling-rate sampling-rate;
    template-name template-name;
}
```

Hierarchy Level

```
[edit services inline-monitoring]
```

Description

Configure inline-monitoring instance parameters. You can use these instances along with firewall filters to monitor different streams of traffic at different sampling rates from the same interface.

You can configure a maximum of sixteen (Junos OS) or seven (Junos OS Evolved) inline-monitoring instances with four collectors each.

Options

name Name of instance.

collector *name* Configure an collector for the inline-monitoring instance. See "collector" on page 4647 for more information.

controller (Junos OS Evolved only) Configure inline-monitoring services for packet redirects to the P4 controller or to the Routing Engine. See "controller" on page 4892 for more information.

export-by-asic For those platforms and line cards that support this feature, export IPFIX packets to a collector using the hardware. See "export-by-asic" on page 6975 for more information.

maximum-clip-length Maximum packet length.

- **Range:** 64 through 126 bytes (Junos OS)

  Range: 64 through 256 bytes (Junos OS Evolved)

- **Default:** 126 bytes (Junos OS)

  Default: 128 bytes (Junos OS Evolved)

sampling-rate (Junos OS Evolved) Rate at which the traffic is sampled. In Junos OS, you do not specify the sampling rate here; you specify the sampling rate at the `[edit services inline-monitoring instance` *`instance-name`* `collector` *`collector-name`*`]` hierarchy level.

For example, if you specify 1000, then 1 packet out of every 1000 packets is sampled.

- **Range:** 1 through 32000000
- **Default:** 1

template-name Name of the template.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS 19.4R1.

Statement introduced in Junos OS Evolved Release 22.2R1.

`export-by-asic` option introduced in Junos OS Evolved 24.4R1.

}
```

Hierarchy Level

```
[edit services traffic-load-balance]
```

Description

Configure a Traffic Load Balancer instance.

Options

client-interface *client-interface*	—For translated mode, client interface where the implicit filter is installed to direct the traffic in the forward direction.
client-vrf *client-vrf*	Use the specified name of the routing instance in which the data traffic in the reverse direction is routed to the clients.
instance *instance-name*	Identifier (text string) for a TLB configuration.
server-inet-bypass-filter *server-inet-bypass-filter*	Name of the firewall filter from which the terms are referenced and added to the server-side implicit filters. This enables the operator to bypass reverse (RIP to VIP) translation of IPv4 traffic.
server-inet6-bypass-filter *server-inet6-bypass-filter*	Name of the firewall filter from which the terms are referenced and added to the server-side implicit filters. This enables the operator to bypass reverse (RIP to VIP) translation of IPv6 traffic.
server-interface *server-interface*	For translated mode, specifies the server interfaces where the server filters are implicitly installed to direct the return traffic to the load balancing next hop.
server-vrf *server-vrf-name*	The routing instance in which the data traffic in the forward direction is routed to the servers

The remaining statements are explained separately. See CLI Explorer.

instance-role

IN THIS SECTION

- Syntax | 9167
- Hierarchy Level | 9167
- Description | 9167
- Options | 9167
- Required Privilege Level | 9168
- Release Information | 9168

Syntax

```
instance-role (access | nni);
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name],
[edit routing-instances routing-instance-name]
```

Description

Define the role of the routing instance in a Layer 2 Wholesale network.

Options

access—Defines the connectivity role of the routing instance in a Layer 2 Wholesale network as an access routing instance. When defined for this role, the same process occurs as in a Layer 3 Wholesale network—when the first packet is received from a given client, authentication for the client initiates with an

external entity (for example, RADIUS). If authentication is successful, a logical interface is created with the appropriate outer and inner VLAN tags for that client.

`nni`—Defines the connectivity role of the routing instance in a Layer 2 Wholesale network as a network to network interface (NNI) routing instance. When defined for this role, only outer VLAN tags are learned. In addition, when the NNI routing instance receives a response from the ISP, the packets are forwarded to the appropriate client, provided the packet has the same two tags that were verified during authentication.

> **NOTE**: If you connect an access node or MSAN device to a router participating in the Layer 2 Wholesale network in an NNI role, you must create a new routing instance of type `l2backhaul-vpn` with an instance role of type `access` for that connection.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

instance-shared

IN THIS SECTION

- Syntax | 9169
- Hierarchy Level | 9169

- Description | 9169
- Required Privilege Level | 9169
- Release Information | 9169

Syntax

```
instance-shared;
```

Hierarchy Level

```
[edit firewall family protocol-family-name filter filter-name],
[edit logical-systems logical-system-name firewall family protocol-family-name filter filter-
name]
```

Description

Specify to share the firewall filter across multiple routing instances. By default, firewall filters are not automatically shared across multiple instances. You can configure both shared and nonshared firewall filters on the same routing device. This statement can be used only when network services for the device are configured with enhanced IP mode.

The following protocol families are supported: Bridge, IPv4, IPv6, Layer 2 CCC, MPLS, and VPLS.

NOTE: Only Modular Port Concentrators (MPCs) are supported.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

instance-type

IN THIS SECTION

- Syntax | 9170
- Hierarchy Level | 9170
- Description | 9170
- Options | 9171
- Required Privilege Level | 9173
- Release Information | 9173

Syntax

```
instance-type type;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name],
[edit routing-instances routing-instance-name]
```

Description

Define the type of routing instance.

> **CAUTION**: We strongly recommend that if you change an `instance-type` referenced under a firewall filter, for example, from `virtual-router` to `forwarding`, make the change during a maintenance window, as follows:
>
> 1. Deactivate the routing instance.
> 2. Change the `instance-type`.
> 3. Activate the routing instance.
>
> This is not required if you are configuring the `instance-type` for the first time.

Options

type—Can be one of the following:

- `evpn`—Enable an Ethernet VPN (EVPN) on the routing instance.
  - On Junos OS Evolved, `instance-type evpn` is not supported. You can configure an EVPN routing instance using `instance-type mac-vrf` with a routing protocol configuration of `protocols evpn`.

    ```
    set routing-instances $EVPN_INSTANCES$ instance-type mac-vrf protocols evpn
    ```

- `evpn-vpws`—Enable an Ethernet VPN (EVPN) Virtual Private Wire Service (VPWS) on the routing instance.
- `forwarding`—Provide support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance. Other instances are used for populating RPD learned routes. For this instance type, there is no one-to-one mapping between an interface and a routing instance. All interfaces belong to the default instance inet.0.
- `l2backhaul-vpn`—Provide support for Layer 2 wholesale VLAN packets with no existing corresponding logical interface. When using this instance, the router learns both the outer tag and inner tag of the incoming packets, when the `instance-role` statement is defined as `access`, or the outer VLAN tag only, when the `instance-role` statement is defined as `nni`.
- `l2vpn`—Enable a Layer 2 VPN on the routing instance. You must configure the `interface`, `route-distinguisher`, `vrf-import`, and `vrf-export` statements for this type of routing instance.
- `layer2-control` —(MX Series routers only) Provide support for RSTP or MSTP in customer edge interfaces of a VPLS routing instance. This instance type cannot be used if the customer edge interface is multihomed to two provider edge interfaces. If the customer edge interface is multihomed to two provider edge interfaces, use the default BPDU tunneling.

- `mac-vrf`—Enable configuring multiple customer-specific EVPN instances (EVIs) of this type, each of which can support a different EVPN service type. You can have customer-specific virtual routing and forwarding (VRF) tables with MAC addresses on each Juniper Networks device that serves as a virtual tunnel endpoint (VTEP) in the EVPN-VXLAN network. See "mac-vrf" on page 10704 for more on this type of EVPN instance.

- `mpls-forwarding`—(MX Series routers only) Allow filtering and translation of route distinguisher (RD) values in IPv4 and IPv6 VPN address families on both routes received and routes sent for selected BGP sessions. In particular, for Inter-AS VPN Option-B networks, this option can prevent the malicious injection of VPN labels from one peer AS boundary router to another.

- `mpls-internet-multicast`—(EX Series, M Series, MX Series, and T Series routers only) Provide support for ingress replication provider tunnels to carry IP multicast data between routers through an MPLS cloud, using MBGP or next-generation MVPN.

- `no-forwarding`—This is the default routing instance. Do not create a corresponding forwarding instance. Use this routing instance type when a separation of routing table information is required. There is no corresponding forwarding table. All routes are installed into the default forwarding table. IS-IS instances are strictly nonforwarding instance types.

- `virtual-router`—Enable a virtual router routing instance. This instance type is similar to a VPN routing and forwarding instance type, but used for non-VPN-related applications. You must configure the `interface` statement for this type of routing instance. You do not need to configure the `route-distinguisher`, `vrf-import`, and `vrf-export` statements.

- `virtual-switch`—(Not supported on QFX5xxx switches running either Junos OS or Junos OS Evolved) Provide support for Layer 2 bridging. Use this routing instance type to isolate a LAN segment with its Spanning Tree Protocol (STP) instance and to separate its VLAN identifier space. We also support this routing instance type for EVPN instances.

> **NOTE**: When you want to configure EVPN protocol settings in a `virtual-switch` instance, you must do so at the same time you configure the `virtual-switch` instance. Otherwise the device has problems adding EVPN Type 2 (MAC-IP) route entries in the EVPN routing tables.
>
> If you need to update an existing `virtual-switch` instance in an active configuration to add EVPN protocol settings (`set … protocols evpn`), you must:
>
> 1. Deactivate the `virtual-switch` instance configuration.
> 2. Add the EVPN protocol statements to the `virtual-switch` instance configuration.

3. Reactivate the updated `virtual-switch` instance configuration with the EVPN protocol updates.

- `vpls`—Enable VPLS on the routing instance. Use this routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN. You must configure the `interface`, `route-distinguisher`, `vrf-import`, and `vrf-export` statements for this type of routing instance.
  - On Junos OS Evolved, `instance-type vpls` is not supported. You can configure a VPLS routing instance using `instance-type virtual-switch` with a routing protocol configuration of `protocols vpls`.

```
set routing-instances $VPLS_INSTANCE$ instance-type virtual-switch protocols vpls
```

- `vrf`—VPN routing and forwarding (VRF) instance. Provides support for Layer 3 VPNs, where interface routes for each instance go into the corresponding forwarding table only. Required to create a Layer 3 VPN. Create a VRF table (*instance-name*.`inet.0`) that contains the routes originating from and destined for a particular Layer 3 VPN. For this instance type, there is a one-to-one mapping between an interface and a routing instance. Each VRF instance corresponds with a forwarding table. Routes on an interface go into the corresponding forwarding table. You must configure the `interface`, `route-distinguisher`, `vrf-import`, and `vrf-export` statements for this type of routing instance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`virtual-switch` and `layer2-control` options introduced in Junos OS Release 8.4.

`mpls-internet-multicast` option introduced in Junos OS Release 11.1 for the EX Series, M Series, MX Series, and T Series.

`evpn` option introduced in Junos OS Release 13.2 for MX 3D Series routers.

`evpn` option introduced in Junos OS Release 17.3 for the QFX Series.

`forwarding` option introduced in Junos OS Release 14.2 for the PTX Series.

`mpls-forwarding` option introduced in Junos OS Release 16.1 for the MX Series.

`evpn-vpws` option introduced in Junos OS Release 17.1 for MX Series routers.

`mac-vrf` option introduced in Junos OS Release 20.4 and Junos OS Evolved Release 21.2R1.

Support for logical systems on MX Series routers added in Junos OS Release 17.4R1.

`evpn-vpws` option introduced in cRPD Release 20.3R1.

intelligent-prescreening

IN THIS SECTION

- Syntax | 9177
- Hierarchy Level | 9178
- Description | 9178
- Required Privilege Level | 9178
- Release Information | 9178

Syntax

```
intelligent-prescreening;
```

Hierarchy Level

```
[edit security utm default-configuration]
[edit security utm feature-profile anti-virus juniper-express-engine profile profile-name scan-options]
[edit security utm feature-profile anti-virus kaspersky-lab-engine profile profile-name scan-options]
```

Description

Enable intelligent prescreening.

Intelligent prescreening tells the antivirus module to begin scanning a file much earlier. In this case, the scan engine uses the first packet or the first several packets to determine if a file could possibly contain malicious code. The scan engine does a quick check on these first packets and if the scan engine finds that it is unlikely that the file is infected, it then determines that it is safe to bypass the normal scanning procedure.

You can disable intelligent prescreening with the `no-intelligent-prescreening` statement.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

The Express and Kaspersky Antivirus feature is not supported from Junos OS Release 15.1x49-D10 onwards. For previous releases, statement introduced in Junos OS Release 9.5.

The `[edit security utm default-configuration]` hierarchy level is introduced in Junos OS Release 18.2R1.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
15.1X49-D10	The Express and Kaspersky Antivirus feature is not supported from Junos OS Release 15.1x49-D10 onwards.

inter-as (Routing Instances)

IN THIS SECTION

- Syntax | 9182
- Hierarchy Level | 9183
- Description | 9183
- Options | 9183
- Required Privilege Level | 9184
- Release Information | 9184

Syntax

```
inter-as{
    ingress-replication {
        create-new-ucast-tunnel;
        label-switched-path-template {
            (default-template lsp-template-name);
        }
    }
    inter-region-segmented {
        fan-out <leaf-AD routes>);
        threshold <kilobits>);
    }
```

```
    ldp-p2mp;
    rsvp-te {
        label-switched-path-template {
            (default-template lsp-template-name);
        }
    }
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name provider-tunnel]
```

Description

These statements add Junos support for segmented RSVP-TE provider tunnels with next-generation Layer 3 multicast VPNs (MVPN), that is, Inter-AS Option B. Inter-AS (autonomous-systems) support is required when an L3VPN spans multiple ASes, which can be under the same or different administrative authority (such as in an inter-provider scenario). Provider-tunnels (p-tunnels) segmentation occurs at the Autonomous System Border Routers (ASBR). The ASBRs are actively involved in BGP-MVPN signaling as well as data-plane setup.

In addition to creating the Intra-AS p-tunnel segment, these Inter-AS configurations are also used for ASBRs to originate the Inter-AS Auto Discovery (AD) route into Exterior Border Gateway Protocol (eBGP).

Options

ingress-replication

Select the ingress replication tunnel for further configuration.

- Choose `create-new-ucast-tunnel` to create a new unicast tunnel for ingress replication.
- Choose `label-switched-path` to create a point-to-point LSP unicast tunnel, and then choose `label-switched-path-template` to use the default template and parameters for dynamic point-to-point LSP.

inter-region-segmented

Select whether Inter-Region Segmented LSPs are triggered by `threshold rate`, or `fan-out`, or both. Supported tunnels are PIM-SSM and PIM-ASM; Inter-region-segmented cannot be set for PIM tunnels.

- Choose `fan-out` and then specify the number (from 1 to 10,000) of remote Leaf-AD routes to use as a trigger point for segmentation.
- Choose `threshold` and then specify a data threshold rate (from 0 to 1,000,000 kilobytes per second) to use to use as a trigger point for segmentation.

ldp-p2mp Select to use LDP point-to-multipoint LSP for flooding; LDP P2MP must be configured in the master routing instance.

rsvp-te Select to use RSVP-TE point-to-multipoint LSP for flooding.

- Choose `label-switched-path-template` to use the default template and parameters for dynamic point-to-point LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.1R1.

inter-domain

IN THIS SECTION

- Syntax | 9185
- Hierarchy Level | 9185
- Description | 9185
- Required Privilege Level | 9185

Release Information | 9185

Syntax

```
inter-domain;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path label-switched-path-name],
[edit protocols mpls label-switched-path label-switched-path-name]
```

Description

Allows the router to search for routes in the IGP database. You need to configure this statement on routers that might be unable to locate a path using intra-domain CSPF (by looking in the traffic engineering database (TED). When you configure inter-area or inter-AS LSPs, the `inter-domain` statement is required.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

wildcard-source],
[edit routing-instances instance-name provider-tunnel selective wildcard-group-inet wildcard-
source],
[edit routing-instances instance-name provider-tunnel selective wildcard-group-inet6 wildcard-
source]
```

Description

Configure segmentation of inter-region on an ingress PE router or transit area boundary routers (ABRs) by specifying only a fan-out factor or threshold rate or both. The inter-region segmentation allows the PE router to signal segmented S-PMSI A-D routes. If the segmentation is based on the threshold, then the MVPN starts migrating the traffic flow to a segmented S-PMSI when the threshold configured for the selective tunnel reaches the threshold rate. The threshold value can be configured for S-PMSI with LDP-P2MP, IR, and RSVP-TE tunnel types. If the fan-out value is configured, then the traffic flow is moved to segmented S-PMSI when the number of leaf A-D routes per S-PMSI meets the configured fan-out value. The fan-out value can be configured for wildcard S-PMSI, and S-PMSI.

If both threshold and fan-out values are set for S-PMSI with LDP-P2MP, IR, and RSVP-TE tunnel types, then the traffic flow to the segmented inter-region happens only when the traffic rate multiplied by the number of leaf A-D routes exceeds the threshold value.

Options

fan-out *fan-out-value*
Specify the number of remote leaf A-D route values for fan-out. Once the number of leaf A-D routes per S-PMSI meets the configured fan-out value, the inter-region segmentation is triggered and the traffic flow is directed to segmented S-PMSI.

- **Range:** 1 through 10000

threshold *rate-value*

Specify the data threshold rate to trigger inter-region segmentation.

> **NOTE**: This option is available only at the following hierarchy levels:
>
> `[edit routing-instances instance-name provider-tunnel selective group multicast IP address source source IP-address]`,
> `[edit routing-instances instance-name provider-tunnel selective group multicast IP address wildcard-source]`

- **Range:** 0 through 1000000 Kilobits

Description

Define MVPN inter-region tunnel mapping template. A template is configured on a transit area boundary router (ABR) to define the tunnel type to be used for a given region. There are four types of tunnels that can be used:

- Incoming — Indicates that the tunnel type used across the ABR remains unchanged.
- Ingress-replication — A tunnel type used for passing multicast traffic between routers through the MPLS cloud, or between PE routers when using MVPN. The ingress replication provider tunnel uses MPLS point-to-point LSPs to create the multicast distribution tree.
- Ldp-p2mp — Specify a point-to-multipoint provider tunnel with LDP signaling for an MBGP MVPN.
- Rsvp-te — Configure RSVP tunnels to multicast traffic flooding using point-to-multipoint LSPs.

The remaining statements are explained separately. See CLI Explorer.

inter-switch-link

IN THIS SECTION

- Syntax | **9192**
- Hierarchy Level | **9193**
- Description | **9193**
- Required Privilege Level | **9193**
- Release Information | **9193**

Syntax

```
inter-switch-link vlan members primary-vlan-name;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family ethernet-switching interface-mode
trunk]
```

Description

Use this configuration statement when a private VLAN (PVLAN) spans multiple switches. The Inter-Switch Link protocol (ISL) must be configured on a trunk port of the primary VLAN in order to connect the switches composing the PVLAN to each other. You do not need to configure an ISL when a PVLAN is configured on a single switch.

Required Privilege Level

system—To view this statement in the configuration.

system–control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1X53-D10.

Description

Use this statement to enable seamless interconnection of:

- EVPN-VXLAN points of delivery (PODs) in a data center.
- Different EVPN-VXLAN data centers. This use case is also known as data center interconnect (DCI).

You can use this statement on devices that support seamless EVPN-VXLAN stitching to interconnect PODs or data centers through either:

- An EVPN-VXLAN WAN network—Use the `encapsulation vxlan` option.
- An EVPN-MPLS WAN network—Use the `encapsulation mpls` option.

The devices that enable the interconnection are called interconnection gateways (iGW devices). If possible, you should configure redundant iGW devices with all-active multihoming on each side of the interconnection, which we call multihoming peer iGW devices. The iGW devices are usually spine layer devices, or they are separate devices in a super-spine layer.

> **NOTE**: You must pair PTX10000 Series devices functioning as multihomed iGWs with other PTX10000 Series devices in the same DCI, due to their handling of broadcast, unknown unicast, and multicast (BUM) traffic. Remote gateways can be any device.

On each iGW device, you set up an EVPN routing instance using the default switching instance. Alternatively, you can configure the EVPN routing instance using `instance-type virtual-switch` or `evpn`, depending on the instance types the device supports. In the instance, specify these elements:

- Two sets of route distinguishers (RDs) and route targets.

  The first set is the local RD and route target for the POD or data center network. The second set, which you specify with this `interconnect` statement, is for the WAN network.

  > **NOTE**: The interconnect RD must be different from the local RD in the routing instance.

When you configure DCI with seamless stitching for EVPN Type 2 routes, the device throws a commit error if you try to configure the same value for the interconnect RD and the local RD.

To enforce this condition for DCI seamless stitching with EVPN Type 5 routes as well, you also see a commit error with Junos OS and Junos OS Evolved Releases starting in 22.4R2 and 23.1R1.

- An interconnection Ethernet segment identifier (iESI) for all-active multihoming among the peer iGW devices on each side of the interconnection.

  You configure the iESI using the `esi` option of this `interconnect` statement. You must use the same iESI value on all peer iGW devices in the same POD or data center, and unique iESI values for each POD or data center.

  NOTE: When configuring the interconnection ESI, keep in mind that the seamless EVPN-VXLAN stitching feature does not support `single-active` mode, the `auto-derive lacp` option, or the `source-bmac` option.

- (Required for iGW devices with interconnect gateway multihoming) A list of the iGW device's peer multihoming iGW devices.

  On each iGW device, configure the "interconnect-multihoming-peer-gateways" on page 9202 statement at the global [edit protocols evpn] hierarchy level to specify the IP loopback addresses of that device's peer multihoming iGW devices. This option simplifies control plane route handling to optimize forwarding among the peer iGW devices, and helps avoid loops during EVPN configuration changes.

- VXLAN network identifiers (VNIs) that the iGW device translates when different VNIs are configured for the same VLAN in the PODs or data centers, and WAN. For more information about setting up VNI translation in DCI use cases, see "translation-vni" on page 31243 and "interconnected-vni-list" on page 9206.

After you configure these elements, the EVPN control plane stitches the EVPN routes from the POD or data center network and from the WAN network into a single MAC forwarding table.

Options

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Option `interconnected-vni-list` introduced in Junos OS Release 20.3R1.

Options `interconnected-vlan-list` and `encapsulation mpls` introduced in Junos OS Release 21.4R1.

interconnect-device (Aliases)

IN THIS SECTION

- Syntax | 9197

Syntax

```
interconnect-device interconnect-device-name {
    assigned-interconnect-device-name;
}
```

Hierarchy Level

```
[edit fabric aliases]
```

Description

(QFabric systems only) Specify the mapping of user-defined names to QFabric system Interconnect devices.

> **NOTE**: The following rules apply to QFabric component alias naming:
>
> - Alias names must use alphabetic (**A** through **Z** and **a** through **z**), numeric (**0** through **9**), or dash (**-**) characters.
> - The maximum length of an alias name is 30 characters.
> - Alias names are case sensitive. For example, **MY-NG-1** and **my-ng-1** refer to different components.
> - You cannot use the reserved names `all`, `fabric`, or `director-group` as an alias name.

Options

interconnect-device-name—Specify a user-defined name for a QFabric system Interconnect device.

assigned-interconnect-device-name—Specify the Interconnect device identifier or name that has been provided. Identifiers are usually auto-generated by the Interconnect software, and names are usually provided by the administrator of the default partition.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

Understanding Interconnect Devices

interconnect-device (Flow Groups)

IN THIS SECTION

- Syntax | 9201
- Hierarchy Level | 9201
- Description | 9201
- Options | 9202
- Required Privilege Level | 9202
- Release Information | 9202

Syntax

```
interconnect-device interconnect-device-name;
```

Hierarchy Level

```
[edit fabric flow-groups flow-group-name]
```

Description

In a QFabric system, a hash function is used to select an interconnect device to forward traffic between two Node devices. Since this hash function is performed on all available Interconnect devices, it is possible for redundant multicast streams to flow through one Interconnect device, making that Interconnect device a potential single point of failure for the redundant flows. You can enforce the use of specific Interconnect devices by using the QFabric system `flow-groups` statement.

```
[edit fabric]
root@qfabric# set flow-groups test1 interconnect-device ?
Possible completions:
        <interconnect-device-name> Serial ID or alias of interconnect-device
        IC-P6601-C  Interconnect-device
```

```
        IC-P6602-C  Interconnect device
        IC-P6603-C  Interconnect device
```

Options

interconnect-device-name assigns Interconnect devices to the named flow group

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1X53-D15.

gateway-IP-address ... ]);
```

Hierarchy Level

```
[edit logical-systems name protocols evpn],
[edit protocols evpn]
```

Description

Specify Ethernet VPN (EVPN) provider edge (PE) multihoming peer Data Center Interconnect (DCI) gateway devices.

When you configure this option, the DCI gateway devices avoid loops during EVPN configuration changes and can handle control plane routing more simply, which helps optimize forwarding between the peer DCI gateway devices.

We require this statement on all peer multihoming DCI gateway devices that use the `interconnect` statement to configure DCI and seamless stitching with EVPN Type 2 or Type 5 routes.

NOTE: In Junos OS Release 24.2R1, this statement was renamed `multihoming-peer-gateways` to support multiple multihoming feature use cases:

- To identify DCI multihoming peer devices (the original function of this `interconnect-multihoming-peer-gateways` statement).
- To statically identify enhanced OISM multihoming peer leaf devices.

In Junos OS and Junos OS Evolved Release 24.4R1, we've restored the `interconnect-multihoming-peer-gateways` statement for the DCI use case. For the enhanced OISM multihoming peers use case, we provide the "static-multihoming-peer" on page 29676 statement. The `multihoming-peer-gateways` statement isn't available in the Junos CLI anymore.

Options

(*multihoming-peer-gateway-IP-address* | [*multihoming-peer-gateway-IP-address* …])—One or more multihoming peer DCI gateway device loopback IPv4 addresses. Specify a single address or list multiple peer device addresses within square brackets.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS and Junos OS Evolved Release 22.2R1.

Hierarchy Level

```
[edit logical-systems name protocols dot1x authenticator],
[edit protocols dot1x authenticator]
```

Description

Configure IEEE 802.1X authentication for Port-Based Network Access Control for all interfaces or for specific interfaces.

Options

(all | [*interface-names*])

Configure either a list of interface names or all interfaces for 802.1x authentication.

disable

Disable 802.1X authentication on a specified interface or all interfaces.

- **Default:** 802.1X authentication is disabled on all interfaces.

guest-bridge-domain *guest-bridge-domain*

(MX Series only) Specify the bridge domain tag identifier or the name of the guest bridge domain to which an interface is moved when no 802.1X supplicants are connected on the interface. The bridge domain specified must already exist on the device.

guest-gbp-tag

(EX or QFX Series) Specify the GBP tag to apply when an interface is moved to a guest VLAN. If the `guest-gbp-tag` is configured and the client authenticates in guest VLAN, then the configured `guest-gbp-tag` filter is also installed for the client. You can only configure the `guest-gbp-tag` when the `guest-vlan` *vlan-id* option is configured.

- **Range:** 1 through 65535.

guest-vlan (*vlan-id* | *vlan-name*

(EX, QFX, and SRX Series only) Specify the VLAN tag identifier or the name of the guest VLAN to which an interface is moved. The VLAN specified must already exist on the device. Guest VLANs can be configured on devices that are using 802.1X authentication to provide limited access—typically only to the Internet—for corporate guests. A guest VLAN is not used for supplicants that

send incorrect credentials. Those supplicants are directed to the server-reject VLAN instead.

ignore-port-bounce

Ignore the port-bounce command contained in a Change of Authorization (CoA) request. CoA requests are RADIUS messages that are used to dynamically modify an authenticated user session already in progress. CoA requests are sent from the authentication, authorization, and accounting (AAA) server to the device, and are typically used to change the VLAN for the host based on device profiling. End devices such as printers do not have a mechanism to detect the VLAN change, so they do not renew the lease for their DHCP address in the new VLAN. The port-bounce command is used to force the end device to initiate DHCP re-negotiation by causing a link flap on the authenticated port.

- **Default:** The port-bounce command is supported by default. If you do not configure the `ignore-port-bounce` statement, the device responds to a port-bounce command by flapping the link to re-initiate DHCP negotiation for the end device.

maximum-requests *number*

Specify the maximum number of times an EAPoL request packet is retransmitted to the supplicant before the authentication session times out.

- **Range:** 1 through 10
- **Default:** 2

no-reauthentication | reauthentication *seconds*

Either disable reauthentication or configure the number of seconds before the 802.1X authentication session times out and the client must reattempt authentication.

> **NOTE**: If the authentication server sends an authentication session timeout to the client, this takes priority over the value configured locally using the `reauthentication` statement. The session timeout value is sent from the server to the client as an attribute of the RADIUS Access-Accept message.

- **Range:** 1 through 65,535 seconds
- **Default:** Reauthentication is enabled, with 3600 seconds until the client can attempt to authenticate again.

no-tagged-mac-authentication

Don't allow a tagged MAC address for RADIUS authentication.

quiet-period *seconds*

Specify the number of seconds the interface remains in the wait state following a failed authentication attempt by a supplicant before reattempting authentication.

- **Range:** 0 through 65,535 seconds
- **Default:** 60 seconds

redirect-url ***redirect-url***

Specify a URL that redirects unauthenticated hosts to a central Web authentication (CWA) server. The CWA server provides a web portal where the user can enter a username and password. If these credentials are validated by the CWA server, the user is authenticated and is allowed access to the network.

The redirect URL for central Web authentication can be configured centrally on the AAA server or locally on the switch. Use the `redirect-url` statement to configure the redirect URL locally on the interface connecting the host to the switch.

The redirect URL and a dynamic firewall filter must both be present for the central Web authentication process to be triggered. For more information about configuring the redirect URL and the dynamic firewall filter for central Web authentication, see *Configuring Central Web Authentication*.

> **NOTE**: When the dynamic firewall filter is configured using the special Filter-ID attribute JNPR_RSVD_FILTER_CWA, the CWA redirect URL must include the IP address of the AAA server, for example, **https://10.10.10.10**.

- **Syntax:** The redirect URL must use the HTTP or HTTPS protocol and include an IP address or website name. The following are examples of valid redirect URL formats:
  - http://www.example.com
  - https://www.example.com
  - http://10.10.10.10
  - https://10.10.10.10
  - http://www.example.com/login.html
  - https://www.example.com/login.html
  - http://10.10.10.10/login.html
  - https://10.10.10.10/login.html

- **Default:** Disabled. The redirect URL is not enabled for central Web authentication by default.

request-retry-count *number*

Configure the authentication server to retry sending an EAP request to the supplicant. This can help prevent a timeout of the authentication session due to an unresponsive supplicant. The number of retries is based on the configured value.

- **Range:** 1 through 10 retries
- **Default:** 2 retries

retain-mac-aged-session

Keep the IEEE 802.1X clients active even after their MAC addresses age out, and relearn the MAC addresses again.

- **Default:** Disabled.

retries *number*

Specify the number of times the device attempts to authenticate the port after an initial failure. When the limit is exceeded, the port waits to reattempt authentication for the number of seconds specified with the `quiet-period` option configured at the same hierarchy level.

- **Range:** 1 through 10 retries
- **Default:** 3 retries

server-fail (bridge-domain *bridge-domain* **| deny | permit | use-cache | vlan-name** *vlan-name***) gbp-tag** *gbp-tag*

Specify how end devices connected to a device are supported if the RADIUS authentication server becomes unavailable. Server fail fallback is triggered most often during reauthentication when the already configured and in-use RADIUS server becomes inaccessible. However, server fail fallback can also be triggered by a supplicant's initial attempt at authentication through the RADIUS server.

You must specify an action that the device applies to end devices when the authentication servers are unavailable. The device can accept or deny access to supplicants or maintain the access already granted to supplicants before the RADIUS timeout occurred. You can also configure the switch to move the supplicants to a specific VLAN or bridge domain. The VLAN or bridge domain must already be configured on the device.

> **NOTE**: The `server-fail` statement is specifically for data traffic. For VoIP-tagged traffic, use the `server-fail-voip` statement. The same interface can have a `server-fail` VLAN and a `server-fail-voip` VLAN configured.

- **Values:** *bridge-domain*—(MX Series only) Move the supplicant on the interface to the bridge domain specified by this name or numeric identifier. This action is allowed only if it is the first supplicant connecting to an interface. If an authenticated supplicant is already connected, then the supplicant is not moved to the bridge domain and is not authenticated. The bridge domain must already be configured on the device.

  `deny`—Force the supplicant authentication to fail. No traffic will flow through the interface.

  `permit`—Force the supplicant authentication to succeed. Traffic will flow through the interface as if it were successfully authenticated by the RADIUS server.

  `use-cache`—Force the supplicant authentication to succeed only if it was previously authenticated successfully. This action ensures that already authenticated supplicants are not affected.

  vlan-name—(EX, QFX, or SRX Series only) Move the supplicant on the interface to the VLAN specified by this name or numeric identifier. This action is allowed only if it is the first supplicant connecting to the interface. If an authenticated supplicant is already connected, then the supplicant is not moved to the VLAN and is not authenticated. The VLAN must already be configured on the device.

- **Default:** If the RADIUS authentication server becomes unavailable, the end device is not authenticated and is denied access to the network.

- gbp-tag *gbp-tag*—(EX or QFX Series) Specify the GBP tag to apply on the interface when the server is inaccessible. If you configure the `gbp-tag` *gbp-tag* and the client authenticates in `server-fail` *vlan-name* or `server-fail permit`, then the configured `gbp-tag` *gbp-tag* filter is also installed for the client.

  You can only configure this option when the `server-fail` *vlan-name* or `server-fail permit` option is configured.

  Range: 1 through 65535.

server-fail-voip (deny | permit | use-cache | vlan-name *vlan-name*)

(EX, QFX Series only) Specify how VoIP clients sending voice traffic are supported if the RADIUS authentication server becomes unavailable. Server fail fallback is triggered most often during reauthentication when the already configured and in-use RADIUS server becomes inaccessible. However, server fail fallback can also be triggered by a VoIP client's initial attempt at authentication through the RADIUS server.

You must specify an action that the switch applies to VoIP clients when the authentication servers are unavailable. The switch can accept or deny access to VoIP clients or maintain the access already granted to clients before the RADIUS timeout occurred. You can also configure the switch to move the VoIP clients to a specific VLAN. The VLAN must already be configured on the switch.

The `server-fail-voip` statement is specific to the VoIP-tagged traffic sent by clients. VoIP clients still require that the `server-fail` statement be configured for the untagged traffic that they generate. Therefore, when you configure the `server-fail-voip` statement you must also configure the `server-fail` statement.

> **NOTE**: An option other than `server-fail deny` must be configured for `server-fail-voip` to successfully commit.

- **Values:** `deny`—Force the VoIP client authentication to fail. No traffic will flow through the interface.

  `permit`—Force the VoIP client authentication to succeed. Traffic will flow through the interface as if it were successfully authenticated by the RADIUS server.

  `use-cache`—Force the VoIP client authentication to succeed only if it was previously authenticated successfully. This action ensures that already authenticated clients are not affected.

  vlan-name—Move the VoIP client on the interface to the VLAN specified by this name or numeric identifier. This action is allowed only if it is the first VoIP client connecting to the interface. If an authenticated VoIP client is already connected, then the VoIP client is not moved to the VLAN and is not authenticated. The VLAN must already be configured on the switch.

- **Default:** If a RADIUS authentication server becomes unavailable, a VoIP client that begins authentication by sending voice traffic is not authenticated, and the voice traffic is dropped.

server-timeout ***seconds***

Specify the amount of time a port will wait for a reply when relaying a response from the supplicant to the authentication server before timing out and invoking the server-fail action.

- **Range:** 1 through 60 seconds
- **Default:** 30 seconds

supplicant (single | single-secure | multiple)

Specify the MAC-based method used to authenticate clients.

- **Values:** Specify one of the following:
  - single—Authenticates only the first client that connects to an authenticator port. All other clients connecting to the authenticator port after the first are permitted free access to the port without further authentication. If the first authenticated client logs out, all other supplicants are locked out until a client authenticates again.
  - single-secure—Authenticates only one client to connect to an authenticator port. The host must be directly connected to the switch.
  - multiple—Authenticates multiple clients individually on one authenticator port. You can configure the number of clients per port. If you also configure a maximum number of devices that can be connected to a port through port security settings, the lower of the configured values is used to determine the maximum number of clients allowed per port.
- **Default:** single

supplicant-timeout *seconds*

Specify the number of seconds the port waits for a response when relaying a request from the authentication server to the supplicant before re-sending the request.

- **Range:** 1 through 60 seconds
- **Default:** 30 seconds

transmit-period *seconds*

Specify the number of seconds the port waits before retransmitting the initial EAPoL PDUs to the supplicant.

- **Range:** 1 through 65,535 seconds
- **Default:** 30 seconds

Release Information

Statement introduced in Junos OS Release 9.0.

`gbp-tag` *`gbp-tag`* and `guest-gbp-tag` *`guest-gbp-tag`* introduced in Junos OS Release 23.4R1 for EX and QFX Series switches.

`server-reject-vlan` introduced in Junos OS Release 9.3 for EX Series switches.

`eapol-block` introduced in Junos OS Release 11.2.

`authentication-order` and `redirect-url` introduced in Junos OS Release 15.1R3.

`server-fail-voip` introduced in Junos OS Releases 14.1X53-D40 and 15.1R4 for EX and QFX Series switches.

`ignore-port-bounce` introduced in Junos OS Release 17.3R1.

`multi-domain` introduced in Junos OS Release 18.3R1.

    unit unit-number {
    link-type (IP | MPLS)
    priority priority-number;
}
```

Hierarchy Level

```
[edit security advance-policy-based-routing]
```

Description

Configure link preference settings for an interface in a APBR profile.

When a list of best paths that meet the SLA requirements are available for the application path, the path selection mechanism selects a path that matches the configured link preference (link type, bandwidth,

and priority). The application traffic distribution depends on the link weight configuration. Paths are the WAN links that are used for forwarding the application traffic.

You can define the link type and priority for the underlay links in the APBR profile. The link preference configuration is applied for the application traffic matching the APBR rule.

> **NOTE**: Prior to Junos OS Release 21.2R1, if any of the parameters are not configured (*link-type* or *priority*) then the path selection mechanism follows the existing behavior. That is, applications traffic is assigned to a particular overlay link based on the SLA metrics of that overlay link only.

Options

link-tag

Configure custom tag for the link selection. You can use the tags such as IP, MPLS, VOIP, DSL and so on as per the requirement. Defining a link-tag along with link-priority allows you to prioritize the link selection.

- Default: IP

multipath-bandwidth

Assign the bandwidth for the link in MB. Use this option if you are configuring AMR.

- Range: 1 through 1000000

  Default: 1 GB

priority

Assign the priority for the link selection. If there are multiple paths available, AppQOE selects the path with the highest priority. Lower the value, higher the priority for the link.

- **Range:** 1 through 255

weight

Configure weight for the application traffic distribution. The weight assigned for a link is based on the factors such as customer preference, CoS, or bandwidth requirement.

- **Range:** 1 through 255

  Default: 1

interface (all | interface-name);
```

Hierarchy Level

```
[edit forwarding-options analyzer analyzer-name input egress],
[edit forwarding-options analyzer  analyzer-name input ingress],
[edit forwarding-options analyzer  analyzer-name output]
```

Description

Configure the interfaces for which traffic is mirrored.

Options

all Apply mirroring to all interfaces on the network device. Mirroring a high volume of traffic can be performance intensive for the device. Therefore, you should generally select specific input interfaces in preference to using the `all` keyword, or use the `all` keyword in combination with setting a ratio for statistical sampling. The `all` keyword is not available for the `[edit forwarding-options analyzer analyzer-name output]` hierarchy level.

interface-name Apply mirroring to the specified interface only.

Required Privilege Level

interface—To view this statement in the configuration.

```
[edit routing-instances instance-name routing-options backup-selection prefix],
[edit routing-options backup-selection destination prefix]
```

Description

Define the backup selection policy for a specific primary next hop.

Options

interface-name Name of the primary next-hop interface.

all All the interfaces.

bandwidth-greater-equal-primary Allow the selection of the backup next hop only if the bandwidth is greater than or equal to the bandwidth of the primary next hop.

dest-metric (highest lowest) Specifiy the metric from the one-hop neighbor or from the remote router such as an RSVP backup label-switched-path (LSP) tail-end router to the final destination.

- **highest** Select the backup path that has the highest destination metric.
- **lowest** Select the backup path that has the lowest destination metric.

downstream-paths-only Select the backup path that is a downstream path to the destination.

evaluation-order [admin-group srlg bandwidth protection-type node metric] Control the order and the criteria of evaluating the backup path. The default order of evaluation is admin-group, srlg, bandwidth, protection-type, node and metric.

> **NOTE**: For the explicitly configured evaluation order, only the listed attributes influence the selection of the backup path.

metric-order [root dest] Specify the order of preference of the root and the destination metric during the backup path selection. The preference order can be:

- [`root dest`] — Backup path selection or preference is first based on the root-metric criteria. If the criteria of all the root-metric is the same, then the selection or preference is based on the dest-metric.
- [`dest root`] — Backup path selection or preference is first based on the dest-metric criteria. If the criteria of all the dest-metric is the same, then the selection is based on the root-metric.

> **NOTE**: Backup path selection or preference is first based on the dest-metric criteria. If the criteria of all the dest-metric is the same, then the selection is based on the root-metric. By default, backup paths with lower destination metric criteria are selected or preferred. If the criteria is the same, then the lowest root metric criteria is preferred or selected.

root The metric to a one-hop neighbor or a remote router.

dest The metric from a one-hop neighbor or remote router to the final destination.

protection-type (link | node | node-link)

Specify the required protection type of the backup path.

> **NOTE**: If no protection-type is configured, then by default the first best path that matches all the other criteria is executed.

link Select the backup path that provides link protection.

node Select the backup path that provides node protection.

node-link Allow either node or link protection LFA where node-protection LFA is preferred over link-protection LFA.

root-metric (highest lowest)

Specify the metric to the one-hop neighbor or to the remote router such as an RSVP backup label-switched-path (LSP) tail-end router.

highest Select the highest root metric.

lowest Select the lowest root metric.

srlg (loose | strict)

Define the backup selection to either allow or reject the common shared risk link groups (SRLGs) between the primary link and any link in the backup path.

loose Allow the backup path that has common srlgs between the primary link and any link in the backup path. A backup path with a fewer number of srlg collisions is preferred.

strict Reject the backup path that has common srlgs between the primary next-hop link and each link in the backup path.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Syntax

```
interface (all | [interface-name]);
```

Hierarchy Level

```
[edit protocols layer2-control bpdu-block]
```

```
[edit ethernet-switching-options bpdu-block]
```

Description

Applies Bridge Protocol Data Unit (BPDU) protection on all interfaces or on one or more specified interfaces.

Spanning Tree Protocol (STP), Rapid Spanning Tree protocol (RSTP), and Multiple Spanning Tree Protocol (MSTP) provide Layer 2 loop prevention for EX Series switches. The spanning-tree protocols use BPDU frames to communicate. Through their exchange, spanning-tree topologies determine which interfaces block traffic and which interfaces become root ports and forward traffic. User bridge applications running on a PC can also generate BPDUs. If these BPDUs are picked up by STP applications running on the switch, they can trigger STP miscalculations that can lead to network outages.

To block outside BPDUs from reaching a switch interface connected to devices that are not part of a spanning-tree topology, configure BPDU protection on interfaces in the topology.

CAUTION: When configuring BPDU protection on an interface without spanning trees connected to a switch with spanning trees, be careful that you do not configure BPDU protection on all interfaces. Doing so could prevent BPDUs being received on switch interfaces (such as a trunk interface) that you intended to have receive BPDUs from a switch with spanning trees.

NOTE: Interfaces that are configured as edge interfaces can transition to a forwarding state immediately because they cannot create network loops. As edge ports are connected to end devices, it is imperative that you configure BPDU protection on edge ports to protect the switch from outside BPDUs. When BPDU protection is enabled on an edge interface, the interface shuts down on encountering an outside BPDU thereby preventing any traffic from passing through the interface.

Options

all—All interfaces.

[*interface-name*]—One or more Ethernet interface names.

The remaining statements are explained separately. See CLI Explorer.

snooping],
[edit routing-instances routing-instance-name bridge-domains bridge-domain-name protocols vlan
vlan-id igmp-snooping]
```

Description

Enable IGMP snooping on an interface and configure interface-specific properties.

Options

interface-name—Name of the interface. Specify the full interface name, including the physical and logical address components. To configure all interfaces, you can specify **all**.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

interface (Captive Portal)

IN THIS SECTION

- Syntax | 9234
- Hierarchy Level | 9235
- Description | 9235
- Options | 9235
- Required Privilege Level | 9237
- Release Information | 9237

Syntax

```
interface (all | [interface-names]) {
    quiet-period seconds;
    retries number-of-retries;
    server-timeout seconds;
    session-expiry seconds;
    supplicant ( multiple | single | single-secure);
    user-keepalive minutes;
}
```

Hierarchy Level

```
[edit services captive-portal]
```

Description

Configure captive portal authentication for all interfaces or for specific interfaces.

Options

all
All interfaces to be configured for captive portal authentication.

[*interface-names*]
List of names of interfaces to be configured for captive portal authentication.

quiet-period *seconds*
Configure time, in seconds, after a user exceeds the maximum number of retries before they can attempt to authenticate.

- **Range:** 1–65535 seconds
- **Default:** 60 seconds

retries *number-of-tries*
Configure the number of times the user can attempt to submit authentication information.

- **Range:** 1–65535 tries
- **Default:** 3 tries

server-timeout *seconds*
Configure the time in seconds an interface will wait for a reply when relaying a response from the client to the authentication server before timing out and invoking the server-fail action.

- **Range:** 1–65535 seconds
- **Default:** 20 seconds

session-expiry *seconds*
Configure the number of seconds before the captive portal authentication session times out and the client must reattempt authentication.

> **NOTE**: If the authentication server sends an authentication session timeout to the client, this takes priority over the value configured locally

using the `session-expiry` statement. The session timeout value is sent from the server to the client as an attribute of the RADIUS Access-Accept message.

- **Range:** 1 through 65535 seconds
- **Default:** 3600 seconds

supplicant (multiple | single | single-secure)

Configure the MAC-based method used to authenticate clients for captive portal authentication.

- **Values:** Configure one of the following:
  - single—Authenticates only the first client that connects to an authenticator port. All other clients connecting to the authenticator port after the first are permitted free access to the port without further authentication. If the first authenticated client logs out, all other supplicants are locked out until a client authenticates again.
  - single-secure—Authenticates only one client to connect to an authenticator port. The host must be directly connected to the switch.
  - multiple—Authenticates multiple clients individually on one authenticator port. You can configure the number of clients per port. If you also configure a maximum number of devices that can be connected to a port through port security settings, the lower of the configured values is used to determine the maximum number of clients allowed per port.
- **Default:** single

user-keepalive *minutes*

Extend a captive portal authentication session after the MAC table aging timer expires, by the configured number of minutes. The keep-alive timer is started when the MAC address of the authenticated host ages out of the Ethernet switching table. If traffic is received within the keep-alive timeout period, the timer is deleted. If there is no traffic within the keep-alive timeout period, the session is deleted, and the host must re-authenticate.

- **Default:** Disabled. The captive portal authentication session ends when the associated MAC address ages out of the Ethernet switching table.
- **Range:** 7 through 65535 minutes

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

`user-keepalive` introduced in Junos OS Release 16.1 for EX Series switches.

interface (Chassis Cluster)

IN THIS SECTION

- Syntax | 9237
- Hierarchy Level | 9238
- Description | 9238
- Options | 9238
- Required Privilege Level | 9238
- Release Information | 9238

Syntax

```
logical-interface-name secondary-ip-address;
```

Hierarchy Level

```
[edit chassis cluster redundancy-group group-number        ip-monitoring family family-name IP-address]
```

Description

Specify the redundant Ethernet interface, including its logical-unit-number, through which the monitored IP address must be reachable. The specified redundant Ethernet interface can be in any redundancy group. Likewise specify a secondary IP address to be used as a ping source for monitoring the IP address through the secondary node's redundant Ethernet interface link.

Options

- *logical-interface-name*—Redundant Ethernet interface through which the monitored IP address must be reachable. You must specify the redundant Ethernet interface logical-unit-number. Note that you must also configure a secondary ping source IP address (see below).
- **Range:** `reth0.`*logical-unit-number* through `reth128.`*logical-unit-number* (device dependent)

> **NOTE**: If the redundant Ethernet interface belongs to a VPN routing and forwarding (VRF) routing instance type, then the IP monitoring feature will not work.

- `secondary-ip-address` *IP-address*—Specify the IP address that are used as the source IP address of ping packets for IP monitoring from the secondary child link of the redundant Ethernet interface. An IP address for sourcing the ping packets on the primary link of the redundant Ethernet interface must be configured before you can configure `secondary-ip-address`. For legacy support reasons, monitoring on an IP address without identifying a redundant Ethernet interface and without configuring a secondary ping source IP address is permitted but not recommended.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

services dhcp-local-server ...],
[edit logical-systems logical-system-name system services dhcp-local-server ...],
[edit routing-instances routing-instance-name system services dhcp-local-server ...]
```

Description

> **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Specify one or more interfaces, or a range of interfaces, that are within a specified group on which the DHCP local server is enabled. You can repeat the `interface` *`interface-name`* statement to specify multiple interfaces within a group, but you cannot specify the same interface in more than one group. Also, you cannot use an interface that is being used by the DHCP relay agent.

> **NOTE**: DHCP values are supported in integrated routing and bridging (IRB) configurations. When you configure an IRB interface in a network that is using DHCP, the DHCP information (for example, authentication, address assignment, and so on) is propagated in the associated bridge domain. This enables the DHCP server to configure client IP addresses residing within the bridge domain. IRB currently supports only static DHCP configurations.

Options

`exclude`—Exclude an interface or a range of interfaces from the group. This option and the `overrides` option are mutually exclusive.

`interface-name`—Name of the interface. You can repeat this option multiple times.

`upto-interface-name`—Upper end of the range of interfaces; the lower end of the range is the interface-name entry. The interface device name of the *`upto-interface-name`* must be the same as the device name of the *`interface-name`*.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

Options `upto` and `exclude` introduced in Junos OS Release 9.1.

[edit forwarding-options dhcp-relay dhcpv6 group group-name],
[edit forwarding-options dhcp-relay group group-name],
[edit logical-systems logical-system-name forwarding-options dhcp-relay ...],
[edit logical-systems logical-system-name routing-instances routing-instance-name forwarding-
options dhcp-relay ...],
[edit routing-instances routing-instance-name forwarding-options dhcp-relay ...]
```

Description

> ⚠ **CAUTION**: Enabling tracing can adversely impact scale and performance and may increase security risk. We strongly recommend using the trace, tracing, or traceoptions commands only under the guidance of a JTAC support engineer. After collecting the debug information, immediately disable tracing to minimize risk and restore normal system performance.

Specify one or more interfaces, or a range of interfaces, that are within a specified group on which the DHCP or DHCPv6 relay agent is enabled. You can repeat the `interface` *`interface-name`* statement to specify

multiple interfaces within a group, but you cannot specify the same interface in more than one group. Also, you cannot use an interface that is being used by the DHCP local server. Use the statement at the `[edit ... dhcpv6]` hierarchy levels to configure DHCPv6 support.

EX Series switches do not support DHCPv6.

> **NOTE**: DHCP values are supported in integrated routing and bridging (IRB) configurations. When you configure an IRB interface in a network that is using DHCP, the DHCP information (for example, authentication, address assignment, and so on) is propagated in the associated bridge domain. This enables the DHCP server to configure client IP addresses residing within the bridge domain. IRB currently only supports static DHCP configurations. .

Options

`exclude`—Exclude an interface or a range of interfaces from the group. This option and the `overrides` option are mutually exclusive.

`interface-name`—Name of the interface. You can repeat this option multiple times.

`overrides`—Override the specified default configuration settings for the interface. The `overrides` statement is described separately.

`upto-interface-name`—Upper end of the range of interfaces; the lower end of the range is the interface-name entry. The interface device name of the *`upto-interface-name`* must be the same as the device name of the *`interface-name`*.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.3.

Options `upto` and `exclude` introduced in Junos OS Release 9.1.

Support at the `[edit ... dhcpv6]` hierarchy levels introduced in Junos OS Release 11.4.

- Required Privilege Level | 9249
- Release Information | 9249

Syntax

```
interface interface-name;
```

Hierarchy Level

```
[edit routing-instances routing-instance-name bridge-domains bridge-domain-name forwarding-options
dhcp-relay group group-name],
[edit routing-instances routing-instance-name forwarding-options dhcp-relay group group-name]
```

Description

Configure Dynamic Host Configuration Protocol (DHCP) snooping on the router. When acting as a snooping agent, the MX Series router typically is located between the client and the DHCP relay agent. It creates filters by “snooping” DHCP messages and binding DHCP-issued IP addresses with the MAC address of the client. These filters help prevent DHCP spoofing.

DHCP snooping is configured by including the appropriate interfaces.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.4 (MX Series routers only).

- Syntax | 9250
- Hierarchy Level | 9250

- Description | 9250
- Options | 9250
- Required Privilege Level | 9251
- Release Information | 9251

Syntax

```
interface interface-name {
    broadcast;
    description text-description;
    no-listen;
    server address <logical-system logical-system-name> <routing-instance routing-instance-name>;
}
```

Hierarchy Level

```
[edit forwarding-options helpers domain],
[edit forwarding-options helpers port port-number],
[edit forwarding-options helpers tftp]
```

Description

Specify the interface for monitoring and forwarding DNS or TFTP requests, or for forwarding LAN broadcast traffic on a custom UDP port to a particular server as unicast traffic.

When configuring port helpers, in releases prior to Junos OS Release 17.2, only one server can be specified for a given port. For Junos OS Release 17.2 and later, multiple servers can be specified for a given port at the global or interface-specific level. In this case, the same packet, with the originator IP address and port requests, is forwarded to the different configured servers; the payload of the UDP packet is not modified.

Options

interface-name—Name of the interface.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced for port helpers in Junos OS Release 17.2R1 for EX4300 switches.

Support for multiple server instances for a given port introduced in Junos OS Release 17.2 for MX Series routers.

Support for multiple server instances for a given port introduced in Junos OS Release 17.3R1 for EX9200 switches.

Enabling IGMP

interface (Dynamic Interface Sets)

IN THIS SECTION

- Syntax | 9254
- Hierarchy Level | 9254
- Description | 9254
- Options | 9254
- Required Privilege Level | 9254
- Release Information | 9255

Syntax

```
interface interface-name {
    unit logical unit number {
        advisory-options {
            downstream-rate rate;
            upstream-rate rate;
        }
    }
}
```

Hierarchy Level

```
[edit dynamic-profiles profile-name interfaces interface-set interface-set-name]
```

Description

Add a subscriber interface to a dynamic interface set.

In a dynamic profile that defines an agent circuit identifier (ACI) interface set, observe the following guidelines when you use the `interface` statement:

- Use the predefined dynamic interface variable `$junos-interface-ifd-name` to represent the interface name. Do not use a specific interface name, such as `demux0`, when defining an ACI interface set.
- Do not include the `unit` *`logical-unit-number`* statement.

Options

interface-name–Either the specific name of the interface to include in the interface set, or the predefined dynamic interface variable `$junos-interface-ifd-name`. The interface variable is dynamically replaced with the interface that the DHCP or PPPoE subscriber accesses when connecting to the router.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

    }
    reachable-time milliseconds;
    retransmit-timer milliseconds;
}
```

Hierarchy Level

```
[edit dynamic-profiles protocols router-advertisement]
```

Description

Dynamically configure router advertisement properties on an interface. To dynamically configure interface properties, include the *$junos-interface-name* dynamic variable for the interface name.

Options

interface-name—Name of an interface. Specify the *$junos-interface-name* dynamic variable or the full, static interface name, including the physical and logical address components.

> **NOTE**: Even though you can specify the static interface name when defining the interface, we recommend using dynamic variable when configuring this statement.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

interface (Dynamic Routing Instances)

IN THIS SECTION

- Syntax | 9259
- Hierarchy Level | 9259
- Description | 9259
- Options | 9259
- Required Privilege Level | 9260
- Release Information | 9260

Syntax

```
interface interface-name;
```

Hierarchy Level

```
[edit dynamic-profiles profile-name routing-instances routing-instance-name]
```

Description

Assign the specified interface to the dynamically created routing instance.

Options

interface-name—The interface name variable (*$junos-interface-name*). The interface name variable is dynamically replaced with the interface the accessing client uses when connecting to the router.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6.

interface (Dynamic Routing Options)

IN THIS SECTION

- Syntax | 9260
- Hierarchy Level | 9260
- Description | 9261
- Options | 9261
- Required Privilege Level | 9261
- Release Information | 9261

Syntax

```
interface interface-names {
    no-qos-adjust;
}
```

Hierarchy Level

```
[edit dynamic-profiles profile-name routing-options multicast],
[edit dynamic-profiles profile-name routing-instances routing-instance-name routing-options
multicast]
```

Description

Define the maximum bandwidth for a dynamic interface on which you want to apply bandwidth management.

Options

interface-name—Names of the physical or logical interface. For details about specifying interfaces, see Types of Interfaces.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6.

interface (EVPN Routing Instances)

IN THIS SECTION

- Syntax | 9262
- Hierarchy Level | 9262
- Description | 9262
- Options | 9262

Required Privilege Level | 9262
Release Information | 9263

Syntax

```
interface interface-name {
    ignore-encapsulation-mismatch;
    interface-mac-limit limit {
        packet-action drop;
    }
    mac-pinning
    no-mac-learning;
    protect-interface
    static-mac mac-address;
    vpws-service-id
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols]
[edit routing-instances routing-instance-name protocols evpn]
```

Description

Specify each interface over which the Ethernet VPN (EVPN) traffic travels between the PE device and customer edge (CE) device. The interfaces are bound to the EVPN routing instance.

Options

interface-name—Name of the interface.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2.

Statement (mac-pinning) introduced in Junos OS Release 16.2 on MX Series routers.

`vpws-service-id` statement introduced in Junos OS Release 17.1 on MX Series routers.

Support for logical systems on MX Series routers added in Junos OS Release 17.4R1.
