

Chapter 5

Connecting IPv6 Islands with IPv4 MPLS

Many service providers are looking for ways to provide new revenue-generating services to their customers. One such service is IPv6. Some enterprise customers are beginning to experiment with this new version of IP, but are reluctant to deploy it broadly. Interconnecting multiple sites that use IPv6 can be challenging. Also, most service providers would prefer to carry this traffic without making major modifications to their core network.

A technique available in JUNOS 5.4 allows you to connect IPv6 sites over an IPv4 Multiprotocol Label Switching (MPLS) enabled backbone. Juniper Networks supports the MP-BGP over IPv4 approach detailed in the Internet Engineering Task Force (IETF) Internet draft *Connecting IPv6 Domains across IPv4 Clouds with BGP* (draft-ietf-ngtrans-bgp-tunnel-04.txt). With this technique, IPv6 islands are connected to each other across an IPv4 backbone enabled with MPLS label stacking while Multiprotocol Border Gateway Protocol (MP-BGP) is used to announce the IPv6 routes across these MPLS tunnels. This feature can be implemented with label-switched paths (LSPs) using Label Distribution Protocol (LDP) or Resource Reservation Protocol (RSVP).

IPv6 packets are carried over an IPv4 MPLS tunnel. To enable this service, you need to deploy Provider Edge (PE) routers that can run IPv4, MPLS, and BGP toward the core and IPv6 toward the edge. Since only the PE routers need to run a dual stack of IPv4 and IPv6, the other provider (P) core routers do not need to be upgraded. As a result, this MPLS tunneling technique allows for interoperability with routers from other vendors.

Because of this flexible method of implementation, it is now more attractive for providers to carry IPv6 traffic over their existing core networks and for customers to roll out IPv6 to more sites.

This feature guide covers these topics:

Overview

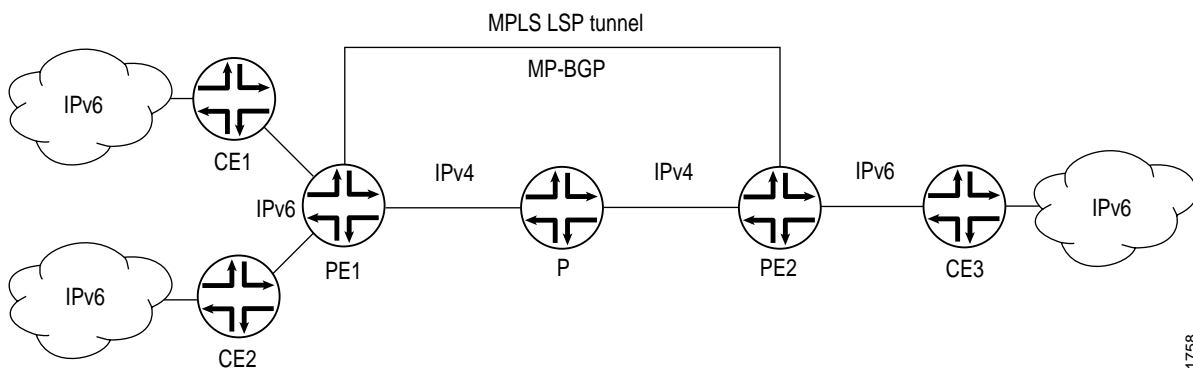

In Figure 23, PE1 and PE2 are Dual Stack Border Gateway Protocol (DS-BGP) routers. They implement IPv4 and IPv6 stacks simultaneously. The IPv6 clouds are separate islands that are connected to PE routers through a Customer Edge (CE) router.

This example shows how to enable IPv6 connectivity between the various IPv6 islands, not how to create an IPv6 VPN service. One of the IPv6 islands can be the global IPv6 Internet.

The connection between the CE and PE routers can use any network layer protocol that carries IPv6 traffic. The provider router can exchange information with the customer routers using IPv6-enabled routing protocols, such as RIPng or MP-BGP, or static routes. The PE routers use IPv6 on the CE-facing interfaces, but use IPv4, BGP, and MPLS to connect to the core.

You must configure appropriate export policies on the PE router to share route information between IBGP and EBGP, and between BGP and other protocols.

Figure 23: Connecting IPv6 Islands over MPLS

Since MP-BGP requires that a BGP next hop use the same address family as the Network Layer Reachability Information (NLRI), the IPv4 address needs to be embedded in an IPv6 format. Such IPv4-mapped IPv6 addresses are defined in RFC 3513, *IP Version 6 Addressing Architecture*. After the PE routers learn the IPv6 routes from their directly attached CE neighbors, each PE router uses its own IPv4 address as the next hop for the IPv6 routes that are advertised in the BGP session.

The two PE routers establish a Multiprotocol BGP (MP-BGP) session with each other using IPv4 addresses. In the session, the routers exchange IPv6 routes with an IPv6 Address Family Identifier (AFI) value of 2 and a Subsequence AFI (SAFI) label with a value of 4. Labels with a value of 2 are explicit null labels for IPv6, as defined in RFC3032. Before sending IPv6 traffic across the IPv4 MPLS tunnel, the PE attaches the two labels. The inner label is 2 (another value if the advertising PE router is not a Juniper router) and the outer label is the LSP label.

A PE router must have MPLS LSPs pointing to the other peer PE router's IPv4 address. The LSPs are signaled across the IPv4 control plane using either LDP or RSVP. These LSPs resolve the next-hop addresses of the IPv6 routes learned through MP-BGP. The next hops are actually IPv4-mapped IPv6 addresses, while the LSPs are associated with IPv4 addresses. Because of this mapping technique, the IPv6 traffic can travel over the IPv4 LSP transparently.

In Figure 23 on page 188, PE1 receives an IPv6 packet from CE1 and performs a lookup in the IPv6 forwarding table. If the destination matches a prefix that was learned from CE2, no labels are necessary and the IPv6 packet is sent to CE2. If the destination matches a prefix that was learned from PE2, then PE1 places two labels on the packet and sends it to P. The inner label is 2 and the outer label is the LSP label needed to reach PE2. Since P is the penultimate-hop router for the LSP to PE2 and the received packet has more than one label, router P pops the outer label and sends the packet to PE2. When PE2 receives the packet, it has a single label with a value of 2. PE2 strips off the label and treats the remaining packet as an IPv6 packet (since 2 is the IPv6 explicit null label) and performs a lookup in the IPv6 forwarding table.

Although the MP-BGP over IPv4 approach can operate using a single level of labels, there is an advantage in using two labels. The penultimate-hop router for the MPLS LSP (P in this case) can pop the outer label and send the packet with the inner label as an MPLS packet. When the packet arrives at egress router PE2, the second label using the explicit null value is popped and the remaining IPv6 packet is sent to the directly connected IPv6 network. Thus, the benefit of using two labels is that penultimate hop-popping (PHP) routers do not require IPv6 capabilities or the need for an upgrade.

Interconnecting IPv6 islands over an IPv4 MPLS tunnel requires:

An exchange of IPv6 reachability information between DS-BGP routers. Using MP-BGP, the DS-BGP (PE) routers exchange IPv6 reachability information over the IPv4 core network with other similarly enabled DS-BGP PE peers. As a result, the Egress DS-BGP (PE) router announces itself as the BGP next hop.

IPv6 packets are tunneled from the ingress DS-BGP router to the egress DS-BGP router by means of MPLS. The ingress DS-BGP router tunnels an IPv6 packet over the IPv4 network toward the egress DS-BGP router identified as the BGP next hop for the packet's destination IPv6 address.

System Requirements

To carry IPv6 traffic over IPv4 MPLS tunnels, your system must meet these minimum requirements:

JUNOS Release 5.4 or later

Two Juniper Networks M5, M10, M20, M40e, or M160 Internet routers or T640 Internet routing nodes to act as the DS-BGP ingress and egress devices

Terms and Acronyms

Dual Stack BGP (DS-BGP)—A router that processes IPv4 and IPv6 packets in a BGP connected network.

Multiprotocol BGP (MP-BGP)—A router that processes packets from a variety of protocols in a BGP-connected network.

Subsequence Address Family Identifier (SAFI)—A field in Multiprotocol BGP messages that identifies MPLS network layer reachability information (NLRI). Common values include 1 (unicast), 2 (multicast), and 4 (MPLS label).

Configure an IPv4 MPLS Tunnel to Carry IPv6 Traffic

To enable IPv6 to be carried over an IPv4 MPLS tunnel, perform the following tasks:

Configure IPv6 on the Customer and Core-Facing Interfaces on page 190

Configure MPLS and RSVP from PE Router to PE Router to Create a Tunnel on page 190

Enable IPv6 Tunneling in MPLS on page 190

Configure Multiprotocol BGP to Carry IPv6 Traffic on page 191

To view a full configuration example, see these sections:

Example: Connecting IPv6 Islands over an MPLS Tunnel Configuration on page 191

Check Your Work on page 198

Configure IPv6 on the Customer and Core-Facing Interfaces

In addition to configuring family inet6 on all the CE-facing interfaces, you must also configure family inet6 on all the core-facing interfaces running MPLS. The router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with label 2. Even though label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.

```
[edit]
interfaces {
  interface-name {
    unit unit-number {
      family inet6 {
        address inet6-address;
      }
    }
  }
}
```

Configure MPLS and RSVP from PE Router to PE Router to Create a Tunnel

This guide assumes you already have experience configuring MPLS and RSVP. For more information about these topics, see the *JUNOS Internet Software Configuration Guide: MPLS Applications*.

Enable IPv6 Tunneling in MPLS

Enter the ipv6-tunneling option on your PE routers at the [edit protocols mpls] hierarchy level.

```
[edit]
protocols {
  mpls {
    ipv6-tunneling;
  }
}
```

Configure Multiprotocol BGP to Carry IPv6 Traffic

The family inet6 statement can be specified on a per-neighbor, per-group, or global basis. The statement allows BGP to carry IPv6 traffic.

At the appropriate global, group, or neighbor hierarchy level in BGP (shown below), configure the family inet6 statement with the labeled-unicast parameter and the explicit-null option. These additional parameters enable the IPv4 MPLS label to be removed at the destination PE router. The remaining label-less IPv6 packet can then be forwarded to the connected IPv6 network.

```
[edit protocols bgp] OR
[edit protocols bgp group group-name] OR
[edit protocols bgp group group-name neighbor neighbor-name]

family inet6 {
  labeled-unicast {
    explicit-null;
  }
}
```

Example: Connecting IPv6 Islands over an MPLS Tunnel Configuration

Figure 24: IPv6 over an MPLS Tunnel

Figure 24 shows a standard CE-PE-P-PE-CE MPLS-style network. CE1 and CE2 are the end customer CE routers using IPv6; PE1 and PE2 are the provider edge routers; and P is a provider core router. The IPv4 MPLS tunnel travels between PE1 and PE2, connecting IPv6 sites CE1 and CE2.

Since the CE-to-PE configuration can use a variety of routing protocols, this example requires that you use EBGP between CE1 and PE1 and RIPng between PE2 and CE2. You must establish policies on PE2 to import and export routes between BGP and RIPng.

To start the configuration, set up the IPv6 connection between CE1 and PE1. In your BGP routing policy, you must advertise the IPv6 loopback address of the CE1 router address to the PE1 router.

```

CE1 [edit]
interfaces {
  ge-7/1/0 {
    unit 0 {
      family inet6 {
        address 8001::1/126;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet6 {
        address 9001::1/128;
      }
    }
  }
}
routing-options {
  autonomous-system 200;
}
protocols {
  bgp {
    group to_PE1 {
      type external;
      local-address 8001::1;
      family inet6 {
        unicast;
      }
    }
    export policy1;
    peer-as 100;
    neighbor 8001::2;
  }
}
policy-options {
  policy-statement policy1 {
    term 1 {
      from {
        family inet6;
        route-filter 9001::1/128 exact;
      }
      then accept;
    }
    term 2 {
      then reject;
    }
  }
}

```

Once you move to PE1, your tasks become more complex. You must complete the IPv6 EBGp connection to CE1 and build the first part of the MPLS tunnel. You must set the inet, inet6, and mpls families on the core-facing interface, configure an inet6 address for the CE-facing interface attached to CE1, and ensure the IPv4 loopback address is advertised in OSPF, since this is the MPLS LSP target for PE2. You must also add the ipv6-tunneling parameter in MPLS, include the labeled-unicast and explicit-null options at the [edit protocols bgp family inet6] hierarchy level, and create an external BGP group pointing to CE1 and an internal group pointing to PE2.

```

PE1 [edit]
interfaces {
  ge-6/1/0 {
    unit 0 {
      family inet6 {
        address 8001::2/126;
      }
    }
  }
  so-6/2/0 {
    unit 0 {
      family inet {
        address 100.255.2.1/24;
      }
      family inet6;
      family mpls;
    }
  }
  lo0 {

  area 0.0.0.0 {
    interface so-6/2/0.0;
    interface lo0.0 {
      passive;
    }
  }
}
```

On Router P, connect the MPLS tunnel between PE1 and PE2. Enable RSVP, MPLS, and IPv4 connectivity on the interfaces and ensure that IP connectivity is available through the routing protocol (in this case, OSPF).

```
P [edit]
interfaces {
  so-1/1/0 {
    unit 0 {
      family inet {
        address 100.255.2.2/24;
      }
      family mpls;
    }
  }
  so-4/0/0 {
    unit 0 {
      family inet {
        address 100.255.3.1/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.255.220/32;
      }
    }
  }
}
routing-options {
  autonomous-system 100;
}
```

```

protocols {
  rsvp {
    interface so-1/1/0.0;
    interface so-4/0/0.0;
  }
  mpls {
    interface so-1/1/0.0;
    interface so-4/0/0.0;
  }
  ospf {
    traffic-engineering;
    area 0.0.0.0 {
      interface so-1/1/0.0;
      interface so-4/0/0.0;
      interface lo0.0 {
        passive;
      }
    }
  }
}

```

At PE2, you must complete a mirror image of the MPLS tunnel configuration started at PE1 and configure a RIPng connection to CE2. Set the inet, inet6, and mpls families on the core-facing interface, configure an inet6 address for the CE facing interface attached to CE2, and ensure the IPv4 loopback address is advertised in OSPF, since this is the MPLS LSP target for PE1. You must also add the ipv6-tunneling parameter in MPLS and include the labeled-unicast and explicit-null options at the [edit protocols bgp family inet6] hierarchy level. Finally, create and apply policies that export BGP routes into RIPng and import RIPng routes to BGP.

```

PE2 [edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family inet {
        address 100.255.3.2/24;
      }
      family inet6;
      family mpls;
    }
  }
  so-4/0/1 {

      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.255.15/32;
      }
      family mpls;
    }
  }
}

```

```

routing-options {
  autonomous-system 100;
}
protocols {
  rsvp {
    interface so-0/0/0.0;
  }
  mpls {
    ipv6-tunneling;
    label-switched-path to_PE1 {
      to 10.255.255.16;
    }
    interface so-0/0/0.0;
  }
  bgp {
    group to_PE1 {
      type internal;
      local-address 10.255.255.15;
      family inet6 {
        labeled-unicast {
          explicit-null;
        }
      }
      export red-export;
      neighbor 10.255.255.16;
    }
  }
  ospf {
    traffic-engineering;
    area 0.0.0.0 {
      interface so-0/0/0.0;
      interface lo0.0 {
        passive;
      }
    }
  }
  ripng {
    group to_CE2 {
      export red-import;
      neighbor so-4/0/1.0;
    }
  }
}
policy-options {
  policy-statement red-export {
    term 1 {
      from protocol ripng;
      then accept;
    }
    term 2 {
      then reject;
    }
  }
  policy-statement red-import {
    from protocol bgp;
    then accept;
  }
}

```

Finally, on CE2, configure IPv6 addresses on the SONET and loopback addresses, enable RIPng, and create and apply a policy for RIPng that permits the IPv6 loopback address to be exported to PE2. Once these tasks are accomplished, your IPv6 connection to CE1 should be ready for use.

```

      }
      then accept;
    }
    term 2 {
      then reject;
    }
  }
}

```

Check Your Work

To verify that IPv6 traffic is being transported over the IPv4 MPLS tunnel, use the following commands:

```
ping
show bgp summary
show route protocol
show route advertising-protocol
show route receive-protocol
show route table
show route table (inet6.0 | inet6.3)
show interfaces terse
```

The following sections show the output of these commands used with the configuration example:
