4. (Optional) To bind a second named instance of Layer 2 port mirroring to the same DPC or FPC, repeat step 3 and specify a different named instance of Layer 2 port mirroring.
5. Verify the minimum configuration of the binding:

```
[edit chassis fpc slot-number port-mirror-instance pm-instance-name]
user@host# top
[edit]
user@host# show chassis

chassis {
 fpc slot-number { # Bind two port mirroring named instances at the FPC level.
 port-mirror-instance pm-instance-name-1;
 port-mirror-instance pm-instance-name-2;
 }
}
```

### Binding Layer 2 Port Mirroring to Ports Grouped at the PIC Level

---

On an MX Series router and on an EX Series switch, you can bind a named instance of Layer 2 port mirroring to the ports associated with a specific Packet Forwarding Engine (on a DPC) or to the ports associated with a specific PIC (installed in an FPC). This is known as binding a named instance of Layer 2 port mirroring *at the PIC level* of the router (or switch) chassis. The port-mirroring properties specified in the named instance are applied to all physical ports associated with the specified Packet Forwarding Engine.

**NOTE:** You can also bind a named instance of Layer 2 port mirroring to a specific DPC or FPC in the router (or switch) chassis.

For any packet-type family supported by Layer 2 port mirroring:

- Port mirroring properties bound to a specific Packet Forwarding Engine override any port-mirroring properties configured at the DPC or FPC level.
- Port mirroring properties bound to a specific DPC or FPC override any port-mirroring properties configured at the global level.

You can apply up to two named instances of Layer 2 port mirroring to the same group of ports within the router (or switch) chassis. By applying two different port-mirroring instances to the same Packet Forwarding Engine or PIC, you can bind two distinct Layer 2 port mirroring specifications to a single group of ports.

For MX960 routers, there is a one-to-one mapping of Packet Forwarding Engines to Ethernet ports. Therefore, on MX960 routers only, you can bind a named instance of Layer 2 port mirroring to a *specific port* by binding the instance to the Packet Forwarding Engine associated with the port.

Before you begin, complete the following tasks:

- Define a named instance of Layer 2 port mirroring. See *Defining a Named Instance of Layer 2 Port Mirroring*.
- Display information about the number and types of DPCs in the MX Series router or in the EX Series switch, the number of Packet Forwarding Engines on each DPC, and the number and types of ports per Packet Forwarding Engine. See *Displaying Information About DPCs or FPCs in an MX Series Router*.

To bind a named instance of Layer 2 port-mirroring to a Packet Forwarding Engine:

1. Enable configuration of the router (or switch) chassis properties:

```
[edit]
user@host# edit chassis
```

2. Enable configuration of a Packet Forwarding Engine or PIC:

```
[edit chassis]
user@host# edit fpc slot-number
user@host# edit pic slot-number
```

3. Bind a named instance of Layer 2 port mirroring (*pm-instance-name*) to the Packet Forwarding Engine or PIC:

```
[edit chassis fpc slot-number pic slot-number]
user@host# set port-mirror-instance pm-instance-name
```

4. (Optional) To bind a second named instance of Layer 2 port mirroring to the same Packet Forwarding Engine or PIC, repeat step 3 and specify a different named instance of Layer 2 port mirroring.
5. Verify the minimum configuration of the binding:

```
[edit forwarding-options ...]
user@host# top
[edit]
user@host# show chassis
chassis {
 fpc slot-number {
 ... optional-binding-of-a-port-mirroring-instance-at-the-dpc-level ...
 pic slot-number { # Bind two port-mirroring named instances at the PIC level.
 port-mirror-instance pm-instance-name-1;
 port-mirror-instance pm-instance-name-2;
 }
 }
}
```

### Disabling Layer 2 Port Mirroring Instances

You can disable the global instance of Layer 2 port mirroring, a particular named instance, or all instances of port mirroring:

- To disable the global instance of Layer 2 port mirroring, include the **disable** statement at the **[edit forwarding-options port-mirroring]** hierarchy level:

```
[edit]
forwarding-options {
 port-mirroring {
 disable; Disables the global instance of Layer 2 port mirroring.
 ...global-instance-of-layer-2-port-mirroring-configuration...
 }
}
```

- To disable the definition of a particular named instance of Layer 2 port mirroring, include the **disable** statement at the **[edit forwarding-options port-mirroring instance instance-name]** hierarchy level:

```
[edit]
forwarding-options {
 port-mirroring {
 ...optional-configuration-of-the-global-instance-of-layer-2-port-mirroring...
 instance {
 port-mirroring-instance-name {
 disable; Disables this named instance of Layer 2 port mirroring.
 ...definition-of-a-named-instance-of-layer-2-port-mirroring...
 }
 }
 }
}
```

- To disable the global instance and all named instances of Layer 2 port mirroring, include the **disable-all-instances** statement at the **[edit forwarding-options port-mirroring]** hierarchy level:

```
[edit]
forwarding-options {
 port-mirroring {
 disable-all-instances; Disables all instances of Layer 2 port mirroring.
 ...optional-configuration-of-the-global-instance-of-layer-2-port-mirroring...
 instance {
 port-mirroring-instance-name {
 ...definition-of-a-named-instance-of-layer-2-port-mirroring...
 }
 }
 }
}
```

## Examples for Layer 2 Port Mirroring at Physical Interfaces

- [Examples: Layer 2 Port-Mirroring at Multiple Levels of the Chassis on page 4218](#)
- [Example: Layer 2 Port Mirroring with Multiple Instances on page 4220](#)

### Examples: Layer 2 Port-Mirroring at Multiple Levels of the Chassis

On an MX Series router or on an EX Series switch, you can apply named instances of Layer 2 port mirroring at the FPC or DPC level of the chassis or at the PIC level of the

chassis. However, you can configure (and implicitly apply) only one global instance of Layer 2 port mirroring to the entire chassis.

- [Layer 2 Port Mirroring at the FPC Level on page 4219](#)
- [Layer 2 Port Mirroring at the PIC Level on page 4219](#)
- [Layer 2 Port Mirroring at the FPC and PIC Levels on page 4219](#)

### ***Layer 2 Port Mirroring at the FPC Level***

In this example configuration of an MX Series router or of an EX Series switch chassis, a named instance of Layer 2 port mirroring (**pm1**) is bound to physical ports grouped at the FPC level:

```
[edit]
chassis {
 fpc 2 {
 port-mirror-instance pm1;
 }
}
```

This is not a complete configuration. The physical interfaces associated with the FPC or DPC in slot 2 must be configured at the **[edit interfaces]** hierarchy level. The Layer 2 port mirroring named instance **pm1** must be configured at the **[edit forwarding-options port-mirroring instance]** hierarchy level.

### ***Layer 2 Port Mirroring at the PIC Level***

In this example configuration of an MX Series router or of an EX Series switch chassis, a named instance of Layer 2 port mirroring (**pm2**) is bound to the physical ports grouped at the PIC level:

```
[edit]
chassis {
 fpc 2 {
 pic 0 {
 port-mirror-instance pm2;
 }
 }
}
```

This is not a complete configuration. The physical interfaces associated with the FPC or DPC in slot 2 must be configured at the **[edit interfaces]** hierarchy level. The Layer 2 port mirroring named instance **pm2** must be configured at the **[edit forwarding-options port-mirroring instance]** hierarchy level.

### ***Layer 2 Port Mirroring at the FPC and PIC Levels***

In this example configuration of an MX Series router chassis or an EX Series switch, one named instance of Layer 2 port mirroring (**pm1**) is applied at the FPC level of the router (or switch) chassis. A second named instance (**pm2**) is applied at the PIC level:

```
[edit]
chassis {
 fpc 2 {
 port-mirror-instance pm1;
 }
 pic 0 {
 port-mirror-instance pm2;
 }
}
```

```

 }
 }
}

```

This is not a complete configuration. Physical interfaces associated with the FPC or DPC in slot 2, including physical interfaces associated with **pic 0**, must be configured at the **[edit interfaces]** hierarchy level. The Layer 2 port mirroring named instances **pm1** and **pm2** must be configured at the **[edit forwarding-options port-mirroring instance]** hierarchy level.

#### Related Documentation

- [Layer 2 Port Mirroring Global Instance on page 4194](#)
- [Layer 2 Port Mirroring Named Instances](#)
- [Configuring the Global Instance of Layer 2 Port Mirroring](#)
- [Defining a Named Instance of Layer 2 Port Mirroring](#)

#### Example: Layer 2 Port Mirroring with Multiple Instances

Because you can configure more than one port-mirroring instance, care is required when specifying which instance is meant. This topic contains the following information:

- [Example: Configuring Multiple Instances of Layer 2 Port Mirroring on page 4220](#)
- [Explicit Reference of a Port Mirroring Instance on page 4223](#)
- [Implicit Reference of Port Mirroring on the Underlying Physical Interface on page 4223](#)

#### Example: Configuring Multiple Instances of Layer 2 Port Mirroring

This configuration example illustrates the configuration of Layer 2 port mirroring at the physical interfaces associated with FPC 2, PIC 0 and at two logical interfaces on one of those ports.

At the physical interface levels of the router (or switch) chassis, two named instances of port mirroring are configured and then bound to the group of physical ports associated with FPC 2, PIC 0.

At two of the logical interfaces on physical interface **ge-2/0/1**, two Layer 2 port-mirroring firewall filters are applied to the input traffic. One filter *explicitly* references the port mirroring properties specified in one of the named instances of port mirroring. The other filter *implicitly* references the port mirroring properties in effect on the underlying physical interface **ge-2/0/1**.

The resulting configuration is an example of the relationships that can exist between multiple instances of Layer 2 port mirroring applied to an MX Series router or an EX Series switch.

1. Configure two named instances of Layer 2 port mirroring (**pm\_instance\_1** and **pm\_instance\_2**), and include mirror destination properties for VLAN traffic (**family ethernet-switching**):

```

[edit]
forwarding-options {

```

```

port-mirroring {
 instance {
 pm_instance_1 {
 input {
 ... packet-selection-properties-configuration ...
 }
 family ethernet-switching {
 ... mirror-destination-properties-configuration ...
 }
 }
 pm_instance_2 {
 input {
 ... packet-selection-properties-configuration ...
 }
 family ethernet-switching {
 ... mirror-destination-properties-configuration ...
 }
 }
 }
}

```

**NOTE:** In this example, no global port-mirroring properties are configured on the router (or switch).

2. Apply the Layer 2 port mirroring instances to the same group of ports in the router (or switch) chassis. In this example, the named instances of Layer 2 port mirroring are applied to the same group of physical interfaces specified at the PIC level of the chassis:

```

[edit]
chassis {
 fpc 2 {
 pic 0 {
 port-mirror-instance pm_instance_1;
 port-mirror-instance pm_instance_2;
 }
 }
}

```

Note that, in this example, two named instances of Layer 2 port mirroring are bound to the PIC level of the chassis at the same group of ports.

3. Configure two Layer 2 port-mirroring firewall filters, both for VLAN traffic and with one of the filters explicitly referencing one of the named instances of Layer 2 port mirroring:
  - Configure the filter **pm\_filter\_1** to use the Layer 2 port-mirroring properties configured in the named port-mirroring instance **pm\_instance\_1**. To refer to the Layer 2 port mirroring properties configured in a particular named instance of port mirroring, use the **port-mirror-instance** *port-mirroring-instance-name* statement.
  - Configure the filter **pm\_filter\_2** to use the Layer 2 port mirroring properties in effect on the underlying physical interface of the logical interface to which the filter is applied. To refer to the Layer 2 port mirroring properties in effect on the underlying physical interface, use the **port-mirror** statement. If two instances of port mirroring are bound to that port, then the firewall filter uses the first instance bound within the **[edit chassis fpc slot-number]** or **[edit chassis fpc slot-number pic slot-number]** hierarchy level.

```
[edit]
firewall {
 family ethernet-switching {
 filter pm_filter_1 {
 term pm {
 then port-mirror-instance pm_instance_1;
 }
 }
 filter pm_filter_2 {
 term pm {
 then port-mirror;
 }
 }
 }
}
```

**NOTE:** Because the **port-mirror** filter action modifier relies on the port-mirroring properties defined at the **[edit forwarding-options port-mirroring]** hierarchy level, the **port-mirror** filter action is not supported for logical systems.

4. Apply the two Layer 2 port-mirroring firewall filters to logical interfaces on interface **ge-2/0/1**:

```
[edit]
interfaces {
 ge-2/0/1 {
 flexible-vlan-tagging;
 encapsulation ethernet-bridge;
 unit 0 {
 vlan-id 201;
 family ethernet-switching {
 filter { # Explicitly references a named instance of port mirroring.
 input pm_filter_1;
 }
 }
 }
 unit 1 {
```

```

vlan-id 202;
family ethernet-switching {
 filter { # Implicitly references the underlying port mirroring.
 input pm_filter_2;
 }
}
}
}
}

```

### ***Explicit Reference of a Port Mirroring Instance***

On logical interface **ge-2/0/1.0**, the **port-mirror-instance** statement explicitly references the Layer 2 port mirroring properties in the named instance **pm\_instance\_1**. In this example, the port mirroring properties specified in **pm\_instance\_1** remain in effect at logical interface **ge-2/0/1.0** under the following conditions:

- The firewall filter **pm\_filter\_1** remains configured (as shown in step 3).
- The named instance **pm\_instance\_1** remains configured (as shown in step 1).

Even if the named instance **pm\_instance\_1** is no longer configured or no longer bound to the router (or switch) chassis at FPC 2, PIC 0, the port mirroring properties specified in **pm\_instance\_1** remain in effect at logical interface **fe-2/0/1.0** through firewall filter **pm\_filter\_1**.

### ***Implicit Reference of Port Mirroring on the Underlying Physical Interface***

On logical interface **ge-2/0/1.1**, the **port-mirror** statement implicitly references the Layer 2 port mirroring properties in effect at the underlying physical interface **ge-2/0/1**. In this example, the port mirroring properties specified in **pm\_instance\_2** remain in effect at the ports associated with FPC 2, PIC 0 under the following conditions:

- The firewall filter **pm\_filter\_2** remains configured (as shown in step 3).
- The named instance **pm\_instance\_2** remains configured (as shown in step 1).
- The named instance **pm\_instance\_2** remains bound to the router (or switch) chassis at FPC 2, PIC 0 (as shown in step 2).

If you disable the named instance **pm\_instance\_2** or delete its binding to the physical ports associated with FPC 2, PIC 0, then—if global Layer 2 port mirroring properties had been configured—the global port mirroring properties would be used at logical interface **ge-2/0/1.1** through firewall filter **pm\_filter\_2**.

**NOTE:** There is a limitation to a Layer 2 port mirroring firewall filter in which you implicitly reference Layer 2 port mirroring properties by including the **port-mirror** statement. If multiple named instances of Layer 2 port mirroring are bound to the underlying physical interface, then only the first binding in the stanza (or the only binding) is used at the logical interface. This is done mainly for backward compatibility.

In the example above, filter **pmff\_bd\_filter\_2** uses the **port-mirror** statement, and so the filter action uses the mirroring properties of the first port mirroring instance applied to the router (or switch) chassis at the **[edit chassis fpc 2 pic 0]** hierarchy level, which is the instance **pm\_instance\_1**.

- [Applying Layer 2 Port Mirroring to Traffic Forwarded or Flooded to a VPLS Routing Instance on page 4233](#)

### Defining a Layer 2 Port-Mirroring Firewall Filter

---

For virtual private LAN service (VPLS) traffic (**family ethernet-switching** or **family vpls**) and for Layer 2 VPNs with **family ccc** on MX Series routers and on EX Series switches only, you can define a firewall filter that specifies Layer 2 port mirroring as the action to be performed if a packet matches the conditions configured in the firewall filter term.

You can use a Layer 2 port-mirroring firewall filter in the following ways:

- To mirror packets received or sent on a logical interface.
- To mirror packets forwarded or flooded to a VLAN.
- To mirror packets forwarded or flooded to a VPLS routing instance.
- To mirror tunnel interface input packets only to multiple destinations.

For a summary of the three types of Layer 2 port-mirroring you can configure on an MX Series router and on an EX Series switch, see *Application of Layer 2 Port Mirroring Types*.

For information about configuring firewall filters in general (including in a Layer 3 environment), see “[Stateless Firewall Filter Overview](#)” on page 4463 and “[How Standard Firewall Filters Evaluate Packets](#)” on page 4475 in the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

To define a firewall filter with a Layer 2 port-mirroring action:

1. Enable configuration of firewall filters for Layer 2 packets that are part of a VLAN, a Layer 2 switching cross-connect, or a virtual private LAN service (VPLS):

```
[edit]
user@host# edit firewall family family
```

The value of the **family** option can be **ethernet-switching**, **ccc**, or **vpls**.

2. Enable configuration of a firewall filter **pm-filter-name**:

```
[edit firewall family family]
user@host# edit filter pm-filter-name
```

3. Enable configuration of a firewall filter term **pm-filter-term-name**:

```
[edit firewall family family filter pm-filter-name]
user@host# edit term pm-filter-term-name
```

For more information about firewall filter terms in general (including in a Layer 3 environment), see [“Guidelines for Configuring Standard Firewall Filters” on page 4478](#) in the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

4. (Optional) Specify the firewall filter match conditions based on the route source address *only if* you want to mirror a subset of the sampled packets.

For information about configuring firewall filter match conditions in general (including in a Layer 3 environment), see [“Firewall Filter Match Conditions Based on Numbers or Text Aliases” on page 4488](#), [“Firewall Filter Match Conditions Based on Bit-Field Values” on page 4489](#), [“Firewall Filter Match Conditions Based on Address Fields” on page 4493](#), and [“Firewall Filter Match Conditions Based on Address Classes” on page 4502](#), in the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

- For detailed information about Layer 2 bridging firewall filter match conditions (which are supported on MX Series routers and EX Series switches only), see [“Standard Firewall Filter Match Conditions for Layer 2 Bridging Traffic” on page 4737](#).
- For detailed information about VPLS firewall filter match conditions, see [“Standard Firewall Filter Match Conditions for VPLS Traffic” on page 4727](#).
- For detailed information about Layer 2 circuit cross-connect (CCC) firewall filter match conditions, see [“Standard Firewall Filter Match Conditions for Layer 2 CCC Traffic” on page 4734](#).

**NOTE:** If you want all sampled packets to be considered to match (and be subjected to the actions specified in the **then** statement), then omit the **from** statement altogether.

5. Enable configuration of the **action** and **action-modifier** to apply to matching packets:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name]
user@host# edit then
```

6. Specify the actions to be taken on matching packets:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set action
```

The recommended value for the **action** is **accept**. If you do not specify an action, or if you omit the **then** statement entirely, all packets that match the conditions in the **from** statement are accepted.

7. Specify Layer 2 port mirroring or a next-hop group as the **action-modifier**:

- To reference the Layer 2 port mirroring properties currently in effect for the Packet Forwarding Engine or PIC associated with the underlying physical interface, use the **port-mirror** statement:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set port-mirror
```

- To reference the Layer 2 port mirroring properties configured in a specific named instance, use the **port-mirror-instance *pm-instance-name*** action modifier:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set port-mirror-instance pm-instance-name
```

If the underlying physical interface is not bound to a named instance of Layer 2 port mirroring but instead is implicitly bound to the global instance of Layer 2 port mirroring, then traffic at the logical interface is mirrored according to the properties specified in the named instance referenced by the **port-mirror-instance** action modifier.

- To reference a next-hop group that specifies the next-hop addresses (for sending additional copies of packets to an analyzer), use the **next-hop-group *pm-next-hop-group-name*** action modifier:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set next-hop-group pm-next-hop-group-name
```

For configuration information about next-hop groups, see [“Defining a Next-Hop Group for Layer 2 Port Mirroring” on page 4245](#). If you specify a next-hop group for Layer 2 port mirroring, the firewall filter term applies to the tunnel interface input only.

## 8. Verify the minimum configuration of the Layer 2 port-mirroring firewall filter:

```
[edit firewall ...]
user@host# top
[edit]
user@host# show firewall
```

```
family (ethernet-switching | ccc | vpls) { # Type of packets to mirror
 filter pm-filter-name { # Firewall filter name
 term pm-filter-term-name {
 from { # Do not specify match conditions based on route source address
 }
 then {
 action; # Recommended action is 'accept'
 action-modifier; # Three options for Layer 2 port mirroring
 }
 }
 }
}
```

In the firewall filter term **then** statement, the **action-modifier** can be **port-mirror**, **port-mirror-instance *pm-instance-name***, or **next-hop-group *pm-next-hop-group-name***.

## Applying Layer 2 Port Mirroring to a Logical Interface

---

You can apply a Layer 2 port-mirroring firewall filter to the input or to the output of a logical interface, including an aggregated Ethernet logical interface. Only packets of the address-type family specified by the filter action are mirrored.

Before you begin, complete the following task:

- Define a Layer 2 port-mirroring firewall filter to be applied to the input to a logical interface or output to a logical interface. For details, see *Defining a Layer 2 Port-Mirroring Firewall Filter*.

**NOTE:** This configuration task shows two Layer 2 port-mirroring firewall filters: one filter applied to the logical interface ingress traffic, and one filter applied to the logical interface egress traffic.

To apply a Layer 2 port-mirroring firewall filter to an input or output logical interface:

1. Configure the underlying physical interface for the logical interface.

- a. Enable configuration of the underlying physical interface:

```
[edit]
user@host# edit interfaces interface-name
```

**NOTE:** A port-mirroring firewall filter can also be applied to an aggregated-Ethernet logical interface.

- b. For Fast Ethernet and Gigabit Ethernet interfaces and aggregated Ethernet interfaces configured for VPLS, enable the reception and transmission of 802.1Q VLAN-tagged frames on the interface:

```
[edit interfaces interface-name]
user@host# set vlan-tagging
```

- c. For Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID, set the logical link-layer encapsulation type:

```
[edit interfaces interface-name]
user@host# set encapsulation extended-vlan-ethernet-switching
```

2. Configure the logical interface to which you want to apply a Layer 2 port-mirroring firewall filter.

- a. Specify the logical unit number:

```
[edit interfaces interface-name]
user@host# edit unit logical-unit-number
```

- b.

For a Fast Ethernet, Gigabit Ethernet, or Aggregated Ethernet interface, bind an 802.1Q VLAN tag ID to the logical interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# set vlan-id number
```

3. Enable specification of an input or output filter to be applied to Layer 2 packets that are part of bridging domain, Layer 2 switching cross-connects, or virtual private LAN service (VPLS).

- If the filter is to be evaluated when packets are received on the interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# set family family filter input pm-filter-name-a
```

- If the filter is to be evaluated when packets are sent on the interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# set family family filter output pm-filter-name-b
```

The value of the *family* option can be **ethernet-switching**, **ccc**, or **vpls**.

**NOTE:** If port-mirroring firewall filters are applied at both the input and output of a logical interface, two copies of each packet are mirrored. To prevent the router or switch from forwarding duplicate packets to the same destination, include the optional **mirror-once** statement at the [edit forwarding-options] hierarchy level.

4. Verify the minimum configuration for applying a named Layer 2 port mirroring firewall filter to a logical interface:

```
[edit interfaces interface-name unit logical-unit-number family family filter ...]
user@host# top
[edit]
user@host# show interfaces
```

```
interfaces {
 interface-name {
 vlan-tagging;
 encapsulation extended-vlan-ethernet-switching;
 unit number { # Apply a filter to the input of this interface
 vlan-id number;
 family (ethernet-switching | ccc | vpls) {
 filter {
 input pm-filter-for-logical-interface-input;
 }
 }
 }
 unit number { # Apply a filter to the output of this interface
 vlan-id number;
 family (ethernet-switching | ccc | vpls) {
 filter {
 output pm-filter-for-logical-interface-output;
 }
 }
 }
 }
}
```

```
 }
 }
}
```

### Applying Layer 2 Port Mirroring to Traffic Forwarded or Flooded to a VLAN

You can apply a Layer 2 port-mirroring firewall filter to traffic being forwarded or flooded to a VLAN. Only packets of the specified family type and forwarded or flooded to that VLAN are mirrored.

Before you begin, complete the following task:

- Define a Layer 2 port-mirroring firewall filter to be applied to the traffic being forwarded to a VLAN or flooded to a VLAN. For details, see *Defining a Layer 2 Port-Mirroring Firewall Filter*.

**NOTE:** This configuration task shows two Layer 2 port-mirroring firewall filters: one filter applied to the VLAN forwarding table ingress traffic, and one filter applied to the VLAN flood table ingress traffic.

To apply a Layer 2 port-mirroring firewall filter to the forwarding table or flood table of a VLAN:

1. Enable configuration of the VLAN **bridge-domain-name** to which you want to apply a Layer 2 port-mirroring firewall filter for forwarded or flooded traffic:

- For a VLAN:

```
[edit]
user@host# edit bridge-domains bridge-domain-name
```

- For a VLAN under a routing instance:

```
[edit]
user@host# edit routing-instances routing-instance-name bridge-domains
bridge-domain-name
user@host# set instance-type virtual-switch
```

For more detailed configuration information, see *Configuring a VPLS Routing Instance*.

2. Configure the VLAN:

```
[edit]
user@host# set domain-type bridge
user@host# set interface interface-name
user@host# set routing-interface routing-interface-name
```

For more detailed configuration information, see *Configuring a Bridge Domain* and *Configuring VLAN Identifiers for Bridge Domains and VPLS Routing Instances*.

3. Enable configuration of traffic forwarding on the VLAN:

```
[edit ... bridge-domains bridge-domain-name]
user@host# edit forwarding-options
```

4. Apply a Layer 2 port-mirroring firewall filter to the VLAN forwarding table or flood table.

- To mirror packets being forwarded to the VLAN:

```
[edit ... bridge-domains bridge-domain-name forwarding-options]
user@host# set filter input pm-filter-for-bd-ingress-forwarded
```

- To mirror packets being flooded to the VLAN:

```
[edit ... bridge-domains bridge-domain-name forwarding-options]
user@host# set flood input pm-filter-for-bd-ingress-flooded
```

5. Verify the minimum configuration for applying a Layer 2 port-mirroring firewall filter to the forwarding table or flood table of the VLAN.

- a. Navigate to the hierarchy level at which the VLAN is configured:

- **[edit]**
- **[edit routing-instances *routing-instance-name*]**

- b. Display the VLAN configurations:

```
user@host# show vlans
```

```
vlans {
 vlan-name {
 instance-type virtual-switch; # For a bridge domain under a routing instance.
 domain-type bridge;
 interface interface-name;
 forwarding-options {
 filter { # Mirror ingress forwarded traffic
 input pm-filter-for-bd-ingress-forwarded;
 }
 flood { # Mirror ingress flooded traffic
 input pm-filter-for-bd-ingress-flooded;
 }
 }
 }
}
```

## Applying Layer 2 Port Mirroring to Traffic Forwarded or Flooded to a VPLS Routing Instance

You can apply a Layer 2 port-mirroring firewall filter to traffic being forwarded or flooded to a VPLS routing instance. Only packets of the specified family type and forwarded or flooded to that VPLS routing instance are mirrored.

Before you begin, complete the following task:

- Define a Layer 2 port-mirroring firewall filter to be applied to the traffic being forwarded to a VPLS routing instance or flooded to a VLAN. For details, see *Defining a Layer 2 Port-Mirroring Firewall Filter*.

**NOTE:** This configuration task shows two Layer\_2 port-mirroring firewall filters: one filter applied to the VPLS routing instance forwarding table ingress traffic, and one filter applied to the VPLS routing instance flood table ingress traffic.

To apply a Layer 2 port-mirroring firewall filter to the forwarding table or flood table of a VPLS routing instance:

1. Enable configuration of the VPLS routing instance to which you want to apply a Layer 2 port-mirroring firewall filter for forwarded or flooded traffic:

```
[edit]
user@host# edit routing-instances routing-instance-name
user@host# set instance-type vpls
user@host# set interface interface-name
user@host# set route-distinguisher (as-number:number | ip-address:number)
user@host# set vrf-import [policy-names]
user@host# set vrf-export [policy-names]
user@host# edit protocols vpls
user@host@ ... vpls-configuration ...
```

For more detailed configuration information, see *Configuring a VPLS Routing Instance*.

2. Enable configuration of traffic forwarding on the VPLS routing instance:

```
[edit routing-instances routing-instance-name protocols vpls]
user@host# up 2
[edit routing-instances routing-instance-name]
user@host# edit forwarding-options
```

3. Apply a Layer 2 port-mirroring firewall filter to the VPLS routing instance forwarding table or flood table.

- To mirror packets being forwarded to the VPLS routing instance:

```
[edit routing-instances routing-instance-name forwarding-options]
user@host# set filter input pm-filter-for-vpls-ri-forwarded
```

- To mirror packets being flooded to the VPLS routing instance:

```
[edit routing-instances routing-instance-name forwarding-options]
```

```
user@host# set flood input pm-filter-for-vpls-ri-flooded
```

4. Verify the minimum configuration for applying a Layer 2 port-mirroring firewall filter to the forwarding table or flood table of the VPLS routing instance:

```
[edit routing-instances routing-instance-name forwarding-options]
user@host# top
[edit]
user@host# show routing-instances
```

```
routing-instances {
 routing-instance-name {
 instance-type vpls;
 interface interface-name;
 route-distinguisher (as-number:number | ip-address:number);
 vrf-import [policy-names];
 vrf-export [policy-names];
 protocols {
 vpls {
 ...vpls-configuration...
 }
 }
 forwarding-options {
 family vpls {
 filter { # Mirror ingress forwarded traffic
 input pm-filter-for-vpls-ri-forwarded;
 }
 flood { # Mirror ingress flooded traffic
 input pm-filter-for-vpls-ri-flooded;
 }
 }
 }
 }
}
```

- [Example: Layer 2 Port Mirroring for a Layer 2 VPN with LAG Links on page 4239](#)

### Example: Layer 2 Port Mirroring at a Logical Interface

The following steps describe an example in which the global port-mirroring instance and a port-mirroring firewall filter are used to configure Layer 2 port mirroring for the input to a logical interface.

1. Configure the VLAN **example-bd-with-analyzer**, which contains the external packet analyzer, and the VLAN **example-bd-with-traffic**, which contains the source and destination of the Layer 2 traffic being mirrored:

```
[edit]
bridge-domains {
 example-bd-with-analyzer { # Contains an external traffic analyzer
 vlan-id 1000;
 interface ge-2/0/0.0; # External analyzer
 }
 example-bd-with-traffic { # Contains traffic input and output interfaces
 vlan-id 1000;
 interface ge-2/0/6.0; # Traffic input port
 interface ge-3/0/1.2; # Traffic output port
 }
}
```

Assume that logical interface **ge-2/0/0.0** is associated with an external traffic analyzer that is to receive port-mirrored packets. Assume that logical interfaces **ge-2/0/6.0** and **ge-3/0/1.2** will be traffic input and output ports, respectively.

2. Configure Layer 2 port-mirroring for the global instance, with the port-mirroring destination being the VLAN interface associated with the external analyzer (logical interface **ge-2/0/0.0** on VLAN **example-bd-with-analyzer**). Be sure to enable the option that allows filters to be applied to this port-mirroring destination:

```
[edit]
forwarding-options {
 port-mirroring {
 input {
 rate 10;
 run-length 5;
 }
 family ethernet-switching {
 output {
 interface ge-2/0/0.0; # Mirror packets to the external analyzer
 no-filter-check; # Allow filters on the mirror destination interface
 }
 }
 }
}
```

The **input** statement at the **[edit forwarding-options port-mirroring]** hierarchy level specifies that sampling begins every tenth packet and that each of the first five packets selected are to be mirrored.

The **output** statement at the **[edit forwarding-options port-mirroring family ethernet-switching]** hierarchy level specifies the output mirror interface for Layer 2 packets in a bridging environment:

- Logical interface **ge-2/0/0.0**, which is associated with the external packet analyzer, is configured as the port-mirroring destination.
- The optional **no-filter-check** statement allows filters to be configured on this destination interface.

3. Configure the Layer 2 port-mirroring firewall filter **example-bridge-pm-filter**:

```
[edit]
firewall {
 family ethernet-switching {
 filter example-bridge-pm-filter {
 term example-filter-terms {
 then {
 accept;
 port-mirror;
 }
 }
 }
 }
}
```

When this firewall filter is applied to the input or output of a logical interface for traffic in a bridging environment, Layer 2 port mirroring is performed according to the input packet-sampling properties and mirror destination properties configured for the Layer 2 port mirroring global instance. Because this firewall filter is configured with the single, default filter action **accept**, all packets selected by the **input** properties (**rate = 10** and **run-length = 5**) match this filter.

4. Configure the logical interfaces:

```
[edit]
interfaces {
 ge-2/0/0 { # Define the interface to the external analyzer
 encapsulation ethernet-bridge;
 unit 0 {
 family ethernet-switching;
 }
 }
 ge-2/0/6 { # Define the traffic input port
 flexible-vlan-tagging;
 encapsulation extended-vlan-bridge;
 unit 0 {
 vlan-id 100;
 family ethernet-switching {
 filter {
 input example-bridge-pm-filter; # Apply the port-mirroring firewall filter
 }
 }
 }
 }
 ge-3/0/1 { # Define the traffic output port
```

```

flexible-vlan-tagging;
encapsulation extended-vlan-bridge;
unit 2 {
 vlan-tags outer 10 inner 20;
 family ethernet-switching;
}
}
}

```

Packets received at logical interface **ge-2/0/6.0** on VLAN **example-bd-with-traffic** are evaluated by the port-mirroring firewall filter **example-bridge-pm-filter**. The firewall filter acts on the input traffic according to the filter actions configured in the firewall filter itself plus the input packet-sampling properties and mirror destination properties configured in the global port-mirroring instance:

- All packets received at **ge-2/0/6.0** are forwarded to their (assumed) normal destination at logical interface **ge-3/0/1.2**.
- For every ten input packets, copies of the first five packets in that selection are forwarded to the external analyzer at logical interface **ge-0/0/0.0** in the other VLAN, **example-bd-with-analyzer**.

If you configure the port-mirroring firewall filter **example-bridge-pm-filter** to take the **discard** action instead of the **accept** action, all original packets are discarded while copies of the packets selected using the global port-mirroring **input** properties are sent to the external analyzer.

#### Example: Layer 2 Port Mirroring for a Layer 2 VPN

The following example is not a complete configuration, but shows all the steps needed to configure port mirroring on an L2VPN using **family ccc**.

1. Configure the VLAN **port-mirror-bd**, which contains the external packet analyzer:

```

[edit]
vllns {
 port-mirror-vlln { # Contains an external traffic analyzer
 interface ge-2/2/9.0; # External analyzer
 }
}

```

2. Configure the Layer 2 VPN CCC to connect logical interface **ge-2/0/1.0** and logical interface **ge-2/0/1.1**:

```

[edit]
protocols {
 mpls {
 interface all;
 }
}

```

```
connections {
 interface-switch if_switch {
 interface ge-2/0/1.0;
 interface ge-2/0/1.1;
 }
}
```

3. Configure Layer 2 port mirroring for the global instance, with the port-mirroring destination being the VLAN interface associated with the external analyzer (logical interface **ge-2/2/9.0** on VLAN **example-bd-with-analyzer**):

```
[edit]
forwarding-options {
 port-mirroring {
 input {
 rate 1;
 maximum-packet-length 200;
 }
 family ccc {
 output {
 interface ge-2/2/9.0; # Mirror packets to the external analyzer
 }
 }
 instance {
 inst1 {
 input {
 rate 1;
 maximum-packet-length 300;
 }
 family ccc {
 output {
 interface ge-2/2/9.0;
 }
 }
 }
 }
 }
}
```

4. Define the Layer 2 port-mirroring firewall filter **pm\_filter\_ccc** for **family ccc**:

```
[edit]
firewall {
 family ccc {
 filter pm_filter_ccc {
 term pm {
 then port-mirror;
 }
 }
 }
}
```

5. Apply the port mirror instance to the chassis:

```
[edit]
chassis {
```

```
fpc 2 {
 port-mirror-instance inst1;
}
```

6. Configure interface **ge-2/2/9** for the VLANs, and configure interface **ge-2/0/1** for port mirroring with the **pm\_filter\_ccc** firewall filter:

```
[edit]
interfaces {
 ge-2/2/9 {
 encapsulation ethernet-bridge;
 unit 0 {
 family ethernet-switching;
 }
 }
 ge-2/0/1 {
 vlan-tagging;
 encapsulation extended-vlan-ccc;
 unit 0 {
 vlan-id 10;
 family ccc {
 filter {
 input pm_filter_ccc;
 }
 }
 }
 unit 1 {
 vlan-id 20;
 family ccc {
 filter {
 output pm_filter_ccc;
 }
 }
 }
 }
}
```

#### Example: Layer 2 Port Mirroring for a Layer 2 VPN with LAG Links

The following example is not a complete configuration, but shows all the steps needed to configure port mirroring on an L2VPN using **family ccc** and aggregated Ethernet links.

1. Configure the VLAN **port\_mirror\_bd**, which contains the external packet analyzer:

```
[edit]
vlands {
 port_mirror_vlan { # Contains an external traffic analyzer
 interface ge-2/2/8.0; # External analyzer
 }
}
```

```
}
```

2. Configure the Layer 2 VPN CCC to connect interface **ae0.0** and interface **ae0.1**:

```
[edit]
protocols {
 mpls {
 interface all;
 }
 connections {
 interface-switch if_switch {
 interface ae0.0;
 interface ae0.1;
 }
 }
}
```

3. Configure Layer 2 port mirroring for the global instance, with the port-mirroring destination being the VLAN interface associated with the external analyzer (logical interface **ge-2/2/9.0** on VLAN **example\_bd\_with\_analyzer**):

```
[edit]
forwarding-options {
 port-mirroring {
 input {
 rate 1;
 maximum-packet-length 200;
 }
 family ccc {
 output {
 interface ge-2/2/8.0; # Mirror packets to the external analyzer
 }
 }
 instance {
 pm_instance_1 {
 input {
 rate 1;
 maximum-packet-length 300;
 }
 family ccc {
 output {
 interface ge-2/2/8.0;
 }
 }
 }
 }
 }
}
```

4. Configure the firewall filter **pm\_ccc** for **family ccc**:

```
[edit]
firewall {
 family ccc {
 filter pm_ccc {
 term pm {
 then port-mirror;
 }
 }
 }
}
```

```

 }
 }
}

```

5. Apply the aggregated Ethernet interfaces and port mirror instance to the chassis:

```

[edit]
chassis {
 aggregated-devices {
 ethernet {
 device-count 10;
 }
 }
 fpc 2 {
 port-mirror-instance pm_instance_1;
 }
}

```

6. Configure interfaces **ae0** and **ge-2/0/2** (for aggregated Ethernet) and **ge-2/2/8** (for port mirroring) with the **pm\_ccc** filter:

```

[edit]
interfaces {
 ae0 {
 vlan-tagging;
 encapsulation extended-vlan-ccc;
 unit 0 {
 vlan-id 10;
 family ccc {
 filter {
 input pm_ccc;
 }
 }
 }
 }
 unit 1 {
 vlan-id 20;
 family ccc {
 filter {
 output pm_ccc;
 }
 }
 }
}
ge-2/0/2 {
 gigether-options {
 802.3ad ae0;
 }
}
ge-2/2/8 {
 encapsulation ethernet-bridge;
 unit 0 {
 family ethernet-switching;
 }
}
}

```

### Defining a Layer 2 Port-Mirroring Firewall Filter

---

For virtual private LAN service (VPLS) traffic (**family ethernet-switching** or **family vpls**) and for Layer 2 VPNs with **family ccc** on MX Series routers and on EX Series switches only, you can define a firewall filter that specifies Layer 2 port mirroring as the action to be performed if a packet matches the conditions configured in the firewall filter term.

You can use a Layer 2 port-mirroring firewall filter in the following ways:

- To mirror packets received or sent on a logical interface.
- To mirror packets forwarded or flooded to a VLAN.
- To mirror packets forwarded or flooded to a VPLS routing instance.
- To mirror tunnel interface input packets only to multiple destinations.

For a summary of the three types of Layer 2 port-mirroring you can configure on an MX Series router and on an EX Series switch, see *Application of Layer 2 Port Mirroring Types*.

For information about configuring firewall filters in general (including in a Layer 3 environment), see “[Stateless Firewall Filter Overview](#)” on page 4463 and “[How Standard Firewall Filters Evaluate Packets](#)” on page 4475 in the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

To define a firewall filter with a Layer 2 port-mirroring action:

1. Enable configuration of firewall filters for Layer 2 packets that are part of a VLAN, a Layer 2 switching cross-connect, or a virtual private LAN service (VPLS):

```
[edit]
user@host# edit firewall family family
```

The value of the **family** option can be **ethernet-switching**, **ccc**, or **vpls**.

2. Enable configuration of a firewall filter **pm-filter-name**:

```
[edit firewall family family]
user@host# edit filter pm-filter-name
```

3. Enable configuration of a firewall filter term **pm-filter-term-name**:

```
[edit firewall family family filter pm-filter-name]
user@host# edit term pm-filter-term-name
```

For more information about firewall filter terms in general (including in a Layer 3 environment), see [“Guidelines for Configuring Standard Firewall Filters” on page 4478](#) in the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

4. (Optional) Specify the firewall filter match conditions based on the route source address *only if* you want to mirror a subset of the sampled packets.

For information about configuring firewall filter match conditions in general (including in a Layer 3 environment), see [“Firewall Filter Match Conditions Based on Numbers or Text Aliases” on page 4488](#), [“Firewall Filter Match Conditions Based on Bit-Field Values” on page 4489](#), [“Firewall Filter Match Conditions Based on Address Fields” on page 4493](#), and [“Firewall Filter Match Conditions Based on Address Classes” on page 4502](#), in the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

- For detailed information about Layer 2 bridging firewall filter match conditions (which are supported on MX Series routers and EX Series switches only), see [“Standard Firewall Filter Match Conditions for Layer 2 Bridging Traffic” on page 4737](#).
- For detailed information about VPLS firewall filter match conditions, see [“Standard Firewall Filter Match Conditions for VPLS Traffic” on page 4727](#).
- For detailed information about Layer 2 circuit cross-connect (CCC) firewall filter match conditions, see [“Standard Firewall Filter Match Conditions for Layer 2 CCC Traffic” on page 4734](#).

**NOTE:** If you want all sampled packets to be considered to match (and be subjected to the actions specified in the **then** statement), then omit the **from** statement altogether.

5. Enable configuration of the **action** and **action-modifier** to apply to matching packets:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name]
user@host# edit then
```

6. Specify the actions to be taken on matching packets:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set action
```

The recommended value for the **action** is **accept**. If you do not specify an action, or if you omit the **then** statement entirely, all packets that match the conditions in the **from** statement are accepted.

7. Specify Layer 2 port mirroring or a next-hop group as the **action-modifier**:

- To reference the Layer 2 port mirroring properties currently in effect for the Packet Forwarding Engine or PIC associated with the underlying physical interface, use the **port-mirror** statement:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set port-mirror
```

- To reference the Layer 2 port mirroring properties configured in a specific named instance, use the **port-mirror-instance** *pm-instance-name* action modifier:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set port-mirror-instance pm-instance-name
```

If the underlying physical interface is not bound to a named instance of Layer 2 port mirroring but instead is implicitly bound to the global instance of Layer 2 port mirroring, then traffic at the logical interface is mirrored according to the properties specified in the named instance referenced by the **port-mirror-instance** action modifier.

- To reference a next-hop group that specifies the next-hop addresses (for sending additional copies of packets to an analyzer), use the **next-hop-group** *pm-next-hop-group-name* action modifier:

```
[edit firewall family family filter pm-filter-name term pm-filter-term-name then]
user@host# set next-hop-group pm-next-hop-group-name
```

For configuration information about next-hop groups, see [“Defining a Next-Hop Group for Layer 2 Port Mirroring” on page 4245](#). If you specify a next-hop group for Layer 2 port mirroring, the firewall filter term applies to the tunnel interface input only.

- Verify the minimum configuration of the Layer 2 port-mirroring firewall filter:

```
[edit firewall ...]
user@host# top
[edit]
user@host# show firewall

family (ethernet-switching | ccc | vpls) { # Type of packets to mirror
 filter pm-filter-name { # Firewall filter name
 term pm-filter-term-name {
 from { # Do not specify match conditions based on route source address
 }
 then {
 action; # Recommended action is 'accept'
 action-modifier; # Three options for Layer 2 port mirroring
 }
 }
 }
}
```

In the firewall filter term **then** statement, the *action-modifier* can be **port-mirror**, **port-mirror-instance** *pm-instance-name*, or **next-hop-group** *pm-next-hop-group-name*.

- *Example: Layer 2 Port Mirroring to Multiple Destinations*

### Defining a Next-Hop Group for Layer 2 Port Mirroring

On MX Series routers and EX Series switches, you can mirror tunnel interface input traffic to multiple destinations. To this form of *multipacket port mirroring*, you specify two or more additional destinations in a next-hop group, define a firewall filter that references the next-hop group as the filter action, and then apply the filter to a logical tunnel interface (**lt-**) or virtual tunnel interface (**vt-**) on the MX Series router and on an EX Series switch.

**NOTE:** This topic describes how to define a next-hop group for Layer 2 port mirroring to multiple destinations. For detailed information about defining a firewall filter for Layer 2 port mirroring to multiple destinations, see *Defining a Layer 2 Port-Mirroring Firewall Filter*.

To define a next-hop group for a Layer 2 port-mirroring firewall filter action:

1. Enable configuration of Layer 2 forwarding options.

- To enable Layer 2 forwarding options at the top level:

```
[edit]
user@host edit forwarding-options port-mirroring family (ccc | vpls) output
```

- To enable Layer 2 forwarding options for a routing instance:

```
[edit]
user@host edit forwarding-options port-mirroring instance instance-name
family (ccc | vpls) output
```

2. Enable configuration of a next-hop-group for Layer 2 port mirroring:

```
[edit forwarding-options port-mirroring ... family (ccc | vpls) output]
user@host# edit next-hop-group pm-next-hop-group-name
```

3. Specify the type of addresses to be used in the next-hop group configuration. By default, the next-hop group is specified using Layer 3 addresses (**group-type inet**). To specify the next-hop group using Layer 2 addresses instead, you must include the **group-type layer-2** statement:

```
[edit forwarding-options port-mirroring ... family (ccc | vpls) output next-hop-group
pm-next-hop-group-name]
user@host# set group-type layer-2
```

4. Specify the logical interfaces of the next-hop route (or switch) r:

```
[edit forwarding-options port-mirroring ... family (ccc | vpls) output next-hop-group
pm-next-hop-group-name]
user@host# set interface logical-interface-name-1
user@host# set interface logical-interface-name-2
```

The MX Series router and the EX Series switch supports up to 30 next-hop groups. Each next-hop group supports up to 16 next-hop addresses. Each next-hop group must specify at least two addresses.

## 5. Verify the configuration of the next-hop group:

```
[edit forwarding-options port-mirroring ... family (ccc | vpls) output next-hop-group
 pm-next-hop-group-name]
user@host# top
[edit]
user@host# show forwarding-options

...
next-hop-group pm-next-hop-group-name { # Next-hop group on a bridge domain.
 group-type layer-2;
 interface logical-interface-name-1;
 interface logical-interface-name-2;
}
...
```

## Applying Layer 2 Port Mirroring to a Logical Interface

You can apply a Layer 2 port-mirroring firewall filter to the input or to the output of a logical interface, including an aggregated Ethernet logical interface. Only packets of the address-type family specified by the filter action are mirrored.

Before you begin, complete the following task:

- Define a Layer 2 port-mirroring firewall filter to be applied to the input to a logical interface or output to a logical interface. For details, see *Defining a Layer 2 Port-Mirroring Firewall Filter*.

**NOTE:** This configuration task shows two Layer 2 port-mirroring firewall filters: one filter applied to the logical interface ingress traffic, and one filter applied to the logical interface egress traffic.

To apply a Layer 2 port-mirroring firewall filter to an input or output logical interface:

1. Configure the underlying physical interface for the logical interface.

- a. Enable configuration of the underlying physical interface:

```
[edit]
user@host# edit interfaces interface-name
```

**NOTE:** A port-mirroring firewall filter can also be applied to an aggregated-Ethernet logical interface.

- b. For Fast Ethernet and Gigabit Ethernet interfaces and aggregated Ethernet interfaces configured for VPLS, enable the reception and transmission of 802.1Q VLAN-tagged frames on the interface:

```
[edit interfaces interface-name]
user@host# set vlan-tagging
```

- c. For Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID, set the logical link-layer encapsulation type:

```
[edit interfaces interface-name]
user@host# set encapsulation extended-vlan-ethernet-switching
```

2. Configure the logical interface to which you want to apply a Layer 2 port-mirroring firewall filter.

- a. Specify the logical unit number:

```
[edit interfaces interface-name]
user@host# edit unit logical-unit-number
```

- b.

For a Fast Ethernet, Gigabit Ethernet, or Aggregated Ethernet interface, bind an 802.1Q VLAN tag ID to the logical interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# set vlan-id number
```

3. Enable specification of an input or output filter to be applied to Layer 2 packets that are part of bridging domain, Layer 2 switching cross-connects, or virtual private LAN service (VPLS).

- If the filter is to be evaluated when packets are received on the interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# set family family filter input pm-filter-name-a
```

- If the filter is to be evaluated when packets are sent on the interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# set family family filter output pm-filter-name-b
```

The value of the *family* option can be **ethernet-switching**, **ccc**, or **vpls**.

**NOTE:** If port-mirroring firewall filters are applied at both the input and output of a logical interface, two copies of each packet are mirrored. To prevent the router or switch from forwarding duplicate packets to the same destination, include the optional **mirror-once** statement at the [edit forwarding-options] hierarchy level.

4. Verify the minimum configuration for applying a named Layer 2 port mirroring firewall filter to a logical interface:

```
[edit interfaces interface-name unit logical-unit-number family family filter ...]
user@host# top
[edit]
user@host# show interfaces
```

```
interfaces {
 interface-name {
 vlan-tagging;
 encapsulation extended-vlan-ethernet-switching;
 unit number { # Apply a filter to the input of this interface
 vlan-id number;
 family (ethernet-switching | ccc | vpls) {
 filter {
 input pm-filter-for-logical-interface-input;
 }
 }
 }
 unit number { # Apply a filter to the output of this interface
 vlan-id number;
 family (ethernet-switching | ccc | vpls) {
 filter {
 output pm-filter-for-logical-interface-output;
 }
 }
 }
 }
}
```

```

 }
 }
}

```

## Examples of Layer 2 Port Mirroring at Multiple Destinations

- [Example: Layer 2 Port Mirroring to Multiple Destinations on page 4249](#)

### Example: Layer 2 Port Mirroring to Multiple Destinations

On MX Series routers and EX Series switches, you can mirror traffic to multiple destinations by configuring next-hop groups in Layer 2 port-mirroring firewall filters applied to tunnel interfaces.

1. Configure the chassis to support tunnel services at PIC 0 on FPC 2. This configuration includes two logical tunnel interfaces on FPC 2, PIC 0, port 10.

```

[edit]
chassis {
 fpc 2 {
 pic 0 {
 tunnel-services {
 bandwidth 1g;
 }
 }
 }
}

```

2. Configure the physical and logical interfaces for three VLANs and one Layer 2 VPN CCC:
  - VLAN **bd** will span logical interfaces **ge-2/0/1.0** and **ge-2/0/1.1**.
  - VLAN **bd\_next\_hop\_group** will span logical interfaces **ge-2/2/9.0** and **ge-2/0/2.0**.
  - VLAN **bd\_port\_mirror** will use the logical tunnel interface **lt-2/0/10.2**.
  - Layer 2 VPN CCC **if\_switch** will connect logical interfaces **ge-2/0/1.2** and **lt-2/0/10.1**.

```

[edit]
interfaces {
 ge-2/0/1 {
 flexible-vlan-tagging;
 }
}

```

```
encapsulation flexible-ethernet-services;
unit 0 { # An interface on bridge domain 'bd'.
 encapsulation vlan-bridge;
 vlan-id 200;
 family ethernet-switching {
 filter {
 input pm_bridge;
 }
 }
}
unit 1 { # An interface on bridge domain 'bd'.
 encapsulation vlan-bridge;
 vlan-id 201;
 family ethernet-switching {
 filter {
 input pm_bridge;
 }
 }
}
unit 2 {
 encapsulation vlan-ccc;
 vlan-id 1000;
}
}
ge-2/0/2 { # For 'bd_next_hop_group'
 encapsulation ethernet-bridge;
 unit 0 {
 family ethernet-switching;
 }
}
lt-2/0/10 {
 unit 1 {
 encapsulation ethernet-ccc;
 peer-unit 2;
 }
 unit 2 {
 encapsulation ethernet-bridge;
 peer-unit 1;
 family ethernet-switching {
 filter {
 output redirect_to_nhg;
 }
 }
 }
}
}
ge-2/2/9 {
 encapsulation ethernet-bridge;
 unit 0 { # For 'bd_next_hop_group'
 family ethernet-switching;
 }
}
}
```

## 3. Configure the three VLANs and the Layer 2 VPN switching CCC:

- VLAN **bd** spans logical interfaces **ge-2/0/1.0** and **ge-2/0/1.1**.
- VLAN **bd\_next\_hop\_group** spans logical interfaces **ge-2/2/9.0** and **ge-2/0/2.0**.
- VLAN **bd\_port\_mirror** uses the logical tunnel interface **lt-2/0/10.2**.
- Layer 2 VPN CCC **if\_switch** connects interfaces **ge-2/0/1.2** and **lt-2/0/10.1**.

```
[edit]
vpls {
 vlans {
 vlans {
 interface ge-2/0/1.0;
 interface ge-2/0/1.1;
 }
 bd_next_hop_group {
 interface ge-2/2/9.0;
 interface ge-2/0/2.0;
 }
 bd_port_mirror {
 interface lt-2/0/10.2;
 }
 }
}
protocols {
 mpls {
 interface all;
 }
}
connections {
 interface-switch if_switch {
 interface ge-2/0/1.2;
 interface lt-2/0/10.1;
 }
}
```

For detailed information about configuring the CCC connection for Layer 2 switching cross-connects, see the *Junos OS MPLS Applications Configuration Guide*.

## 4. Configure forwarding options:

- Configure global port mirroring properties to mirror **family vpls** traffic to an interface on the bridge domain **bd\_port\_mirror**.
- Configure the next-hop group **nhg\_mirror\_to\_bd** to forward Layer 2 traffic to the VLAN **bd\_next\_hop\_group**.

Both of these forwarding options will be referenced by the port-mirroring firewall filter:

```
[edit]
forwarding-options {
 port-mirroring { # Global port mirroring properties.
 input {
 rate 1;
 }
 family vpls {
 output {
 interface lt-2/0/10.2; # Interface on 'bd_port_mirror' bridge domain.
 no-filter-check;
 }
 }
 }
}
```

```

 }
 }
}
next-hop-group nhg_mirror_to_bd { # Configure a next-hop group.
 group-type layer-2; # Specify 'layer-2' for Layer 2; default 'inet' is for Layer 3.
 interface ge-2/0/2.0; # Interface on 'bd_next_hop_group' bridge domain.
 interface ge-2/2/9.0; # Interface on 'bd_next_hop_group' bridge domain.
}
}

```

5. Configure two Layer 2 port-mirroring firewall filters for **family bridge** traffic:

- **filter\_pm\_bridge**—Sends all **family bridge** traffic to the global port mirroring destination.
- **filter\_redirect\_to\_nhg**—Sends all **family bridge** traffic to the final next-hop group **nhg\_mirror\_to\_bd**.

Layer 2 port-mirroring firewall filters for **family bridge** traffic applies to traffic on a physical interface configured with encapsulation **ethernet-bridge**.

```

[edit]
firewall {
 family bridge {
 filter filter_pm_bridge {
 term term_port_mirror {
 then port-mirror;
 }
 }
 filter filter_redirect_to_nhg {
 term term_nhg {
 then next-hop-group nhg_mirror_to_bd;
 }
 }
 }
}

```

## Configuring Inline Port Mirroring

- [Configuring Inline Port Mirroring on page 4252](#)

### Configuring Inline Port Mirroring

Inline port mirroring provides you with the ability to specify instances that are not bound to the flexible PIC concentrator (FPC) in the firewall filter's **then port-mirror-instance** action. This way, you are not limited to only two port-mirror instances per FPC. Inline port mirroring decouples the port-mirror destination from the input parameters like **rate**. While

the input parameters are programmed in the switch interface board, the next-hop destination of the mirrored packet is available in the packet itself. Inline port mirroring is supported only on Trio-based modular port concentrators (MPCs).

Using inline port mirroring, a port-mirror instance will have an option to inherit input parameters from another instance that specifies it, as shown in the following CLI configuration example:

```
instance pm2 {
 + input-parameters-instance pm1;
 family inet {
 output {
 interface ge-1/2/3.0 {
 next-hop 50.0.0.3;
 }
 }
 }
}
```

Multiple levels of inheritance are not allowed. One instance can be referred by multiple instances. An instance can refer to another instance that is defined before it. Forward references are not allowed and an instance cannot refer to itself, doing so will cause an error during configuration parsing.

The user can specify an instance that is not bound to the FPC in the firewall filter. The specified filter should inherit one of the two instances that have been bound to the FPC. If it does not, the packet is not marked for port-mirroring. If it does, then the packet will be sampled using the input parameters specified by the referred instance but the copy will be sent to the its own destination.

## instance

---

**Syntax**

```
instance {
 instance-name {
 input {
 maximum-packet-length bytes;
 rate number;
 run-length number;
 }
 family (ccc| inet | inet6 | vpls) {
 output {
 interface interface-name {
 next-hop address;
 }
 no-filter-check;
 }
 }
 }
}
```

**Hierarchy Level** [edit [forwarding-options](#) port-mirroring]

**Release Information** Statement introduced in Junos OS Release 9.3 (MX Series routers only). Support extended to M120 and M320 routers in Junos OS Release 9.5. **maximum-packet-length** and **ccc** options introduced in Junos OS Release 9.6 for M120 and M320 routers only.

**Description** Configure a port-mirroring instance.

**Options** *port-mirroring-instance-name*—Name of the port-mirroring instance.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control-level—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.                                                                                                                                                                                                                             |
| <b>Description</b>              | Set the ratio of the number of packets to be sampled. For example, if you specify a rate of 10, every tenth packet (1 packet out of 10) is sampled.                                                                                                                           |
| <b>Options</b>                  | <b>number</b> —Denominator of the ratio.<br><b>Range:</b> 1 through 65,535                                                                                                                                                                                                    |
| <b>Usage Guidelines</b>         | See <i>Configuring Port Mirroring</i> or <i>Configuring Traffic Sampling</i> .                                                                                                                                                                                                |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration.                                                                                                                                                       |

## run-length

### Displaying Layer 2 Port-Mirroring Instance Settings and Status

To display the current state of port-mirroring instances, use the `show forwarding-options port-mirroring <terse | detail> <instance-name>` operational command.

For more information about displaying port mirroring instance settings and status, see the *Junos OS System Basics Configuration Guide*.

---

### Displaying Next-Hop Group Settings and Status

To display the current state of next-hop groups, use the **show forwarding-options next-hop-group** *<terse | brief | detail>* *<group-name>* operational command.

For more information, see the *Junos OS Operational Mode Commands*.

| <b>Description</b>                                   | (M320, MX Series, and T Series routers, EX8200 switches, and PTX Series Packet Transport Switches only) Display the state of the electrical switch fabric links between the Flexible PIC Concentrators (FPCs) and the Switch Interface Boards (SIBs).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>                                       | <p><b>none</b>—Display the switch fabric link state. On a TX Matrix router, display the switching fabric link states for the FPCs in all T640 routers connected to the TX Matrix router. On a TX Matrix Plus router, display the switching fabric link states for the FPCs in all T1600 routers connected to the TX Matrix Plus router.</p> <p><b>all-members</b>—(EX Series switches only) (Optional) Display the switching fabric link states for the FPCs in all members of the Virtual Chassis configuration.</p> <p><b>fcc <i>number</i></b>—(TX Matrix and TX Matrix Plus router only) (Optional) On a TX Matrix router, display the switch fabric link state for the FPCs in the specified T640 router (or line-card chassis) that is connected to the TX Matrix router. On a TX Matrix Plus router, display the switch fabric link state for the FPCs in the specified T1600 router (or line-card chassis) that is connected to the TX Matrix Plus router. Replace <b><i>number</i></b> with a value from 0 through 3.</p> <p><b>local</b>—(EX Series switches only) (Optional) Display the switching fabric link states for the FPCs in the local Virtual Chassis member.</p> <p><b>member <i>member-id</i></b>—(EX Series switches only) (Optional) Display the switching fabric link states for the FPCs in the specified member of the Virtual Chassis configuration. Replace <b><i>member-id</i></b> with a value of 0 or 1.</p> |

**slot *fpc-slot***—(PTX Series Packet Transport Switches only) (Optional) Display the fabric state of the specified FPC slot. If no value is provided, display the status of all FPCs.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Output Fields</b>            | Table 317 on page 4267 lists the output fields for the <b>show chassis fabric fpcs</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>                                          | Display status information about the installed Flexible PIC Concentrators (FPCs) and PICs.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Options** **none**—Display status information for all FPCs. On a TX Matrix router, display status information for all FPCs on the attached T640 routers in the routing matrix. On a TX Matrix Plus router, display status information for all FPCs on the attached T1600 routers in the routing matrix.

**NOTE:** In EX8200 switches, line cards initialize Packet Forwarding Engine during startup. If an error occurs during hardware initialization, the FPCs with bad hardware parts power down after transferring the debug information to the Routing Engine. The Routing Engine marks the FPC offline, logs the error in system log messages (/var/log/messages), and generates an alarm to inform the user.

See the following sample output:

```
user@host> show chassis fpc
```

| Utilization (%) |         | Temp                 | CPU Utilization (%) |           | Memory    |      |
|-----------------|---------|----------------------|---------------------|-----------|-----------|------|
| Slot            | State   | (C)                  | Total               | Interrupt | DRAM (MB) | Heap |
| Buffer          |         |                      |                     |           |           |      |
| 0               | Empty   |                      |                     |           |           |      |

| 3               | Empty   |                      |                     |           |           |      |
| 4               | Empty   |                      |                     |           |           |      |
| 5               | Offline | ---Hard FPC error--- |                     |           |           |      |
| 6               | Empty   |                      |                     |           |           |      |
| 7               | Online  | 26                   | 4                   | 0         | 1024      | 0    |
| 32              |         |                      |                     |           |           |      |

The following sample output shows the alarm raised for the failed FPCs.

```
user@host > show chassis alarms
4 alarms currently active
```

| Alarm time              | Class | Description                          |
|-------------------------|-------|--------------------------------------|
| 2011-03-24 00:52:51 UTC | Major | FPC 5 Hard errors                    |
| 2011-03-24 00:52:31 UTC | Major | Fan Tray Failure                     |
| 2011-03-24 00:52:31 UTC | Major | Fan Tray Failure                     |
| 2011-03-24 00:51:26 UTC | Minor | Loss of communication with Backup RE |

**NOTE:** On T4000 routers, when you include the **enhanced-mode** statement at the **[edit chassis network-services]** hierarchy level and reboot the system, only the T4000 Type 5 FPCs present on the router become online while the remaining FPCs are offline, and FPC misconfiguration alarms are generated. The **show chassis alarm** command output displays FPC misconfiguration (**FPC *fpc-slot* misconfig**) as the reason for the generation the alarms.

The following sample output shows the FPC status after the **enhanced-mode** statement is configured on the T4000 router. The T4000 Type 5 FPC present in slot 5 becomes online while the remaining FPCs are offline.

```
user@host> show chassis fpc
```

|                 | Temp | CPU Utilization (%)        |           | Memory    |      |

The following sample output shows FPC misconfiguration alarms.

```
user@host > show chassis alarms
```

3 alarms currently active

| Alarm time              | Class | Description     |
|-------------------------|-------|-----------------|
| 2011-03-24 00:52:51 PST | Major | FPC 1 misconfig |
| 2011-03-24 00:52:31 PST | Major | FPC 2 misconfig |
| 2011-03-24 00:52:31 PST | Major | FPC 3 misconfig |

**detail**—(Optional) Display detailed status information for all FPCs or for the FPC in the specified slot (see ***fpc-slot*** or ***slot***).

**all-members**—(MX Series routers and EX Series switches only) (Optional) Display status information for all FPCs on all members of the Virtual Chassis configuration.

**interconnect-device *name***—(QFabric systems only) (Optional) Display status information for all FPCs on the Interconnect device.

***fpc-slot***—(Optional) FPC slot number:

- (TX Matrix and TX Matrix Plus router only)—On a TX Matrix router, if you specify the number of the T640 router (or line-card chassis) by using the ***lcc number*** option (the recommended method), replace ***fpc-slot*** with a value from 0 through 7. Otherwise, replace ***fpc-slot*** with a value from 0 through 31. Likewise, on a TX Matrix Plus router, if you specify the number of the T1600 router (or line-card chassis)

by using the **lcc number** option (the recommended method), replace **fpc-slot** with a value from 0 through 7. Otherwise, replace **fpc-slot** with a value from 0 through 31. For example, the following commands have the same result:

```
user@host> show chassis fpc detail 1 lcc 1
user@host> show chassis fpc detail 9
```

- M120 router—Replace **fpc-slot** with a value from 0 through 5.
- MX80 router—Replace **fpc-slot** with a value from 0 through 1.
- MX240 router—Replace **fpc-slot** with a value from 0 through 2.
- MX480 router—Replace **fpc-slot** with a value from 0 through 5.
- MX-960 router—Replace **fpc-slot** with a value from 0 through 11.
- MX2010 router—Replace **fpc-slot-number** with a value from 0 through 9.
- MX2020 router—Replace **fpc-slot-number** with a value from 0 through 19.
- Other routers—Replace **fpc-slot** with a value from 0 through 7.
- EX Series switches:
  - EX3200 switches and EX4200 standalone switches—Replace **fpc-slot** with 0.
  - EX4200 switches in a Virtual Chassis configuration—Replace **fpc-slot** with a value from 0 through 9.
  - EX6210 switches—Replace **fpc-slot** with a value from 0 through 9.
  - EX8208 switches—Replace **fpc-slot** with a value from 0 through 7.
  - EX8216 switches—Replace **fpc-slot** with a value from 0 through 15.
- QFX Series:
  - QFX3500 switches—Replace **fpc-slot** with 0.
  - QFabric systems—Replace **fpc-slot** with 0 through 31 on the Interconnect device.
- PTX Series Packet Transport Switches:
  - PTX5000 Packet Transport Switch—Replace **fpc-slot** with a value from 0 through 7.
- ACX Series Universal Access Routers:
  - ACX1000 and ACX2000 Universal Access Routers—Replace **fpc-slot** with 0.

**local**—(MX Series routers and EX Series switches only) (Optional) Display status information for all FPCs on the local Virtual Chassis member.

**member member-id**—(MX Series routers and EX Series switches only) (Optional) Display status information for all FPCs on the specified member of the Virtual Chassis configuration. Replace **member-id** with a value of 0 or 1.

**node-device name**—(QFabric systems only) (Optional) Display status information for each Node device. Each Node device is equivalent to an FPC.

**pic-status**—(Optional) Display status information for all PICs or for the PIC in the specified slot (see *fpc-slot*).

**NOTE:** On T1600 routers, Type 4 FPCs with ASICs based on the SL2.0 chipset do not support the 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (10x10GE [LAN/WAN] SFPP). If you issue the `show chassis fpc` command with the `pic-status` option, the CLI displays the string “Not Supported” for 10x10GE(LAN/WAN) SFPP PICs installed on such FPCs. The following is a sample output:

```
user@host> show chassis fpc pic-status
Slot 0 Online E2-FPC Type 1
 PIC 0 Online 1x G/E SFP, 1000 BASE
 PIC 1 Online Adaptive Services-II
 PIC 2 Online 1x G/E IQ, 1000 BASE
 PIC 3 Online 1x G/E IQ, 1000 BASE
Slot 1 Online FPC Type 3-ES
 PIC 0 Present UNUSED- Not Supported
Slot 2 Online FPC Type 4-ES
 PIC 0 Offline 4x OC-192 SONET XFP
 PIC 1 Present 10x10GE(LAN/WAN) SFPP- Not Supported
<<<<<<
Slot 4 Offline FPC Type 1-ES
Slot 5 Offline FPC Type 2-ES
Slot 6 Online E2-FPC Type 3
 PIC 0 Online 1x OC-192 SONET XFP
 PIC 1 Online 4x OC-48 SONET
 PIC 2 Online 4x OC-48 SONET
 PIC 3 Online MultiServices 500
Slot 7 Online FPC Type 4-ES
 PIC 0 Online 4x 10GE (LAN/WAN) XFP
 PIC 1 Online 4x 10GE (LAN/WAN) XFP
```

In addition, an entry is logged in the system log messages (`/var/log/messages`) that the PIC is not supported. The following is a sample message logged in the system log:

```
Apr 5 08:47:36 router1 chassisd[2770]: CHASSISD_UNSUPPORTED_PIC:
PIC 1 in FPC 2 (type 763, version 257) is not supported
```

**lcc number**—(TX Matrix and TX Matrix Plus router only) (Optional) On a TX Matrix router, display status information for a T640 router (or line-card chassis) that is connected to the TX Matrix router. On a TX Matrix Plus router, display status information for a T1600 router (or line-card chassis) that is connected to the TX Matrix Plus router. Replace *number* with a value from 0 through 3.

**Output Fields** [Table 318 on page 4304](#) lists the output fields for the **show chassis fpc** command. Output fields are listed in the approximate order in which they appear.

**Table 318: show chassis fpc Output Fields**

| Field Name                       | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Level of Output |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Slot</b> or <b>Slot State</b> | Slot number and state. The state can be one of the following conditions: <ul style="list-style-type: none"> <li>• <b>Dead</b>—Held in reset because of errors.</li> <li>• <b>Diag</b>—Slot is being ignored while the FPC is running diagnostics.</li> <li>• <b>Dormant</b>—Held in reset.</li> <li>• <b>Empty</b>—No FPC is present.</li> <li>• <b>Offline</b>—(PTX Series Packet Transport Switches only) One of the following two states is displayed:               <ul style="list-style-type: none"> <li>• <b>FPC offlined due to unreachable destinations</b></li> <li>• <b>FPC Offlined due to degraded FPC action</b></li> </ul> </li> <li>• <b>Online</b>—FPC is online and running.</li> <li>• <b>Present</b>—FPC is detected by the chassis daemon but either is not supported by the current version of Junos OS or is inserted in the wrong slot. The output also states either <b>Hardware Not Supported</b> or <b>Hardware Not In Right Slot</b>. The FPC is coming up but not yet online.</li> <li>• <b>Probed</b>—Probe is complete; awaiting restart of the Packet Forwarding Engine.</li> <li>• <b>Probe-wait</b>—Waiting to be probed.</li> </ul> | all levels      |
| <b>Logical slot</b>              | Slot number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | all levels      |

Table 318: show chassis fpc Output Fields (*continued*)

| Field Name                           | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Level of Output          |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| <b>Temp (C) or Temperature</b>       | Temperature of the air passing by the FPC, in degrees Celsius or in both Celsius and Fahrenheit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | all levels<br>all levels |
| <b>Temperature (PTX Series)</b>      | On PTX Series Packet Transport Switches, temperature details are provided in degrees Celsius and Fahrenheit. Output includes: <ul style="list-style-type: none"> <li>• Temperature (PMB)—Temperature of the air passing by the Processor Mezzanine Board (PMB) at the bottom of the FPC.</li> <li>• Temperature (Intake)—Temperature of the air flowing into the chassis.</li> <li>• Temperature (Exhaust)—Exhaust temperatures for multiple zones (Exhaust A and Exhaust B).</li> <li>• Temperature (TLn)—Temperature of the specified Lookup ASIC (TL) of the packet forwarding engine on the FPC.</li> <li>• Temperature (TQn)—Temperature of the specified Queuing and Memory Interface ASIC (TQ) of the packet forwarding engine on the FPC.</li> </ul> | <b>detail</b>            |
| <b>Total CPU Utilization (%)</b>     | Total percentage of CPU being used by the FPC's processor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | all levels               |
| <b>Interrupt CPU Utilization (%)</b> | Of the total CPU being used by the FPC's processor, the percentage being used for interrupts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | none specified           |
| <b>Memory DRAM (MB)</b>              | Total DRAM, in megabytes, available to the FPC's processor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | none specified           |
| <b>Heap Utilization (%)</b>          | Percentage of heap space (dynamic memory) being used by the FPC's processor. If this number exceeds 80 percent, there may be a software problem (memory leak).<br><br><b>NOTE:</b> On MX Series routers and EX Series switches in a broadband edge environment, heap utilization levels higher than 70 percent can affect unified ISSU, router stability, or scaling capability.                                                                                                                                                                                                                                                                                                                                                                             | none specified           |
| <b>Buffer Utilization (%)</b>        | Percentage of buffer space being used by the FPC's processor for buffering internal messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | none specified           |
| <b>Total CPU DRAM</b>                | Amount of DRAM available to the FPC's CPU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>detail</b>            |
| <b>Total RLDRAM</b>                  | Amount of reduced latency dynamic random access memory (RLDRAM) available to the FPC CPU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <b>detail</b>            |
| <b>Total DDR DRAM</b>                | Amount of double data rate dynamic random access memory (DDR DRAM) available to the FPC CPU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>detail</b>            |
| <b>Total SRAM</b>                    | Amount of static RAM (SRAM) used by the FPC's CPU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <b>detail</b>            |
| <b>Total SDRAM</b>                   | Total amount of memory used for storing packets and notifications.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <b>detail</b>            |
| <b>I/O Manager ASICs information</b> | I/O Manager version number, manufacturer, and part number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>detail</b>            |

Table 318: show chassis fpc Output Fields (*continued*)

| Field Name        | Field Description                                                                                                   | Level of Output |
|-------------------|---------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Start time</b> | Time when the Routing Engine detected that the FPC was running.                                                     | <b>detail</b>   |
| <b>Uptime</b>     | How long the Routing Engine has been connected to the FPC and, therefore, how long the FPC has been up and running. | <b>detail</b>   |
| <b>PIC type</b>   | (pic-status output only) Type of PIC.                                                                               | none specified  |

## Sample Output

### show chassis fpc (EX6210 Switch)

```

user@switch> show chassis fpc

```

| Slot | State  | Temp<br>(C) | CPU Utilization (%)<br>Total Interrupt | Memory<br>DRAM (MB) | Utilization (%)<br>Heap | Buffer |
|------|--------|-------------|----------------------------------------|---------------------|-------------------------|--------|

### show chassis fpc pic-status

```

user@host> show chassis fpc pic-status
Slot 0 Online
 PIC 1 1x OC-12 ATM, MM
 PIC 2 1x OC-12 ATM, MM
 PIC 3 1x OC-12 ATM, MM
Slot 1 Online
 PIC 0 1x OC-48 SONET, SMIR
Slot 2 Online
 PIC 0 1x OC-192 SONET, SMSR

```

### show chassis fpc pic-status (M Series Routers)

```

user@host> show chassis fpc pic-status

```

```

Slot 1 Online FPC Type 1
 PIC 0 Present 2x OC-3 ATM, MM- Hardware Error
 PIC 1 Online 4x OC-3 SONET, SMIR
Slot 2 Online E-FPC Type 2
 PIC 0 Online 4x G/E, 1000 BASE-SX
 PIC 1 Online 2x G/E SFP, 1000 BASE
 PIC 3 Online 1x Tunnel
Slot 3 Online E-FPC Type 1
 PIC 0 Online 1x G/E IQ, 1000 BASE
 PIC 2 Online 1x G/E SFP, 1000 BASE
Slot 4 Online E-FPC Type 2
 PIC 0 Online 4x G/E SFP, 1000 BASE
 PIC 1 Online 4x G/E SFP, 1000 BASE
 PIC 2 Online 4x G/E SFP, 1000 BASE
 PIC 3 Online 4x G/E SFP, 1000 BASE
Slot 5 Online FPC Type 2
...

```

#### show chassis fpc pic-status (M120 Router)

```

user@host> show chassis fpc pic-status
Slot 1 Online M120 CFPC 10GE
 PIC 0 Online 1x 10GE(LAN/WAN) XFP
Slot 3 Online M120 FPC Type 2 (proto)
 PIC 0 Online 2x G/E IQ, 1000 BASE
 PIC 1 Online 4x OC-3 SONET, SMIR
 PIC 2 Online 2x G/E IQ, 1000 BASE
 PIC 3 Online 8x 1GE(LAN), IQ2
Slot 4 Online M120 FPC Type 3 (proto)
 PIC 0 Online 10x 1GE(LAN), 1000 BASE
Slot 5 Online M120 FPC Type 1 (proto)
 PIC 0 Present 1x G/E, 1000 BASE-LX- Not Supported
 PIC 1 Online 1x CHOC3 IQ SONET, SMLR
 PIC 2 Online 4x CHDS3 IQ
 PIC 3 Online 1x G/E SFP, 1000 BASE

```

#### show chassis fpc pic-status (MX240, MX480, and MX960 Routers with Application Services Modular Line Card)

In the following output **Slot 1** and **Slot 5** are the Application Services Modular Carrier Cards (AS MCC), **PIC 0** is the Application Services Modular Storage Card (AS MSC), and **PIC 2** is the Application Services Modular Processing Card (AS MXC).

```

user@host> show chassis fpc pic-status
Slot 2 Online MPC Type 1 3D Q
Slot 1 Online AS-MCC
 PIC 0 Online AS-MSC
 PIC 2 Online AS-MXC
Slot 4 Offline MPC 3D 16x 10GE
Slot 5 Offline AS-MCC

```

#### show chassis fpc lcc (TX Matrix Router)

```

### show chassis fpc detail (T4000 Router)

```
user@host> show chassis fpc detail
```

Slot 0 information:

```
State Online
Temperature 48 degrees C / 118 degrees F
Total CPU DRAM 2816 MB
Total SRAM 1554 MB
Total SDRAM 10752 MB
Start time 2012-02-09 22:56:25 PST
Uptime 2 hours, 40 minutes, 52 seconds
```

Slot 3 information:

```
State Online
Temperature 51 degrees C / 123 degrees F
Total CPU DRAM 2816 MB
Total SRAM 1554 MB
Total SDRAM 10752 MB
Start time 2012-02-09 22:56:22 PST
Uptime 2 hours, 40 minutes, 55 seconds
```

Slot 5 information:

```
State Online
Temperature 39 degrees C / 102 degrees F
Total CPU DRAM 2048 MB
Total SRAM 128 MB
```

```

Total SDRAM 2560 MB
Start time 2012-02-09 22:51:27 PST
Uptime 2 hours, 45 minutes, 50 seconds
Slot 6 information:
State Online
Temperature 49 degrees C / 120 degrees F
Total CPU DRAM 2816 MB
Total SRAM 1554 MB
Total SDRAM 10752 MB
Start time 2012-02-09 22:56:29 PST
Uptime 2 hours, 40 minutes, 48 seconds

```

                              Command introduced in Junos OS Release 12.3 for MX2020 3D Universal Edge Routers.  
                              Command introduced in Junos OS Release 12.3 for MX2010 3D Universal Edge Routers.

**Description**    Display a list of all Flexible PIC Concentrators (FPCs) and PICs installed in the router or switch chassis, including the hardware version level and serial number.

In the EX Series switch command output, FPC refers to the following:

- On EX2200 switches, EX3200 switches, EX4200 standalone switches, and EX4500 switches—Refers to the switch; FPC **number** is always 0.
- On EX4200 switches in a Virtual Chassis configuration—Refers to the member of a Virtual Chassis; FPC **number** equals the member ID, from 0 through 9.
- On EX8208 and EX8216 switches—Refers to a line card; FPC **number** equals the slot number for the line card.

On a QFX3500 standalone switch, both the FPC and FPC **number** are always 0.

On Type 5 FPC on T4000 routers, there are no **top temperature sensor** or **bottom temperature sensor** parameters. Instead, **fan intake temperature sensor** and **fan exhaust temperature sensors** parameters are displayed.

**Options**    **none**—Display information about hardware. For a TX Matrix router, display information about the TX Matrix router and its attached T640 routers. For a TX Matrix Plus router, display information about the TX Matrix Plus router and its attached T1600 routers.

**clei-models**—(Optional) Display Common Language Equipment Identifier (CLEI) barcode and model number for orderable field-replaceable units (FRUs).

**detail**—(Optional) Include RAM and disk information in output.

**extensive**—(Optional) Display ID EEPROM information.

**all-members**—(MX Series routers and EX Series switches only) (Optional) Display hardware-specific information for all the members of the Virtual Chassis configuration.

**interconnect-device name**—(QFabric systems only) (Optional) Display hardware-specific information for the Interconnect device.

**lcc *number***—(TX Matrix and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display hardware information for a specified T640 router (or line-card chassis) that is connected to the TX Matrix router. On a TX Matrix Plus router, display hardware information for a specified T1600 router (or line-card chassis) that is connected to the TX Matrix Plus router. Replace *number* with a value from 0 through 3.

**local**—(MX Series routers and EX Series switches only) (Optional) Display hardware-specific information for the local Virtual Chassis members.

**member *member-id***—(MX Series routers and EX Series switches only) (Optional) Display hardware-specific information for the specified member of the Virtual Chassis configuration. Replace *member-id* with a value of 0 or 1.

**models**—(Optional) Display model numbers and part numbers for orderable FRUs and, for components that use ID EEPROM format v2, the CLEI code.

**node-device *name***—(QFabric systems only) (Optional) Display hardware-specific information for the Node device.

**scc**—(TX Matrix router only) (Optional) Display hardware information for the TX Matrix router (or switch-card chassis).

**sfc *number***—(TX Matrix Plus router only) (Optional) Display hardware information for the TX Matrix Plus router (or switch-fabric chassis). Replace *number* with 0.

**Additional Information** The **show chassis hardware detail** command now displays DIMM information for the following Routing Engines:

**Table 319: Routing Engines Displaying DIMM Information**

| Routing Engines             | Routers                         |
|-----------------------------|---------------------------------|
| RE-S-1800x2 and RE-S-1800x4 | MX240, MX480, and MX960 routers |
| RE-A-1800x2                 | M120 and M320 routers           |

**Output Fields** [Table 60 on page 649](#) lists the output fields for the **show chassis hardware** command. Output fields are listed in the approximate order in which they appear.

Table 320: show chassis hardware Output Fields

| Field Name                    | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Level of Output  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>Item</b>                   | <p>Chassis component:</p> <ul style="list-style-type: none"> <li>(EX Series switches)—Information about the chassis, Routing Engine (SRE and Routing Engine modules in EX8200 switches), power supplies, fan trays, and LCD panel. Also displays information about Flexible PIC Concentrators (FPCs) and associated Physical Interface Cards (PICs). Information about the backplane, midplane, and SIBs (SF modules) is displayed for EX8200 switches. See <i>EX Series Switches Hardware and CLI Terminology Mapping</i>.</li> <li>(MX Series routers and EX Series switches)—Information about the backplane, Routing Engine, Power Entry Modules (PEMs), and fan trays. Also displays information about Flexible PIC Concentrators (FPCs) and associated Physical Interface Cards (PICs), Modular Port Concentrators (MPCs) and associated Modular Interface Cards (MICs), or Dense Port Concentrators (DPCs). MX80 routers have a single Routing Engine and a built-in Packet Forwarding Engine that attaches directly to MICs. The Packet Forwarding Engine has two “pseudo” FPCs (FPC 0 and FPC1). MX80 routers also have a Forwarding Engine Board (FEB).</li> <li>(M Series routers, except for the M320 router)—Information about the backplane; power supplies; fan trays; Routing Engine; maxicab (the connection between the Routing Engine and the backplane, for the M40 router only); SCB, SSB, SFM, or FEB; MCS and PCG (for the M160 router only); each FPC and PIC; and each fan, blower, and impeller.</li> <li>(M120, M320, and T Series routers)—Information about the backplane, power supplies, fan trays, midplane, FPM (craft interface), CIP, PEM, SCG, CB, FPC, PIC, SFP, SPMB, and SIB.</li> <li>(QFX Series)—Information about the chassis, Routing Engine, power supplies, fan trays, Interconnect devices, and Node devices. Also displays information about Flexible PIC Concentrators (FPCs) and associated Physical Interface Cards (PICs).</li> <li>(PTX Series)—Information about the chassis, midplane, craft interface (FPM), power distribution units (PDUs) and Power Supply Modules (PSMs), Centralized Clock Generators (CCGs), Routing Engines, Control Boards (CBs) and Switch Processor Mezzanine Boards (SPMBs), Flexible PIC Concentrators (FPCs), PICs, Switch Interface Boards (SIBs), and fan trays (vertical and horizontal).</li> <li>(MX2010 and MX2020 routers)—Information about the chassis, midplane, craft interface (FPM), power midplane (PMP), Power Supply Modules (PSMs), Power Distribution Modules (PDMs), Routing Engines, Control Boards (CBs) and Switch Processor Mezzanine Boards (SPMBs), Switch Fabric Boards (SFBs), Flexible PIC Concentrators (FPCs), PICs, adapter cards (ADCs) and fan trays.</li> </ul> | All levels       |
| <b>Version</b>                | Revision level of the chassis component.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | All levels       |
| <b>Part number</b>            | Part number of the chassis component.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | All levels       |
| <b>Serial number</b>          | Serial number of the chassis component. The serial number of the backplane is also the serial number of the router chassis. Use this serial number when you need to contact Juniper Networks Customer Support about the router or switch chassis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | All levels       |
| <b>Assb ID or Assembly ID</b> | ( <b>extensive</b> keyword only) Identification number that describes the FRU hardware.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>extensive</b> |

| Description                                          | Display status information about the PIC installed in the specified Flexible PIC Concentrator (FPC) and PIC slot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Options                                              | <p><b>fpc-slot <i>slot-number</i></b>—Display information about the PIC in this particular FPC slot:</p> <ul style="list-style-type: none"> <li>On a TX Matrix router, if you specify the number of the T640 router by using the <b>lcc <i>number</i></b> option (the recommended method), replace <b><i>slot-number</i></b> with a value from 0 through 7. Otherwise, replace <b><i>slot-number</i></b> with a value from 0 through 31.</li> </ul> <p>Likewise, on a TX Matrix Plus router, if you specify the number of the T1600 router by using the <b>lcc <i>number</i></b> option (the recommended method), replace <b><i>slot-number</i></b> with a value from 0 through 7. Otherwise, replace <b><i>slot-number</i></b> with a value from 0 through 31. For example, the following commands have the same result:</p> <pre> user@host&gt; show chassis pic fpc-slot 1 lcc 1 pic-slot 1 user@host&gt; show chassis pic fpc-slot 9 pic-slot 1 </pre> <ul style="list-style-type: none"> <li>M120 routers only—Replace <b><i>slot-number</i></b> with a value from 0 through 5.</li> <li>MX80 routers only—Replace <b><i>slot-number</i></b> with a value from 0 through 1.</li> <li>MX240 routers only—Replace <b><i>slot-number</i></b> with a value from 0 through 2.</li> </ul> |

- MX480 routers only—Replace **slot-number** with a value from 0 through 5.
- MX960 routers only—Replace **slot-number** with a value from 0 through 11.
- MX2020 routers only—Replace **slot-number** with a value from 0 through 19.
- Other routers—Replace **slot-number** with a value from 0 through 7.
- EX Series switches:
  - EX3200 switches and EX4200 standalone switches—Replace **slot-number** with 0.
  - EX4200 switches in a Virtual Chassis configuration—Replace **slot-number** with a value from 0 through 9 (switch's member ID).
  - EX8208 switches—Replace **slot-number** with a value from 0 through 7 (line card).
  - EX8216 switches—Replace **slot-number** with a value from 0 through 15 (line card).
- QFX Series:
  - QFX3500 switches—Replace **slot-number** with 0. In the command output, FPC refers to a line card. The FPC number equals the slot number for the line card.
  - QFabric systems—Replace **slot-number** with any number between 0 and 15. In the command output, FPC refers to a line card. The FPC number equals the slot number for the line card.

**all-members**—(MX Series routers and EX Series switches only) (Optional) Display PIC information for all member routers in the Virtual Chassis configuration.

**interconnect-device name**—(QFabric systems only) (Optional) Display PIC information for a specified Interconnect device.

**lcc-number**—(TX Matrix and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display PIC information for a specified T640 router (or line-card chassis) that is connected to the TX Matrix router. On a TX Matrix Plus router, display PIC information for a specified T1600 router (or line-card chassis) that is connected to the TX Matrix Plus router. Replace **number** with a value from 0 through 3.

**local**—(MX Series routers and EX Series switches only) (Optional) Display PIC information for the local Virtual Chassis member.

**member member-id**—(MX Series routers and EX Series switches only) (Optional) Display PIC information for the specified member of the Virtual Chassis configuration. Replace **member-id** with a value of 0 or 1.

**node-device name**—(QFabric systems only) (Optional) Display PIC information for a specified Node device.

**pic-slot slot-number**—Display information about the PIC in this particular PIC slot. For routers, replace **slot-number** with a value from 0 through 3. For EX3200 and EX4200

switches, replace *slot-number* with 0 for built-in network interfaces and 1 for interfaces on uplink modules. For EX8208 and EX8216 switches, replace *slot-number* with 0. For the QFX3500 standalone switch and the QFabric system, replace *slot-number* with 0 or 1.

## Sample Output

### show chassis pic fpc-slot pic-slot

```

user@host> show chassis pic fpc-slot 2 pic-slot 0
PIC fpc slot 2 pic slot 0 information:
 Type 10x 1GE(LAN), 1000 BASE
 ASIC type H chip
 State Online
 PIC version 1.1
 Uptime 1 day, 50 minutes, 58 seconds
PIC Port Information:
 Port Cable Xcvr Xcvr Vendor
 Number Type Vendor Name Part Number
 0 GIGE 1000EX FINISAR CORP. FTRJ8519P1BNL-J3
 1 GIGE 1000EX FINISAR CORP. FTRJ-8519-7D-JUN

```

**show chassis pic fpc-slot pic-slot (PIC Offline)**

```

user@host> show chassis pic fpc-slot 1 pic-slot 0
PIC fpc slot 1 pic slot 0 information:
 State Offline

```

**show chassis pic fpc-slot pic-slot (FPC Offline)**

```

user@host> show chassis pic fpc-slot 1 pic-slot 0
FPC 1 is not online

```

**show chassis pic fpc-slot pic-slot (FPC Not Present)**

```

user@host> show chassis pic fpc-slot 4 pic-slot 0
FPC slot 4 is empty

```

**show chassis pic fpc-slot pic-slot (PIC Not Present)**

```

user@host> show chassis pic fpc-slot 5 pic-slot 2
FPC 5, PIC 2 is empty

```

**show chassis pic fpc-slot 3 pic-slot 0 (M120 Router)**

```

user@host> show chassis pic fpc-slot 3 pic-slot 0
PIC slot 3, PIC slot 0 information:
 Type 2x G/E IQ, 1000 BASE
 ASIC type IQ GE 2 VLAN-TAG FPGA
 State Online
 PIC version 1.16
 Uptime 3 hours, 3 minutes

PIC Port Information:
 Port Cable Xcvr Xcvr Vendor
 Number Type Vendor Name Part Number
 0 GIGE 1000SX FINISAR CORP. FTRJ8519P1BNL-J3
 1 GIGE 1000SX FINISAR CORP. FTRJ-8519-7D-JUN

```

**show chassis pic fpc-slot pic-slot (MX960 Router with Bidirectional Optics)**

**Table 322: show forwarding-options port-mirroring Output Fields**

| Field Name               | Field Description                                   | Level of Output |
|--------------------------|-----------------------------------------------------|-----------------|
| Instance Name            | Name of port-mirroring instance.                    | All levels      |
| Instance Id              | Instance identification number.                     | All levels      |
| State                    | Instance state, either <b>up</b> or <b>down</b> .   | All levels      |
| <b>Input parameters</b>  |                                                     |                 |
| Rate                     | Rate (ratio of packets sampled).                    | <b>detail</b>   |
| Run-length               | Run length (number of consecutive packets sampled). | <b>detail</b>   |
| Maximum-packet-length    | Maximum packet length.                              | <b>detail</b>   |
| <b>Output parameters</b> |                                                     |                 |
| Family                   | Protocol family.                                    | <b>detail</b>   |
| State                    | Instance state, either <b>up</b> or <b>down</b> .   | <b>detail</b>   |
| Destination              | Destination (next-hop group name).                  | <b>detail</b>   |

## Sample Output

### show forwarding-options port-mirroring terse

```
user@host> show forwarding-options port-mirroring terse
Instance Name Instance Id State
&global_instance 1 up
inst1 2 up
```

### show forwarding-options port-mirroring detail

```
user@host> show forwarding-options port-mirroring detail
Instance Name: &global_instance
Instance Id: 1 State: up
 Input parameters:
 Rate: 10
 Run-length: 4
 Maximum-packet-length: 0
 Output parameters:
 Family: inet State: up Destination: inet_nhg
 Family: vpls/eth-switch State: up Destination: vpls_nhg

Instance Name: inst1
Instance Id: 2 State: up
 Input parameters:
 Rate: 1
 Run-length: 0
 Maximum-packet-length: 200
 Output parameters:
 Family: inet State: up Destination: inet_nhg
 Family: vpls/eth-switch State: down Destination: vpls_nhg_2
```

## Operational Mode Commands for Firewall Filter Statistics and Logs

## clear firewall

---

|                                    |                                                                                                                                                                                                                                                         |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                      | clear firewall (all   counter <i>counter-name</i>   filter <i>filter-name</i>   log (all   <i>logical-system-name</i> )   logical-system <i>logical-system-name</i> )                                                                                   |
| <b>Syntax (EX Series Switches)</b> | clear firewall (all   counter <i>counter-name</i>   filter <i>filter-name</i>   log (all   <i>logical-system-name</i> )   policer counter (all   counter-id <i>counter-index</i> ))                                                                     |
| <b>Release Information</b>         | Command introduced before Junos OS Release 7.4.<br>Command introduced in Junos OS Release 9.0 for EX Series switches.<br><b>logical-system</b> option introduced in Junos OS Release 9.3.<br><b>log</b> option introduced before Junos OS Release 11.4. |
| <b>Description</b>                 | Clear statistics about configured firewall filters.<br><br>When you clear the counters of a filter, this impacts not only the counters shown by the CLI, but also the ones tracked by SNMP2.                                                            |

**NOTE:** The clear firewall command cannot be used to clear the Routing Engine filter counters on a backup Routing Engine that is enabled for graceful Routing Engine switchover (GRES).

If you clear statistics for firewall filters that are applied to Trio-based DPCs and that also use the **prefix-action** action on matched packets, wait at least 5 seconds before you enter the **show firewall prefix-action-stats** command. A 5-second pause between issuing the **clear firewall** and **show firewall prefix-action-stats** commands avoids a possible timeout of the **show firewall prefix-action-stats** command.

- Options**
- all**—Clear the packet and byte counts for all filters. On EX Series switches, this option also clears the packet counts for all policer counters.
  - counter *counter-name***—Clear the packet and byte counts for a filter counter that has been configured with the counter firewall filter action.
  - filter *filter-name***—Clear the packet and byte counts for the specified firewall filter.
  - log (all | *logical-system-name*)**—Clear log entries for IPv4 firewall filters that have **then log** as an action. Use **log all** to clear all log entries or **log *logical-system-name*** to clear log entries for the specified logical system.
  - logical-system *logical-system-name***—Clear the packet and byte counts for the specified logical system.
  - policer counter (all | counter-id *counter-index*)**—(EX8200 switches only) Clear all policer counters using the **policer counter all** command, or clear a specific policer counter using the **policer counter counter-id *counter-index*** command. The value of *counter-index* can be 0, 1, or 2.

|                          |                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Filter</b>   | <p>Name of a filter that has been configured with the <b>filter</b> statement at the <b>[edit firewall]</b> hierarchy level.</p> <p>Except on EX Series switches:</p> <ul style="list-style-type: none"> <li>• When an interface-specific filter is displayed, the name of the filter is followed by the full interface name and by either <b>-i</b> for an input filter or <b>-o</b> for an output filter.</li> <li>• When dynamic filters are displayed, the name of the filter is followed by the full interface name and by either <b>-in</b> for an input filter or <b>-out</b> for an output filter. When a logical system-specific filter is displayed, the name of the filter is prefixed with two underscore (__) characters and the name of the logical system (for example, <b>__ls1/filter1</b>).</li> </ul>                        |
| <b>Counters</b> | <p>Display filter counter information:</p> <ul style="list-style-type: none"> <li>• <b>Name</b>—Name of a filter counter that has been configured with the <b>counter</b> firewall filter action.</li> <li>• <b>Bytes</b>—Number of bytes that match the filter term under which the <b>counter</b> action is specified.</li> <li>• <b>Packets</b>—Number of packets that matched the filter term under which the <b>counter</b> action is specified.</li> </ul> <p><b>NOTE:</b> On M and T series routers, firewall filters cannot count <b>ip-options</b> packets on a per option type and per interface basis. A limited work around is to use the <b>show pfe statistics ip options</b> command to see <b>ip-options</b> statistics on a per Packet Forwarding Engine (PFE) basis. See <i>show pfe statistics ip</i> for sample output.</p> |

Table 323: show firewall Output Fields (*continued*)

| Field Name                   | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Policers</b>              | <p>Display policer information:</p> <ul style="list-style-type: none"> <li>• <b>Name</b>—Name of policer.</li> <li>• <b>Bytes</b>—(For two-color policers on MX Series routers and EX Series switches, and for hierarchical policers on interfaces hosted on MICs and MPCs in MX Series routers) Number of bytes that match the filter term under which the policer action is specified. This is only the number out-of-specification (out-of-spec) byte counts, not all the bytes in all packets policed by the policer.<br/>For other platforms, this field is blank.</li> <li>• <b>Packets</b>—Number of packets that matched the filter term under which the policer action is specified. This is only the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.</li> </ul> |
| <b>Policer Counter Index</b> | (EX8200 switch only) Global management counter ID. The counter ID value ( <i>counter-index</i> ) can be 0, 1, or 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Green</b>                 | (EX8200 switch only) Number of packets within the limits. The number of packets is smaller than the committed information rate (CIR).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Yellow</b>                | (EX8200 switch only) Number of packets partially within the limits. The number of packets is greater than the CIR, but the burst size is within the excess burst size (EBS) limit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Discard</b>               | (EX8200 switch only) Number of discarded packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Bytes</b>                 | (EX8200 switch only) Number of green, yellow, red, or discarded packets in bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Packets</b>               | (EX8200 switch only) Number of green, yellow, red, or discarded packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Filter name</b>           | (EX8200 switch only) Name of the filter with a term associated to a policer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### ***Stateless Firewall Filter Overview***

This topic covers the following information:

- [Packet Flow Control on page 4464](#)
- [Stateless and Stateful Firewall Filters on page 4464](#)
- [Purpose of Stateless Firewall Filters on page 4464](#)

### ***Packet Flow Control***

To influence which packets are allowed to transit the system and to apply special actions to packets as necessary, you can configure *stateless firewall filters*. A stateless firewall specifies a sequence of one or more packet-filtering rules, called *filter terms*. A filter term specifies *match conditions* to use to determine a match and *actions* to take on a matched packet. A stateless firewall filter enables you to manipulate any packet of a particular protocol family, including fragmented packets, based on evaluation of Layer 3 and Layer 4 header fields. You typically apply a stateless firewall filter to one or more interfaces that have been configured with protocol family features. You can apply a stateless firewall filter to an ingress interface, an egress interface, or both.

### ***Data Packet Flow Control***

To control the flow of data packets transiting the device as the packets are being forwarded from a source to a destination, you can apply stateless firewall filters to the input or output of the router's or switch's physical interfaces.

To enforce a specified bandwidth and maximum burst size for traffic sent or received on an interface, you can configure *policers*. Policers are a specialized type of stateless firewall filter and a primary component of the Junos OS *class-of-service* (CoS).

### ***Local Packet Flow Control***

To control the flow of local packets between the physical interfaces and the Routing Engine, you can apply stateless firewall filters to the input or output of the *loopback interface*. The loopback interface (**lo0**) is the interface to the Routing Engine and carries no data packets.

### ***Stateless and Stateful Firewall Filters***

A stateless firewall filter, also known as an *access control list* (ACL), does not statefully inspect traffic. Instead, it evaluates packet contents statically and does not keep track of the state of network connections. In contrast, a *stateful firewall filter* uses connection state information derived from other applications and past communications in the data flow to make dynamic control decisions.

The *Junos OS Firewall Filters and Traffic Policers Configuration Guide* describes *stateless firewall filters* supported on T Series, M Series, MX Series routers and EX Series switches.

### ***Purpose of Stateless Firewall Filters***

The basic purpose of a stateless firewall filter is to enhance security through the use of packet filtering. Packet filtering enables you to inspect the components of incoming or outgoing packets and then perform the actions you specify on packets that match the criteria you specify. The typical use of a stateless firewall filter is to protect the Routing Engine processes and resources from malicious or untrusted packets.

#### **Related Documentation**

- [Router Data Flow Overview](#)
- [Stateless Firewall Filter Types on page 4465](#)
- [“Traffic Policing Overview on page 1440” in the Junos OS Firewall Filters and Traffic Policers Configuration Guide](#)

### **Stateless Firewall Filter Types**

This topic covers the following information:

- [Standard Stateless Firewall Filters on page 4465](#)
- [Service Filters on page 4465](#)
- [Simple Filters on page 4465](#)

### **Standard Stateless Firewall Filters**

The Junos OS standard stateless firewall filters support a rich set of packet-matching criteria that you can use to match on specific traffic and perform specific actions, such as forwarding or dropping packets that match the criteria you specify. You can configure firewall filters to protect the local router (or switch) or to protect another device that is either directly or indirectly connected to the local router (or switch). For example, you can use the filters to restrict the local packets that pass from the router's (or switch's) physical interfaces to the Routing Engine. Such filters are useful in protecting the IP services that run on the Routing Engine, such as Telnet, SSH, and BGP, from denial-of-service attacks.

**NOTE:** If you configured targeted broadcast for virtual routing and forwarding (VRF) by including the `forward-and-send-to-re` statement, any firewall filter that is configured on the Routing Engine loopback interface (lo0) cannot be applied to the targeted broadcast packets that are forwarded to the Routing Engine. This is because broadcast packets are forwarded as flood next hop traffic and not as local next hop traffic, and you can only apply a firewall filter to local next hop routes for traffic directed toward the Routing Engine.

### **Service Filters**

A service filter defines packet-filtering (a set of match conditions and a set of actions) for IPv4 or IPv6 traffic. You can apply a service filter to the inbound or outbound traffic at an adaptive services interface to perform packet filtering on traffic before it is accepted for service processing. You can also apply a service filter to the traffic that is returning to the services interface after service processing to perform postservice processing.

Service filters filter IPv4 and IPv6 traffic only and can be applied to logical interfaces on Adaptive Services PICs, MultiServices PICs, and MultiServices DPCs only. Service filters are not supported on J Series devices and Branch SRX devices.

### **Simple Filters**

Simple filters are supported on Gigabit Ethernet intelligent queuing (IQ2) and Enhanced Queuing Dense Port Concentrator (EQ DPC) interfaces only. Unlike standard filters, simple filters support IPv4 traffic only and have a number of restrictions. For example, you cannot configure a terminating action for a simple filter. Simple filters always accept packets. Also, simple filters can be applied only as input filters. They are not supported

on outbound traffic. Simple filters are recommended for metropolitan Ethernet applications.

**Terms**

Under the **filter**, **service-filter**, or **simple-filter** statement, you must configure at least one firewall filter *term*. A term is a named structure in which match conditions and actions are defined. Within a firewall filter, you must configure a unique name for each term.

**TIP:** You cannot apply a different filter on each direction of traffic on the same interface. As a result, it is common to create firewall filters with multiple terms.

All stateless firewall filters contain one or more terms, and each term consists of two components—match conditions and actions. The match conditions define the values or fields that the packet must contain to be considered a match. If a packet is a match, the

corresponding action is taken. By default, a packet that does not match a firewall filter is discarded.

If a packet arrives on an interface for which no firewall filter is applied for the incoming traffic on that interface, the packet is accepted by default.

**NOTE:** A firewall filter with a large number of terms can adversely affect both the configuration commit time and the performance of the Routing Engine.

Additionally, you can configure a stateless firewall filter within the term of another filter. This method enables you to add common terms to multiple filters without having to modify all filter definitions. You can configure one filter with the desired common terms, and configure this filter as a term in other filters. Consequently, to make a change in these common terms, you need to modify only one filter that contains the common terms, instead of multiple filters.

### **Match Conditions**

A firewall filter term must contain at least one packet-filtering criteria, called a *match condition*, to specify the field or value that a packet must contain in order to be considered a match for the firewall filter term. For a match to occur, the packet must match all the conditions in the term. If a packet matches a firewall filter term, the router (or switch) takes the configured action on the packet.

If a firewall filter term contains multiple match conditions, a packet must meet *all* match conditions to be considered a match for the firewall filter term.

If a single match condition is configured with multiple values, such as a range of values, a packet must match only *one* of the values to be considered a match for the firewall filter term.

The scope of match conditions you can specify in a firewall filter term depends on the protocol family under which the firewall filter is configured. You can define various match conditions, including the IP source address field, IP destination address field, TCP or UDP source port field, IP protocol field, Internet Control Message Protocol (ICMP) packet type, IP options, TCP flags, incoming logical or physical interface, and outgoing logical or physical interface.

Each protocol family supports a different set of match conditions, and some match conditions are supported only on certain routing devices. For example, a number of match conditions for VPLS traffic are supported only on the MX Series 3D Universal Edge Routers.

In the **from** statement in a firewall filter term, you specify characteristics that the packet must have for the action in the subsequent **then** statement to be performed. The characteristics are referred to as *match conditions*. The packet must match all conditions in the **from** statement for the action to be performed, which also means that the order of the conditions in the **from** statement is not important.

If an individual match condition can specify a list of values (such as multiple source and destination addresses) or a range of numeric values, a match occurs if any of the values matches the packet.

If a filter term does not specify match conditions, the term accepts all packets and the actions specified in the term's **then** statement are optional.

**NOTE:**

Some of the numeric range and bit-field match conditions allow you to specify a text synonym. For a complete list of synonyms:

- If you are using the J-Web interface, select the synonym from the appropriate list.
- If you are using the CLI, type a question mark (?) after the **from** statement.

---

### **Actions**

The actions specified in a firewall filter term define the actions to take for any packet that matches the conditions specified in the term.

Actions that are configured within a single term are all taken on traffic that matches the conditions configured.

**BEST PRACTICE:** We strongly recommend that you explicitly configure one or more actions per firewall filter term. Any packet that matches all the conditions of the term is automatically accepted unless the term specifies other or additional actions.

---

Firewall filter actions fall into the following categories:

#### ***Filter-Terminating Actions***

A filter-terminating action halts all evaluation of a firewall filter for a specific packet. The router (or switch) performs the specified action, and no additional terms are examined.

#### ***Nonterminating Actions***

Nonterminating actions are used to perform other functions on a packet, such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality.

The presence of a nonterminating action, such as **count**, **log**, or **syslog**, without an explicit terminating action, such as **accept**, **discard**, or **reject**, results in a default terminating action of **accept**. If you do not want the firewall filter action to terminate, use the **next term** action after the nonterminating action.

In this example, term 2 is never evaluated, because term 1 has the implicit default **accept** terminating action.

[edit firewall filter test]

```

term 1 {
 from {
 source-address {
 0.0.0.0/0;
 }
 }
 then {
 log;
 <accept> #By default if not specified
 }
}
term 2 {
 then {
 reject;
 }
}

```

In this example, term 2 is evaluated, because term 1 has the explicit **next term** flow control action.

```

[edit firewall filter test]
term 1 {
 from {
 source-address {
 0.0.0.0/0;
 }
 }
 then {
 log;
 next term;
 }
}
term 2 {
 then {
 reject;
 }
}

```

### **Flow Control Action**

For standard stateless firewall filters only, the action **next term** enables the router (or switch) to perform configured actions on the packet and then evaluate the following term in the filter, rather than terminating the filter.

A maximum of 1024 **next term** actions are supported per standard stateless firewall filter configuration. If you configure a standard filter that exceeds this limit, your candidate configuration results in a commit error.

### Stateless Firewall Filter Application Points

After you define the firewall filter, you must apply it to an application point. These application points include logical interfaces, physical interfaces, routing interfaces, and routing instances.

In most cases, you can apply a firewall filter as an *input* filter or an *output* filter, or both at the same time. Input filters take action on packets being received on the specified interface, whereas output filters take action on packets that are transmitted through the specified interface.

You typically apply one filter with multiple terms to a single logical interface, to incoming traffic, outbound traffic, or both. However, there are times when you might want to chain together multiple firewall filters (with single or multiple terms) and apply them to an interface. You use an *input list* to apply multiple firewall filters to the incoming traffic on an interface. You use an *output list* to apply multiple firewall filters to the outbound traffic on an interface. You can include up to 16 filters in an input list or an output list.

There is no limit to the number of filters and counters you can set, but there are some practical considerations. More counters require more terms, and a large number of terms can take a long time to process during a commit operation. However, filters with more than 4000 terms and counters have been implemented successfully.

Table 328 on page 4472 describes each point to which you can apply a firewall filter. For each application point, the table describes the types of firewall filters supported at that point, the router (or switch) hierarchy level at which the filter can be applied, and any platform-specific limitations.

**Table 328: Stateless Firewall Filter Configuration and Application Summary**

| Filter Type                                                                                                                                                                                                                                                                                                            | Application Point                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Restrictions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### ***Standard Stateless Firewall Filter Overview***

Firewall filters provide a means of protecting your router (and switch) from excessive traffic transiting the router (and switch) to a network destination or destined for the Routing Engine. Firewall filters that control local packets can also protect your router (and switch) from external incidents.

You can configure a firewall filter to do the following:

- Restrict traffic destined for the Routing Engine based on its source, protocol, and application.
- Limit the traffic rate of packets destined for the Routing Engine to protect against flood, or denial-of-service (DoS) attacks.
- Address special circumstances associated with fragmented packets destined for the Routing Engine. Because the device evaluates every packet against a firewall filter (including fragments), you must configure the filter to accommodate fragments that do not contain packet header information. Otherwise, the filter discards all but the first fragment of a fragmented packet.

- [Single Firewall Filter Attached to Multiple Interfaces on page 4478](#)

### ***Firewall Filter Packet Evaluation Overview***

The following sequence describes how the device evaluates a packet entering or exiting an interface if the input or output traffic at a device interface is associated with a firewall filter. Packet evaluation proceeds as follows:

1. The device evaluates the packet against the terms in the firewall filter sequentially, beginning with the first term in the filter.
  - If the packet matches all the conditions specified in a term, the device performs all the actions specified in that term.

- If the packet does not match all the conditions specified in a term, the device proceeds to the next term in the filter (if a subsequent term exists) and evaluates the packet against that term.
  - If the packet does not match any term in the firewall filter, the device implicitly discards the packet.
2. Unlike service filters and simple filters, firewall filters support the **next term** action, which is neither a terminating action nor a nonterminating action but a flow control action.
- If the matched term includes the **next term** action, the device continues evaluation of the packet at the next term within the firewall filter.
  - If the matched term does not include the **next term** action, evaluation of the packet against the given firewall filter ends at this term. The device does not evaluate the packet against any subsequent terms in this filter.
- A maximum of 1024 **next term** actions are supported per firewall filter configuration. If you configure a firewall filter that exceeds this limit, your candidate configuration results in a commit error.
3. The device stops evaluating a packet against a given firewall filter when either the packet matches a term without the **next term** action or the packet fails to match the last term in the firewall filter.

#### ***Packet Evaluation at a Single Firewall Filter***

Table 329 on page 4476 describes packet-filtering behaviors at a device interface associated with a single firewall filter.

**Table 329: Packet Evaluation at a Single Firewall Filter**

| Firewall Filter Event                                                                                               | Action                                                                                                  | Subsequent Action                                                                                                                                                                      |
|---------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The firewall filter term does not specify any match conditions.                                                     | The term matches all packets by default, and so the device performs the actions specified by that term. | If the term actions include the <b>next term</b> action, the device continues evaluation of the packet against the next term within the firewall filter (if a subsequent term exists). |
| The packet matches all conditions specified by the firewall filter term.                                            | The device performs the actions specified by that term.                                                 | If the term actions include the <b>next term</b> action, the device continues evaluation of the packet against the next term within the firewall filter (if a subsequent term exists). |
| The packet matches all conditions specified by the firewall filter term, but the term does not specify any actions. | The device implicitly accepts the packet.                                                               | If the term actions include the <b>next term</b> action, the device continues evaluation of the packet against the next term                                                           |

Table 329: Packet Evaluation at a Single Firewall Filter (*continued*)

| Firewall Filter Event                                                           | Action                                                                                                                                                                                                                                                                                                                                                                             | Subsequent Action                                                                                                    |
|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
|                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                    | within the firewall filter (if a subsequent term exists).                                                            |
| The packet does not match all conditions specified by the firewall filter term. | The device does not perform the actions specified by that term.                                                                                                                                                                                                                                                                                                                    | The device continues evaluation of the packet against the next term within the filter (if a subsequent term exists). |
| The packet does not match any term in the filter                                | <p>The device implicitly discards the packet</p> <p>Every firewall filter configuration includes an implicit <b>discard</b> action at the end of the filter. This implicit terminating action is equivalent to including the following example term <b>t_explicit_discard</b> as the final term in the firewall filter:</p> <pre>term t_explicit_discard {   then discard; }</pre> |                                                                                                                      |

**Best Practice: Explicitly Accept Any Traffic That Is Not Specifically Discarded**

You might want a firewall filter to accept any traffic that the filter does not specifically discard. In this case, we recommend that you configure the firewall filter with a final term that specifies the **accept** terminating action.

In the following example snippet, configuring the **t\_allow\_all\_else** term as the final term in the firewall filter explicitly configures the firewall filter to accept any traffic that the filter did not specifically discard :

```
term t_allow_all_else {
 then accept;
}
```

Following this best practice can simplify troubleshooting of the firewall filter.

**Best Practice: Explicitly Reject Any Traffic That Is Not Specifically Accepted**

On the other hand, you might want a firewall filter to reject any traffic that the firewall filter does not specifically accept. In this case, we recommend that you configure the firewall filter with a final term that specifies the **reject** terminating action.

In the following example snippet, configuring the **t\_deny\_all\_else** term as the final term in the firewall filter explicitly configures the firewall filter to reject any traffic that the filter did not specifically accept:

```
term t_deny_all_else {
 then reject;
}
```

Following this best practice can simplify troubleshooting of the firewall filter.

**Multiple Firewall Filters Attached to a Single Interface**

On supported device interfaces, you can attach multiple firewall filters to a single interface. For more information, see [“Multiple Standard Firewall Filters Applied as a List Overview” on page 4505](#).

**NOTE:** On supported interfaces, you can attach a protocol-independent (family any) firewall filter and a protocol-specific (family inet or family inet6) firewall filter to the same interface. The protocol-independent firewall filter executes first. For more information, see [“Guidelines for Applying Standard Firewall Filters” on page 4483](#).

---

### ***Single Firewall Filter Attached to Multiple Interfaces***

On supported interfaces, you can associate a single firewall filter with multiple interfaces, and Junos OS creates an *interface-specific instance* of that firewall filter for each associated interface.

- Junos OS associates each interface-specific instantiation of a firewall filter with a system-generated, interface-specific name.
- For any **count** actions in the filter terms, the Packet Forwarding Engine maintains separate, interface-specific counters, and Junos OS associates each counter with a system-generated, interface-specific name.
- For any **policer** actions in the filter terms, Junos OS creates separate, interface-specific instances of the policer actions.

For more information, see *Interface-Specific Firewall Filter Instances Overview*.

### ***Guidelines for Configuring Standard Firewall Filters***

This topic covers the following information:

- [Statement Hierarchy for Configuring Standard Firewall Filters on page 4478](#)
- [Standard Firewall Filter Protocol Families on page 4479](#)
- [Standard Firewall Filter Names and Options on page 4480](#)
- [Standard Firewall Filter Terms on page 4480](#)
- [Standard Firewall Filter Match Conditions on page 4480](#)
- [Standard Firewall Filter Actions on page 4482](#)

### ***Statement Hierarchy for Configuring Standard Firewall Filters***

To configure a standard firewall filter, you can include the following statements. For an IPv4 standard firewall filter, the **family inet** statement is optional.

```
firewall {
```

```

family family-name {
 filter filter-name {
 accounting-profile name;
 interface-specific;
 physical-interface-filter;
 term term-name {
 filter filter-name;
 }
 term term-name {
 from {
 match-conditions;
 ip-version ipv4 {
 match-conditions;
 protocol (tcp | udp) {
 match conditions;
 }
 }
 }
 then {
 actions;
 }
 }
 }
}

```

You can include the firewall configuration at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

**NOTE:** For stateless firewall filtering, you must allow the output tunnel traffic through the firewall filter applied to input traffic on the interface that is the next-hop interface toward the tunnel destination. The firewall filter affects only the packets exiting the router (or switch) by way of the tunnel.

### Standard Firewall Filter Protocol Families

A standard firewall filter configuration is specific to a particular protocol family. Under the **firewall** statement, include one of the following statements to specify the protocol family for which you want to filter traffic:

- **family any**—To filter protocol-independent traffic.
- **family inet**—To filter Internet Protocol version 4 (IPv4) traffic.
- **family inet6**—To filter Internet Protocol version 6 (IPv6) traffic.
- **family mpls**—To filter MPLS traffic.
- **family vpls**—To filter virtual private LAN service (VPLS) traffic.
- **family ccc**—To filter Layer 2 circuit cross-connection (CCC) traffic.

- **family bridge**—To filter Layer 2 bridging traffic for MX Series 3D Universal Edge Routers only.
- **family ethernet-switching**—To filter Layer 2 (Ethernet) traffic.

The **family *family-name*** statement is required only to specify a protocol family other than IPv4. To configure an IPv4 firewall filter, you can configure the filter at the **[edit firewall]** hierarchy level without including the **family inet** statement, because the **[edit firewall]** and **[edit firewall family inet]** hierarchy levels are equivalent.

### ***Standard Firewall Filter Names and Options***

Under the **family *family-name*** statement, you can include **filter *filter-name*** statements to create and name standard firewall filters. The filter name can contain letters, numbers, and hyphens (-) and be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

At the **[edit firewall family *family-name* filter *filter-name*]** hierarchy level, the following statements are optional:

- **accounting-profile**
- **interface-specific**
- **physical-interface-filter**

### ***Standard Firewall Filter Terms***

Under the **filter *filter-name*** statement, you can include **term *term-name*** statements to create and name filter terms.

- You must configure at least one term in a firewall filter.
- You must specify a unique name for each term within a firewall filter. The term name can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").
- The order in which you specify terms within a firewall filter configuration is important. Firewall filter terms are evaluated in the order in which they are configured. By default, new terms are always added to the end of the existing filter. You can use the **insert** configuration mode command to reorder the terms of a firewall filter.

At the **[edit firewall family *family-name* filter *filter-name* term *term-name*]** hierarchy level, the **filter *filter-name*** statement is not valid in the same term as **from** or **then** statements. When included at this hierarchy level, the **filter *filter-name*** statement is used to *nest* firewall filters.

### ***Standard Firewall Filter Match Conditions***

Standard firewall filter match conditions are specific to the type of traffic being filtered.

With the exception of MPLS-tagged IPv4 or IPv6 traffic, you specify the term's match conditions under the **from** statement. For MPLS-tagged IPv4 traffic, you specify the term's IPv4 address-specific match conditions under the **ip-version ipv4** statement and the term's IPv4 port-specific match conditions under the **protocol (tcp | udp)** statement.

For MPLS-tagged IPv6 traffic, you specify the term's IPv6 address-specific match conditions under the **ip-version ipv6** statement and the term's IPv6 port-specific match conditions under the **protocol (tcp | udp)** statement.

[Table 330 on page 4481](#) describes the types of traffic for which you can configure standard stateless firewall filters.

**Table 330: Standard Firewall Filter Match Conditions by Protocol Family**

| Traffic Type                 | Hierarchy Level at Which Match Conditions Are Specified                                                                                                                                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol-independent         | <p><b>[edit firewall family any filter <i>filter-name</i> term <i>term-name</i>]</b></p> <p>For the complete list of match conditions, see <a href="#">“Standard Firewall Filter Match Conditions for Protocol-Independent Traffic” on page 4706</a>.</p>                                           |

**Table 330: Standard Firewall Filter Match Conditions by Protocol Family (*continued*)**

| Traffic Type                                    | Hierarchy Level at Which Match Conditions Are Specified                                                                                                                                                                                                                         |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Layer 2 CCC                                     | <p>[edit firewall family ccc filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Standard Firewall Filter Match Conditions for Layer 2 CCC Traffic” on page 4734.</p>                                                       |
| Layer 2 Bridging                                | <p>[edit firewall family bridge filter <i>filter-name</i> term <i>term-name</i>]</p>                                                                                                                                                                                            |
| (MX Series routers and EX Series switches only) | <p>[edit firewall family ethernet-switching filter <i>filter-name</i> term <i>term-name</i>]<br/>(for EX Series switches only)</p> <p>For the complete list of match conditions, see “Standard Firewall Filter Match Conditions for Layer 2 Bridging Traffic” on page 4737.</p> |

If you specify an IPv6 address in a match condition (the **address**, **destination-address**, or **source-address** match conditions), use the syntax for text representations described in RFC 2373, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see “IPv6 Overview” and “IPv6 Standards” in the *Junos OS Routing Protocols Configuration Guide*.

### Standard Firewall Filter Actions

Under the **then** statement for a standard stateless firewall filter term, you can specify the actions to be taken on a packet that matches the term.

Table 331 on page 4482 summarizes the types of actions you can specify in a standard stateless firewall filter term.

**Table 331: Standard Firewall Filter Action Categories**

| Type of Action | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Comment                                                          |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| Terminating    | <p>Halts all evaluation of a firewall filter for a specific packet. The router (or switch) performs the specified action, and no additional terms are used to examine the packet.</p> <p>You can specify only one <i>terminating action</i> in a standard firewall filter. You can, however, specify one terminating action with one or more <i>nonterminating actions</i> in a single term. For example, within a term, you can specify <b>accept</b> with <b>count</b> and <b>syslog</b>.</p> | See “Standard Firewall Filter Terminating Actions” on page 4742. |

Table 331: Standard Firewall Filter Action Categories (*continued*)

| Type of Action | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Nonterminating | Performs other functions on a packet (such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality), but any additional terms are used to examine the packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | See <a href="#">"Standard Firewall Filter Nonterminating Actions"</a> on page 4744.                                                                                                                                                                                                                                                                                                                                                                              |
| Flow control   | <p>For standard stateless firewall filters only, the <b>next term</b> action directs the router (or switch) to perform configured actions on the packet and then, rather than terminate the filter, use the next term in the filter to evaluate the packet. If the <b>next term</b> action is included, the matching packet is evaluated against the next term in the firewall filter. Otherwise, the matching packet is not evaluated against subsequent terms in the firewall filter.</p> <p>For example, when you configure a term with the nonterminating action <b>count</b>, the term's action changes from an implicit <b>discard</b> to an implicit <b>accept</b>. The <b>next term</b> action forces the continued evaluation of the firewall filter.</p> | <p>You cannot configure the <b>next term</b> action with a terminating action in the same filter term. However, you can configure the next term action with another nonterminating action in the same filter term.</p> <p>A maximum of 1024 <b>next term</b> actions are supported per standard stateless firewall filter configuration. If you configure a standard filter that exceeds this limit, your candidate configuration results in a commit error.</p> |

**Applying Firewall Filters Overview**

You can apply a standard firewall filter to a loopback interface on the router or to a physical or logical interface on the router. [Table 332 on page 4484](#) summarizes the behavior of firewall filters based on the point to which you attach the filter.

Table 332: Firewall Filter Behavior by Filter Attachment Point

| Filter Attachment Point                                                                    | Filter Behavior                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Loopback interface                                                                         | The router's loopback interface, <b>lo0</b> , is the interface to the Routing Engine and carries no data packets. When you apply a firewall filter to the loopback interface, the filter evaluates the local packets received or transmitted by the Routing Engine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Physical interface or logical interface                                                    | When you apply a filter to a physical interface on the router or to a logical interface (or member of an aggregated Ethernet bundle defined on the interface), the filter evaluates all data packet that pass through that interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Multiple interfaces                                                                        | <p>You can use the same firewall filter one or more times.</p> <p>On M Series routers, except the M120 and M320 routers, if you apply a firewall filter to multiple interfaces, the filter acts on the sum of traffic entering or exiting those interfaces.</p> <p>On T Series, M120, M320, and MX Series routers, interfaces are distributed among multiple packet-forwarding components. On these routers, you can configure firewall filters and service filters that, when applied to multiple interfaces, act on the individual traffic streams entering or exiting each interface, regardless of the sum of traffic on the multiple interfaces.</p> <p>For more information, see <i>Interface-Specific Firewall Filter Instances Overview</i>.</p>                                                                                                                                                                                                                                                                                                             |
| Single interface with protocol-independent and protocol-specific firewall filters attached | <p>For interfaces hosted on the following hardware only, you can attach a protocol-independent (<b>family any</b>) firewall filter and a protocol-specific (<b>family inet</b> or <b>family inet6</b>) firewall filter simultaneously. The protocol-independent firewall executes first.</p> <ul style="list-style-type: none"> <li>ACX Series Universal Access Routers</li> <li>Flexible PIC Concentrators (FPCs) in M7i and M10i Multiservice Edge Routers</li> <li>Modular Interface Cards (MICs) and Modular Port Concentrators (MPCs) in MX Series 3D Universal Edge Routers</li> <li>T Series Core Routers</li> </ul> <p><b>NOTE:</b></p> <p>Interfaces hosted on the following hardware do not support protocol-independent firewall filters:</p> <ul style="list-style-type: none"> <li>Forwarding Engine Boards (FEBs) in M120 routers</li> <li>Enhanced III FPCs in M320 routers</li> <li>FPC2 and FPC3 modules in MX Series routers</li> <li>Dense Port Concentrators (DPCs) in MX Series routers</li> <li>PTX Series Packet Transport Routers</li> </ul> |

#### Statement Hierarchy for Applying Firewall Filters

To apply a standard firewall filter to a logical interface, configure the **filter** statement for the logical interface defined under either the **[edit]** or **[edit logical-systems logical-system-name]** hierarchy level. Under the **filter** statement, you can include one or more of the following statements: **group group-number**, **input filter-name**, **input-list filter-name**, **output filter-name**, or **output-list filter-name**. The hierarchy level at which you attach the **filter** statement depends on the filter type and device type you are configuring.

### Protocol-Independent Firewall Filters on MX Series Routers

To apply a protocol-independent firewall filter to a logical interface on an MX Series router, configure the **filter** statement *directly* under the logical unit:

```
interfaces {
 interface-name {
 unit logical-unit-number {
 filter {
 group group-number;
 input filter-name;
 input-list [filter-names];
 output filter-name;
 output-list [filter-names];
 }
 }
 }
}
```

### All Other Firewall Filters on Logical Interfaces

To apply a standard firewall filter to a logical interface for all cases *other than* a protocol-independent filter on an MX Series router, configure the **filter** statement under the protocol family:

```
interfaces {
 interface-name {
 unit logical-unit-number {
 family family-name {
 ...
 filter {
 group group-number;
 input filter-name;
 input-list [filter-names];
 output filter-name;
 output-list [filter-names];
 }
 }
 }
 }
}
```

### Restrictions on Applying Firewall Filters

- [Number of Input and Output Filters Per Logical Interface on page 4485](#)
- [MPLS and Layer 2 CCC Firewall Filters in Lists on page 4486](#)
- [Layer 2 CCC Firewall Filters on MX Series Routers and EX Series Switches on page 4486](#)

### Number of Input and Output Filters Per Logical Interface

**Input filters**—Although you can use the same filter multiple times, you can apply only one input filter or one input filter list to an interface.

- To specify a single firewall filter to be used to evaluate packets received on the interface, include the **input filter-name** statement in the **filter** stanza.

- To specify an ordered list of firewall filters to be used to evaluate packets received on the interface, include the **input-list [ *filter-names* ]** statement in the **filter** stanza. You can specify up to 16 firewall filters for the filter input list.

**Output filters**—Although you can use the same filter multiple times, you can apply only one output filter or one output filter list to an interface.

- To specify a single firewall filter to be used to evaluate packets transmitted on the interface, include the **output *filter-name*** statement in the **filter** stanza.
- To specify an ordered list of firewall filters to be used to evaluate packets transmitted on the interface, include the **output-list [ *filter-names* ]** statement in the **filter** stanza. You can specify up to 16 firewall filters in a filter output list.

### ***MPLS and Layer 2 CCC Firewall Filters in Lists***

The **input-list *filter-names*** and **output-list *filter-names*** statements for firewall filters for the **ccc** and **mpls** protocol families are supported on all interfaces with the exception of the following:

- Management interfaces and internal Ethernet interfaces (**fxp** or **em0**)
- Loopback interfaces (**lo0**)
- USB modem interfaces (**umd**)

### ***Layer 2 CCC Firewall Filters on MX Series Routers and EX Series Switches***

Only on MX Series routers and EX Series switches, you cannot apply a Layer 2 CCC stateless firewall filter (a firewall filter configured at the **[edit firewall filter family ccc]** hierarchy level) as an output filter. On MX Series routers and EX Series switches, firewall filters configured for the **family ccc** statement can be applied only as input filters.

### ***Understanding How to Use Standard Firewall Filters***

This topic covers the following information:

- [Using Standard Firewall Filters to Affect Local Packets on page 4486](#)
- [Using Standard Firewall Filters to Affect Data Packets on page 4487](#)

#### ***Using Standard Firewall Filters to Affect Local Packets***

On a router (or switch), you can configure one physical loopback interface, **lo0**, and one or more addresses on the interface. The loopback interface is the interface to the Routing

Engine, which runs and monitors all the control protocols. The loopback interface carries local packets only. Standard firewall filters applied to the loopback interface affect the local packets destined for or transmitted from the Routing Engine.

**NOTE:** When you create an additional loopback interface, it is important to apply a filter to it so the Routing Engine is protected. We recommend that when you apply a filter to the loopback interface, you include the `apply-groups` statement. Doing so ensures that the filter is automatically inherited on every loopback interface, including `lo0` and other loopback interfaces.

### ***Trusted Sources***

The typical use of a standard stateless firewall filter is to protect the Routing Engine processes and resources from malicious or untrusted packets. To protect the processes and resources owned by the Routing Engine, you can use a standard stateless firewall filter that specifies which protocols and services, or applications, are allowed to reach the Routing Engine. Applying this type of filter to the loopback interface ensures that the local packets are from a trusted source and protects the processes running on the Routing Engine from an external attack.

### ***Flood Prevention***

You can create standard stateless firewall filters that limit certain TCP and ICMP traffic destined for the Routing Engine. A router (or switch) without this kind of protection is vulnerable to TCP and ICMP flood attacks, which are also called denial-of-service (DoS) attacks. For example:

- A TCP flood attack of SYN packets initiating connection requests can overwhelm the device until it can no longer process legitimate connection requests, resulting in denial of service.
- An ICMP flood can overload the device with so many echo requests (ping requests) that it expends all its resources responding and can no longer process valid network traffic, also resulting in denial of service.

Applying the appropriate firewall filters to the Routing Engine protects against these types of attacks.

### ***Using Standard Firewall Filters to Affect Data Packets***

Standard firewall filters that you apply to your router's (or switch's) transit interfaces evaluate only the user data packets that transit the router (or switch) from one interface directly to another as they are being forwarded from a source to a destination. To protect the network as a whole from unauthorized access and other threats at specific interfaces, you can apply firewall filters router (or switch) transit interfaces.

#### **Related Documentation**

## Standard Firewall Filter Match Conditions Overview

---

- [Firewall Filter Match Conditions Based on Numbers or Text Aliases on page 4488](#)
- [Firewall Filter Match Conditions Based on Bit-Field Values on page 4489](#)
- [Firewall Filter Match Conditions Based on Address Fields on page 4493](#)
- [Firewall Filter Match Conditions Based on Address Classes on page 4502](#)

### ***Firewall Filter Match Conditions Based on Numbers or Text Aliases***

This topic covers the following information:

- [Matching on a Single Numeric Value on page 4488](#)
- [Matching on a Range of Numeric Values on page 4488](#)
- [Matching on a Text Alias for a Numeric Value on page 4488](#)
- [Matching on a List of Numeric Values or Text Aliases on page 4488](#)

#### ***Matching on a Single Numeric Value***

You can specify a firewall filter match condition based on whether a particular packet field value is a specified numeric value. In the following example, a match occurs if the packet source port number is 25:

```
[edit firewall family inet filter filter1 term term1 from]
user@host# set source-port 25
```

#### ***Matching on a Range of Numeric Values***

You can specify a firewall filter match condition based on whether a particular packet field value falls within a specified range of numeric values. In the following example, a match occurs for source ports values from 1024 through 65,535, inclusive:

```
[edit firewall family inet filter filter2 term term1 from]
user@host# set source-port 1024-65535
```

#### ***Matching on a Text Alias for a Numeric Value***

You can specify a firewall filter match condition based on whether a particular packet field value is a numeric value that you specify by using a text string as an *alias* for the numeric value. In the following example, a match occurs if the packet source port number is 25. For the **source-port** and **destination-port** match conditions, the text alias **smtp** corresponds to the numeric value 25.

```
[edit firewall family inet filter filter3 term term1 from]
user@host# set source-port smtp
```

#### ***Matching on a List of Numeric Values or Text Aliases***

You can specify a firewall filter match condition based on whether a particular packet field value matches any one of multiple numeric values or text aliases that you specify within square brackets and delimited by spaces. In the following example, a match occurs if the packet source port number is any of the following values: 20 (which corresponds to the text aliases **ftp-data**), 25, or any value from 1024 through 65535.

```
[edit firewall family inet filter filter3 term term1 from]
user@host# set source-port [smtp ftp-data 25 1024-65535]
```

**Match Conditions for Bit-Field Values**

Table 333 on page 4489 lists the firewall filter match conditions that are based on whether certain bit fields in a packet are set or not set. The second and third columns list the types of traffic for which the match condition is supported.

**Table 333: Binary and Bit-Field Match Conditions for Firewall Filters**

| Bit-Field Match Condition           | Match Values                                                                                        | Protocol Families for Standard Stateless Firewall Filters | Protocol Families for Service Filters |
|-------------------------------------|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------|---------------------------------------|
| <b>fragment-flags <i>flags</i></b>  | Hexadecimal values or text aliases for the three-bit IP fragmentation flags field in the IP header. | <b>family inet</b>                                        | <b>family inet</b>                    |
| <b>fragment-offset <i>value</i></b> | Hexadecimal values or text aliases for the 13-bit fragment offset field in the IP header.           | <b>family inet</b>                                        | <b>family inet</b>                    |

<sup>†</sup> The Junos OS does not automatically check the first fragment bit when matching TCP flags for IPv4 traffic. To check the first fragment bit for IPv4 traffic only, use the **first-fragment** match condition.

**Table 333: Binary and Bit-Field Match Conditions for Firewall Filters** (*continued*)

| Bit-Field Match Condition           | Match Values                                                                                                | Protocol Families for Standard Stateless Firewall Filters                                                                                                   | Protocol Families for Service Filters     |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| <b>tcp-flags value</b> <sup>†</sup> | Hexadecimal values or text aliases for the low-order 6 bits of the 8-bit TCP flags field in the TCP header. | <b>family inet</b><br><b>family inet6</b><br><b>family vpls</b><br><b>family bridgefamily</b><br><b>ethernet-switching</b><br>(only for EX Series switches) | <b>family inet</b><br><b>family inet6</b> |

<sup>†</sup> The Junos OS does not automatically check the first fragment bit when matching TCP flags for IPv4 traffic. To check the first fragment bit for IPv4 traffic only, use the **first-fragment** match condition.

#### **Match Conditions for Common Bit-Field Values or Combinations**

Table 334 on page 4490 describes firewall filter match conditions that are based on whether certain commonly used values or *combinations* of bit fields in a packet are set or not set.

You can use text synonyms to specify some common bit-field matches. In the previous example, you can specify **tcp-initial** as the same match condition.

#### **NOTE:**

Some of the numeric range and bit-field match conditions allow you to specify a text synonym. For a complete list of synonyms:

- If you are using the J-Web interface, select the synonym from the appropriate list.
- If you are using the CLI, type a question mark (?) after the from statement.

**Table 334: Bit-Field Match Conditions for Common Combinations**

| Match Condition       | Description                                                                                                                        | Protocol Families for Standard Stateless Firewall Filters | Protocol Families for Service Filters |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|---------------------------------------|
| <b>first-fragment</b> | Text alias for the bit-field match condition <b>fragment-offset 0</b> , which indicates the first fragment of a fragmented packet. | <b>family inet</b>                                        | <b>family inet</b>                    |

**Table 334: Bit-Field Match Conditions for Common Combinations** (*continued*)

| Match Condition        | Description                                                                                                                                                             | Protocol Families for Standard Stateless Firewall Filters | Protocol Families for Service Filters |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|---------------------------------------|
| <b>is-fragment</b>     | Text alias for the bit-field match condition <b>fragment-offset 0 except</b> , which indicates a trailing fragment of a fragmented packet.                              | <b>family inet</b>                                        | <b>family inet</b>                    |
| <b>tcp-established</b> | Alias for the bit-field match condition <b>tcp-flags "(ack   rst)"</b> , which indicates an established TCP session, but not the first packet of a TCP connection.      | <b>family inet</b><br><b>family inet6</b>                 | —                                     |
| <b>tcp-initial</b>     | Alias for the bit-field match condition <b>tcp-flags "(!ack &amp; syn)"</b> , which indicates the first packet of a TCP connection, but not an established TCP session. | <b>family inet</b><br><b>family inet6</b>                 | —                                     |

#### Logical Operators for Bit-Field Values

Table 335 on page 4491 lists the logical operators you can apply to *single* bit-field values when specifying stateless firewall filter match conditions. The operators are listed in order, from highest precedence to lowest precedence. Operations are left-associative, meaning that the operations are processed from left to right.

**Table 335: Bit-Field Logical Operators**

| Precedence Order | Bit-Field Logical Operator                                                                                                         | Description                                                                                                 |
|------------------|------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| 1                | <b>(<i>complex-match-condition</i>)</b>                                                                                            | Grouping—The complex match condition is evaluated before any operators outside the parentheses are applied. |
| 2                | <b>! <i>match-condition</i></b>                                                                                                    | Negation—A match occurs if the match condition is false.                                                    |
| 3                | <b><i>match-condition-1</i> &amp; <i>match-condition-2</i></b><br>or<br><b><i>match-condition-1</i> + <i>match-condition-2</i></b> | Logical AND—A match occurs if both match conditions are true.                                               |
| 4                | <b><i>match-condition-1</i>   <i>match-condition-2</i></b><br>or<br><b><i>match-condition-1</i> , <i>match-condition-2</i></b>     | Logical OR—A match occurs if either match condition is true.                                                |

### ***Matching on a Single Bit-Field Value or Text Alias***

For the **fragment-flags** and **tcp-flags** bit-match conditions, you can specify firewall filter match conditions based on whether a particular bit in the packet field is set or not set.

- Numeric value to specify a single bit—You can specify a single bit-field match condition by using a numeric value that has one bit set. Depending on the match condition, you can specify a decimal value, a binary value, or a hexadecimal value. To specify a binary value, specify the number with the prefix **b**. To specify a hexadecimal value, specify the number with the prefix **0x**.

In the following example, a match occurs if the **RST** bit in the TCP flags field is set:

```
[edit firewall family inet filter filter_tcp_rst_number term term1 from]
user@host# set tcp-flags 0x04
```

- Text alias to specify a single bit—You generally specify a single bit-field match condition by using a text alias enclosed in double-quotation marks (" ").

In the following example, a match occurs if the **RST** bit in the TCP flags field is set:

```
[edit firewall family inet filter filter_tcp_rst_alias term term1 from]
user@host# set tcp-flags "rst"
```

### ***Matching on Multiple Bit-Field Values or Text Aliases***

You can specify a firewall filter match condition based on whether a particular set of bits in a packet field are set.

- Numeric values to specify multiple set bits—When you specify a numeric value whose binary representation has more than one set bit, the value is treated as a logical AND of the set bits.

In the following example, the two match conditions are the same. A match occurs if either bit **0x01** or **0x02** is not set:

```
[edit firewall family inet filter reset_or_not_initial_packet term term5 from]
user@host# set tcp-flags "!0x3"
user@host# set tcp-flags "!(0x01 & 0x02)"
```

- Text aliases that specify common bit-field matches—You can use text aliases to specify some common bit-field matches. You specify these matches as a single keyword.

In the following example, the **tcp-established** condition, which is an alias for **"(ack | rst)"**, specifies that a match occurs on TCP packets other than the first packet of a connection:

```
[edit firewall family inet filter reset_or_not_initial_packet term term6 from]
user@host# set tcp-established
```

### ***Matching on a Negated Bit-Field Value***

To negate a match, precede the value with an exclamation point.

In the following example, a match occurs if the **RST** bit in the TCP flags field is *not* set:

```
[edit firewall family inet filter filter_tcp_rst term term1 from]
user@host# set tcp-flags "!rst"
```

### ***Matching on the Logical OR of Two Bit-Field Values***

You can use the *logical OR operator* (`|` or `,`) to specify that a match occurs if a bit field matches either of two bit-field values specified.

In the following example, a match occurs if the packet is *not* the initial packet in a TCP session:

```
[edit firewall family inet filter not_initial_packet term term3 from]
user@host# set tcp-flags "!syn | ack"
```

In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet. In a packet that is not the initial packet in a TCP session, either the SYN flag is not set or the ACK flag is set.

### ***Matching on the Logical AND of Two Bit-Field Values***

You can use the *logical AND operator* (`&` or `+`) to specify that a match occurs if a bit field matches both of two bit-field values specified.

In the following example, a match occurs if the packet is the initial packet in a TCP session:

```
[edit firewall family inet filter initial_packet term term2 from]
user@host# set tcp-flags "syn & !ack"
```

In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet. In a packet that is an initial packet in a TCP session, the SYN flag is set and the ACK flag is not set.

### ***Grouping Bit-Field Match Conditions***

You can use the *logical grouping notation* to specify that the complex match condition inside the parentheses is evaluated before any operators outside the parentheses are applied.

In the following example, a match occurs if the packet is a TCP reset or if the packet is not the initial packet in the TCP session:

```
[edit firewall family inet filter reset_or_not_initial_packet term term4 from]
user@host# set tcp-flags "!(syn & !ack) | rst"
```

In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet. In a packet that is *not* the initial packet in a TCP session, the SYN flag is not set and the ACK field is set.

#### **Related Documentation**

- [Guidelines for Configuring Standard Firewall Filters on page 4478](#)
- [Firewall Filter Match Conditions Based on Numbers or Text Aliases on page 4488](#)
- [Firewall Filter Match Conditions Based on Address Fields on page 4493](#)
- [Firewall Filter Match Conditions Based on Address Classes on page 4502](#)

### ***Firewall Filter Match Conditions Based on Address Fields***

You can configure firewall filter match conditions that evaluate packet address fields—IPv4 source and destination addresses, IPv6 source and destination addresses,

or media access control (MAC) source and destination addresses—against specified addresses or prefix values.

- [Implied Match on the '0/0 except' Address for Firewall Filter Match Conditions Based on Address Fields on page 4494](#)
- [Matching an Address Field to a Subnet Mask or Prefix on page 4494](#)
- [Matching an Address Field to an Excluded Value on page 4495](#)
- [Matching Either IP Address Field to a Single Value on page 4499](#)
- [Matching an Address Field to Noncontiguous Prefixes on page 4499](#)
- [Matching an Address Field to a Prefix List on page 4501](#)

#### ***Implied Match on the '0/0 except' Address for Firewall Filter Match Conditions Based on Address Fields***

Every firewall filter match condition based on a set of addresses or address prefixes is associated with an implicit match on the address **0.0.0.0/0 except** (for IPv4 or VPLS traffic) or **0:0:0:0:0:0:0:0/0 except** (for IPv6 traffic). As a result, any packet whose specified address field does not match any of the specified addresses or address prefixes fails to match the entire term.

#### ***Matching an Address Field to a Subnet Mask or Prefix***

You can specify a single match condition to match a source address or destination address that falls within a specified address prefix.

#### ***IPv4 Subnet Mask Notation***

For an IPv4 address, you can specify a subnet mask value rather than a prefix length. For example:

```
[edit firewall family inet filter filter_on_dst_addr term term3 from]
user@host# set address 10.0.0.10/255.0.0.255
```

#### ***Prefix Notation***

To specify the address prefix, use the notation **prefix/prefix-length**. In the following example, a match occurs if a destination address matches the prefix **10.0.0.0/8**:

```
[edit firewall family inet filter filter_on_dst_addr term term1 from]
user@host# set destination-address 10.0.0.0/8
```

#### ***Default Prefix Length for IPv4 Addresses***

If you do not specify **/prefix-length** for an IPv4 address, the prefix length defaults to **/32**. The following example illustrates the default prefix value:

```
[edit firewall family inet filter filter_on_dst_addr term term2 from]
user@host# set destination-address 10
user@host# show
destination-address {
 10.0.0.0/32;
}
```

### Default Prefix Length for IPv6 Addresses

If you do not specify */prefix-length* for an IPv6 address, the prefix length defaults to */128*. The following example illustrates the default prefix value:

```
[edit firewall family inet6 filter filter_on_dst_addr term term1 from]
user@host# set destination-address ::10
user@host# show
destination-address {
 ::10/128;
}
```

### Default Prefix Length for MAC Addresses

If you do not specify */prefix-length* for a media access control (MAC) address of a VPLS, Layer 2 CCC, or Layer 2 bridging packet, the prefix length defaults to */48*. The following example illustrates the default prefix value:

```
[edit firewall family vpls filter filter_on_dst_mac_addr term term1 from]
user@host# set destination-mac-address 01:00:0c:cc:cc:cd
user@host# show
destination-address {
 01:00:0c:cc:cc:cd/48;
}
```

### Matching an Address Field to an Excluded Value

For the address-field match conditions, you can include the **except** keyword to specify that a match occurs for an address field that does not match the specified address or prefix.

### Excluding IP Addresses in IPv4 or IPv6 Traffic

For the following IPv4 and IPv6 match conditions, you can include the **except** keyword to specify that a match occurs for an IP address field that does not match the specified IP address or prefix:

- **address address except**—A match occurs if either the source IP address or the destination IP address does not match the specified address or prefix.
- **source-address address except**—A match occurs if the source IP address does not match the specified address or prefix.
- **destination-address address except**—A match occurs if the destination IP address does not match the specified address or prefix.

In the following example, a match occurs for any IPv4 destination addresses that fall under the **192.168.10.0/8** prefix, except for addresses that fall under **192.168.0.0/16**. All other addresses implicitly do not match this condition.

```
[edit firewall family inet filter filter_on_dst_addr term term1 from]
user@host# set 192.168.0.0/16 except
user@host# set 192.168.10.0/8
user@host# show
destination-address {
 192.168.0.0/16 except;
 192.168.10.0/8;
}
```

```
}
```

In the following example, a match occurs for any IPv4 destination address that does not fall within the prefix 10.1.1.0/24:

```
[edit firewall family inet filter filter_on_dst_addr term term24 from]
user@host# set destination-address 0.0.0.0/0
user@host# set destination-address 10.1.1.0/24 except
user@host# show
destination-address {
 0.0.0.0/0;
 10.1.1.0/24 except;
}
```

#### *Excluding IP Addresses in VPLS or Layer 2 Bridging Traffic*

For the following VPLS and Layer 2 bridging match conditions on MX Series routers and EX Series switches only, you can include the **except** keyword to specify that a match occurs for an IP address field that does not match the specified IP address or prefix:

- **ip-address address except**—A match occurs if either the source IP address or the destination IP address does not match the specified address or prefix.
- **source-ip-address address except**—A match occurs if the source IP address does not match the specified address or prefix.
- **destination-ip-address address except**—A match occurs if the destination IP address does not match the specified address or prefix.

In the following example for filtering VPLS traffic on an MX Series router and on an EX Series switch, a match occurs if the source IP address falls within the exception range of **55.0.1.0/255.0.255.0** and the destination IP address matches **55.0.0.0/8**:

```
[edit]
firewall {
 family vpls {
 filter fvpls {
 term 1 {
 from {
 ip-address {
 55.0.0.0/8;
 55.0.1.0/255.0.255.0 except;
 }
 }
 then {
 count from-55/8;
 discard;
 }
 }
 }
 }
}
```

#### ***Excluding MAC Addresses in VPLS or Layer 2 Bridging Traffic***

For the following VPLS or Layer 2 bridging traffic match conditions, you can include the **except** keyword to specify that a match occurs for a MAC address field that does not match the specified MAC address or prefix:

- **source-mac-address address except**—A match occurs if the source MAC address does not match the specified address or prefix.
- **destination-mac-address address except**—A match occurs if either the destination MAC address does not match the specified address or prefix.

#### ***Excluding All Addresses Requires an Explicit Match on the '0/0' Address***

If you specify a firewall filter match condition that consists of one or more address-*exception* match conditions (address match conditions that use the **except** keyword) but no *matchable* address match conditions, packets that do not match any of the configured prefixes fails the overall match operation. To configure a firewall filter term of address-exception match conditions to match any address that is not in the prefix list, include an explicit match of **0/0** so that the term contain a matchable address.

For the following example firewall filter for IPv4 traffic, the **from-trusted-addresses** term fails to discard matching traffic, and the **INTRUDERS-COUNT** counter is missing from the output of the **show firewall** operational mode command:

```
[edit]
user@host# show policy-options
prefix-list TRUSTED-ADDRESSES {
 10.2.1.0/24;
 192.168.122.0/24;
}
```

```
[edit firewall family inet filter protect-RE]
```

```
user@host# show
```

```
term from-trusted-addresses {
 from {
 source-prefix-list {
 TRUSTED-ADDRESSES except;
 }
 protocol icmp;
 }
 then {
 count INTRUDERS-COUNT;
 discard;
 }
}
term other-icmp {
 from {
 protocol icmp;
 }
 then {
 count VALID-COUNT;
 accept;
 }
}
term all {
 then accept;
}
```

```
[edit]
```

```
user@host# run show firewall
```

```
Filter: protect-RE
```

```
Counters:
```

| Name        | Bytes | Packets |
|-------------|-------|---------|
| VALID-COUNT | 2770  | 70      |

```
Filter: __default_bpdu_filter__
```

To cause a filter term of address-exception match conditions to match any address that is not in the prefix list, include an explicit match of **0/0** in the set of match conditions:

```
[edit firewall family inet filter protect-RE]
```

```
user@host# show term from-trusted-addresses
```

```
from {
 source-address {
 0.0.0.0/0;
 }
 source-prefix-list {
 TRUSTED-ADDRESSES except;
 }
 protocol icmp;
}
```

With the addition of the **0.0.0.0/0** source prefix address to the match condition, the **from-trusted-addresses** term discards matching traffic, and the INTRUDERS-COUNT counter displays in the output of the **show firewall** operational mode command:

```
[edit]
```

```
user@host# run show firewall
```

```
Filter: protect-RE
```

```
Counters:
```

| Name                            | Bytes | Packets |
|---------------------------------|-------|---------|
| VALID-COUNT                     | 2770  | 70      |
| INTRUDERS-COUNT                 | 420   | 5       |
| Filter: __default_bpdu_filter__ |       |         |

### ***Matching Either IP Address Field to a Single Value***

For IPv4 and IPv6 traffic and for VPLS and Layer 2 bridging traffic only on MX Series routers and on EX Series switches, you can use a single match condition to match a single address or prefix value to either the source or destination IP address field.

### ***Matching Either IP Address Field in IPv4 or IPv6 Traffic***

For IPv4 or IPv6 traffic, you can use a single match condition to specify the same address or prefix value as the match for either the source or destination IP address field. Instead of creating separate filter terms that specify the same address for the **source-address** and **destination-address** match conditions, you use only the **address** match condition. A match occurs if *either* the source IP address *or* the destination IP address matches the specified address or prefix.

If you use the **except** keyword with the **address** match condition, a match occurs if *both* the source IP address and the destination IP address match the specified value *before* the exception applies.

In a firewall filter term that specifies either the **source-address** or the **destination-address** match condition, you cannot also specify the **address** match condition.

### ***Matching Either IP Address Field in VPLS or Layer 2 Bridging Traffic***

For VPLS or Layer 2 bridging traffic on MX Series routers and EX Series switches only, you can use a single match condition to specify the same address or prefix value as the match for either the source or destination IP address field. Instead of creating separate filter terms that specify the same address for the **source-ip-address** and **destination-ip-address** match conditions, you use only the **ip-address** match condition. A match occurs if *either* the source IP address *or* the destination IP address matches the specified address or prefix.

If you use the **except** keyword with the **ip-address** match condition, a match occurs if *both* the source IP address and the destination IP address match the specified value *before* the exception applies.

In a firewall filter term that specifies either the **source-ip-address** or the **destination-ip-address** match condition, you cannot also specify the **ip-address** match condition.

### ***Matching an Address Field to Noncontiguous Prefixes***

For IPv4 traffic only, specify a single match condition to match the IP source or destination address field to any prefix specified. The prefixes do not need to be contiguous. That is, the prefixes under the **source-address** or **destination-address** match condition do not need to be adjacent or neighboring to one another.

In the following example, a match occurs if a destination address matches either the **10.0.0.0/8** prefix or the **192.168.0.0/32** prefix:

```
[edit firewall family inet filter filter_on_dst_addr term term5 from]
user@host# set destination-address 10.0.0.0/8
user@host# set destination-address 192.168.0.0/32
user@host# show
destination-address {
 destination-address 10.0.0.0/8;
 destination-address 192.168.0.0/32;
}
```

The order in which you specify the prefixes within the match condition is not significant. Packets are evaluated against all the prefixes in the match condition to determine whether a match occurs. If prefixes overlap, longest-match rules are used to determine whether a match occurs. A match condition of noncontiguous prefixes includes an implicit **0/0 except** statement, which means that any prefix that does not match any prefix included in the match condition is explicitly considered not to match.

Because the prefixes are order-independent and use longest-match rules, longer prefixes subsume shorter ones as long as they are the same type (whether you specify **except** or not). This is because anything that would match the longer prefix would also match the shorter one.

Consider the following example:

```
[edit firewall family inet filter filter_on_src_addr term term1 from]
source-address {
 172.16.0.0/10;
 172.16.2.0/24 except;
 192.168.1.0;
 192.168.1.192/26 except;
 192.168.1.254;
 172.16.3.0/24; # ignored
 10.2.2.2 except; # ignored
}
```

Within the **source-address** match condition, two addresses are ignored. The **172.16.3.0/16** value is ignored because it falls under the address **172.16.0.0/10**, which is the same type. The **10.2.2.2 except** value is ignored because it is subsumed by the implicit **0.0.0.0/0 except** match value.

Suppose the following source IP address are evaluated by this firewall filter:

- Source IP address **172.16.1.2**—This address matches the **172.16.0.0/10** prefix, and thus the action in the **then** statement is taken.
- Source IP address **172.16.2.2**—This address matches the **172.16.2.0/24** prefix. Because this prefix is negated (that is, includes the **except** keyword), an explicit *mismatch* occurs. The next term in the filter is evaluated, if there is one. If there are no more terms, the packet is discarded.
- Source IP address **10.1.2.3**—This address does not match any of the prefixes included in the **source-address** condition. Instead, it matches the implicit **0.0.0.0/0 except** at

the end of the list of prefixes configured under the **source-address** match condition, and is considered to be a mismatch.

The **172.16.3.0/24** statement is ignored because it falls under the address **172.16.0.0/10**—both are the same type.

The **10.2.2.2 except** statement is ignored because it is subsumed by the implicit **0.0.0.0/0 except** statement at the end of the list of prefixes configured under the **source-address** match condition.

**BEST PRACTICE:** When a firewall filter term includes the **from address address** match condition and a subsequent term includes the **from source-address address** match condition for the same address, packets might be processed by the latter term before they are evaluated by any intervening terms. As a result, packets that should be rejected by the intervening terms might be accepted instead, or packets that should be accepted might be rejected instead.

To prevent this from occurring, we recommend that you do the following. For every firewall filter term that contains the **from address address** match condition, replace that term with two separate terms: one that contains the **from source-address address** match condition, and another that contains the **from destination-address address** match condition.

### *Matching an Address Field to a Prefix List*

You can define a list of IPv4 or IPv6 address prefixes for use in a routing policy statement or in a stateless firewall filter match condition that evaluates packet address fields.

To define a list of IPv4 or IPv6 address prefixes, include the **prefix-list prefix-list** statement.

```
prefix-list name {
 ip-addresses;
 apply-path path;
}
```

You can include the statement at the following hierarchy levels:

- **[edit policy-options]**
- **[edit logical-systems logical-system-name policy-options]**

After you have defined a prefix list, you can use it when specifying a firewall filter match condition based on an IPv4 or IPv6 address prefix.

```
[edit firewall family family-name filter filter-name term term-name]
from {
 source-prefix-list {
 prefix-lists;
 }
 destination-prefix-list {
 prefix-lists;
 }
}
```

```
}
```

***Firewall Filter Match Conditions Based on Address Classes***

For IPv4 and IPv6 traffic only, you can use class-based firewall filter conditions to match packet fields based on source class or destination class.

- [Source-Class Usage on page 4502](#)
- [Destination-Class Usage on page 4502](#)
- [Guidelines for Applying SCU or DCU Firewall Filters to Output Interfaces on page 4502](#)

***Source-Class Usage***

A *source class* is a set of source prefixes grouped together and given a class name. To configure a firewall filter term that matches an IP source address field to one or more source classes, use the **source-class class-name** match condition under the **[edit firewall family (inet | inet6) filter filter-name term term-name from]** hierarchy level.

*Source-class usage* (SCU) enables you to monitor the amount of traffic originating from a specific prefix. With this feature, usage can be tracked and customers can be billed for the traffic they receive.

***Destination-Class Usage***

A *destination class* is a set of destination prefixes grouped together and given a class name. To configure a firewall filter term that matches an IP destination address field to one or more destination classes, use the **destination-class class-name** match condition at the **[edit firewall family (inet | inet6) filter filter-name term term-name from]** hierarchy level.

*Destination-class usage* (DCU) enables you can track how much traffic is sent to a specific prefix in the core of the network originating from one of the specified interfaces.

Note, however, that DCU limits your ability to keep track of traffic moving in the reverse direction. It can account for all traffic that arrives on a core interface and heads toward a specific customer, but it cannot count traffic that arrives on a core interface from a specific prefix.

***Guidelines for Applying SCU or DCU Firewall Filters to Output Interfaces***

When applying a SCU or DCU firewall filter to an interface, keep the following guidelines in mind:

- Output interfaces—Class-based firewall filter match conditions work only for firewall filters that you apply to output interfaces. This is because the SCU and DCU are determined after route lookup occurs.

- Input interfaces—Although you can specify a source class and destination class for an input firewall filter, the counters are incremented only if the firewall filter is applied on the output interface.
- Output interfaces for tunnel traffic—SCU and DCU are not supported on the interfaces you configure as the output interface for tunnel traffic for transit packets exiting the router (or switch) through the tunnel.

**Introduction to Standard Firewall Filters for Fragment Handling**

---

- [Firewall Filters That Handle Fragmented Packets Overview on page 4503](#)

***Firewall Filters That Handle Fragmented Packets Overview***

You can create stateless firewall filters that handle fragmented packets destined for the Routing Engine. By applying these policies to the Routing Engine, you protect against the use of IP fragmentation as a means to disguise TCP packets from a firewall filter.

For example, consider an IP packet that is fragmented into the smallest allowable fragment size of 8 bytes (a 20-byte IP header plus an 8-byte payload). If this IP packet carries a TCP packet, the first fragment (fragment offset of 0) that arrives at the device contains only the TCP source and destination ports (first 4 bytes), and the sequence number (next 4 bytes). The TCP flags, which are contained in the next 8 bytes of the TCP header, arrive in the second fragment (fragment offset of 1).

On all SRX Series and J Series devices, fragmented packets are not sampled correctly by the firewall filter. When file sampling, port-mirroring and CFLOW is applied on an interface in output direction, packets are sampled before fragmenting the packet and packet-capture captures packet after fragmentation.

See RFC 1858, *Security Considerations for IP Fragment Filtering*.

### ***Stateless Firewall Filters That Reference Policers Overview***

Policing, or rate limiting, is an important component of firewall filters that lets you limit the amount of traffic that passes into or out of an interface.

A stateless firewall filter that references a policer can provide protection from denial-of-service (DOS) attacks. Traffic that exceeds the rate limits configured for the policer is either discarded or marked as lower priority than traffic that conforms to the configured rate limits. Packets can be marked for a lower priority by being set to a specific output queue, set to a specific packet loss priority (PLP) level, or both. When necessary, low-priority traffic can be discarded to prevent congestion.

A policer specifies two types of rate limits on traffic:

- **Bandwidth limit**—The average traffic rate permitted, specified as a number of bits per second.
- **Maximum burst size**—The packet size permitted for bursts of data that exceed the bandwidth limit.

Policing uses an algorithm to enforce a limit on average bandwidth while allowing bursts up to a specified maximum value. You can use policing to define specific classes of traffic on an interface and apply a set of rate limits to each class. After you name and configure a policer, it is stored as a template. You can then apply the policer in an interface configuration or, to rate-limit packet-filtered traffic only, in a firewall filter configuration.

For an IPv4 firewall filter term only, you can also specify a *prefix-specific action* as a nonterminating action that applies a policer to the matched packets. A prefix-specific action applies additional matching criteria on the filter-matched packets based on specified address prefix bits and then associates the matched packets with a counter and policer instance for that filter term or for all terms in the firewall filter.

To apply a policer or a prefix action to packet-filtered traffic, you can use the following firewall filter nonterminating actions:

- ***policer* *policer-name***
- ***three-color-policer* (*single-rate* | *two-rate*) *policer-name***

- **prefix-action** *action-name*

**NOTE:** The packet lengths that a policer considers depends on the address family of the firewall filter. See [“Understanding the Frame Length for Policing Packets” on page 4811](#).

- [How Filter Lists Evaluate Packets When the Matched Term Includes Terminating or Next Term Actions on page 4507](#)
- [How Filter Lists Evaluate Packets When the List Includes Protocol-Independent and IP Firewall Filters on page 4508](#)

#### ***The Challenge: Simplify Large-Scale Firewall Filter Administration***

Typically, you apply a single stateless firewall filter to an interface in the input or output direction or both. However, this approach might not be practical, when you have a device configured with many interfaces. In large environments, you want the flexibility of being able to modify filtering terms common to multiple interfaces without having to reconfigure the filter of every affected interface.

In general, the solution is to apply an effectively “chained” structure of multiple stateless firewall filters to a single interface. You partition your filtering terms into multiple firewall filters that each perform a filtering task. You can then choose which filtering tasks you want to perform for a given interface and apply the filtering tasks to that interface. In this way, you only manage the configuration for a filtering task in a single firewall filter.

The Junos OS policy framework provides two options for managing the application of multiple separate firewall filters to individual router (or switch) interfaces. One option is to apply multiple filters as a single input list or output list. The other option is to reference a stateless firewall filter from within the term of another stateless firewall filter.

#### ***A Solution: Apply Lists of Firewall Filters***

The most straightforward way to avoid configuring duplicate filtering terms common to multiple stateless firewall filters is to configure multiple firewall filters and then apply a

customized *list* of filters to each interface. The Junos OS uses the filters—in the order in which they appear in the list—to evaluate packets that transit the interface. If you need to modify filtering terms shared across multiple interfaces, you only need to modify one firewall filter that contains those terms.

**NOTE:** In contrast with the alternative approach (configuring nested firewall filters) applying firewall filter lists combines multiple firewall filters at each interface application point.

---

### ***Configuration of Multiple Filters for Filter Lists***

Configuring firewall filters to be applied in unique lists for each router (or switch) interface involves separating shared packet-filtering rules from interface-specific packet-filtering rules as follows:

- **Unique filters**—For each set of packet-filtering rules unique to a specific interface, configure a separate firewall filter that contains only the filtering terms for that interface.
- **Shared filters**—For each set of packet-filtering rules common across two or more interfaces, consider configuring a separate firewall filter that contains the shared filtering terms.

**TIP:** When planning for a large number firewall filters to be applied using filter lists, administrators often organize the shared filters by filtering criteria, by the services to which customers subscribe, or by the purposes of the interfaces.

---

### ***Application of Filter Lists to a Router or Switch Interface***

Applying a list of firewall filters to an interface is a matter of selecting the filters that meet the packet-filtering requirements of that interface. For each interface, you can include an **input-list** or **output-list** statement (or both) within the **filter** stanza to specify the relevant filters in the order in which they are to be used:

- Include any filters that contain common filtering terms relevant to the interface.
- Include the filter that contain only the filtering terms unique to the interface.

### Interface-Specific Names for Filter Lists

Because a filter list is configured under an interface, the resulting concatenated filter is *interface-specific*.

**NOTE:** When a filter list is configured under an interface, the resulting concatenated filter is interface-specific, regardless whether the firewall filters in the filter list are configured as interface-specific or not. Furthermore, the instantiation of interface-specific firewall filters not only create separate instances of any firewall filter counters, but also separate instances of any policer actions. Any policers applied through an action specified in the firewall filter configuration are applied separately to each interface in the interface group.

The system-generated name of an interface-specific filter consists of the full interface name followed by either '-i' for an input filter list or '-o' for an output filter list.

- **Input filter list name**—For example, if you use the **input-list** statement to apply a chain of filters to logical interface **ge-1/3/0.0**, the Junos OS uses the following name for the filter:

**ge-1/3/0.0-i**

- **Output filter list name**—For example, if you use the **output-list** statement to apply a chain of filters to logical interface **fe-0/1/2.0**, the Junos OS uses the following name for the filter:

**fe-0/1/2.0-o**

You can use the interface-specific name of a filter list when you enter a Junos OS operational mode command that specifies a stateless firewall filter name.

### How Filter Lists Evaluate Packets When the Matched Term Includes Terminating or Next Term Actions

The device evaluates a packet against the filters in a list sequentially, beginning with the first filter in the list until either a terminating action occurs or the packet is implicitly discarded.

[Table 336 on page 4508](#) describes how a firewall filter list evaluates a packet based on whether the matched term specifies a terminating action and the **next term** action. The **next term** action is neither a terminating action nor a nonterminating action but a *flow control* action.

Table 336: Firewall Filter List Behavior

| Firewall Filter Actions Included in the Matched Term |           | Term Description                                                                                             | Packet-Filtering Behavior                                                                                                                                                                                                                                         |
|------------------------------------------------------|-----------|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Terminating                                          | next term |                                                                                                              |                                                                                                                                                                                                                                                                   |
| Yes                                                  | —         | The matched term includes a terminating action (such as <b>discard</b> ) but not the <b>next term</b> action | The device executes the terminating action. No subsequent terms in the filter and no subsequent filters in the list are used to evaluate the packet.                                                                                                              |
| —                                                    | Yes       | The matched term includes the <b>next term</b> action, but it does not include any terminating actions.      | The device executes any nonterminating actions, then the device evaluates the packet against the next term in the filter or the next filter in the list.                                                                                                          |
| —                                                    | —         | The matched term includes neither the <b>next term</b> action nor any terminating actions.                   | The device executes any nonterminating actions, then the device implicitly accepts the packet. Because the <b>accept</b> action is a terminating action, no subsequent terms in the filter and no subsequent filters in the list are used to evaluate the packet. |

For information about terminating actions, see “[Standard Firewall Filter Terminating Actions](#)” on page 4742.

**NOTE:** You cannot configure the **next term** action with a terminating action in the same firewall filter term.

#### *How Filter Lists Evaluate Packets When the List Includes Protocol-Independent and IP Firewall Filters*

On a single interface associated with a protocol-independent (**family any**) firewall filter and a protocol-specific (**family inet** or **family inet6**) firewall filter simultaneously, the protocol-independent firewall filter executes first.

The terminating action of the first filter determines whether the second filter also evaluates the packet:

- If the first filter terminates by executing the **accept** action, the second filter also evaluates the packet.
- If the first filter terminates without any terms matching the packet (an *implicit discard* action), the second filter also evaluates the packet.
- If the first filter terminates by executing an *explicit discard* action, the second filter does not evaluate the packet.

#### **Related Documentation**

- [How Standard Firewall Filters Evaluate Packets on page 4475](#)
- [Guidelines for Applying Multiple Standard Firewall Filters as a List on page 4509](#)
- [Example: Applying Lists of Multiple Standard Firewall Filters on page 4621](#)

### ***Guidelines for Applying Multiple Standard Firewall Filters as a List***

This topic covers the following information:

- [Statement Hierarchy for Applying Lists of Multiple Firewall Filters on page 4509](#)
- [Filter Input Lists and Output Lists for Router or Switch Interfaces on page 4509](#)
- [Types of Filters Supported in Lists on page 4509](#)
- [Restrictions on Applying Filter Lists for MPLS or Layer 2 CCC Traffic on page 4510](#)

### ***Statement Hierarchy for Applying Lists of Multiple Firewall Filters***

To apply a single filter to the input or output direction of a router (or switch) logical interface, you include the **input** *filter-name* or **output** *filter-name* statement under the **filter** stanza for a protocol family.

To apply a list of multiple filters to the input or output direction of a router (or switch) logical interface, include the **input-list** [ *filter-names* ] or **output-list** [ *filter-names* ] statement under the **filter** stanza for a protocol family:

```

interfaces {
 interface-name {
 unit logical-unit-number {
 family family-name {
 filter {
 ...filter-options...
 input-list [filter-names];
 output-list [filter-names];
 }
 }
 }
 }
}

```

You can include the interface configuration at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

### ***Filter Input Lists and Output Lists for Router or Switch Interfaces***

When applying a list of firewall filters as a list, the following limitations apply:

- You can specify up to 16 firewall filters for a filter input list.
- You can specify up to 16 firewall filters for a filter output list.

### ***Types of Filters Supported in Lists***

Lists of multiple firewall filters applied to a router (or switch) interface support standard stateless firewall filters only. You cannot apply lists containing service filters or simple filters to a router (or switch) interface.

***Restrictions on Applying Filter Lists for MPLS or Layer 2 CCC Traffic***

When applying stateless firewall filters that evaluate MPLS traffic (**family mpls**) or Layer 2 circuit cross-connection traffic (**family ccc**), you can use the **input-list [ *filter-names* ]** and **output-list [ *filter-names* ]** statements for all interfaces except the following:

- Management and internal Ethernet (**fxp**) interfaces
- Loopback (**lo0**) interfaces
- USB modem (**umd**) interfaces

**Related Documentation**

- [A Solution: Configure Nested References to Firewall Filters on page 4510](#)
- [Configuration of Nested Firewall Filters on page 4511](#)
- [Application of Nested Firewall Filters to a Router or Switch Interface on page 4511](#)

***The Challenge: Simplify Large-Scale Firewall Filter Administration***

Typically, you apply a single stateless firewall filter to an interface in the input or output direction or both. This approach might not be practical, however, when you have a router (or switch) configured with many, even hundreds of interfaces. In an environment of this scale, you want the flexibility of being able to modify filtering terms common to multiple interfaces without having to reconfigure the filter of every affected interface.

In general, the solution is to apply an effectively “chained” structure of multiple stateless firewall filters to a single interface. You partition your filtering terms into multiple firewall filters configured so that you can apply a unique filter to each router (or switch) interface but also apply common filters to multiple router (or switch) interfaces as required. The Junos OS policy framework provides two options for managing the application of multiple separate firewall filters to individual router (or switch) interfaces. One option is to apply multiple filters as a single input list or output list. The other option is to reference a stateless firewall filter from within the term of another stateless firewall filter.

***A Solution: Configure Nested References to Firewall Filters***

The most structured way to avoid configuring duplicate filtering terms common to multiple stateless firewall filters is to configure multiple stateless firewall filters so that each filter includes the shared filtering terms by *referencing* a separate filter that contains the common filtering terms. The Junos OS uses the filter terms—in the order in which they appear in the filter definition—to evaluate packets that transit the interface. If you need to modify filtering terms shared across multiple interfaces, you only need to modify one firewall filter.

**NOTE:** Similar to the alternative approach (applying a list of firewall filters), configuring a nested firewall filter combines multiple firewall filters into a new firewall filter definition.

### ***Configuration of Nested Firewall Filters***

Configuring a nested firewall filter for each router (or switch) interface involves separating shared packet-filtering rules from interface-specific packet-filtering rules as follows:

- For each set of packet-filtering rules common across multiple interfaces, configure a separate firewall filter that contains the shared filtering terms.
- For each router (or switch) interface, configure a separate firewall filter that contains:
  - All the filtering terms unique to that interface.
  - An additional filtering term that includes a **filter** reference to the firewall filter that contains the common filtering terms.

### ***Application of Nested Firewall Filters to a Router or Switch Interface***

Applying nested firewall filters is no different from applying an unnested firewall filter. For each interface, you can include an **input** or **output** statement (or both) within the **filter** stanza to specify the appropriate nested firewall filter.

Applying nested firewall filters to an interface, the shared filtering terms and the interface-specific firewall filters are applied through a *single nested firewall filter* that includes other filters through the **filter** statement within a separate filtering term.

### ***Guidelines for Nesting References to Multiple Standard Firewall Filters***

This topic covers the following information:

- [Statement Hierarchy for Configuring Nested Firewall Filters on page 4511](#)
- [Filter-Defining Terms and Filter-Referencing Terms on page 4512](#)
- [Types of Filters Supported in Nested Configurations on page 4512](#)
- [Number of Filter References in a Single Filter on page 4512](#)
- [Depth of Filter Nesting on page 4512](#)

### ***Statement Hierarchy for Configuring Nested Firewall Filters***

To reference a filter from within a filter, include the **filter filter-name** statement as a separate filter term:

```
firewall firewall-name {
 family family-name {
 filter filter-name {
 term term-name {
```

```
 filter filter-name;
 }
}
}
```

You can include the firewall configuration at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

### ***Filter-Defining Terms and Filter-Referencing Terms***

You cannot configure a firewall filter term that both references another firewall filter and defines a match condition or action. If a firewall filter term includes the **filter** statement, then it cannot also include the **from** or **then** statement.

For example, the firewall filter term **term term1** in the configuration is *not* valid:

```
[edit]
firewall {
 family inet {
 filter filter_1 {
 term term1 {
 filter filter_2;
 from {
 source-address 1.1.1.1/32;
 }
 then {
 accept;
 }
 }
 }
 }
}
```

In order for **term term1** to be a valid filter term, you must either remove the **filter filter\_2** statement or remove both the **from** and **then** stanzas.

### ***Types of Filters Supported in Nested Configurations***

Nested configurations of firewall filters support standard stateless firewall filters only. You cannot use service filters or simple filters in a nested firewall filter configuration.

### ***Number of Filter References in a Single Filter***

The total number of filters referenced from within a filter cannot exceed 256.

### ***Depth of Filter Nesting***

The Junos OS supports a single level of firewall filter nesting. If **filter\_1** references **filter\_2**, you cannot configure a filter that references a filter that references **filter\_1**.

### *Interface-Specific Firewall Filter Instances Overview*

This topic covers the following information:

- [Instantiation of Interface-Specific Firewall Filters on page 4513](#)
- [Interface-Specific Names for Firewall Filter Instances on page 4513](#)
- [Interface-Specific Firewall Filter Counters on page 4514](#)
- [Interface-Specific Firewall Filter Policers on page 4514](#)

### *Instantiation of Interface-Specific Firewall Filters*

On T Series, M120, M320, MX Series routers, and EX Series switches, you can enable the Junos OS to automatically create an interface-specific instance of a firewall filter for each interface to which you apply the filter. If you enable interface-specific instantiation of a firewall filter and then apply that filter to multiple interfaces, any **count** actions or **policer** actions configured in the filter terms act on the traffic stream entering or exiting each individual interface, regardless of the sum of traffic on the multiple interfaces.

You can enable this option per firewall filter by including the **interface-specific** statement in the filter configuration.

**NOTE:** On T Series, M120, M320, MX Series routers, and EX Series switches, interfaces are distributed among multiple packet-forwarding components.

Interface-specific firewall filtering is not supported on M Series routers other than the M120 and M320 routers. If you apply a firewall filter to multiple interfaces on an M Series router other than the M120 or M320 routers, the filter acts on the sum of traffic entering or exiting those interfaces.

Interface-specific firewall filtering is supported for standard stateless firewall filters and for service filters. Interface-specific instances are not supported for simple filters.

### *Interface-Specific Names for Firewall Filter Instances*

When the Junos OS creates a separate instance of a firewall filter for a logical interface, the instance is associated with an interface-specific name. The system-generated name of a firewall filter instance consists of the name of the configured filter followed by a hyphen ('-'), the full interface name, and either '-i' for an input filter instance or '-o' for an output filter instance.

- **Input filter instance name**—For example, if you apply the interface-specific firewall filter **filter\_s\_tcp** to the input at logical interface **at-1/1/1.0**, the Junos OS instantiates an interface-specific filter instance with the following system-generated name:

**filter\_s\_tcp-at-1/1/1.0-i**

- **Output filter instance name**—For example, if you apply the interface-specific firewall filter **filter\_s\_tcp** to the output at logical interface **ge-2/2/2.2**, the Junos OS instantiates an interface-specific filter instance with the following system-generated name:

**count\_s\_tcp-ge-2/2/2.2-o**

You can use the interface-specific name of a filter instance when you enter a Junos OS operational mode command that specifies a stateless firewall filter name.

**TIP:** When you configure a firewall filter with interface-specific instances enabled, we recommend you limit the filter name to *52 bytes* in length. This is because firewall filter names are restricted to *64 bytes* in length. If a system-generated filter instance name exceeds this maximum length, the policy framework software might reject the instance name.

---

### ***Interface-Specific Firewall Filter Counters***

Instantiation of interface-specific firewall filters causes the Packet Forwarding Engine to maintain any counters for the firewall filter separately for each interface. You specify interface-specific counters per firewall filter term by specifying the **count counter-name** non-terminating action.

The system-generated name of an interface-specific firewall filter counter consists of the name of the configured counter followed by a hyphen ('-'), the full interface name, and either '-i' for an input filter instance or '-o' for an output filter instance.

- **Interface-specific input filter counter name**—For example, suppose you configure the filter counter **count\_tcp** for an interface-specific firewall filter. If the filter is applied to the input at logical interface **at-1/1/1.0**, the Junos OS creates the following system-generated counter name:

**count\_tcp-at-1/1/1.0-i**

- **Interface-specific output filter counter name**—For example, suppose you configure the filter counter **count\_udp** for an interface-specific firewall filter. If the filter is applied to the output at logical interface **ge-2/2/2.2**, the Junos OS creates the following system-generated counter name:

**count\_udp-ge-2/2/2.2-o**

### ***Interface-Specific Firewall Filter Policers***

Instantiation of interface-specific firewall filters not only creates separate instances of any firewall filter counters but also creates separate instances of any policer actions. Any policers applied through an action specified in the firewall filter configuration are applied separately to each interface in the interface group. You specify interface-specific policers per firewall filter term by specifying the **policer policer-name** non-terminating action.

### ***Filtering Packets Received on a Set of Interface Groups Overview***

You can configure a firewall filter term that matches packets tagged for a specified *interface group* or set of interface groups. An interface group consists of one or more

logical interfaces with the same group number. Packets received on an interface in an interface group are tagged as being part of that group.

For standard stateless firewall filters, you can filter packets received on an interface group for IPv4, IPv6, virtual private LAN service ( VPLS), Layer 2 circuit cross-connection (CCC), and Layer 2 bridging traffic. For service filters, you can filter packets received on an interface group for either IPv4 or IPv6 traffic.

**NOTE:** You can also configure a firewall filter term that matches on packets tagged for a specified *interface set*. For more information, see [“Filtering Packets Received on an Interface Set Overview”](#) on page 4515.

***Filtering Packets Received on an Interface Set Overview***

You can configure a standard stateless firewall filter term that matches packets tagged for a specified *interface set*. An interface set groups two or more physical or logical interfaces into a single interface-set name. You can filter packets received on an interface set for protocol-independent, IPv4, IPv6, MPLS, VPLS, or bridging traffic.

**NOTE:** You can also configure a standard stateless firewall filter term or a service filter term that matches on packets tagged for a specified *interface group*. For more information, see [“Filtering Packets Received on a Set of Interface Groups Overview”](#) on page 4514.

**Related  
Documentation**

***Filter-Based Forwarding Overview***

- [Filters That Classify Packets or Direct Them to Routing Instances](#) on page 4516
- [Input Filtering to Classify and Forward Packets Within the Router or Switch](#) on page 4516
- [Output Filtering to Forward Packets to Another Routing Table](#) on page 4517
- [Restrictions for Applying Filter-Based Forwarding](#) on page 4517

### ***Filters That Classify Packets or Direct Them to Routing Instances***

For IPv4 or IPv6 traffic only, you can use stateless firewall filters in conjunction with forwarding classes and routing instances to control how packets travel in a network. This is called *filter-based forwarding* (FBF).

You can define a filtering term that matches incoming packets based on source address and then classifies matching packets to a specified forwarding class. This type of filtering can be configured to grant certain types of traffic preferential treatment or to improve load balancing. To configure a stateless firewall filter to classify packets to a forwarding class, configure a term with the *nonterminating action* **forwarding-class class-name**.

You can also define a filtering term that directs matching packets to a specified routing instance. This type of filtering can be configured to route specific types of traffic through a firewall or other security device before the traffic continues on its path. To configure a stateless firewall filter to direct traffic to a routing instance, configure a term with the *terminating action* **routing-instance routing-instance-name <topology topology-name>** to specify the routing instance to which matching packets will be forwarded.

To forward traffic to the master routing instance, reference **routing-instance default** in the firewall configuration, as shown here:

```
[edit firewall]
family inet {
 filter test {
 term 1 {
 then {
 routing-instance default;
 }
 }
 }
}
```

**NOTE:** Do not reference **routing-instance master**. This does not work.

---

### ***Input Filtering to Classify and Forward Packets Within the Router or Switch***

You can configure filters to classify packets based on source address and specify the forwarding path the packets take within the router or switch by configuring a filter on the ingress interface.

For example, you can use this filter for applications to differentiate traffic from two clients that have a common access layer (for example, a Layer 2 switch) but are connected to different Internet service providers (ISPs). When the filter is applied, the router or switch can differentiate the two traffic streams and direct each to the appropriate network. Depending on the media type the client is using, the filter can use the source IP address to forward the traffic to the corresponding network through a tunnel. You can also configure filters to classify packets based on IP protocol type or IP precedence bits.

### ***Output Filtering to Forward Packets to Another Routing Table***

You can also forward packets based on output filters by configuring a filter on the egress interfaces. In the case of port mirroring, it is useful for port-mirrored packets to be distributed to multiple monitoring PICs and collection PICs based on patterns in packet headers. FBF on the port-mirroring egress interface must be configured.

Packets forwarded to the output filter have been through at least one route lookup when an FBF filter is configured on the egress interface. After the packet is classified at the egress interface by the FBF filter, it is redirected to another routing table for further route lookup.

### ***Restrictions for Applying Filter-Based Forwarding***

An interface configured with filter-based forwarding does not support source-class usage (SCU) filter matching and unicast reverse-path forwarding (RPF) check filters.

### ***Accounting for Standard Firewall Filters Overview***

Juniper Networks devices can collect various kinds of data about traffic passing through the device. You can set up one or more accounting profiles that specify some common characteristics of this data, including the following:

- Fields used in the accounting records.
- Number of files that the routing platform retains before discarding, and the number of bytes per file.
- Polling period that the system uses to record the data

There are several types of accounting profiles: interface, firewall filter, source class and destination class usage, and Routing Engine. If you apply the same profile name to both a firewall filter and an interface, it causes an error.

### ***System Logging Overview***

The Junos OS generates system log messages (also called *syslog messages*) to record *system events* that occur on the device. Events consist of routine operations, failure and error conditions, and critical conditions that might require urgent resolution. This system logging utility is similar to the UNIX **syslogd** utility.

Each Junos OS system log message belongs to a message category, called a *facility*, that reflects the hardware- or software-based source of the triggering event. A group of messages belonging to the same facility are either generated by the same software

process or concern a similar hardware condition or user activity (such as authentication attempts). Each system log message is also preassigned a *severity*, which indicates how seriously the triggering event affects router (or switch) functions. Together, the facility and severity of an event are known as the message *priority*. The content of a syslog message identifies the Junos OS *process* that generates the message and briefly describes the operation or error that occurred.

By default, syslog messages that have a severity of **info** or more serious are written to the main system log file **messages** in the **/var/log** directory of the local Routing Engine. To configure global settings and facility-specific settings that override these default values, you can include statements at the **[edit system syslog]** hierarchy level.

For all syslog facilities or for a specified facility, you can configure the syslog message utility to redirect messages of a specified severity to a specified file instead of to the main system log file. You can also configure the syslog message utility to write syslog messages of a specified severity, for all syslog facilities or for a specified facility, to additional destinations. In addition to writing syslog messages to a log file, you can write syslog messages to the terminal sessions of any logged-in users, to the router (or switch) console, or to a remote host or the other Routing Engine.

At the global level—for all system logging messages, regardless of facility, severity, or destination—you can override the default values for file-archiving properties and the default timestamp format.

**Related  
Documentation**

- [System Logging of Events Generated for the Firewall Facility on page 4518](#)
- [Logging of Packet Headers Evaluated by a Firewall Filter Term on page 4520](#)
- [Example: Configuring Logging for a Stateless Firewall Filter Term](#)

### ***System Logging of Events Generated for the Firewall Facility***

System log messages generated for firewall filter actions belong to the **firewall** facility. Just as you can for any other Junos OS system logging facility, you can direct **firewall** facility syslog messages to one or more specific destinations: to a specified file, to the terminal session of one or more logged in users (or to all users), to the router (or switch) console, or to a remote host or the other Routing Engine on the router (or switch).

When you configure a syslog message destination for **firewall** facility syslog messages, you include a statement at the **[edit system syslog]** hierarchy level, and you specify the **firewall** facility name together with a severity level. Messages from the **firewall** that are rated at the specified level or more severe are logged to the destination.

System log messages with the **DFWD\_** prefix are generated by the firewall process (**dfwd**), which manages compilation and downloading of Junos OS firewall filters. System log messages with the **PFE\_FW\_** prefix are messages about firewall filters, generated by the Packet Forwarding Engine controller, which manages packet forwarding functions. For more information, see the *Junos OS System Log Messages Reference*.

[Table 337 on page 4519](#) lists the system log destinations you can configure for the **firewall** facility.

Table 337: Syslog Message Destinations for the Firewall Facility

| Destination                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Configuration Statements                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Router (or switch) console              | <p>Configuring this option causes a copy of the <b>firewall</b> syslog messages to be written to the router (or switch) console.</p>                                                                                                                                                                                                                                                                                                                                                       | <pre>[edit] system {   syslog {     console {       firewall <i>severity</i>;     }     time-format (<i>option</i>); # Local destinations   } }</pre>                                                                                                                                                                                                                                                                                                                 |
| Remote host or the other Routing Engine | <p>Configuring this option causes a copy of the <b>firewall</b> syslog messages to be written to the specified remote host or to the other Routing Engine.</p> <p>To override the default alternative facility for forwarding <b>firewall</b> syslog messages to a remote machine (<b>local3</b>), include the <b>facility-override firewall</b> statement.</p> <p>To include priority and facility with messages written to the file, include the <b>explicit-priority</b> statement.</p> | <pre>[edit] system {   syslog {     host (<i>hostname</i>   other-routing-engine) {       firewall <i>severity</i>;       allow-duplicates; # Host option       archive <i>archive-options</i>; # File option       facility-override firewall; # Host option       explicit-priority; # Host option     }     allow-duplicates; # All destinations     archive <i>archive-options</i>; # All files     time-format (<i>option</i>); # Local destinations   } }</pre> |

<sup>†</sup> When the **structured-data** statement is included, other statements that specify the format for messages written to the file are ignored (the **explicit-priority** statement at the [edit system syslog file *filename*] hierarchy level and the **time-format** statement at the [edit system syslog] hierarchy level).

By default, the timestamp recorded in a standard-format system log message specifies the month, date, hour, minute, and second when the message was logged, as in the example:

**Sep 07 08:00:10**

To include the year, the millisecond, or both in the timestamp for all system logging messages, regardless of the facility, include one of the following statement at the **[edit system syslog]** hierarchy level:

- **time-format year;**
- **time-format millisecond;**
- **time-format year millisecond;**

The following example illustrates the format for a timestamp that includes both the millisecond (401) and the year (2010):

**Sep 07 08:00:10.401.2010**

#### **Logging of Packet Headers Evaluated by a Firewall Filter Term**

Built in to the stateless firewall filtering software is the capability to log packet-header information for the packets evaluated by a stateless firewall filter term. You can write the packet header information to the system log file on the local Routing Engine or to a firewall filter buffer in the Packet Forwarding Engine. Logging of packet headers evaluated by firewall filters is supported for standard stateless firewall filters for IPv4 or IPv6 traffic only. Service filters and simple filters do not support logging of packet headers.

Table 338 on page 4521 lists the packet-header logs you can configure for a firewall filter action.

**Table 338: Packet-Header Logs for Stateless Firewall Filter Terms**

| Log                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Configuration Statements                                                                                                                                                                          |

### Introduction to Service Filters Configuration

- [Service Filter Overview on page 4522](#)
- [How Service Filters Evaluate Packets on page 4523](#)
- [Guidelines for Configuring Service Filters on page 4524](#)
- [Guidelines for Applying Service Filters on page 4526](#)

### Service Filter Overview

This topic covers the following information:

- [Services on page 4522](#)
- [Service Rules on page 4522](#)
- [Service Rule Refinement on page 4522](#)
- [Service Filter Counters on page 4522](#)

### Services

The Adaptive Services Physical Interface Cards (PICs), Multiservices PICs, and Multiservices Dense Port Concentrators (DPCs) provide *adaptive services interfaces*. Adaptive services interfaces enable you to coordinate a special range of services on a single PIC or DPC by configuring a set of services and applications.

**NOTE:** Service filters are not supported on T4000 routers, J Series devices and Branch SRX devices.

### Service Rules

A *service set* is an optional definition you can apply to the traffic at an adaptive services interface. A service set enables you to configure combinations of directional rules and default settings that control the behavior of each service in the service set.

### Service Rule Refinement

When you apply a service set to the traffic at an adaptive services interface, you can optionally use *service filters* to refine the target of the set of services and also to process traffic. Service filters enable you to manipulate traffic by performing packet filtering to a defined set of services on an adaptive services interface before the traffic is delivered to its destination. You can apply a service filter to traffic before packets are accepted for input or output service processing or after packets return from input service processing.

### Service Filter Counters

Like standard firewall filters, service filters support counting of matched packets. When you display counters for a service filter, however, the syntax for specifying the filter name includes the name of the *service set* to which the service filter is applied.

- To enable counting of the packets matched by a service filter term, specify the **count counter-name** nonterminating action in that term.
- To display counters for service filters, use the **show firewall filter filter-name <counter counter-name>** operational mode command, and specify the **filter-name** as follows:

**`__service-service-set-name:service-filter-name`**

For example, suppose you configure a service filter named **out\_filter** with a counter named **out\_counter** and apply that service filter to a logical interface to direct certain packets for processing by the output services associated with the service set **nat\_set**. In this scenario, the syntax for using the **show firewall** operational mode command to display the counter is as follows:

```
[edit]
user@host> show firewall filter __service-nat_set:out_filter counter out_counter
```

#### **How Service Filters Evaluate Packets**

This topic covers the following information:

- [Service Filters That Contain a Single Term on page 4523](#)
- [Service Filters That Contain Multiple Terms on page 4524](#)
- [Service Filter Terms That Do Not Contain Any Match Conditions on page 4524](#)
- [Service Filter Terms That Do Not Contain Any Actions on page 4524](#)
- [Service Filter Default Action on page 4524](#)

#### **Service Filters That Contain a Single Term**

For a service filter that consists of a single term, the policy framework software evaluates a packet as follows:

- If the packet matches all the conditions, the actions are taken.
- If the packet matches all the conditions and no actions are specified, the packet is accepted.
- If the packet does not match all the conditions, it is discarded.

### ***Service Filters That Contain Multiple Terms***

For a service filter that consists of multiple terms, the policy framework software evaluates a packet against the terms in the filter sequentially, beginning with the first term in the filter, until either the packet matches all the conditions in one of the terms or there are no more terms in the filter.

- If the packet matches all the conditions in a term, the actions in that term are performed and evaluation of the packet ends at that term. Any subsequent terms in the filter are not used.
- If the packet does not match all the conditions in the term, evaluation of the packet proceeds to the next term in the filter.

### ***Service Filter Terms That Do Not Contain Any Match Conditions***

For service filters with a single term and for filters with multiple terms, if a term does not contain any match conditions, the actions are taken on any packet evaluated.

### ***Service Filter Terms That Do Not Contain Any Actions***

If a term does not contain any actions, and if the packet matches the conditions in the term, the packet is accepted.

### ***Service Filter Default Action***

Each service filter has an *implicit skip* action at the end of the filter, which is equivalent to including the following example term **explicit\_skip** as the final term in the service filter:

```
term explicit_skip {
 then skip;
}
```

By default, if a packet matches none of the terms in a service filter, the packet bypasses service processing.

- [Example: Configuring and Applying Service Filters on page 4678](#)

### ***Guidelines for Configuring Service Filters***

This topic covers the following information:

- [Statement Hierarchy for Configuring Service Filters on page 4525](#)
- [Service Filter Protocol Families on page 4525](#)
- [Service Filter Names on page 4525](#)
- [Service Filter Terms on page 4525](#)
- [Service Filter Match Conditions on page 4526](#)
- [Service Filter Terminating Actions on page 4526](#)

### Statement Hierarchy for Configuring Service Filters

To configure a service filter, include the **service-filter service-filter-name** statement at the **[edit firewall family (inet | inet6)]** hierarchy level:

```
[edit]
firewall {
 family (inet | inet6) {
 service-filter service-filter-name {
 term term-name {
 from {
 match-conditions;
 }
 then {
 actions;
 }
 }
 }
 }
}
```

Individual statements supported under the **service-filter service-filter-name** statement are described separately in this topic and are illustrated in the example of configuring and applying a service filter.

### Service Filter Protocol Families

You can configure service filters to filter IPv4 traffic (**family inet**) and IPv6 traffic (**family inet6**) only. No other protocol families are supported for service filters.

### Service Filter Names

Under the **family inet** or **family inet6** statement, you can include **service-filter service-filter-name** statements to create and name service filters. The filter name can contain letters, numbers, and hyphens (-) and be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

### Service Filter Terms

Under the **service-filter service-filter-name** statement, you can include **term term-name** statements to create and name filter terms.

- You must configure at least one term in a firewall filter.
- You must specify a unique name for each term within a firewall filter. The term name can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").
- The order in which you specify terms within a firewall filter configuration is important. Firewall filter terms are evaluated in the order in which they are configured. By default, new terms are always added to the end of the existing filter. You can use the **insert** configuration mode command to reorder the terms of a firewall filter.

### ***Service Filter Match Conditions***

Service filter terms support only a subset of the IPv4 and IPv6 match conditions that are supported for standard stateless firewall filters.

If you specify an IPv6 address in a match condition (the **address**, **destination-address**, or **source-address** match conditions), use the syntax for text representations described in RFC 2373, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see “IPv6 Overview” and “IPv6 Standards” in the *Junos OS Routing Protocols Configuration Guide*.

### ***Service Filter Terminating Actions***

When configuring a service filter term, you must specify one of the following filter-terminating actions:

- **service**
- **skip**

**NOTE:** These actions are unique to service filters.

---

Service filter terms support only a subset of the IPv4 and IPv6 nonterminating actions that are supported for standard stateless firewall filters:

- **count** *counter-name*
- **log**
- **port-mirror**
- **sample**

Service filters do not support the **next** action.

### ***Guidelines for Applying Service Filters***

This topic covers the following information:

- [Restrictions for Adaptive Services Interfaces on page 4527](#)
- [Statement Hierarchy for Applying Service Filters on page 4527](#)

- [Associating Service Rules with Adaptive Services Interfaces on page 4528](#)
- [Filtering Traffic Before Accepting Packets for Service Processing on page 4528](#)
- [Postservice Filtering of Returning Service Traffic on page 4529](#)

### ***Restrictions for Adaptive Services Interfaces***

The following restrictions apply to adaptive services interfaces and service filters.

#### ***Adaptive Services Interfaces***

You can apply a service filter to IPv4 or IPv6 traffic associated with a service set at an *adaptive services interface* only. Adaptive services interfaces are supported for the following hardware only:

- Adaptive Services (AS) PICs on M Series and T Series routers
- Multiservices (MS) PICs on M Series and T Series routers
- Multiservices (MS) DPCs on MX Series routers (and EX Series switches)

#### ***System Logging to a Remote Host from M Series Routers***

Logging of adaptive services interfaces messages to an external server by means of the **fxp0** or **em0** port is not supported on M Series routers. The architecture does not support system logging traffic out of a management interface. Instead, access to an external server is supported on a Packet Forwarding Engine interface.

#### ***Statement Hierarchy for Applying Service Filters***

You can enable packet filtering of IPv4 or IPv6 traffic before a packet is accepted for input or output service processing. To do this, apply a service filter to the adaptive services interface input or output in conjunction with an interface service set.

You can also enable packet filtering of IPv4 or IPv6 traffic that is returning to the Packet Forwarding Engine after input service processing completes. To do this, apply a post-service filter to the adaptive services interface input.

The following configuration shows the hierarchy levels at which you can apply the service filters to adaptive services interfaces:

```
[edit]
interfaces {
 interface-name {
 unit unit-number {
 family (inet | inet6) {
 service {
 input {
 service-set service-set-name service-filter service-filter-name;
 post-service-filter service-filter-name;
 }
 output {
 service-set service-set-name service-filter service-filter-name;
 }
 }
 }
 }
 }
}
```

```
}
}
```

### ***Associating Service Rules with Adaptive Services Interfaces***

To define and group the service rules to be applied to an adaptive services interface, you define an *interface service set* by including the **service-set service-set-name** statement at the **[edit services]** hierarchy level.

To apply an interface service set to the input and output of an adaptive services interface, you include the **service-set service-set-name** at the following hierarchy levels:

- **[edit interfaces interface-name unit unit-number input]**
- **[edit interfaces interface-name unit unit-number output]**

If you apply a service set to one direction of an adaptive services interface but do not apply a service set to the other direction, an error occurs when you commit the configuration.

The adaptive services PIC performs different actions depending on whether the packet is sent to the PIC for input service or for output service. For example, you can configure a single service set to perform Network Address Translation (NAT) in one direction and destination NAT (dNAT) in the other direction.

### ***Filtering Traffic Before Accepting Packets for Service Processing***

To filter IPv4 or IPv6 traffic before accepting packets for input or output service processing, include the **service-set service-set-name service-filter service-filter-name** at one of the following interfaces:

- **[edit interfaces interface-name unit unit-number family (inet | inet6) service input]**
- **[edit interfaces interface-name unit unit-number family (inet | inet6) service output]**

For the **service-set-name**, specify a service set configured at the **[edit services service-set]** hierarchy level.

The service set retains the input interface information even after services are applied, so that functions such as filter-class forwarding and destination class usage (DCU) that depend on input interface information continue to work.

The following requirements apply to filtering inbound or outbound traffic before accepting packets for service processing:

- You configure the same service set on the input and output sides of the interface.
- If you include the **service-set** statement without an optional **service-filter** definition, the Junos OS assumes the match condition is true and selects the service set for processing automatically.
- The service filter is applied only if a service set is configured and selected.

You can include more than one service set definition on each side of an interface. The following guidelines apply:

- If you include multiple service sets, the router (or switch) software evaluates them in the order in which they appear in the configuration. The system executes the first service set for which it finds a match in the service filter and ignores the subsequent definitions.
- A maximum of six service sets can be applied to an interface.
- When you apply multiple service sets to an interface, you must also configure and apply a service filter to the interface.

### ***Postservice Filtering of Returning Service Traffic***

As an option to filtering of IPv4 or IPv6 input service traffic, you can apply a service filter to IPv4 or IPv6 traffic that is returning to the services interface after the service set is executed. To apply a service filter in this manner, include the **post-service-filter service-filter-name** statement at the **[edit interfaces interface-name unit unit-number family (inet | inet6) service input]** hierarchy level.

- [How Simple Filters Evaluate Packets on page 4530](#)
- [Guidelines for Configuring Simple Filters on page 4531](#)
- [Guidelines for Applying Simple Filters on page 4534](#)

### ***Simple Filter Overview***

Simple filters are supported on Gigabit Ethernet intelligent queuing 2 (IQ2) and Enhanced Queuing Dense Port Concentrator (DPC) interfaces only.

Simple filters are recommended for metropolitan Ethernet applications.

### ***How Simple Filters Evaluate Packets***

This topic covers the following information:

- [Simple Filters That Contain a Single Term on page 4530](#)
- [Simple Filters That Contain Multiple Terms on page 4530](#)
- [Simple Filter Terms That Do Not Contain Any Match Conditions on page 4530](#)
- [Simple Filter Terms That Do Not Contain Any Actions on page 4530](#)
- [Simple Filter Default Action on page 4530](#)

### ***Simple Filters That Contain a Single Term***

For a simple filter that consists of a single term, the policy framework software evaluates a packet as follows:

- If the packet matches all the conditions, the actions are taken.
- If the packet matches all the conditions and no actions are specified, the packet is accepted.
- If the packet does not match all the conditions, it is discarded.

### ***Simple Filters That Contain Multiple Terms***

For a simple filter that consists of multiple terms, the policy framework software evaluates a packet against the terms in the filter sequentially, beginning with the first term in the filter, until either the packet matches all the conditions in one of the terms or there are no more terms in the filter.

- If the packet matches all the conditions in a term, the actions in that term are performed and evaluation of the packet ends at that term. Any subsequent terms in the filter are not used.
- If the packet does not match all the conditions in the term, evaluation of the packet proceeds to the next term in the filter.

### ***Simple Filter Terms That Do Not Contain Any Match Conditions***

For simple filters with a single term and for filters with multiple terms, if a term does not contain any match conditions, the actions are taken on any packet evaluated.

### ***Simple Filter Terms That Do Not Contain Any Actions***

If a simple filter term does not contain any actions, and if the packet matches the conditions in the term, the packet is accepted.

### ***Simple Filter Default Action***

Each simple filter has an *implicit discard* action at the end of the filter, which is equivalent to including the following example term **explicit\_discard** as the final term in the simple filter:

```
term explicit_discard {
```

```

 then discard;
}

```

By default, if a packet matches none of the terms in a simple filter, the packet is discarded.

#### *Guidelines for Configuring Simple Filters*

This topic covers the following information:

- [Statement Hierarchy for Configuring Simple Filters on page 4531](#)
- [Simple Filter Protocol Families on page 4531](#)
- [Simple Filter Names on page 4532](#)
- [Simple Filter Terms on page 4532](#)
- [Simple Filter Match Conditions on page 4532](#)
- [Simple Filter Terminating Actions on page 4533](#)
- [Simple Filter Nonterminating Actions on page 4533](#)

#### *Statement Hierarchy for Configuring Simple Filters*

To configure a simple filter, include the **simple-filter** *simple-filter-name* statement at the **[edit firewall family inet]** hierarchy level.

```

[edit]
firewall {
 family inet {
 simple-filter simple-filter-name {
 term term-name {
 from {
 match-conditions;
 }
 then {
 actions;
 }
 }
 }
 }
}

```

Individual statements supported under the **simple-filter** *simple-filter-name* statement are described separately in this topic and are illustrated in the example of configuring and applying a simple filter.

#### *Simple Filter Protocol Families*

You can configure simple filters to filter IPv4 traffic (**family inet**) only. No other protocol family is supported for simple filters.

### ***Simple Filter Names***

Under the **family inet** statement, you can include **simple-filter *simple-filter-name*** statements to create and name simple filters. The filter name can contain letters, numbers, and hyphens (-) and be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

### ***Simple Filter Terms***

Under the **simple-filter *simple-filter-name*** statement, you can include **term *term-name*** statements to create and name filter terms.

- You must configure at least one term in a firewall filter.
- You must specify a unique name for each term within a firewall filter. The term name can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").
- The order in which you specify terms within a firewall filter configuration is important. Firewall filter terms are evaluated in the order in which they are configured. By default, new terms are always added to the end of the existing filter. You can use the **insert** configuration mode command to reorder the terms of a firewall filter.

Simple filters do *not* support the **next term** action.

### ***Simple Filter Match Conditions***

Simple filter terms support only a subset of the IPv4 match conditions that are supported for standard stateless firewall filters.

Unlike standard stateless firewall filters, the following restrictions apply to simple filters:

- On MX Series routers with the Enhanced Queuing DPC and on EX Series switches, simple filters do *not* support the **forwarding-class** match condition.
- Simple filters support only one **source-address** and one **destination-address** prefix for each filter term. If you configure multiple prefixes, only the last one is used.
- Simple filters do *not* support multiple source addresses and destination addresses in a single term. If you configure multiple addresses, only the last one is used.
- Simple filters do *not* support negated match conditions, such as the **protocol-except** match condition or the **exception** keyword.
- Simple filters support a range of values for **source-port** and **destination-port** match conditions only. For example, you can configure **source-port 400-500** or **destination-port 600-700**.
- Simple filters do *not* support noncontiguous mask values.

[Table 339 on page 4533](#) lists the simple filter match conditions.

Table 339: Simple Filter Match Conditions

| Match Condition                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>source-address</b><br><i>ip-source-address</i>        | Match the IP source address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>source-port</b> <i>number</i>                         | <p>Match the UDP or TCP source port field.</p> <p>If you configure this match condition, we recommend that you also configure the <b>protocol</b> match statement to determine which protocol is being used on the port.</p> <p>In place of the numeric field, you can specify one of the text aliases listed for <b>destination-port</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### Simple Filter Terminating Actions

Simple filters do *not* support explicitly configurable terminating actions, such as **accept**, **reject**, and **discard**. Terms configured in a simple filter always accept packets.

Simple filters do *not* support the **next** action.

### Simple Filter Nonterminating Actions

Simple filters support only the following nonterminating actions:

- **forwarding-class** (*forwarding-class* | **assured-forwarding** | **best-effort** | **expedited-forwarding** | **network-control**)

**NOTE:** On MX Series routers and EX Series switches with the Enhanced Queuing DPC, the forwarding class is not supported as a from match condition.

- **loss-priority (high | low | medium-high | medium-low)**

Simple filters do not support actions that perform other functions on a packet (such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality).

- [Restrictions for Applying Simple Filters on page 4534](#)

#### *Statement Hierarchy for Applying Simple Filters*

You can apply a simple filter to the IPv4 ingress traffic at a logical interface by including the **simple-filter** input *simple-filter-name* statement at the [edit interfaces *interface-name* unit *unit-number* family inet] hierarchy level.

```
[edit]
interfaces {
 interface-name {
 unit logical-unit-number {
 family inet {
 simple-filter {
 input filter-name;
 }
 }
 }
 }
}
```

#### *Restrictions for Applying Simple Filters*

You can apply a simple filter to the ingress IPv4 traffic at a logical interface configured on the following hardware only:

- Gigabit Ethernet intelligent queuing (IQ2) PICs installed on M120, M320, or T Series routers.
- Enhanced Queuing Dense Port Concentrators (EQ DPCs) installed on MX Series routers and EX Series switches.

For more information about Ethernet IQ2 PICs and EQ DPCs and related features, see the *Junos OS Class of Service Configuration Guide*. For more information about configuring the MX Series routers, on which EQ DPCs are supported, see the *Junos OS Layer 2 Configuration Guide*.

The following additional restrictions pertain to applying simple filters:

- Simple filters are not supported on Modular Port Concentrator (MPC) interfaces, including Enhanced Queuing MPC interfaces.
- Simple filters are not supported for interfaces in an aggregated-Ethernet bundle.
- You can apply simple filters to **family inet** traffic only. No other protocol family is supported.
- You can apply simple filters to ingress traffic only. Egress traffic is not supported.
- You can apply only a single simple filter to a supported logical interface. Input lists are not supported.

#### ***Stateless Firewall Filters in Logical Systems Overview***

This topic covers the following information:

- [Logical Systems on page 4535](#)
- [Stateless Firewall Filters in Logical Systems on page 4536](#)
- [Identifiers for Firewall Objects in Logical Systems on page 4536](#)

#### ***Logical Systems***

With the Junos OS, you can partition a single physical router or switch into multiple logical devices that perform independent routing tasks. Because logical systems perform a subset of the tasks once handled by the physical router or switch, logical systems offer an effective way to maximize the use of a single router or switch.

### ***Stateless Firewall Filters in Logical Systems***

You can configure a separate set of stateless firewall filters for each logical system on a router or switch. To configure a filter in a logical system, you must define the filter in the **firewall** stanza at the **[edit logical-systems *logical-system-name*]** hierarchy level, and you must apply the filter to a logical interface that is also configured at the **[edit logical-systems *logical-system-name*]** hierarchy level.

### ***Identifiers for Firewall Objects in Logical Systems***

To identify firewall objects configured under logical systems, operational **show** commands and firewall-related SNMP MIB objects include a **\_\_logical-system-name/** prefix in the object name. For example, firewall objects configured under the **ls1** logical system include **\_\_ls1/** as the prefix.

### ***Statement Hierarchy for Configuring Firewall Filters in Logical Systems***

To configure a firewall filter in a logical system, include the **filter**, **service-filter**, or **simple-filter** statement at the **[edit logical-systems *logical-system-name* firewall family *family-name*]** hierarchy level.

```
[edit]
logical systems {
 logical-system-name {
 firewall {
 family family-name {
```

```
filter filter-name {
 interface-specific;
 physical-interface-filter;
 term term-name {
 filter filter-name;
 from {
 match-conditions;
 }
 then {
 actions;
 }
 }
}

service-filter filter-name { # For 'family inet' or 'family inet6' only.
 term term-name {
 from {
 match-conditions;
 }
 then {
 actions;
 }
 }
}

simple-filter filter-name { # For 'family inet' only.
 term term-name {
 from {
 match-conditions;
 }
 then {
 actions;
 }
 }
}
}
```

## Filter Types in Logical Systems

There are no special restrictions on the types of stateless firewall filter types that you can configure in logical systems.

In a logical system, you can use the same types of stateless firewall filters that are available on a physical router or switch:

- Standard stateless firewall filters
- Service filters
- Simple filters

## Firewall Filter Protocol Families in Logical Systems

There are no special restrictions on the protocol families supported with stateless firewall filters in logical systems.

In a logical system, you can filter the same protocol families as you can on a physical router or switch.

- Standard stateless firewall filters—In logical systems, you can filter the following traffic types: protocol-independent, IPv4, IPv6, MPLS, MPLS-tagged IPv4 or IPv6, VPLS, Layer 2 circuit cross-connection, and Layer 2 bridging.
- Service filters—In logical systems, you can filter IPv4 and IPv6 traffic.
- Simple filters—In logical systems, you can filter IPv4 traffic only.

### ***Firewall Filter Match Conditions in Logical Systems***

There are no special restrictions on the match conditions supported with stateless firewall filters in logical systems.

### ***Firewall Filter Actions in Logical Systems***

There are no special restrictions on the actions supported with stateless firewall filters in logical systems.

### ***Statement Hierarchy for Applying Firewall Filters in Logical Systems***

To apply a firewall filter in a logical system, include the **filter** *filter-name*, **service-filter** *service-filter-name*, or **simple-filter** *simple-filter-name* statement to a logical interface in the logical system.

The following configuration shows the hierarchy levels at which you can apply the statements:

```
[edit]
logical-systems logical-system-name {
 interfaces {
 interface-name {
 unit logical-unit-number {
 family family-name {
 filter {
 group group-name;
 input filter-name;
 input-list [filter-names];
 output filter-name;
 output-list [filter-names]
 }
 rpf-check { # For 'family inet' or 'family inet6' only.
 fail-filter filter-name;
 mode loose;
 }
 service { # For 'family inet' or 'family inet6' only.
 input {
 service-set service-set-name <service-filter service-filter-name>;
 post-service-filter service-filter-name;
 }
 output {
 service-set service-set-name <service-filter service-filter-name>;
 }
 }
 simple-filter { # For 'family inet' only.
```

```

 input simple-filter-name;
 }
 }
 }
}

```

#### *References from a Firewall Filter in a Logical System to Subordinate Objects*

This topic covers the following information:

- [Resolution of References from a Firewall Filter to Subordinate Objects on page 4539](#)
- [Valid Reference from a Firewall Filter to a Subordinate Object on page 4539](#)

#### *Resolution of References from a Firewall Filter to Subordinate Objects*

If a firewall filter defined in a logical system references a subordinate object (for example, a policer or prefix list), that subordinate object must be defined within the **firewall** stanza of the same logical system. For example, if a firewall filter configuration references a policer, the firewall filter and the policer must be configured under the same **[edit logical-systems logical-system-name firewall]** hierarchy level.

This rule applies even if the same policer is configured under the main firewall configuration or if the same policer is configured as part of a firewall in another logical system.

#### *Valid Reference from a Firewall Filter to a Subordinate Object*

In this example, the firewall filter **filter1** references the policer **pol1**. Both **filter1** and **pol1** are defined under the same firewall object. This configuration is valid. If **pol1** had been defined under another firewall object, the configuration would not be valid.

```

[edit]
logical systems {
 ls-A {
 firewall {
 policer pol1 {
 if-exceeding {
 bandwidth-limit 401k;
 burst-size-limit 50k;
 }
 }
 }
 }
}

```

```
 then discard;
 }
 filter filter1 {
 term one {
 from {
 source-address 12.1.0.0/16;
 }
 then {
 reject host-unknown;
 }
 }
 term two {
 from {
 source-address 12.2.0.0/16;
 }
 then policer pol1;
 }
 }
}
```

***References from a Firewall Filter in a Logical System to Nonfirewall Objects***

This topic covers the following information:

- [Resolution of References from a Firewall Filter to Nonfirewall Objects on page 4540](#)
- [Valid Reference to a Nonfirewall Object Outside of the Logical System on page 4541](#)

***Resolution of References from a Firewall Filter to Nonfirewall Objects***

In many cases, a firewall configuration references objects outside the firewall configuration. As a general rule, the referenced object must be defined under the same logical system as the referencing object. However, there are cases when the configuration of the referenced object is not supported at the `[edit logical-systems logical-system-name]` hierarchy level.

### *Valid Reference to a Nonfirewall Object Outside of the Logical System*

This example configuration illustrates an exception to the general rule that the objects referenced by a firewall filter in a logical system must be defined under the same logical system as the referencing object.

In the following scenario, the service filter **inetsf1** is applied to IPv4 traffic associated with the service set **fred** at the logical interface **fe-0/3/2.0**, which is on an adaptive services interface.

- Service filter **inetsf1** is defined in **ls-B** and references prefix list **prefix1**.
- Service set **fred** is defined at the main services hierarchy level, and the policy framework software searches the **[edit services]** hierarchy for the definition of the **fred** service set.

Because service rules cannot be configured in logical systems, firewall filter configurations in the **[edit logical-systems logical-system logical-system-name]** hierarchy are allowed to reference *service sets* outside the logical system hierarchy.

```
[edit]
logical-systems {
 ls-B {
 interfaces {
 fe-0/3/2 {
 unit 0 {
 family inet {
 service {
 input {
 service-set fred service-filter inetsf1;
 }
 }
 }
 }
 }
 }
 }
 policy-options {
 prefix-list prefix1 {
 1.1.0.0/16;
 1.2.0.0/16;
 1.3.0.0/16;
 }
 }
 firewall { # Under logical-system 'ls-B'.
 family inet {

***References from a Nonfirewall Object in a Logical System to a Firewall Filter***

This topic covers the following information:

- [Resolution of References from a Nonfirewall Object to a Firewall Filter on page 4543](#)
- [Invalid Reference to a Firewall Filter Outside of the Logical System on page 4543](#)
- [Valid Reference to a Firewall Filter Within the Logical System on page 4544](#)
- [Valid Reference to a Firewall Filter Outside of the Logical System on page 4546](#)

**Resolution of References from a Nonfirewall Object to a Firewall Filter**

If a nonfirewall filter object in a logical system references an object in a firewall filter configured in a logical system, the reference is resolved using the following logic:

- If the nonfirewall filter object is configured in a logical system that includes firewall filter configuration statements, the policy framework software searches the **[edit logical-systems logical-system-name firewall]** hierarchy level. Firewall filter configurations that belong to *other* logical systems or to the main **[edit firewall]** hierarchy level are not searched.
- If the nonfirewall filter object is configured in a logical system that does not include any firewall filter configuration statements, the policy framework software searches the firewall configurations defined at the **[edit firewall]** hierarchy level.

**Invalid Reference to a Firewall Filter Outside of the Logical System**

This example configuration illustrates an unresolvable reference from a nonfirewall object in a logical system to a firewall filter.

In the following scenario, the stateless firewall filters **filter1** and **fred** are applied to the logical interface **fe-0/3/2.0** in the logical system **ls-C**.

- Filter **filter1** is defined in **ls-C**.
- Filter **fred** is defined in the main firewall configuration.

Because **ls-C** contains firewall filter statements (for **filter1**), the policy framework software resolves references to and from firewall filters by searching the **[edit logical systems ls-C firewall]** hierarchy level. Consequently, the reference from **fe-0/3/2.0** in the logical system to **fred** in the main firewall configuration cannot be resolved.

```
[edit]
logical-systems {
 ls-C {
 interfaces {
 fe-0/3/2 {
 unit 0 {
 family inet {
 filter {
 input-list [filter1 fred];
 }
 }
 }
 }
 }
 }
 firewall { # Under logical system 'ls-C'.
 family inet {
 filter filter1 {
 term one {
 from {
 source-address 12.1.0.0/16;
 }
 then {
 reject host-unknown;
 }
 }
 }
 }
 }
}
```

```
 }
 term two {
 from {
 source-address 12.2.0.0/16;
 }
 then policer pol1;
 }
 }
}
policer pol1 {
 if-exceeding {
 bandwidth-limit 401k;
 burst-size-limit 50k;
 }
 then discard;
}
}
}
} # End of logical systems
firewall { # Under the main firewall hierarchy level
 family inet {
 filter fred {
 term one {
 from {
 source-address 11.1.0.0/16;
 }
 then {
 log;
 reject host-unknown;
 }
 }
 }
 }
}
} # End of main firewall configurations.
```

#### ***Valid Reference to a Firewall Filter Within the Logical System***

This example configuration illustrates resolvable references from a nonfirewall object in a logical system to two firewall filter.

In the following scenario, the stateless firewall filters **filter1** and **fred** are applied to the logical interface **fe-0/3/2.0** in the logical system **ls-C**.

- Filter **filter1** is defined in **ls-C**.
- Filter **fred** is defined in **ls-C** and also in the main firewall configuration.

Because **ls-C** contains firewall filter statements, the policy framework software resolves references to and from firewall filters by searching the **[edit logical systems ls-C firewall]** hierarchy level. Consequently, the references from **fe-0/3/2.0** in the logical system to **filter1** and **fred** use the stateless firewall filters configured in **ls-C**.

```
[edit]
logical-systems {
 ls-C {
 interfaces {
 fe-0/3/2 {
```

```

 unit 0 {
 family inet {
 filter {
 input-list [filter1 fred];
 }
 }
 }
}
firewall { # Under logical system 'ls-C'.
 family inet {
 filter filter1 {
 term one {
 from {
 source-address 12.1.0.0/16;
 }
 then {
 reject host-unknown;
 }
 }
 term two {
 from {
 source-address 12.2.0.0/16;
 }
 then policer pol1;
 }
 }
 filter fred { # This 'fred' is in 'ls-C'.
 term one {
 from {
 source-address 10.1.0.0/16;
 }
 then {
 log;
 reject host-unknown;
 }
 }
 }
 }
}
policer pol1 {
 if-exceeding {
 bandwidth-limit 401k;
 burst-size-limit 50k;
 }
 then discard;
}
}
} # End of logical systems configurations.
firewall { # Main firewall filter hierarchy level
 family inet {
 filter fred {
 term one {
 from {
 source-address 11.1.0.0/16;
 }
 }
 }
 }
}

```

```
 then {
 log;
 reject host-unknown;
 }
 }
}
}
} # End of main firewall configurations.
```

### ***Valid Reference to a Firewall Filter Outside of the Logical System***

This example configuration illustrates resolvable references from a nonfirewall object in a logical system to two firewall filter.

In the following scenario, the stateless firewall filters **filter1** and **fred** are applied to the logical interface **fe-0/3/2.0** in the logical system **ls-C**.

- Filter **filter1** is defined in the main firewall configuration.
- Filter **fred** is defined in the main firewall configuration.

Because **ls-C** does not contain any firewall filter statements, the policy framework software resolves references to and from firewall filters by searching the **[edit firewall]** hierarchy level. Consequently, the references from **fe-0/3/2.0** in the logical system to **filter1** and **fred** use the stateless firewall filters configured in the main firewall configuration.

```
[edit]
logical-systems {
 ls-C {
 interfaces {
 fe-0/3/2 {
 unit 0 {
 family inet {
 filter {
 input-list [filter1 fred];
 }
 }
 }
 }
 }
 }
}
} # End of logical systems configurations.
firewall { # Main firewall hierarchy level.
 family inet {
 filter filter1 {
 term one {
 from {
 source-address 12.1.0.0/16;
 }
 then {
 reject host-unknown;
 }
 }
 term two {
 from {
 source-address 12.2.0.0/16;
 }
 }
 }
 }
}
```

```

 then policer pol1;
 }
}
filter fred {
 term one {
 from {
 source-address 11.1.0.0/16;
 }
 then {
 log;
 reject host-unknown;
 }
 }
}
}
policer pol1 {
 if-exceeding {
 bandwidth-limit 701k;
 burst-size-limit 70k;
 }
 then discard;
}
} # End of main firewall configurations.

```

## Standard Firewall Filter Configurations to Match Packets

---

- [Example: Configuring a Filter to Match on IPv6 Flags on page 4548](#)
- [Example: Configuring a Filter to Match on Port and Protocol Fields on page 4549](#)
- [Example: Configuring a Filter to Match on Two Unrelated Criteria on page 4552](#)
- [Example: Configuring a Filter to Limit TCP Access to a Port Based On a Prefix List on page 4555](#)

### **Example: Configuring a Filter to Match on IPv6 Flags**

This example shows how to configure a filter to match on IPv6 TCP flags.

- [Requirements on page 4548](#)
- [Overview on page 4548](#)
- [Configuration on page 4548](#)
- [Verification on page 4549](#)

### **Requirements**

No special configuration beyond device initialization is required before configuring this example.

### **Overview**

In this example, you configure a filter to match on IPv6 TCP flags. You can use this example to configure IPv6 TCP flags in the SRX100, SRX210, SRX240, SRX650, and J Series security devices and in M Series, MX Series, and T Series routing devices.

### **Configuration**

#### **Step-by-Step Procedure**

To configure a filter to match on IPv6 TCP flags:

1. Include the family statement at the firewall hierarchy level, specifying **inet6** as the protocol family.  
  
[edit]  
user@host# **edit firewall family inet6**
2. Create the stateless firewall filter.  
  
[edit firewall family inet6]  
user@host# **edit filter tcpfilt**
3. Define the first term for the filter.  
  
[edit firewall family inet6 filter tcpfilt]  
user@host# **edit term 1**
4. Define the source address match conditions for the term.  
  
[edit firewall family inet6 filter tcpfilt term 1]  
user@host# **set from next-header tcp tcp-flags syn**
5. Define the actions for the term.  
  
[edit firewall family inet6 filter tcpfilt term 1]

```
user@host# set then count tcp_syn_pkt log accept
```

6. If you are done configuring the device, commit the configuration.

```
[edit firewall family inet6 filter tcpfilt term 1]
```

```
user@host top
```

```
[edit]
```

```
user@host# commit
```

### Verification

To confirm that the configuration is working properly, enter the **show firewall filter tcpfilt** command.

### Example: Configuring a Filter to Match on Port and Protocol Fields

This example shows how to configure a standard stateless firewall filter to match on destination port and protocol fields.

- [Requirements on page 4549](#)
- [Overview on page 4549](#)
- [Configuration on page 4549](#)
- [Verification on page 4552](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, you configure a stateless firewall filter that accepts all IPv4 packets except for TCP and UDP packets. TCP and UDP packets are accepted if destined for the SSH port or the Telnet port. All other packets are rejected.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure the Stateless Firewall Filter on page 4550](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4550](#)
- [Confirm and Commit Your Candidate Configuration on page 4551](#)

### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level:

```
set firewall family inet filter filter1 term term1 from protocol-except tcp
set firewall family inet filter filter1 term term1 from protocol-except udp
set firewall family inet filter filter1 term term1 then accept
set firewall family inet filter filter1 term term2 from address 192.168.0.0/16
set firewall family inet filter filter1 term term2 then reject
set firewall family inet filter filter1 term term3 from destination-port ssh
```

```
set firewall family inet filter filter1 term term3 from destination-port telnet
set firewall family inet filter filter1 term term3 then accept
set firewall family inet filter filter1 term term4 then reject
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input filter1
```

### *Configure the Stateless Firewall Filter*

#### **Step-by-Step Procedure**

To configure the stateless firewall filter **filter1**:

1. Create the IPv4 stateless firewall filter.

```
[edit]
user@host# edit firewall family inet filter filter1
```

2. Configure a term to accept all traffic except for TCP and UDP packets.

```
[edit firewall family inet filter filter1]
user@host# set term term1 from protocol-except tcp
user@host# set term term1 from protocol-except udp
user@host# set term term1 then accept
```

3. Configure a term to reject packets to or from the 192.168/16 prefix.

```
[edit firewall family inet filter filter1]
user@host# set term term2 from address 192.168.0.0/16
user@host# set term term2 then reject
```

4. Configure a term to accept packets destined for either the SSH port or the Telnet port.

```
[edit firewall family inet filter filter1]
user@host# set term term3 from destination-port ssh
user@host# set term term3 from destination-port telnet
user@host# set term term3 then accept
```

5. Configure the last term to reject all packets.

```
[edit firewall family inet filter filter1]
user@host# set term term4 then reject
```

### *Apply the Stateless Firewall Filter to a Logical Interface*

#### **Step-by-Step Procedure**

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input filter1
```

*Confirm and Commit Your Candidate Configuration***Step-by-Step  
Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter filter1 {
 term term1 {
 from {
 protocol-except [tcp udp];
 }
 then {
 accept;
 }
 }
 term term2 {
 from {
 address 192.168/16;
 }
 then {
 reject;
 }
 }
 term term3 {
 from {
 destination-port [ssh telnet];
 }
 then {
 accept;
 }
 }
 term term4 {
 then {
 reject;
 }
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input filter1;
 }
 }
 }
}
```

```
 address 10.1.2.3/30;
 }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### **Verification**

To confirm that the configuration is working properly, enter the [show firewall filter filter1](#) operational mode command.

### **Related Documentation**

- [Understanding How to Use Standard Firewall Filters on page 3293](#)
- [Example: Configuring a Filter to Match on IPv6 Flags on page 4548](#)
- [Example: Configuring a Filter to Match on Two Unrelated Criteria on page 4552](#)

### **Example: Configuring a Filter to Match on Two Unrelated Criteria**

This example shows how to configure a standard stateless firewall filter to match on two unrelated criteria.

- [Requirements on page 4552](#)
- [Overview on page 4552](#)
- [Configuration on page 4552](#)
- [Verification on page 4554](#)

### **Requirements**

No special configuration beyond device initialization is required before configuring this example.

### **Overview**

In this example, you use a standard stateless firewall filter to match IPv4 packets that are either OSPF packets or packets that come from an address in the prefix **10.108/16**, and send an **administratively-prohibited** ICMP message for all packets that do not match.

### **Configuration**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the IPv4 Firewall Filter on page 4553](#)
- [Applying the IPv4 Firewall Filter to a Logical Interface on page 4554](#)

**CLI Quick Configuration** To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter ospf_or_131 term protocol_match from protocol ospf
set firewall family inet filter ospf_or_131 term address-match from source-address
 10.108.0.0/16
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input ospf_or_131
```

### *Configuring the IPv4 Firewall Filter*

**Step-by-Step Procedure** To configure the IPv4 firewall filter:

1. Enable configuration of the IPv4 firewall filter.

```
[edit]
user@host# edit firewall family inet filter ospf_or_131
```

2. Configure the first term to accept OSPF packets.

```
[edit firewall family inet filter ospf_or_131]
user@host# set term protocol_match from protocol ospf
```

Packets that match the condition are accepted by default. Because another term follows this term, packets that do not match this condition are evaluated by the next term.

3. Configure the second term to accept packets from any IPv4 address in a particular prefix.

```
[edit firewall family inet filter ospf_or_131]
user@host# set term address_match from source-address 10.108.0.0/16
```

Packets that match this condition are accepted by default. Because this is the last term in the filter, packets that do not match this condition are discarded by default.

**Results** Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter ospf_or_131 {
 term protocol_match {
 from {
 protocol ospf;
 }
 }
 term address_match {
 from {
 source-address {
 10.108.0.0/16;
 }
 }
 }
 }
}
```

```
}
}
```

### *Applying the IPv4 Firewall Filter to a Logical Interface*

**Step-by-Step Procedure** To apply the stateless firewall filter to a logical interface:

1. Enable configuration of a logical interface.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure an IP address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the IPv4 firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input ospf_or_131
```

**Results** Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input ospf_or_131;
 }
 address 10.1.2.3/30;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Verification*

To confirm that the configuration is working properly, enter the **show firewall filter ospf\_or\_131** operational mode command.

**Related Documentation**

- [Understanding How to Use Standard Firewall Filters on page 3293](#)
- [Example: Configuring a Filter to Match on IPv6 Flags on page 4548](#)
- [Example: Configuring a Filter to Match on Port and Protocol Fields on page 4549](#)

**Example: Configuring a Filter to Limit TCP Access to a Port Based On a Prefix List**

This example shows how to configure a standard stateless firewall filter that limits certain TCP and Internet Control Message Protocol (ICMP) traffic destined for the Routing Engine by specifying a list of prefix sources that contain allowed BGP peers.

- [Requirements on page 4555](#)
- [Overview on page 4555](#)
- [Configuration on page 4555](#)
- [Verification on page 4557](#)

**Requirements**

No special configuration beyond device initialization is required before configuring this example.

**Overview**

In this example, you create a stateless firewall filter that blocks all TCP connection attempts to port 179 from all requesters except BGP peers that have a specified prefix.

A source prefix list, **plist\_bgp179**, is created that specifies the list of source prefixes that contain allowed BGP peers.

The stateless firewall filter **filter\_bgp179** matches all packets from the source prefix list **plist\_bgp179** to the destination port number 179.

**Configuration**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure the Filter on page 4556](#)
- [Results on page 4556](#)

**CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set policy-options prefix-list plist_bgp179 apply-path "protocols bgp group <*> neighbor
<*>"
set firewall family inet filter filter_bgp179 term 1 from source-address 0.0.0.0/0
set firewall family inet filter filter_bgp179 term 1 from source-prefix-list plist_bgp179 except
set firewall family inet filter filter_bgp179 term 1 from destination-port bgp
set firewall family inet filter filter_bgp179 term 1 then reject
set firewall family inet filter filter_bgp179 term 2 then accept
set interfaces lo0 unit 0 family inet filter input filter_bgp179
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

### Configure the Filter

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure the filter:

1. Expand the prefix list **bgp179** to include all prefixes pointed to by the BGP peer group defined by **protocols bgp group <\*> neighbor <\*>**.

```
[edit policy-options prefix-list plist_bgp179]
user@host# set apply-path "protocols bgp group <*> neighbor <*>"
```

2. Define the filter term that rejects TCP connection attempts to port 179 from all requesters except the specified BGP peers.

```
[edit firewall family inet filter filter_bgp179]
user@host# set term term1 from source-address 0.0.0.0/0
user@host# set term term1 from source-prefix-list bgp179 except
user@host# set term term1 from destination-port bgp
user@host# set term term1 then reject
```

3. Define the other filter term to accept all packets.

```
[edit firewall family inet filter filter_bgp179]
user@host# set term term2 then accept
```

4. Apply the firewall filter to the loopback interface.

```
[edit interfaces lo0 unit 0 family inet]
user@host# set filter input filter_bgp179
user@host# set address 127.0.0.1/32
```

### Results

From configuration mode, confirm your configuration by entering the **show firewall**, **show interfaces**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show firewall
family inet {
 filter filter_bgp179 {
 term 1 {
 from {
 source-address {
 0.0.0.0/0;
 }
 source-prefix-list {
 plist_bgp179 except;
 }
 destination-port bgp;
 }
 then {
 reject;
 }
 }
 }
}
```

```

 term 2 {
 then {
 accept;
 }
 }
}

user@host# show interfaces
lo0 {
 unit 0 {
 family inet {
 filter {
 input filter_bgp179;
 }
 address 127.0.0.1/32;
 }
 }
}

user@host# show policy-options
prefix-list plist_bgp179 {
 apply-path "protocols bgp group <*> neighbor <*>";
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Repeat the procedure, where appropriate, for every BGP-enabled device in the network, using the appropriate interface names and addresses for each BGP-enabled device.

### Verification

Confirm that the configuration is working properly.

### Displaying the Firewall Filter Applied to the Loopback Interface

**Purpose** Verify that the firewall filter **filter\_bgp179** is applied to the IPv4 input traffic at logical interface **lo0.0**.

**Action** Use the **show interfaces statistics** operational mode command for logical interface **lo0.0**, and include the **detail** option. Under the **Protocol inet** section of the command output section, the **Input Filters** field displays the name of the stateless firewall filter applied to the logical interface in the input direction:

```

[edit]
user@host> show interfaces statistics lo0.0 detail
Logical interface lo0.0 (Index 321) (SNMP ifIndex 16) (Generation 130)
Flags: SNMP-Traps Encapsulation: Unspecified
Traffic statistics:
 Input bytes : 0
 Output bytes : 0
 Input packets: 0
 Output packets: 0
Local statistics:
 Input bytes : 0
 Output bytes : 0
 Input packets: 0
 Output packets: 0

```

```
Transit statistics:
Input bytes : 0 0 bps
Output bytes : 0 0 bps
Input packets: 0 0 pps
Output packets: 0 0 pps
Protocol inet, MTU: Unlimited, Generation: 145, Route table: 0
Flags: Sendbroadcast-pkt-to-re
Input Filters: filter_bgp179
Addresses, Flags: Primary
Destination: Unspecified, Local: 127.0.0.1, Broadcast: Unspecified,
Generation: 138
```

**Example: Configuring a Filter to Count Accepted and Rejected Packets**

This example shows how to configure a firewall filter to count packets.

- [Requirements on page 4558](#)
- [Overview on page 4558](#)
- [Configuration on page 4559](#)
- [Verification on page 4561](#)

**Requirements**

No special configuration beyond device initialization is required before configuring this example.

**Overview**

In this example, you use a stateless firewall filter to reject all addresses except 192.168.5.0/24.

**Topology**

In the first term, the match condition **address 192.168.5.0/24 except** causes this address to be considered a mismatch, and this address is passed to the next term in the filter. The match condition **address 0.0.0.0/0** matches all other packets, and these are counted, logged, and rejected.

In the second term, all packets that passed through the first term (that is, packets whose address matches **192.168.5.0/24**) are counted, logged, and accepted.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4559](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4560](#)
- [Confirm and Commit Your Candidate Configuration on page 4560](#)

### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter fire1 term 1 from address 192.168.5.0/24 except
set firewall family inet filter fire1 term 1 from address 0.0.0.0/0
set firewall family inet filter fire1 term 1 then count reject_pref1_1
set firewall family inet filter fire1 term 1 then log
set firewall family inet filter fire1 term 1 then reject
set firewall family inet filter fire1 term 2 then count reject_pref1_2
set firewall family inet filter fire1 term 2 then log
set firewall family inet filter fire1 term 2 then accept
set interfaces ge-0/0/1 unit 0 family inet filter input fire1
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
```

### Configure the Stateless Firewall Filter

### Step-by-Step Procedure

To configure the stateless firewall filter **fire1**:

1. Create the stateless firewall filter **fire1**.  
  

```
[edit]
user@host# edit firewall family inet filter fire1
```
2. Configure the first term to reject all addresses except those to or from the **192.168.5.0/24** prefix and then count, log, and reject all other packets.  
  

```
[edit firewall family inet filter fire1]
user@host# set term 1 from address 192.168.5.0/24 except
user@host# set term 1 from address 0.0.0.0/0
user@host# set term 1 then count reject_pref1_1
user@host# set term 1 then log
user@host# set term 1 then reject
```
3. Configure the next term to count, log, and accept packets in the **192.168.5.0/24** prefix.  
  

```
[edit firewall family inet filter fire1]
user@host# set term 2 then count reject_pref1_2
user@host# set term 2 then log
user@host# set term 2 then accept
```

### *Apply the Stateless Firewall Filter to a Logical Interface*

#### **Step-by-Step Procedure**

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input fire1
```

### *Confirm and Commit Your Candidate Configuration*

#### **Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter fire1 {
 term 1 {
 from {
 address {
 192.168.5.0/24 except;
 0.0.0.0/0;
 }
 }
 then {
 count reject_pref1_1;
 log;
 reject;
 }
 }
 term 2 {
 then {
 count reject_pref1_2;
 log;
 accept;
 }
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input fire1;
 }
 address 10.1.2.3/30;
 }
 }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### Verification

To confirm that the configuration is working properly, enter the **show firewall filter fire1** operational mode command. You can also display the log and individual counters separately by using the following forms of the command:

- **show firewall counter reject\_pref1\_1**
- **show firewall counter reject\_pref1\_2**
- **show firewall log**

### Related Documentation

- [Understanding How to Use Standard Firewall Filters on page 3293](#)

- [Example: Configuring a Filter to Count and Discard IP Options Packets on page 4561](#)

### Example: Configuring a Filter to Count and Discard IP Options Packets

This example shows how to configure a standard stateless firewall to count packets.

- [Requirements on page 4561](#)
- [Overview on page 4562](#)
- [Configuration on page 4562](#)
- [Verification on page 4564](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

Because the filter term matches on *any* IP option value, the filter term can use the **count** nonterminating action without the **discard** terminating action or (alternatively) without requiring an interface on a 10-Gigabit Ethernet Modular Port Concentrator (MPC), 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, or 60-Gigabit Ethernet Enhanced Queuing MPC on an MX Series router.

### Overview

In this example, you use a standard stateless firewall filter to count and discard packets that include any IP option value but accept all other packets.

The IP option header field is an optional field in IPv4 headers only. The **ip-options** and **ip-options-except** match conditions are supported for standard stateless firewall filters and service filters only.

**NOTE:** On M and T series routers, firewall filters cannot count **ip-options** packets on a per option type and per interface basis. A limited work around is to use the `show pfe statistics ip options` command to see **ip-options** statistics on a per Packet Forwarding Engine (PFE) basis. See *show pfe statistics ip* for sample output.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4562](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4563](#)
- [Confirm and Commit Your Candidate Configuration on page 4563](#)

#### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter block_ip_options term 10 from ip-options any
set firewall family inet filter block_ip_options term 10 then count option_any
set firewall family inet filter block_ip_options term 10 then discard
set firewall family inet filter block_ip_options term 999 then accept
set interfaces ge-0/0/1 unit 0 family inet filter input block_ip_options
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
```

#### Configure the Stateless Firewall Filter

#### Step-by-Step Procedure

To configure the stateless firewall filter:

1. Create the stateless firewall filter **block\_ip\_options**.

```
[edit]
user@host# edit firewall family inet filter block_ip_options
```

2. Configure the first term to count and discard packets that include any IP options header fields.

```
[edit firewall family inet filter block_ip_options]
user@host# set term 10 from ip-options any
user@host# set term 10 then count option_any
user@host# set term 10 then discard
```

3. Configure the other term to accept all other packets.

```
[edit firewall family inet filter block_ip_options]
user@host# set term 999 then accept
```

### *Apply the Stateless Firewall Filter to a Logical Interface*

#### **Step-by-Step Procedure**

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input block_ip_options
```

### *Confirm and Commit Your Candidate Configuration*

#### **Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter block_ip_options {
 term 10 {
 from {
 ip-options any;
 }
 then {
 count option_any;
 discard;
 }
 }
 term 999 {
 then accept;
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input block_ip_options;
 }
 address 10.1.2.3/30;
 }
 }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### Verification

To confirm that the configuration is working properly, enter the **show firewall filter block\_ip\_options** operational mode command. To display the count of discarded packets separately, enter the **show firewall count option\_any** form of the command.

### Related Documentation

- [Understanding How to Use Standard Firewall Filters on page 3293](#)
- [Example: Configuring a Filter to Count Accepted and Rejected Packets on page 4558](#)
- [Example: Configuring a Filter to Count IP Options Packets on page 4564](#)

### Example: Configuring a Filter to Count IP Options Packets

This example shows how use a stateless firewall filter to count individual IP options packets:

- [Requirements on page 4564](#)
- [Overview on page 4565](#)
- [Configuration on page 4565](#)
- [Verification on page 4569](#)

### Requirements

This example uses an interface on a 10-Gigabit Ethernet Modular Port Concentrator (MPC), 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, or 60-Gigabit Ethernet Enhanced Queuing MPC on an MX Series router. This interface enables you to apply an IPv4 firewall filter (standard or service filter) that can use the **count**, **log**, and **syslog** nonterminating actions on packets that match a *specific ip-option* value without having to also use the **discard** terminating action.

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, you use a stateless firewall filter to count IP options packets but not block any traffic. Also, the filter logs packets that have loose or strict source routing.

The IP option header field is an optional field in IPv4 headers only. The **ip-options** and **ip-options-except** match conditions are supported for standard stateless firewall filters and service filters only.

**NOTE:** On M and T series routers, firewall filters cannot count **ip-options** packets on a per option type and per interface basis. A limited work around is to use the `show pfe statistics ip options` command to see **ip-options** statistics on a per Packet Forwarding Engine (PFE) basis. See *show pfe statistics ip* for sample output.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4566](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4567](#)
- [Confirm and Commit Your Candidate Configuration on page 4567](#)

### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter ip_options_filter term match_strict_source from ip-options
strict-source-route
set firewall family inet filter ip_options_filter term match_strict_source then count
strict_source_route
set firewall family inet filter ip_options_filter term match_strict_source then log
set firewall family inet filter ip_options_filter term match_strict_source then accept
set firewall family inet filter ip_options_filter term match_loose_source from ip-options
loose-source-route
set firewall family inet filter ip_options_filter term match_loose_source then count
loose_source_route
set firewall family inet filter ip_options_filter term match_loose_source then log
set firewall family inet filter ip_options_filter term match_loose_source then accept
set firewall family inet filter ip_options_filter term match_record from ip-options
record-route
set firewall family inet filter ip_options_filter term match_record then count record_route
set firewall family inet filter ip_options_filter term match_record then accept
set firewall family inet filter ip_options_filter term match_timestamp from ip-options
timestamp
set firewall family inet filter ip_options_filter term match_timestamp then count timestamp
```

```
set firewall family inet filter ip_options_filter term match_timestamp then accept
set firewall family inet filter ip_options_filter term match_router_alert from ip-options
router-alert
set firewall family inet filter ip_options_filter term match_router_alert then count
router_alert
set firewall family inet filter ip_options_filter term match_router_alert then accept
set firewall family inet filter ip_options_filter term match_all then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input ip_options_filter
```

### *Configure the Stateless Firewall Filter*

#### **Step-by-Step Procedure**

To configure the stateless firewall filter `ip_option_filter`:

1. Create the stateless firewall filter `ip_option_filter`.  

```
[edit]
user@host# edit firewall family inet filter ip_options_filter
```
2. Configure the first term to count, log, and accept packets with the `strict_source_route` IP optional header field.  

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_strict_source from ip-options strict_source_route
user@host# set term match_strict_source then count strict_source_route
user@host# set term match_strict_source then log
user@host# set term match_strict_source then accept
```
3. Configure the next term to count, log, and accept packets with the `loose-source-route` IP optional header field.  

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_loose_source from ip-options loose-source-route
user@host# set term match_loose_source then count loose_source_route
user@host# set term match_loose_source then log
user@host# set term match_loose_source then accept
```
4. Configure the next term to count and accept packets with the `record-route` IP optional header field.  

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_record from ip-options record-route
user@host# set term match_record then count record_route
user@host# set term match_record then accept
```
5. Configure the next term to count and accept packets with the `timestamp` IP optional header field.  

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_timestamp from ip-options timestamp
user@host# set term match_timestamp then count timestamp
user@host# set term match_timestamp then accept
```
6. Configure the next term to count and accept packets with the `router-alert` IP optional header field.  

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_router_alert from ip-options router-alert
user@host# set term match_router_alert then count router_alert
```

```
user@host# set term match_router_alert then accept
```

7. Create the last term to accept any packet without incrementing any counters.

```
[edit firewall family inet filter ip_option_filter]
user@host# set term match_all then accept
```

### *Apply the Stateless Firewall Filter to a Logical Interface*

#### **Step-by-Step Procedure**

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input ip_options_filter
```

### *Confirm and Commit Your Candidate Configuration*

#### **Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter ip_options_filter {
 term match_strict_source {
 from {
 ip-options strict-source-route;
 }
 then {
 count strict_source_route;
 log;
 accept;
 }
 }
 }
 term match_loose_source {
 from {
 ip-options loose-source-route;
 }
 then {
 count loose_source_route;
 log;
 accept;
 }
 }
}
```

```
}
term match_record {
 from {
 ip-options record-route;
 }
 then {
 count record_route;
 accept;
 }
}
term match_timestamp {
 from {
 ip-options timestamp;
 }
 then {
 count timestamp;
 accept;
 }
}
term match_router_alert {
 from {
 ip-options router-alert;
 }
 then {
 count router_alert;
 accept;
 }
}
term match_all {
 then accept;
}
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input ip_option_filter;
 }
 address 10.1.2.3/30;
 }
 }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### Verification

To confirm that the configuration is working properly, enter the [show firewall filter ip\\_option\\_filter](#) operational mode command. You can also display the log and individual counters separately by using the following forms of the command:

- `show firewall counter strict_source_route`
- `show firewall counter loose_source_route`
- `show firewall counter record_route`
- `show firewall counter timestamp`
- `show firewall counter router_alert`
- `show firewall log`

### Standard Firewall Filters to Act on Packets

- [Example: Configuring a Filter to Set the DSCP Bit to Zero on page 4569](#)
- [Example: Configuring a Filter to Count and Sample Accepted Packets on page 4572](#)

#### *Example: Configuring a Filter to Set the DSCP Bit to Zero*

This example shows how to configure a standard stateless firewall filter based on the Differentiated Services code point (DSCP).

- [Requirements on page 4569](#)
- [Overview on page 4569](#)
- [Configuration on page 4569](#)
- [Verification on page 4571](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, you use a stateless firewall filter to match packets on DSCP bit patterns. If the DSCP is **2**, the packet is classified to the **best-effort** forwarding class, and the DSCP is set to **0**. If the DSCP is **3**, the packet is classified to the **best-effort** forwarding class.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4570](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4570](#)
- [Confirm and Commit Your Candidate Configuration on page 4571](#)

#### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter filter1 term 1 from dscp 2
set firewall filter filter1 term 1 then forwarding-class best-effort
set firewall filter filter1 term 1 then dscp 0
set firewall filter filter1 term 2 from dscp 3
set firewall filter filter1 term 2 then forwarding-class best-effort
set interfaces ge-0/1/0 unit 0 family inet filter input filter1
```

#### *Configure the Stateless Firewall Filter*

#### Step-by-Step Procedure

To configure the stateless firewall filter **filter1**:

1. Create the stateless firewall filter.

```
[edit]
user@host# edit firewall filter filter1
```

2. Configure the first term to match a packet with a DSCP of **2**, change the DSCP to **0**, and classify the packet to the **best-effort** forwarding class.

```
[edit firewall filter filter1]
user@host# set term 1 from dscp 2
user@host# set term 1 then forwarding-class best-effort
user@host# set term 1 then dscp 0
```

3. Configure the other term to match a packet with a DSCP of **3** and classify the packet to the **best-effort** forwarding class.

```
[edit firewall filter filter1]
user@host# set term 2 from dscp 3
user@host# set term 2 then forwarding-class best-effort
```

#### *Apply the Stateless Firewall Filter to a Logical Interface*

#### Step-by-Step Procedure

To apply the stateless firewall filter to the logical interface corresponding to the VPN routing and forwarding (VRF) instance:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/1/0 unit 0 family inet
```

2. Apply the stateless firewall filter to the logical interface.

```
[input filter1]
user@host# set filter input filter1
```

**Confirm and Commit Your Candidate Configuration****Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
filter filter1 {
 term term1 {
 from {
 dscp 2;
 }
 then {
 forwarding-class best-effort;
 dscp 0;
 }
 }
 term term2 {
 from {
 dscp 3;
 }
 then {
 forwarding-class best-effort;
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/1/0 {
 unit 0 {
 family inet {
 filter input filter1;
 }
 }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

**Verification**

To confirm that the configuration is working properly, enter the following operational mode commands:

- **show class-of-service**—Displays the entire class-of-service (CoS) configuration, including system-chosen defaults.

- **show class-of-service classifier type dscp**—Displays only the classifiers of the DSCP for IPv4 type.

**Related  
Documentation**

- [Understanding How to Use Standard Firewall Filters on page 3293](#)
- [Example: Configuring a Filter to Count and Sample Accepted Packets on page 4572](#)

**Example: Configuring a Filter to Count and Sample Accepted Packets**

This example shows how to configure a standard stateless firewall filter to count and sample accepted packets.

- [Requirements on page 4572](#)
- [Overview on page 4572](#)
- [Configuration on page 4572](#)
- [Verification on page 4574](#)

**Requirements**

No special configuration beyond device initialization is required before configuring this example.

Before you begin, configure traffic sampling by including the **sampling** statement at the [\[edit forwarding-options\]](#) hierarchy level.

**Overview**

In this example, you use a standard stateless firewall filter to count and sample all packets received on a logical interface.

**NOTE:** When you enable reverse path forwarding (RPF) on an interface with an input filter for firewall log and count, the input firewall filter does not log the packets rejected by RPF, although the rejected packets are counted. To log the rejected packets, use an RPF check fail filter.

**Configuration**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4573](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4573](#)
- [Confirm and Commit Your Candidate Configuration on page 4574](#)

**CLI Quick Configuration** To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter sam term all then count count_sam
set firewall family inet filter sam term all then sample
set interfaces at-2/0/0 unit 301 family inet address 10.1.2.3/30
set interfaces at-2/0/0 unit 301 family inet filter input sam
```

#### *Configure the Stateless Firewall Filter*

**Step-by-Step Procedure** To configure the stateless firewall filter **sam**:

1. Create the stateless firewall filter **sam**.  
  
[edit]  
user@host# edit firewall family inet filter sam
2. Configure the term to count and sample all packets.  
  
[edit firewall family inet filter sam]  
user@host# set term all then count count\_sam  
user@host# set term all then sample

#### *Apply the Stateless Firewall Filter to a Logical Interface*

**Step-by-Step Procedure** To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.  
  
[edit]  
user@host# edit interfaces ge-0/0/1 unit 0 family inet
2. Configure the interface address for the logical interface.  
  
[edit interfaces ge-0/0/1 unit 0 family inet]  
user@host# set address 10.1.2.3/30
3. Apply the stateless firewall filter to the logical interface.  
  
[edit interfaces ge-0/0/1 unit 0 family inet]  
user@host# set filter input sam

**NOTE:** The Junos OS does not sample packets originating from the router or switch. If you configure a filter and apply it to the output side of an interface, then only the transit packets going through that interface are sampled. Packets that are sent from the Routing Engine to the Packet Forwarding Engine are not sampled.

### *Confirm and Commit Your Candidate Configuration*

#### **Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter sam {
 term all {
 then {
 count count_sam;
 sample; # default action is accept
 }
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
interfaces {
 at-2/0/0 {
 unit 301 {
 family inet {
 filter {
 input sam;
 }
 address 10.1.2.3/30;
 }
 }
 }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### *Verification*

Confirm that the configuration is working properly.

- [Displaying the Packet Counter on page 4574](#)
- [Displaying the Firewall Filter Log Output on page 4575](#)
- [Displaying the Sampling Output on page 4575](#)

### *Displaying the Packet Counter*

**Purpose** Verify that the firewall filter is evaluating packets.

**Action** user@host> show firewall filter sam  
 Filter:  
 Counters:

| Name  | Bytes | Packets |
|-------|-------|---------|
| sam   |       |         |
| sam-1 | 98    | 8028    |

### Displaying the Firewall Filter Log Output

**Purpose** Display the packet header information for all packets evaluated by the firewall filter.

**Action** user@host> show firewall log

| Time     | Filter | A | Interface    | Pro | Source address | Destination address |
|----------|--------|---|--------------|-----|----------------|---------------------|
| 23:09:09 | -      | A | at-2/0/0.301 | TCP | 10.2.0.25      | 10.211.211.1:80     |
| 23:09:07 | -      | A | at-2/0/0.301 | TCP | 10.2.0.25      | 10.211.211.1:56     |
| 23:09:07 | -      | A | at-2/0/0.301 | ICM | 10.2.0.25      | 10.211.211.1:49552  |
| 23:02:27 | -      | A | at-2/0/0.301 | TCP | 10.2.0.25      | 10.211.211.1:56     |
| 23:02:25 | -      | A | at-2/0/0.301 | TCP | 10.2.0.25      | 10.211.211.1:80     |
| 23:01:22 | -      | A | at-2/0/0.301 | ICM | 10.2.2.101     | 10.211.211.1:23251  |
| 23:01:21 | -      | A | at-2/0/0.301 | ICM | 10.2.2.101     | 10.211.211.1:16557  |
| 23:01:20 | -      | A | at-2/0/0.301 | ICM | 10.2.2.101     | 10.211.211.1:29471  |
| 23:01:19 | -      | A | at-2/0/0.301 | ICM | 10.2.2.101     | 10.211.211.1:26873  |

**Meaning** This output file contains the following fields:

- **Time**—Time at which the packet was received (not shown in the default).
- **Filter**—Name of a filter that has been configured with the **filter** statement at the **[edit firewall]** hierarchy level. A hyphen (-) or the abbreviation **pfe** indicates that the packet was handled by the Packet Forwarding Engine. A space (no hyphen) indicates that the packet was handled by the Routing Engine.
- **A**—Filter action:
  - **A**—Accept (or next term)
  - **D**—Discard
  - **R**—Reject
- **Interface**—Interface on which the filter is configured.

**NOTE:** We strongly recommend that you always explicitly configure an action in the **then** statement.

- **Pro**—Packet's protocol name or number.
- **Source address**—Source IP address in the packet.
- **Destination address**—Destination IP address in the packet.

### Displaying the Sampling Output

**Purpose** Verify that the sampling output contains appropriate data.

| Action | File      | Size                   | Last changed                  |
|--------|-----------|------------------------|-------------------------------|

### Example: Configuring a Stateless Firewall Filter to Accept Traffic from Trusted Sources

This example shows how to create a stateless firewall filter that protects the Routing Engine from traffic originating from untrusted sources.

- Requirements on page 4576
- Overview on page 4576
- Configuration on page 4577
- Verification on page 4579

## Requirements

No special configuration beyond device initialization is required before configuring stateless firewall filters.

## Overview

In this example, you create a stateless firewall filter called protect-RE that discards all traffic destined for the Routing Engine except SSH and BGP protocol packets from specified trusted sources. This example includes the following firewall filter terms:

- **ssh-term**—Accepts TCP packets with a source address of 192.168.122.0/24 and a destination port that specifies SSH.

- **bgp-term**—Accepts TCP packets with a source address of 10.2.1.0/24 and a destination port that specifies BGP.
- **discard-rest-term**—For all packets that are not accepted by **ssh-term** or **bgp-term**, creates a firewall filter log and system logging records, then discards all packets.

**NOTE:** You can move terms within the firewall filter using the `insert` command. See *insert* in the *CLI User Guide*.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter protect-RE term ssh-term from source-address
 192.168.122.0/24
set firewall family inet filter protect-RE term ssh-term from protocol tcp
set firewall family inet filter protect-RE term ssh-term from destination-port ssh
set firewall family inet filter protect-RE term ssh-term then accept
set firewall family inet filter protect-RE term bgp-term from source-address 10.2.1.0/24
set firewall family inet filter protect-RE term bgp-term from protocol tcp
set firewall family inet filter protect-RE term bgp-term from destination-port bgp
set firewall family inet filter protect-RE term bgp-term then accept
set firewall family inet filter protect-RE term discard-rest-term then log
set firewall family inet filter protect-RE term discard-rest-term then syslog
set firewall family inet filter protect-RE term discard-rest-term then discard
set interfaces lo0 unit 0 family inet filter input protect-RE
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure the stateless firewall filter:

1. Create the stateless firewall filter.

```
[edit]
user@host# edit firewall family inet filter protect-RE
```

2. Create the first filter term.

```
[edit firewall family inet filter protect-RE]
user@host# edit term ssh-term
```

3. Define the protocol, destination port, and source address match conditions for the term.

```
[edit firewall family inet filter protect-RE term ssh-term]
user@host# set from protocol tcp destination-port ssh source-address
 192.168.122.0/24
```

4. Define the actions for the term.

```
[edit firewall family inet filter protect-RE term ssh-term]
user@host# set then accept
```

5. Create the second filter term.

```
[edit firewall family inet filter protect-RE]
user@host# edit term bgp-term
```

6. Define the protocol, destination port, and source address match conditions for the term.

```
[edit firewall family inet filter protect-RE term bgp-term]
user@host# set from protocol tcp destination-port bgp source-address 10.2.1.0/24
```

7. Define the action for the term.

```
[edit firewall family inet filter protect-RE term bgp-term]
user@host# set then accept
```

8. Create the third filter term.

```
[edit firewall family inet filter protect-RE]
user@host# edit term discard-rest-term
```

9. Define the action for the term.

```
[edit firewall family inet filter protect-RE term discard-rest]
user@host# set then log syslog discard
```

10. Apply the filter to the input side of the Routing Engine interface.

```
[edit]
user@host# set interfaces lo0 unit 0 family inet filter input protect-RE
```

**Results** Confirm your configuration by entering the **show firewall** command and the **show interfaces lo0** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show firewall
family inet {
 filter protect-RE {
 term ssh-term {
 from {
 source-address {
 192.168.122.0/24;
 }
 protocol tcp;
 destination-port ssh;
 }
 then accept;
 }
 term bgp-term {
 from {
 source-address {
 10.2.1.0/24;
 }
 }
 }
 }
}
```

```

 protocol tcp;
 destination-port bgp;
 }
 then accept;
}
term discard-rest-term {
 then {
 log;
 syslog;
 discard;
 }
}
}
}

user@host# show interfaces lo0
unit 0 {
 family inet {
 filter {
 input protect-RE;
 }
 address 127.0.0.1/32;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

```

[edit]
user@host# commit

```

### **Verification**

To confirm that the configuration is working properly, perform these tasks:

- [Displaying Stateless Firewall Filter Configurations on page 4579](#)
- [Verifying a Services, Protocols, and Trusted Sources Firewall Filter on page 4579](#)
- [Displaying Stateless Firewall Filter Logs on page 4580](#)

### **Displaying Stateless Firewall Filter Configurations**

|                |                                                                                                                                                                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Verify the configuration of the firewall filter.                                                                                                                                                                                                                           |
| <b>Action</b>  | From configuration mode, enter the <b>show firewall</b> command and the <b>show interfaces lo0</b> command.                                                                                                                                                                |
| <b>Meaning</b> | Verify that the output shows the intended configuration of the firewall filter. In addition, verify that the terms are listed in the order in which you want the packets to be tested. You can move terms within a firewall filter by using the <b>insert</b> CLI command. |

### **Verifying a Services, Protocols, and Trusted Sources Firewall Filter**

|                |                                                                 |
|----------------|-----------------------------------------------------------------|
| <b>Purpose</b> | Verify that the actions of the firewall filter terms are taken. |
|----------------|-----------------------------------------------------------------|

**Action** Send packets to the device that match the terms. In addition, verify that the filter actions are *not* taken for packets that do not match.

- Use the **ssh *host-name*** command from a host at an IP address that matches **192.168.122.0/24** to verify that you can log in to the device using only SSH from a host with this address prefix.
- Use the **show route summary** command to verify that the routing table on the device does not contain any entries with a protocol other than **Direct**, **Local**, **BGP**, or **Static**.

## Sample Output

```
% ssh 192.168.249.71
%ssh host
user@host's password:
--- JUNOS 6.4-20040518.0 (JSERIES) #0: 2004-05-18 09:27:50 UTC

user@host>

user@host> show route summary
Router ID: 192.168.249.71

inet.0: 34 destinations, 34 routes (33 active, 0 holddown, 1 hidden)
 Direct: 10 routes, 9 active
 Local: 9 routes, 9 active
 BGP: 10 routes, 10 active
 Static: 5 routes, 5 active
...
```

**Meaning** Verify the following information:

- You can successfully log in to the device using SSH.
- The **show route summary** command does not display a protocol other than **Direct**, **Local**, **BGP**, or **Static**.

### *Displaying Stateless Firewall Filter Logs*

**Purpose** Verify that packets are being logged. If you included the **log** or **syslog** action in a term, verify that packets matching the term are recorded in the firewall log or your system logging facility.

**Action** From operational mode, enter the **show firewall log** command.

## Sample Output

```
user@host> show firewall log
Log :
Time Filter Action Interface Protocol Src Addr Dest Addr
15:11:02 pfe D ge-0/0/0.0 TCP 172.17.28.19 192.168.70.71
15:11:01 pfe D ge-0/0/0.0 TCP 172.17.28.19 192.168.70.71
15:11:01 pfe D ge-0/0/0.0 TCP 172.17.28.19 192.168.70.71
15:11:01 pfe D ge-0/0/0.0 TCP 172.17.28.19 192.168.70.71
...
```

**Meaning** Each record of the output contains information about the logged packet. Verify the following information:

- Under **Time**, the time of day the packet was filtered is shown.
- The **Filter** output is always **pfe**.
- Under **Action**, the configured action of the term matches the action taken on the packet—**A** (accept), **D** (discard), **R** (reject).
- Under **Interface**, the inbound (ingress) interface on which the packet arrived is appropriate for the filter.
- Under **Protocol**, the protocol in the IP header of the packet is appropriate for the filter.
- Under **Src Addr**, the source address in the IP header of the packet is appropriate for the filter.
- Under **Dest Addr**, the destination address in the IP header of the packet is appropriate for the filter.

**Example: Configuring a Filter to Block Telnet and SSH Access**

- [Requirements on page 4581](#)
- [Overview on page 4581](#)
- [Configuration on page 4582](#)
- [Verification on page 4584](#)

**Requirements**

You must have access to a remote host that has network connectivity with this router or switch.

**Overview**

In this example, you create an IPv4 stateless firewall filter that logs and rejects Telnet or SSH access packets unless the packet is destined for or originates from the 192.168.1.0/24 subnet.

- To match packets destined for or originating from the **address 192.168.1.0/24** subnet, you use the **address 192.168.1.0/24** IPv4 match condition.
- To match packets destined for or originating from a TCP port, Telnet port, or SSH port, you use the **protocol tcp**, **port telnet**, and **telnet ssh** IPv4 match conditions.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4582](#)
- [Apply the Firewall Filter to the Loopback Interface on page 4583](#)
- [Confirm and Commit Your Candidate Configuration on page 4583](#)

#### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter local_acl term terminal_access from address 192.168.1.0/24
set firewall family inet filter local_acl term terminal_access from protocol tcp
set firewall family inet filter local_acl term terminal_access from port ssh
set firewall family inet filter local_acl term terminal_access from port telnet
set firewall family inet filter local_acl term terminal_access then accept
set firewall family inet filter local_acl term terminal_access_denied from protocol tcp
set firewall family inet filter local_acl term terminal_access_denied from port ssh
set firewall family inet filter local_acl term terminal_access_denied from port telnet
set firewall family inet filter local_acl term terminal_access_denied then log
set firewall family inet filter local_acl term terminal_access_denied then reject
set firewall family inet filter local_acl term default-term then accept
set interfaces lo0 unit 0 family inet filter input local_acl
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

### Configure the Stateless Firewall Filter

#### Step-by-Step Procedure

To configure the stateless firewall filter that selectively blocks Telnet and SSH access:

1. Create the stateless firewall filter **local\_acl**.

```
[edit]
user@myhost# edit firewall family inet filter local_acl
```

2. Define the filter term **terminal\_access**.

```
[edit firewall family inet filter local_acl]
user@myhost# set term terminal_access from address 192.168.1.0/24
user@myhost# set term terminal_access from protocol tcp
user@myhost# set term terminal_access from port ssh
user@myhost# set term terminal_access from port telnet
user@myhost# set term terminal_access then accept
```

3. Define the filter term **terminal\_access\_denied**.

```
[edit firewall family inet filter local_acl]
user@myhost# set term terminal_access_denied from protocol tcp
user@myhost# set term terminal_access_denied from port ssh
user@myhost# set term terminal_access_denied from port telnet
user@myhost# set term terminal_access_denied then log
user@myhost# set term terminal_access_denied then reject
```

```
user@myhost# set term default-term then accept
```

### *Apply the Firewall Filter to the Loopback Interface*

#### **Step-by-Step Procedure**

- To apply the firewall filter to the loopback interface:

```
[edit]
user@myhost# set interfaces lo0 unit 0 family inet filter input local_acl
user@myhost# set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

### *Confirm and Commit Your Candidate Configuration*

#### **Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@myhost# show firewall
family inet {
 filter local_acl {
 term terminal_access {
 from {
 address {
 192.168.1.0/24;
 }
 protocol tcp;
 port [ssh telnet];
 }
 then accept;
 }
 term terminal_access_denied {
 from {
 protocol tcp;
 port [ssh telnet];
 }
 then {
 log;
 reject;
 }
 }
 term default-term {
 then accept;
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@myhost# show interfaces
lo0 {
 unit 0 {
```

```
family inet {
 filter {
 input local_acl;
 }
 address 127.0.0.1/32;
}
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@myhost# commit
```

### ***Verification***

Confirm that the configuration is working properly.

- [Verifying Accepted Packets on page 4584](#)
- [Verifying Logged and Rejected Packets on page 4585](#)

### ***Verifying Accepted Packets***

**Purpose** Verify that the actions of the firewall filter terms are taken.

- Action** 1. Clear the firewall log on your router or switch.

```
user@myhost> clear firewall log
```

2. From a host at an IP address *within* the 192.168.1.0/24 subnet, use the **ssh *hostname*** command to verify that you can log in to the device using only SSH. This packet should be accepted, and the packet header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-A> ssh myhost
user@myhosts's password:
--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC

% cli
user@myhost>
```

3. From a host at an IP address *within* the 192.168.1.0/24 subnet, use the **telnet *hostname*** command to verify that you can log in to your router or switch using only Telnet. This packet should be accepted, and the packet header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-A> telnet myhost
Trying 192.168.249.71...
Connected to myhost-fxp0.acme.net.
Escape character is '^J'.

host (ttyp0)

login: user
Password:

--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC

% cli
user@myhost>
```

4. Use the **show firewall log** command to verify that the routing table on the device does not contain any entries with a source address in the 192.168.1.0/24 subnet.

```
user@myhost> show firewall log
```

#### ***Verifying Logged and Rejected Packets***

- Purpose** Verify that the actions of the firewall filter terms are taken.

- Action** 1. Clear the firewall log on your router or switch.

```
user@myhost> clear firewall log
```

2. From a host at an IP address *outside of* the 192.168.1.0/24 subnet, use the **ssh hostname** command to verify that you cannot log in to the device using only SSH. This packet should be rejected, and the packet header information for this packet should be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-B ssh myhost
ssh: connect to host sugar port 22: Connection refused
--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC
%
```

3. From a host at an IP address *outside of* the 192.168.1.0/24 subnet, use the **telnet hostname** command to verify that you can log in to the device using only Telnet. This packet should be rejected, and the packet header information for this packet should be logged in the firewall filter log buffer in the PFE.

```
user@host-B> telnet myhost
Trying 192.168.249.71...
telnet: connect to address 192.168.187.3: Connection refused
telnet: Unable to connect to remote host
%
```

4. Use the **show firewall log** command to verify that the routing table on the device does not contain any entries with a source address in the 192.168.1.0/24 subnet.

```
user@myhost> show firewall log
```

| Time     | Filter    | Action | Interface | Protocol | Src Addr      | Dest Addr     |
|----------|-----------|--------|-----------|----------|---------------|---------------|
| 18:41:25 | local_acl | R      | fxp0.0    | TCP      | 192.168.187.5 | 192.168.187.1 |

#### Example: Configuring a Filter to Block TFTP Access

- [Requirements on page 4587](#)
- [Overview on page 4587](#)

- [Configuration on page 4587](#)
- [Verification on page 4589](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

By default, to decrease vulnerability to denial-of-service (DoS) attacks, the Junos OS filters and discards Dynamic Host Configuration Protocol (DHCP) or Bootstrap Protocol (BOOTP) packets that have a source address of 0.0.0.0 and a destination address of 255.255.255.255. This default filter is known as a unicast RPF check. However, some vendors' equipment automatically accepts these packets.

To interoperate with other vendors' equipment, you can configure a filter that checks for both of these addresses and overrides the default RPF-check filter by accepting these packets. In this example, you block Trivial File Transfer Protocol (TFTP) access, logging any attempts to establish TFTP connections.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4587](#)
- [Apply the Firewall Filter to the Loopback Interface on page 4588](#)
- [Confirm and Commit Your Candidate Configuration on page 4588](#)

#### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter tftp_access_control term one from protocol udp
set firewall family inet filter tftp_access_control term one from port tftp
set firewall family inet filter tftp_access_control term one then log
set firewall family inet filter tftp_access_control term one then discard
set interfaces lo0 unit 0 family inet filter input tftp_access_control
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

### Configure the Stateless Firewall Filter

#### Step-by-Step Procedure

To configure the stateless firewall filter that selectively blocks TFTP access:

1. Create the stateless firewall filter **tftp\_access\_control**.

```
[edit]
user@host# edit firewall family inet filter tftp_access_control
```

2. Specify a match on packets received on UDP port 69.

```
[edit firewall family inet filter tftp_access_control]
```

```
user@host# set term one from protocol udp
user@host# set term one from port tftp
```

3. Specify that matched packets be logged to the buffer on the Packet Forwarding Engine and then discarded.

```
[edit firewall family inet filter tftp_access_control]
user@host# set term one then log
user@host# set term one then discard
```

### *Apply the Firewall Filter to the Loopback Interface*

**Step-by-Step Procedure** To apply the firewall filter to the loopback interface:

- [edit]  
user@host# set interfaces lo0 unit 0 family inet filter input tftp\_access\_control  
user@host# set interfaces lo0 unit 0 family inet address 127.0.0.1/32

### *Confirm and Commit Your Candidate Configuration*

**Step-by-Step Procedure** To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter tftp_access_control {
 term one {
 from {
 protocol udp;
 port tftp;
 }
 then {
 log;
 discard;
 }
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
lo0 {
 unit 0 {
 family inet {
 filter {
 input tftp_access_control;
 }
 address 127.0.0.1/32;
 }
 }
}
```

```
}
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### **Verification**

Confirm that the configuration is operating properly:

- [Verifying Logged and Discarded Packets on page 4589](#)

### **Verifying Logged and Discarded Packets**

**Purpose** Verify that the actions of the firewall filter terms are taken.

**Action** To

1. Clear the firewall log on your router or switch.  

```
user@myhost> clear firewall log
```
2. From another host, send a packet to UDP port 69 on this router or switch.

### **Related Documentation**

- [Example: Configuring a Stateless Firewall Filter to Accept Traffic from Trusted Sources on page 4576](#)
- [Example: Configuring a Filter to Block Telnet and SSH Access on page 4581](#)
- [Example: Configuring a Filter to Accept OSPF Packets from a Prefix on page 4589](#)
- [Example: Configuring a Filter to Accept DHCP Packets Based on Address on page 4592](#)

### **Example: Configuring a Filter to Accept OSPF Packets from a Prefix**

This example shows how to configure a standard stateless firewall filter to accept packets from a trusted source.

- [Requirements on page 4589](#)
- [Overview on page 4590](#)
- [Configuration on page 4590](#)
- [Verification on page 4592](#)

### **Requirements**

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, you create a filter that accepts only OSPF packets from an address in the prefix 10.108.0.0/16, discarding all other packets with an **administratively-prohibited** ICMP message.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 4590](#)
- [Apply the Firewall Filter to the Loopback Interface on page 4591](#)
- [Confirm and Commit Your Candidate Configuration on page 4591](#)

#### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter ospf_filter term term1 from source-address 10.108.0.0/16
set firewall family inet filter ospf_filter term term1 from protocol ospf
set firewall family inet filter ospf_filter term term1 then accept
set firewall family inet filter ospf_filter term default-term then reject
 administratively-prohibited
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input ospf_filter
```

### Configure the Stateless Firewall Filter

#### Step-by-Step Procedure

To configure the stateless firewall filter **ospf\_filter**:

1. Create the filter.

```
[edit]
user@host# edit firewall family inet filter ospf_filter
```

2. Configure the term that accepts packets.

```
[edit firewall family inet filter ospf_filter]
user@host# set term term1 from source-address 10.108.0.0/16
user@host# set term term1 from protocol ospf
user@host# set term term1 then accept
```

3. Configure the term that rejects all other packets.

```
[edit firewall family inet filter ospf_filter]
user@host# set term default_term then reject administratively-prohibited
```

*Apply the Firewall Filter to the Loopback Interface***Step-by-Step Procedure**

To apply the firewall filter to the loopback interface:

1. Configure the interface.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the logical interface IP address.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the filter to the input.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input ospf_filter
```

*Confirm and Commit Your Candidate Configuration***Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter ospf_filter {
 term term1 {
 from {
 source-address {
 10.108.0.0/16;
 }
 protocol ospf;
 }
 then {
 accept;
 }
 }
 term default_term {
 then {
 reject administratively-prohibited; # default reject action
 }
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
lo0 {
```

```
unit 0 {
 family inet {
 filter {
 input ospf_filter;
 }
 address 10.1.2.3/30;
 }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### **Verification**

To confirm that the configuration is working properly, enter the [show firewall filter ospf\\_filter](#) operational mode command.

### **Related Documentation**

- [Understanding How to Use Standard Firewall Filters on page 3293](#)

- [Example: Configuring a Filter to Accept DHCP Packets Based on Address on page 4592](#)

### **Example: Configuring a Filter to Accept DHCP Packets Based on Address**

This example shows how to configure a standard stateless firewall filter to accept packets from a trusted source.

- [Requirements on page 4592](#)
- [Overview on page 4592](#)
- [Configuration on page 4593](#)
- [Verification on page 4594](#)

### **Requirements**

This example is supported only on MX Series routers and EX Series switches.

### **Overview**

In this example, you create a filter (**rpfdhcp**) that accepts DHCP packets with a source address of **0.0.0.0** and a destination address of **255.255.255.255**.

**Configuration**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure the Stateless Firewall Filter on page 4593](#)
- [Apply the Firewall Filter to the Loopback Interface on page 4593](#)
- [Confirm and Commit Your Candidate Configuration on page 4594](#)

**CLI Quick Configuration**

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter rpf_dhcp term dhcp_term from source-address 0.0.0.0/32
set firewall family inet filter rpf_dhcp term dhcp_term from destination-address
 255.255.255.255/32
set firewall family inet filter rpf_dhcp term dhcp_term then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input sam
```

**Configure the Stateless Firewall Filter****Step-by-Step Procedure**

To configure the stateless firewall filter:

1. Create the stateless firewall filter **rpf\_dhcp**.  
  
[edit]  
user@host# edit firewall family inet filter rpf\_dhcp
2. Configure the term to match packets with a source address of **0.0.0.0** and a destination address of **255.255.255.255**.  
  
[edit firewall family inet filter rpf\_dhcp]  
user@host# set term dhcp\_term from source-address 0.0.0.0/32  
user@host# set term dhcp\_term from destination-address 255.255.255.255/32
3. Configure the term to accept packets that match the specified conditions.  
  
[edit firewall family inet filter rpf\_dhcp]  
set term dhcp\_term then accept

**Apply the Firewall Filter to the Loopback Interface****Step-by-Step Procedure**

To apply the filter to the input at the loopback interface:

1. Apply the **rpf\_dhcp** filter if packets are not arriving on an expected path.  
  
[edit]  
user@host# set interfaces lo0 unit 0 family inet **rpf-check** fail-filter rpf\_dhcp
2. Configure an address for the loopback interface.  
  
[edit]  
user@host# set interfaces lo0 unit 0 family inet address 127.0.0.1/32

### *Confirm and Commit Your Candidate Configuration*

#### **Step-by-Step Procedure**

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
 filter rpf_dhcp {
 term dhcp_term {
 from {
 source-address {
 0.0.0.0/32;
 }
 destination-address {
 255.255.255.255/32;
 }
 }
 then accept;
 }
 }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
lo0 {
 unit 0 {
 family inet {
 filter {
 rpf-check {
 fail-filter rpf_dhcp;
 mode loose;
 }
 }
 address 127.0.0.1/32;
 }
 }
}
```

3. When you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

### *Verification*

To confirm that the configuration is working properly, enter the **show firewall** operational mode command.

**Related Documentation**

**Example: Configuring a Filter to Block TCP Access to a Port Except from Specified BGP Peers**

This example shows how to configure a standard stateless firewall filter that blocks all TCP connection attempts to port 179 from all requesters except from specified BGP peers.

- [Requirements on page 4595](#)
- [Overview on page 4595](#)
- [Configuration on page 4596](#)
- [Verification on page 4599](#)

**Requirements**

No special configuration beyond device initialization is required before you configure this example.

**Overview**

In this example, you create a stateless firewall filter that blocks all TCP connection attempts to port 179 from all requesters except the specified BGP peers.

The stateless firewall filter **filter\_bgp179** matches all packets from the directly connected interfaces on Device A and Device B to the destination port number 179.

[Figure 94 on page 4595](#) shows the topology used in this example. Device C attempts to make a TCP connection to Device E. Device E blocks the connection attempt. This example shows the configuration on Device E.

**Figure 94: Typical Network with BGP Peer Sessions**

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device C**

```
set interfaces ge-1/2/0 unit 10 description to-E
set interfaces ge-1/2/0 unit 10 family inet address 10.10.10.10/30
set protocols bgp group external-peers type external
set protocols bgp group external-peers peer-as 17
set protocols bgp group external-peers neighbor 10.10.10.9
set routing-options autonomous-system 22
```

**Device E**

```
set interfaces ge-1/2/0 unit 0 description to-A
set interfaces ge-1/2/0 unit 0 family inet address 10.10.10.1/30
set interfaces ge-1/2/1 unit 5 description to-B
set interfaces ge-1/2/1 unit 5 family inet address 10.10.10.5/30
set interfaces ge-1/0/0 unit 9 description to-C
set interfaces ge-1/0/0 unit 9 family inet address 10.10.10.9/30
set interfaces lo0 unit 2 family inet filter input filter_bgp179
set interfaces lo0 unit 2 family inet address 192.168.0.1/32
set protocols bgp group external-peers type external
set protocols bgp group external-peers peer-as 22
set protocols bgp group external-peers neighbor 10.10.10.2
set protocols bgp group external-peers neighbor 10.10.10.6
set protocols bgp group external-peers neighbor 10.10.10.10
set routing-options autonomous-system 17
set firewall family inet filter filter_bgp179 term 1 from source-address 10.10.10.2/32
set firewall family inet filter filter_bgp179 term 1 from source-address 10.10.10.6/32
set firewall family inet filter filter_bgp179 term 1 from destination-port bgp
set firewall family inet filter filter_bgp179 term 1 then accept
set firewall family inet filter filter_bgp179 term 2 then reject
```

### Configuring Device E

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure Device E with a stateless firewall filter that blocks all TCP connection attempts to port 179 from all requestors except specified BGP peers:

1. Configure the interfaces.

```
user@E# set interfaces ge-1/2/0 unit 0 description to-A
user@E# set interfaces ge-1/2/0 unit 0 family inet address 10.10.10.1/30
```

```
user@E# set interfaces ge-1/2/1 unit 5 description to-B
user@E# set interfaces ge-1/2/1 unit 5 family inet address 10.10.10.5/30
```

```
user@E# set interfaces ge-1/0/0 unit 9 description to-C
user@E# set interfaces ge-1/0/0 unit 9 family inet address 10.10.10.9/30
```

2. Configure BGP.

```
[edit protocols bgp group external-peers]
user@E# set type external
user@E# set peer-as 22
user@E# set neighbor 10.10.10.2
user@E# set neighbor 10.10.10.6
user@E# set neighbor 10.10.10.10
```

3. Configure the autonomous system number.

```
[edit routing-options]
user@E# set autonomous-system 17
```

4. Define the filter term that accepts TCP connection attempts to port 179 from the specified BGP peers.

```
[edit firewall family inet filter filter_bgp179]
user@E# set term 1 from source-address 10.10.10.2/32
user@E# set term 1 from source-address 10.10.10.6/32
user@E# set term 1 from destination-port bgp
user@E# set term 1 then accept
```

5. Define the other filter term to reject packets from other sources.

```
[edit firewall family inet filter filter_bgp179]
user@E# set term 2 then reject
```

6. Apply the firewall filter to the loopback interface.

```
[edit interfaces lo0 unit 2 family inet]
user@E# set filter input filter_bgp179
user@E# set address 192.168.0.1/32
```

**Results** From configuration mode, confirm your configuration by entering the **show firewall**, **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@E# show firewall
family inet {
 filter filter_bgp179 {
 term 1 {
 from {
 source-address {
 10.10.10.2/32;
 10.10.10.6/32;
 }
 destination-port bgp;
 }
 then accept;
 }
 term 2 {
 then {
 reject;
 }
 }
 }
}
```

```
user@E# show interfaces
lo0 {
 unit 2 {
 family inet {
 filter {
 input filter_bgp179;
 }
 address 192.168.0.1/32;
 }
 }
}
ge-1/2/0 {
 unit 0 {
 description to-A;
 family inet {
 address 10.10.10.1/30;
 }
 }
}
ge-1/2/1 {
 unit 5 {
 description to-B;
 family inet {
 address 10.10.10.5/30;
 }
 }
}
ge-1/0/0 {
 unit 9 {
 description to-C;
 family inet {
 address 10.10.10.9/30;
 }
 }
}
```

```
user@E# show protocols
bgp {
 group external-peers {
 type external;
 peer-as 22;
 neighbor 10.10.10.2;
 neighbor 10.10.10.6;
 neighbor 10.10.10.10;
 }
}
```

```
user@E# show routing-options
autonomous-system 17;
```

If you are done configuring the device, enter **commit** from configuration mode.

**Verification**

Confirm that the configuration is working properly.

- [Verifying That the Filter Is Configured on page 4599](#)
- [Verifying the TCP Connections on page 4599](#)
- [Monitoring Traffic on the Interfaces on page 4599](#)

**Verifying That the Filter Is Configured**

**Purpose** Make sure that the filter is listed in output of the `show firewall filter` command.

**Action** `user@E> show firewall filter filter_bgp179`  
 Filter: filter\_bgp179

**Verifying the TCP Connections**

**Purpose** Verify the TCP connections.

**Action** From operational mode, run the `show system connections extensive` command on Device C and Device E.

The output on Device C shows the attempt to establish a TCP connection. The output on Device E shows that connections are established with Device A and Device B only.

`user@C> show system connections extensive | match 10.10.10`

|      |   |   |                  |                 |          |
|------|---|---|------------------|-----------------|----------|
| tcp4 | 0 | 0 | 10.10.10.9.51872 | 10.10.10.10.179 | SYN_SENT |
|------|---|---|------------------|-----------------|----------|

`user@E> show system connections extensive | match 10.10.10`

|      |   |   |                  |                  |             |
|------|---|---|------------------|------------------|-------------|
| tcp4 | 0 | 0 | 10.10.10.5.179   | 10.10.10.6.62096 | ESTABLISHED |
| tcp4 | 0 | 0 | 10.10.10.6.62096 | 10.10.10.5.179   | ESTABLISHED |
| tcp4 | 0 | 0 | 10.10.10.1.179   | 10.10.10.2.61506 | ESTABLISHED |
| tcp4 | 0 | 0 | 10.10.10.2.61506 | 10.10.10.1.179   | ESTABLISHED |

**Monitoring Traffic on the Interfaces**

**Purpose** Use the `monitor traffic` command to compare the traffic on an interface that establishes a TCP connection with the traffic on an interface that does not establish a TCP connection.

**Action** From operational mode, run the `monitor traffic` command on the Device E interface to Device B and on the Device E interface to Device C. The following sample output verifies that in the first example, acknowledgment (**ack**) messages are received. In the second example, **ack** messages are not received.

```
user@E> monitor traffic size 1500 interface ge-1/2/1.5
19:02:49.700912 Out IP 10.10.10.5.bgp > 10.10.10.6.62096: P

#### *Example: Configuring a Stateless Firewall Filter to Protect Against TCP and ICMP Floods*

This example shows how to create a stateless firewall filter that protects against TCP and ICMP denial-of-service attacks.

- [Requirements on page 4600](#)
- [Overview on page 4600](#)
- [Configuration on page 4602](#)
- [Verification on page 4606](#)

#### **Requirements**

No special configuration beyond device initialization is required before configuring stateless firewall filters.

#### **Overview**

In this example, you create a stateless firewall filter called **protect-RE** that polices TCP and ICMP packets. This example includes the following policers:

- **tcp-connection-policer**—Limits the traffic rate of the TCP packets to 500,000 bps and the burst size to 15,000 bytes. Packets that exceed the traffic rate are discarded.

- **icmp-policer**—Limits the traffic rate of the ICMP packets to 1,000,000 bps and the burst size to 15,000 bytes. Packets that exceed the traffic rate are discarded.

When specifying limits, the bandwidth limit can be from 32,000 bps to 32,000,000,000 bps and the burst-size limit can be from 1,500 bytes through 100,000,000 bytes. Use the following abbreviations when specifying limits: k (1,000), m (1,000,000), and g (1,000,000,000).

Each policer is incorporated into the action of a filter term. This example includes the following terms:

- **tcp-connection-term**—Policies certain TCP packets with a source address of 192.168.0.0/24 or 10.0.0.0/24. These addresses are defined in the **trusted-addresses** prefix list.

Filtered packets include **tcp-established** packets. The **tcp-established** match condition is an alias for the bit-field match condition **tcp-flags "(ack | rst)"**, which indicates an established TCP session, but not the first packet of a TCP connection.

- **icmp-term**—Polices ICMP packets. All ICMP packets are counted in the **icmp-counter** counter.

**NOTE:** You can move terms within the firewall filter by using the `insert` command. See *insert* in the *CLI User Guide*.

You can apply a stateless firewall to the input or output sides, or both, of an interface. To filter packets transiting the device, apply the firewall filter to any non-Routing Engine interface. To filter packets originating from, or destined for, the Routing Engine, apply the firewall filter to the loopback (lo0) interface.

Figure 95 on page 4601 shows the sample network.

Figure 95: Firewall Filter to Protect Against TCP and ICMP Floods

Because this firewall filter limits Routing Engine traffic to TCP packets, routing protocols that use other transport protocols for Layer 4 cannot successfully establish sessions when this filter is active. To demonstrate, this example sets up OSPF between Device R1 and Device R2.

[“CLI Quick Configuration” on page 4602](#) shows the configuration for all of the devices in [Figure 95 on page 4601](#).

The section [“Step-by-Step Procedure” on page 4603](#) describes the steps on Device R2.

### **Configuration**

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>CLI Quick Configuration</b> | To quickly configure the stateless firewall filter, copy the following commands to a text file, remove any line breaks, and then paste the commands into the CLI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

```

set firewall policer icmp-policer filter-specific
set firewall policer icmp-policer if-exceeding bandwidth-limit 1m
set firewall policer icmp-policer if-exceeding burst-size-limit 15k
set firewall policer icmp-policer then discard

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure stateless firewall filter policers:

1. Configure the device interfaces.

```

[edit interfaces fe-1/2/0 unit 0 family inet]
user@R2# set address 10.0.0.2/30

```

```

[edit interfaces lo0 unit 0 family inet]
user@R2# set address 192.168.0.2/32 primary
user@R2# set address 172.16.0.2/32

```

2. Configure the BGP peering session.

```

[edit protocols bgp group ext]
user@R2# set type external
user@R2# set export send-direct
user@R2# set neighbor 10.0.0.1 peer-as 100

```

3. Configure the autonomous system (AS) number and router ID.

```

[edit routing-options]
user@R2# set autonomous-system 200
user@R2# set router-id 192.168.0.2

```

4. Configure OSPF.

```

[edit protocols ospf area 0.0.0.0]
user@R2# set interface lo0.0 passive
user@R2# set interface fe-1/2/0.0

```

5. Define the list of trusted addresses.

```

[edit policy-options prefix-list trusted-addresses]
user@R2# set 10.0.0.0/24
user@R2# set 192.168.0.0/24

```

6. Configure a policy to advertise direct routes.

```

[edit policy-options policy-statement send-direct term 1]
user@R2# set from protocol direct
user@R2# set then accept

```

7. Configure the TCP policer.

```

[edit firewall policer tcp-connection-policer]
user@R2# set filter-specific
user@R2# set if-exceeding bandwidth-limit 1m
user@R2# set if-exceeding burst-size-limit 15k
user@R2# set then discard

```

8. Create the ICMP policer.

```
[edit firewall policer icmp-policer]
user@R2# set filter-specific
user@R2# set if-exceeding bandwidth-limit 1m
user@R2# set if-exceeding burst-size-limit 15k
user@R2# set then discard
```

9. Configure the TCP filter rules.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# set from source-prefix-list trusted-addresses
user@R2# set from protocol tcp
user@R2# set from tcp-established
user@R2# set then policer tcp-connection-policer
user@R2# set then accept
```

10. Configure the ICMP filter rules.

```
[edit firewall family inet filter protect-RE term icmp-term]
user@R2# set from source-prefix-list trusted-addresses
user@R2# set from protocol icmp
user@R2# set then policer icmp-policer
user@R2# set then count icmp-counter
user@R2# set then accept
```

11. Apply the filter to the loopback interface.

```
[edit interfaces lo0 unit 0]
user@R2# set family inet filter input protect-RE
```

**Results** Confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-options**, and **show firewall** commands from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
fe-1/2/0 {
 unit 0 {
 family inet {
 address 10.0.0.2/30;
 }
 }
}
lo0 {
 unit 0 {
 family inet {
 filter {
 input protect-RE;
 }
 address 192.168.0.2/32 {
 primary;
 }
 address 172.16.0.2/32;
 }
 }
}
```

```
user@R2# show protocols
bgp {
 group ext {
 type external;
 export send-direct;
 neighbor 10.0.0.1 {
 peer-as 100;
 }
 }
}
ospf {
 area 0.0.0.0 {
 interface lo0.0 {
 passive;
 }
 interface fe-1/2/0.0;
 }
}

user@R2# show policy-options
prefix-list trusted-addresses {
 10.0.0.0/24;
 192.168.0.0/24;
}
policy-statement send-direct {
 term 1 {
 from protocol direct;
 then accept;
 }
}

user@R2# show routing-options
router-id 192.168.0.2;
autonomous-system 200;

user@R2# show firewall
family inet {
 filter protect-RE {
 term tcp-connection-term {
 from {
 source-prefix-list {
 trusted-addresses;
 }
 protocol tcp;
 tcp-established;
 }
 then {
 policer tcp-connection-policer;
 accept;
 }
 }
 term icmp-term {
 from {
 source-prefix-list {
 trusted-addresses;
 }
 protocol icmp;
 }
 }
 }
}
```

```

 }
 then {
 policer icmp-policer;
 count icmp-counter;
 accept;
 }
}
}
}
policer tcp-connection-policer {
 filter-specific;
 if-exceeding {
 bandwidth-limit 1m;
 burst-size-limit 15k;
 }
 then discard;
}
policer icmp-policer {
 filter-specific;
 if-exceeding {
 bandwidth-limit 1m;
 burst-size-limit 15k;
 }
 then discard;
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Verification

Confirm that the configuration is working properly.

**NOTE:** To verify the TCP policer, you can use a packet generation tool. This task is not shown here.

### Displaying Stateless Firewall Filter That Are in Effect

**Purpose** Verify the configuration of the firewall filter.

**Action** From operational mode, enter the **show firewall** command.

```
user@R2> show firewall
```

```
Filter: protect-RE
```

```
Counters:
```

| Name         | Bytes | Packets |
|--------------|-------|---------|
| icmp-counter | 0     | 0       |

|                        |       |         |  |
|------------------------|-------|---------|--|
| Policers:              |       |         |  |
| Name                   | Bytes | Packets |  |
| icmp-policer           |       | 0       |  |
| tcp-connection-policer |       | 0       |  |

**Meaning** The output shows the filter, the counter, and the policers that are in effect on Device R2.

### *Using telnet to Verify the tcp-established Condition in the TCP Firewall Filter*

**Purpose** Make sure that telnet traffic works as expected.

**Action** Verify that the device can establish only TCP sessions with hosts that meet the **from tcp-established** condition..

1. From Device R2, make sure that the BGP session with Device R1 is established.

```
user@R2> show bgp summary | match down
Groups: 1 Peers: 1 Down peers: 0
```

2. From Device R2, telnet to Device R1.

```
user@R2> telnet 192.168.0.1
Trying 192.168.0.1...
Connected to R1.acme.net.
Escape character is '^['.
```

R1 (ttyp4)

Login:

3. From Device R1, telnet to Device R2.

```
user@R1> telnet 192.168.0.2
Trying 192.168.0.2...
telnet: connect to address 192.168.0.2: Operation timed out
telnet: Unable to connect to remote host
```

4. On Device R2, deactivate the **from tcp-established** match condition.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# deactivate from tcp-established
user@R2# commit
```

5. From Device R1, try again to telnet to Device R2.

```
user@R1> telnet 192.168.0.1
Trying 192.168.0.2...
Connected to R2.acme.net.
Escape character is '^['.
```

R2 (ttyp4)

Login:

**Meaning** Verify the following information:

- As expected, the BGP session is established. The **from tcp-established** match condition is not expected to block BGP session establishment.

- From Device R2, you can telnet to Device R1. Device R1 has no firewall filter configured, so this is the expected behavior.
- From Device R1, you cannot telnet to Device R2. Telnet uses TCP as the transport protocol, so this result might be surprising. The cause for the lack of telnet connectivity is the **from tcp-established** match condition. This match condition limits the type of TCP traffic that is accepted of Device R2. After this match condition is deactivated, the telnet session is successful.

### *Using telnet to Verify the Trusted Prefixes Condition in the TCP Firewall Filter*

**Purpose** Make sure that telnet traffic works as expected.

**Action** Verify that the device can establish only telnet sessions with a host at an IP address that matches one of the trusted source addresses. For example, log in to the device with the **telnet** command from another host with one of the trusted address prefixes. Also, verify that telnet sessions with untrusted source addresses are blocked.

1. From Device R1, telnet to Device R2 from an untrusted source address.

```
user@R1> telnet 172.16.0.2 source 172.16.0.1
Trying 172.16.0.2...
^C
```

2. From Device R2, add 172.16/16 to the list of trusted prefixes.

```
[edit policy-options prefix-list trusted-addresses]
user@R2# set 172.16.0.0/16
user@R2# commit
```

3. From Device R1, try again to telnet to Device R2.

```
user@R1> telnet 172.16.0.2 source 172.16.0.1
Trying 172.16.0.2...
Connected to R2.acme.net.
Escape character is '^J'.
```

```
R2 (ttyp4)
```

```
login:
```

**Meaning** Verify the following information:

- From Device R1, you cannot telnet to Device R2 with an untrusted source address. After the 172.16/16 prefix is added to the list of trusted prefixes, the telnet request from source address 172.16.0.1 is accepted.
- OSPF session establishment is blocked. OSPF does not use TCP as its transport protocol. After the **from protocol tcp** match condition is deactivated, OSPF session establishment is not blocked.

### *Using OSPF to Verify the TCP Firewall Filter*

**Purpose** Make sure that OSPF traffic works as expected.

\_\_\_\_\_

```
--- 192.168.0.2 ping statistics ---
600 packets transmitted, 536 packets received, 10% packet loss
pinground-trip min/avg/max/stddev = 2.976/3.405/42.380/2.293 ms
```

3. From Device R2, check the firewall statistics.

```
user@R2> show firewall
```

```
Filter: protect-RE
```

```
Counters:
```

| Name         | Bytes   | Packets |
|--------------|---------|---------|
| icmp-counter | 1180804 | 1135    |

```
Policers:
```

| Name                   | Bytes | Packets |
|------------------------|-------|---------|
| icmp-policer           |       | 66      |
| tcp-connection-policer |       | 0       |

4. From an untrusted source address on Device R1, send a ping request to Device R2's loopback interface.

```
user@R1> ping 172.16.0.2 source 172.16.0.1
```

```
PING 172.16.0.2 (172.16.0.2): 56 data bytes
```

```
^C
```

```
--- 172.16.0.2 ping statistics ---
```

```
14 packets transmitted, 0 packets received, 100% packet loss
```

**Meaning** Verify the following information:

- The ping output shows that 10% packet loss is occurring.
- The ICMP packet counter is incrementing, and the icmp-policer is incrementing.
- Device R2 does not send ICMP responses to the **ping 172.16.0.2 source 172.16.0.1** command.

**Example: Configuring a Filter to Accept Packets Based on IPv6 TCP Flags**

This example shows how to configure a standard stateless firewall filter to accept packets from a trusted source.

- [Requirements on page 4610](#)
- [Overview on page 4611](#)
- [Configuration on page 4611](#)
- [Verification on page 4612](#)

**Requirements**

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, you create a filter that accepts packets with specific IPv6 TCP flags.

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure the Stateless Firewall Filter on page 4611](#)
- [Apply the Firewall Filter to the Loopback Interface on page 4611](#)
- [Confirm and Commit Your Candidate Configuration on page 4612](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```

set firewall family inet6 filter tcp_filter term 1 from next-header tcp
set firewall family inet6 filter tcp_filter term 1 from tcp-flags syn
set firewall family inet6 filter tcp_filter term 1 then count tcp_syn_pkt
set firewall family inet6 filter tcp_filter term 1 then log
set firewall family inet6 filter tcp_filter term 1 then accept
set interfaces lo0 unit 0 family inet6 filter input tcp_filter
set interfaces lo0 unit 0 family inet6 address ::10.34.1.0/120

```

### Configure the Stateless Firewall Filter

### Step-by-Step Procedure

To configure the firewall filter

1. Create the IPv6 stateless firewall filter **tcp\_filter**.
 

```

[edit]
user@host# edit firewall family inet6 filter tcp_filter

```
2. Specify that a packet matches if it is the initial packet in a TCP session and the next header after the IPv6 header is type TCP.
 

```

[edit firewall family inet6 filter tcp_filter]
user@host# set term 1 from next-header tcp
user@host# set term 1 from tcp-flags syn

```
3. Specify that matched packets are counted, logged to the buffer on the Packet Forwarding Engine, and accepted.
 

```

[edit firewall family inet6 filter tcp_filter]
user@host# set term 1 then count tcp_syn_pkt
user@host# set term 1 then log
user@host# set term 1 then accept

```

### Apply the Firewall Filter to the Loopback Interface

### Step-by-Step Procedure

To apply the firewall filter to the loopback interface:

- ```

[edit]
user@host# set interfaces lo0 unit 0 family inet6 filter input tcp_filter
user@host# set interfaces lo0 unit 0 family inet6 address ::10.34.1.0/120

```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet6 {
  filter tcp_filter {
    term 1 {
      from {
        next-header tcp;
        tcp-flags syn;
      }
      then {
        count tcp_syn_pkt;
        log;
        accept;
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
lo0 {
  unit 0 {
    family inet6 {
      filter {
        input tcp_filter;
      }
      address ::10.34.1.0/120;
    }
  }
}
```

3. When you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the **show firewall** operational mode command.

Example: Configuring a Stateless Firewall Filter to Handle Fragments

This example shows how to create a stateless firewall filter that handles packet fragments.

- [Requirements on page 4613](#)
- [Overview on page 4613](#)
- [Configuration on page 4614](#)
- [Verification on page 4617](#)

Requirements

No special configuration beyond device initialization is required before configuring stateless firewall filters.

Overview

In this example, you create a stateless firewall filter called **fragment-RE** that accepts fragmented packets originating from 10.2.1.0/24 and destined for the BGP port. This example includes the following firewall filter terms:

- **not-from-prefix-term**—Discards packets that are not from 10.2.1.0/24 to ensure that subsequent terms in the firewall filter are matched against packets from 10.2.1.0/24 only.
- **small-offset-term**—Discards small (1–5) offset packets to ensure that subsequent terms in the firewall filter can be matched against all the headers in the packet. In addition, the term adds a record to the system logging destinations for the firewall facility.
- **not-fragmented-term**—Accepts unfragmented TCP packets with a destination port that specifies the BGP protocol. A packet is considered unfragmented if the MF flag is not set and the fragment offset equals 0.
- **first-fragment-term**—Accepts the first fragment of a fragmented TCP packet with a destination port that specifies the BGP protocol.
- **fragment-term**—Accepts all fragments that were not discarded by **small-offset-term**. (packet fragments 6–8191). However, only those fragments that are part of a packet containing a first fragment accepted by **first-fragment-term** are reassembled by the destination device.

Packet fragments offset can be from 1 through 8191.

NOTE: You can move terms within the firewall filter by using the `insert` command. For more information, see “*insert*” in the *CLI User Guide*.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the `[edit]` hierarchy level.

```
set firewall family inet filter fragment-RE term not-from-prefix-term from source-address 0.0.0.0/0
set firewall family inet filter fragment-RE term not-from-prefix-term from source-address 10.2.1.0/24 except
set firewall family inet filter fragment-RE term not-from-prefix-term then discard
set firewall family inet filter fragment-RE term small-offset-term from fragment-offset 1-5
set firewall family inet filter fragment-RE term small-offset-term then syslog
set firewall family inet filter fragment-RE term small-offset-term then discard
set firewall family inet filter fragment-RE term not-fragmented-term from fragment-offset 0
set firewall family inet filter fragment-RE term not-fragmented-term from fragment-flags "!more-fragments"
set firewall family inet filter fragment-RE term not-fragmented-term from protocol tcp
set firewall family inet filter fragment-RE term not-fragmented-term from destination-port bgp
set firewall family inet filter fragment-RE term not-fragmented-term then accept
set firewall family inet filter fragment-RE term first-fragment-term from first-fragment
set firewall family inet filter fragment-RE term first-fragment-term from protocol tcp
set firewall family inet filter fragment-RE term first-fragment-term from destination-port bgp
set firewall family inet filter fragment-RE term first-fragment-term then accept
set firewall family inet filter fragment-RE term fragment-term from fragment-offset 6-8191
set firewall family inet filter fragment-RE term fragment-term then accept
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see “[Using the CLI Editor in Configuration Mode](#)” on page 4704 in the *CLI User Guide*.

To configure the stateless firewall filter:

1. Define the stateless firewall filter.

```
[edit]
user@host# edit firewall family inet filter fragment-RE
```

2. Configure the first term for the filter.

```
[edit firewall family inet filter fragment-RE ]
user@host# set term not-from-prefix-term from source-address 0.0.0.0/0
user@host# set term not-from-prefix-term from source-address 10.2.1.0/24 except
user@host# set term not-from-prefix-term then discard
```

3. Define the second term for the filter.

```
[edit firewall family inet filter fragment-RE]
user@host# edit term small-offset-term
```
4. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term small-offset-term]
user@host# set from fragment-offset 1-5
```
5. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term small-offset-term]
user@host# set then syslog discard
```
6. Define the third term for the filter.

```
[edit]
user@host# edit firewall family inet filter fragment-RE term not-fragmented-term
```
7. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term not-fragmented-term]
user@host# set from fragment-flags "!more-fragments" fragment-offset 0 protocol
tcp destination-port bgp
```
8. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term not-fragmented-term]
user@host# set then accept
```
9. Define the fourth term for the filter.

```
[edit]
user@host# edit firewall family inet filter fragment-RE term first-fragment-term
```
10. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term first-fragment-term]
user@host# set from first-fragment protocol tcp destination-port bgp
```
11. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term first-fragment-term]
user@host# set then accept
```
12. Define the last term for the filter.

```
[edit]
user@host# edit firewall family inet filter fragment-RE term fragment-term
```
13. Define the match conditions for the term.

```
[edit firewall family inet filter fragment-RE term fragment-term]
user@host# set from fragment-offset 6-8191
```
14. Define the action for the term.

```
[edit firewall family inet filter fragment-RE term fragment-term]
user@host# set then accept
```

Results Confirm your configuration by entering the **show firewall** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show firewall
family inet {
  filter fragment-RE {
    term not-from-prefix-term {
      from {
        source-address {
          0.0.0.0/0;
          10.2.1.0/24 except;
        }
      }
      then discard;
    }
    term small-offset-term {
      from {
        fragment-offset 1-5;
      }
      then {
        syslog;
        discard;
      }
    }
    term not-fragmented-term {
      from {
        fragment-offset 0;
        fragment-flags "!more-fragments";
        protocol tcp;
        destination-port bgp;
      }
      then accept;
    }
    term first-fragment-term {
      from {
        first-fragment;
        protocol tcp;
        destination-port bgp;
      }
      then accept;
    }
    term fragment-term {
      from {
        fragment-offset 6-8191;
      }
      then accept;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Displaying Stateless Firewall Filter Configurations on page 4617](#)
- [Verifying a Firewall Filter that Handles Fragments on page 4617](#)

Displaying Stateless Firewall Filter Configurations

Purpose Verify the configuration of the firewall filter. You can analyze the flow of the filter terms by displaying the entire configuration.

Action From configuration mode, enter the **show firewall** command.

Meaning Verify that the output shows the intended configuration of the firewall filter. In addition, verify that the terms are listed in the order in which you want the packets to be tested. You can move terms within a firewall filter by using the **insert** CLI command.

Verifying a Firewall Filter that Handles Fragments

Purpose Verify that the actions of the firewall filter terms are taken.

Action Send packets to the device that match the terms.

Meaning Verify that packets from 10.2.1.0/24 with small fragment offsets are recorded in the device's system logging destinations for the firewall facility.

Related Documentation • *show route summary* in the *Junos OS Operational Mode Commands*.

Standard Firewall Filters for Setting Rate Limits

- [Example: Configuring a Rate-Limiting Filter Based on Destination Class on page 4617](#)

Example: Configuring a Rate-Limiting Filter Based on Destination Class

This example shows how to configure a rate-limiting stateless firewall filter.

- [Requirements on page 4617](#)
- [Overview on page 4618](#)
- [Configuration on page 4618](#)
- [Verification on page 4620](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Before you begin, configure the destination class **class1**.

Overview

In this example, you use a stateless firewall filter to set rate limits based on a destination class.

To activate a policer from within a stateless firewall filter configuration:

- Create a template for the policer by including the **policer policer-name** statement.
- Reference the policer in a filter term that specifies the policer in the **policer policer-name** nonterminating action.

You can also activate a policer by including the **policer (input | output) policer-template-name** statement at a logical interface.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure the Stateless Firewall Filter on page 4618](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4619](#)
- [Confirm and Commit Your Candidate Configuration on page 4619](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter rl_dclass1 policer police_class1 if-exceeding bandwidth-limit 25
set firewall filter rl_dclass1 policer police_class1 if-exceeding burst-size-limit 1000
set firewall filter rl_dclass1 policer police_class1 then discard
set firewall filter rl_dclass1 term term1 from destination-class class1
set firewall filter rl_dclass1 term term1 then policer police_class1
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input ospf_or_131
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **rl_dclass1** with policer **police_class1** for destination class **class1**:

1. Create the stateless firewall filter **rl_dclass1**.

```
[edit]
user@host# edit firewall filter rl_dclass1
```

2. Configure the policer template **police_class1**.

```
[edit firewall filter rl_dclass1]
user@host# set policer police_class1 if-exceeding bandwidth-limit 25
user@host# set policer police_class1 if-exceeding burst-size-limit 1000
user@host# set policer police_class1 then discard
```

3. Configure a filter term that uses policer **police_class1** to rate-limit traffic for destination class **class1**.

```
[edit firewall filter rl_dclass1]
user@host# set term term1 from destination-class class1
user@host# set term term1 then policer police_class1
```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the filter **rl_dclass1** to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input rl_dclass1
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
filter rl_dclass1 {
  policer police_class1 {
    if-exceeding {
      bandwidth-limit 25;
      burst-size-limit 1000;
    }
    then {
      discard;
    }
  }
  term term1 {
    from {
      destination-class class1;
    }
    then {
      policer police_class1;
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      filter {
        input rl_dclass1;
      }
      address 10.1.2.3/30;
    }
  }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@host# commit
```

Verification

To confirm that the configuration is working properly, enter the **show class-of-service ge-0/0/1** operational mode command.

Example: Applying Lists of Multiple Standard Firewall Filters

This example shows how to apply lists of multiple stateless firewall filters.

- [Requirements on page 4621](#)
- [Overview on page 4621](#)
- [Configuration on page 4622](#)
- [Verification on page 4625](#)

Requirements

Before you begin, be sure that you have:

- Installed your router or switch, and supported PIC, DPC, or MPC and performed the initial router or switch configuration.
- Configured basic Ethernet in the topology.
- Configured a logical interface to run the IP version 4 (IPv4) protocol (**family inet**) and configured the logical interface with an interface address. This example uses logical interface **ge-1/3/0.0** configured with the IP address 1.1.1.2/30.

NOTE: For completeness, the configuration section of this example includes setting an IP address for logical interface **ge-1/3/0.0**.

- Verified that traffic is flowing in the topology and that ingress and egress IPv4 traffic is flowing through logical interface **ge-1/3/0.0**.
- Verified that you have access to the remote host that is connected to this router's or switch's logical interface **ge-1/3/0.0**.

Overview

In this example, you configure three IPv4 stateless firewall filters and apply each filter directly to the same logical interface by using a list.

Topology

This example applies the following firewall filters as a *list of input filters* at logical interface **ge-1/3/0.0**. Each filter contains a single term that evaluates IPv4 packets and accepts packets based on the value of the **destination port** field in the TCP header:

- Filter **filter_FTP** matches on the FTP port number (21).
- Filter **filter_SSH** matches on the SSH port number (22).
- Filter **filter_Telnet** matches on the Telnet port number (23).

If an inbound packet does not match any of the filters in the input list, the packet is discarded.

NOTE: The Junos OS uses filters in a list in the order in which the filter names appear in the list. In this simple example, the order is irrelevant because all of the filters specify the same action.

Any of the filters can be applied to other interfaces, either alone (using the **input** or **output** statement) or in combination with other filters (using the **input-list** or **output-list** statement). The objective is to configure multiple “minimalist” firewall filters that you can reuse in interface-specific filter lists.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure Multiple IPv4 Stateless Firewall Filters on page 4622](#)
- [Apply the Filters to a Logical Interface as an Input List and an Output List on page 4623](#)
- [Confirm and Commit Your Candidate Configuration on page 4623](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter filter_FTP term 0 from protocol tcp
set firewall family inet filter filter_FTP term 0 from destination-port 21
set firewall family inet filter filter_FTP term 0 then count pkts_FTP
set firewall family inet filter filter_FTP term 0 then accept
set firewall family inet filter filter_SSH term 0 from protocol tcp
set firewall family inet filter filter_SSH term 0 from destination-port 23
set firewall family inet filter filter_SSH term 0 then count pkts_SSH
set firewall family inet filter filter_SSH term 0 then accept
set firewall family inet filter filter_Telnet term 0 from protocol tcp
set firewall family inet filter filter_Telnet term 0 from destination-port 22
set firewall family inet filter filter_Telnet term 0 then count pkts_Telnet
set firewall family inet filter filter_Telnet term 0 then accept
set firewall family inet filter filter_discard term 1 then count pkts_discarded
set firewall family inet filter filter_discard term 1 then discard
set interfaces ge-1/3/0 unit 0 family inet address 1.1.1.2/30
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_FTP
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_SSH
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_Telnet
set interfaces ge-1/3/0 unit 0 family inet filter input-list filter_discard
```

Configure Multiple IPv4 Stateless Firewall Filters

Step-by-Step Procedure

To configure the IPv4 stateless firewall filters:

1. Navigate the CLI to the hierarchy level at which you configure IPv4 firewall filters.

```
[edit]
user@host# edit firewall family inet
```
2. Configure the first firewall filter to count and accept packets for port 21.

```
[edit firewall family inet]
```

```

user@host# set filter filter_FTP term 0 from protocol tcp
user@host# set filter filter_FTP term 0 from destination-port 21
user@host# set filter filter_FTP term 0 then count pkts_FTP
user@host# set filter filter_FTP term 0 then accept

```

3. Configure the second firewall filter to count and accept packets for port 23.

```

[edit firewall family inet]
user@host# set filter filter_SSH term 0 from protocol tcp
user@host# set filter filter_SSH term 0 from destination-port 23
user@host# set filter filter_SSH term 0 then count pkt_SSH
user@host# set filter filter_SSH term 0 then accept

```

4. Configure the third firewall filter to count and accept packets from port 22.

```

[edit firewall family inet]
user@host# set filter filter_Telnet term 0 from protocol tcp
user@host# set filter filter_Telnet term 0 from destination-port 22
user@host# set filter filter_Telnet term 0 then count pkts_Telnet
user@host# set filter filter_Telnet term 0 then accept

```

5. Configure the last firewall filter to count the discarded packets.

```

[edit firewall family inet]
user@host# set filter filter_discard term 1 then count pkts_discarded
user@host# set filter filter_discard term 1 then discard

```

Apply the Filters to a Logical Interface as an Input List and an Output List

Step-by-Step Procedure To apply the six IPv4 stateless firewall filters as a list of input filters and a list of output filters:

1. Navigate the CLI to the hierarchy level at which you apply IPv4 firewall filters to logical interface **ge-1/3/0.0**.

```

[edit]
user@host# edit interfaces ge-1/3/0 unit 0 family inet

```

2. Configure the IPv4 protocol family for the logical interface.

```

[edit interfaces ge-1/3/0 unit 0 family inet]
user@host# set address 1.1.1.2/30

```

3. Apply the filters as a list of input filters.

```

[edit interfaces ge-1/3/0 unit 0 family inet]
user@host# set filter input-list [ filter_FTP filter_SSH filter_Telnet filter_discard ]

```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filters by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show firewall

```

```
family inet {
  filter filter_FTP {
    term 0 {
      from {
        protocol tcp;
        destination-port 21;
      }
      then {
        count pkts_FTP;
        accept;
      }
    }
  }
  filter filter_SSH {
    term 0 {
      from {
        protocol tcp;
        destination-port 23;
      }
      then {
        count pkts_SSH;
        accept;
      }
    }
  }
  filter filter_Telnet {
    term 0 {
      from {
        protocol tcp;
        destination-port 22;
      }
      then {
        count pkts_Telnet;
        accept;
      }
    }
  }
  filter filter_discard {
    term 1 {
      then {
        count pkts_discarded;
        discard;
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/0 {
  unit 0 {
    family inet {
```

```

        filter {
            input-list [ filter_FTP filter_SSH filter_Telnet filter_discard ];
        }
        address 1.1.1.2/30;
    }
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

Confirm that the configuration is working properly.

- [Verifying That Inbound Packets Are Accepted Only If Destined for the FTP, SSH or Telnet Port on page 4625](#)

Verifying That Inbound Packets Are Accepted Only If Destined for the FTP, SSH or Telnet Port

Purpose Verify that all three filters are active for the logical interface.

Action To verify that input packets are accepted according to the three filters:

1. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with destination port number 21 in the header. The packet should be accepted.
2. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with destination port number 23 in the header. The packet should be accepted.
3. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with destination port number 22 in the header. The packet should be accepted.
4. From the remote host that is connected to this router's (or switch's) logical interface **ge-1/3/0.0**, send a packet with a destination port number *other than* 21, 22, or 23. The packet should be discarded.
5. To display counter information for the list of filters applied to the input at **ge-1/3/0.0-i** enter the **show firewall filter ge-1/3/0.0-i** operational mode command. The command output displays the number of bytes and packets that match filter terms associated with the following counters:
 - **pkts_FTP-ge-1/3/0.0-i**
 - **pkts_SSH-ge-1/3/0.0-i**
 - **pkts_Telnet-ge-1/3/0.0-i**
 - **pkts_discard-ge-1/3/0.0-i**

Example: Nesting References to Multiple Standard Firewall Filters

This example shows how to configure nested references to multiple stateless firewall filters.

- [Requirements on page 4626](#)
- [Overview on page 4626](#)
- [Configuration on page 4626](#)
- [Verification on page 4629](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you configure a stateless firewall filter for a match condition and action combination that can be shared among multiple firewall filters. You then configure two firewall filters that reference the first firewall filter. Later, if the common filtering criteria needs to be changed, you would modify only the one shared firewall filter configuration.

Topology

The **common_filter** firewall filter discards packets that have a UDP source or destination port field number of 69. Both of the two additional firewall filters, **filter1** and **filter2**, reference the **common_filter**.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure the Nested Firewall Filters on page 4627](#)
- [Apply Both Nested Firewall Filters to Interfaces on page 4627](#)
- [Confirm and Commit Your Candidate Configuration on page 4628](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter common_filter term common_term from protocol udp
set firewall family inet filter common_filter term common_term from port tftp
set firewall family inet filter common_filter term common_term then discard
set firewall family inet filter filter1 term term1 filter common-filter
set firewall family inet filter filter1 term term2 from address 192.168.0.0/16
set firewall family inet filter filter1 term term2 then reject
set firewall family inet filter filter2 term term1 filter common-filter
set firewall family inet filter filter2 term term2 from protocol udp
set firewall family inet filter filter2 term term2 from port bootps
```

```

set firewall family inet filter filter2 term term2 then accept
set interfaces ge-0/0/0 unit 0 family inet address 10.1.0.1/24
set interfaces ge-0/0/0 unit 0 family inet filter input filter1
set interfaces ge-0/0/3 unit 0 family inet address 10.1.3.1/24
set interfaces ge-0/0/0 unit 0 family inet filter input filter2

```

Configure the Nested Firewall Filters

Step-by-Step Procedure

To configure two nested firewall filters that share a common filter:

1. Navigate the CLI to the hierarchy level at which you configure IPv4 firewall filters.

```

[edit]
user@host# edit firewall family inet

```

2. Configure the common filter that will be referenced by multiple other filters.

```

[edit firewall family inet]
user@host# set filter common_filter term common_term from protocol udp
user@host# set filter common_filter term common_term from port tftp
user@host# set filter common_filter term common_term then discard

```

3. Configure a filter that references the common filter.

```

[edit firewall family inet]
user@host# set filter filter1 term term1 filter common-filter
user@host# set filter filter1 term term2 from address 192.168.0.0/16
user@host# set filter filter1 term term2 then reject

```

4. Configure a second filter that references the common filter.

```

[edit firewall family inet]
user@host# set filter filter2 term term1 filter common-filter
user@host# set filter filter2 term term2 from protocol udp
user@host# set filter filter2 term term2 from port bootps
user@host# set filter filter2 term term2 then accept

```

Apply Both Nested Firewall Filters to Interfaces

Step-by-Step Procedure

To apply both nested firewall filters to logical interfaces:

1. Apply the first nested filter to a logical interface input.

```

[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.0.1/24
user@host# set interfaces ge-0/0/0 unit 0 family inet filter input filter1

```

2. Apply the second nested filter to a logical interface input.

```

[edit]
user@host# set interfaces ge-0/0/3 unit 0 family inet address 10.1.3.1/24
user@host# set interfaces ge-0/0/0 unit 0 family inet filter input filter2

```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter common_filter {
    term common_term {
      from {
        protocol udp;
        port tftp;
      }
      then {
        discard;
      }
    }
  }
  filter filter1 {
    term term1 {
      filter common-filter;
    }
    term term2 {
      from {
        address 192.168/16;
      }
      then {
        reject;
      }
    }
  }
  filter filter2 {
    term term1 {
      filter common-filter;
    }
    term term2 {
      from {
        protocol udp;
        port bootps;
      }
      then {
        accept;
      }
    }
  }
}
```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
```

```

user@host# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      filter {
        input filter1;
      }
      address 10.1.0.1/24;
    }
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      filter {
        input filter2;
      }
      address 10.1.3.1/24;
    }
  }
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To confirm that the configuration is working properly, enter the `show firewall filter filter1` and `show firewall filter filter2` operational mode commands.

Related Documentation

- [Multiple Standard Firewall Filters in a Nested Configuration Overview on page 4510](#)
- [Guidelines for Nesting References to Multiple Standard Firewall Filters on page 4511](#)

Example: Configuring Interface-Specific Firewall Filter Counters

This example shows how to configure and apply an interface-specific standard stateless firewall filter.

- [Requirements on page 4629](#)
- [Overview on page 4630](#)
- [Configuration on page 4630](#)
- [Verification on page 4632](#)

Requirements

Interface-specific stateless firewall filters are supported on T Series, M120, M320, MX Series routers, and EX Series switches only.

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you create an interface-specific stateless firewall filter that counts and accepts packets with source or destination addresses in a specified prefix and the IP protocol type field set to a specific value.

Topology

You configure the interface-specific stateless firewall filter **filter_s_tcp** to count and accept packets with IP source or destination addresses in the **10.0.0.0/12** prefix and the IP protocol type field set to **tcp** (or the numeric value **6**).

The name of the firewall filter counter is **count_s_tcp**.

You apply the firewall filter to multiple logical interfaces:

- **at-1/1/1.0** input
- **ge-2/2/2.2** output

Applying the filter to these two interfaces results in two instances of the filter: **filter_s_tcp-at-1/1/1.0-i** and **filter_s_tcp-ge-2/2/2.2-o**, respectively.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Interface-Specific Firewall Filter on page 4630](#)
- [Apply the Interface-Specific Firewall Filter to Multiple Interfaces on page 4631](#)
- [Confirm Your Candidate Configuration on page 4631](#)
- [Clear the Counters and Commit Your Candidate Configuration on page 4632](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter filter_s_tcp interface-specific
set firewall family inet filter filter_s_tcp term 1 from address 10.0.0.0/12
set firewall family inet filter filter_s_tcp term 1 from protocol tcp
set firewall family inet filter filter_s_tcp term 1 then count count_s_tcp
set firewall family inet filter filter_s_tcp term 1 then accept
set interfaces at-1/1/1 unit 0 family inet filter input filter_s_tcp
set interfaces ge-2/2/2 unit 2 family inet filter filter_s_tcp
```

Configure the Interface-Specific Firewall Filter

Step-by-Step Procedure

To configure the interface-specific firewall filter:

1. Create the IPv4 firewall filter **filter_s_tcp**.

[edit]
user@host# edit firewall family inet filter filter_s_tcp

2. Enable interface-specific instances of the filter.

```
[edit firewall family inet filter filter_s_tcp]
user@host# set interface-specific
```

3. Configure the match conditions for the term.

```
[edit firewall family inet filter filter_s_tcp]
user@host# set term 1 from address 10.0.0.0/12
user@host# set term 1 from protocol tcp
```

4. Configure the actions for the term.

```
[edit firewall family inet filter filter_s_tcp]
user@host# set term 1 then count count_s_tcp
user@host# set term 1 then accept
```

Apply the Interface-Specific Firewall Filter to Multiple Interfaces

Step-by-Step Procedure

To apply the filter **filter_s_tcp** to logical interfaces **at-1/1/1.0** and **ge-2/2/2.2**:

1. Apply the interface-specific filter to packets received on logical interface **at-1/1/1.0**.

```
[edit]
user@host# set interfaces at-1/1/1 unit 0 family inet filter input filter_s_tcp
```

2. Apply the interface-specific filter to packets transmitted from logical interface **ge-2/2/2.2**.

```
[edit]
user@host# set interfaces ge-2/2/2 unit 2 family inet filter filter_s_tcp
```

Confirm Your Candidate Configuration

Step-by-Step Procedure

To confirm your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter_s_tcp {
    interface-specific;
    term 1 {
      from {
        address {
          10.0.0.0/12;
        }
        protocol tcp;
      }
      then {
        count count_s_tcp;
        accept;
      }
    }
  }
}
```

```
}  
}
```

2. Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]  
user@host# show interfaces  
at-1/1/1 {  
  unit 0  
    family inet {  
      filter {  
        input filter_s_tcp;  
      }  
    }  
  }  
}  
ge-2/2/2 {  
  unit 2  
    family inet {  
      filter {  
        output filter_s_tcp;  
      }  
    }  
  }  
}
```

Clear the Counters and Commit Your Candidate Configuration

Step-by-Step Procedure

To clear the counters and commit your candidate configuration:

1. From operational command mode, use the **clear firewall all** command to clear the statistics for all firewall filters.

To clear only the counters used in this example, include the interface-specific filter instance names:

```
[edit]  
user@host> clear firewall filter filter_s_tcp-at-1/1/1.0-i  
user@host> clear firewall filter filter_s_tcp-ge-2/2/2.2-o
```

2. Commit your candidate configuration.

```
[edit]  
user@host# commit
```

Verification

Confirm that the configuration is working properly.

- [Verifying That the Filter Is Applied to Each of the Multiple Interfaces on page 4632](#)
- [Verifying That the Counters Are Collected Separately by Interface on page 4633](#)

Verifying That the Filter Is Applied to Each of the Multiple Interfaces

Purpose Verify that the filter is applied to each of the multiple interfaces.

Action Run the **show interfaces** command with the **detail** or **extensive** output level.

1. Verify that the filter is applied to the input for **at-1/1/1.0**:

```
user@host> show interfaces at-1/1/1 detail
Physical interface: at-1/1/1, Enabled, Physical link is Up
  Interface index: 300, SNMP ifIndex: 194, Generation: 183
...
  Logical interface at-1/1/1.0 (Index 64) (SNMP ifIndex 204) (Generation 5)
    Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: ATM-SNAP
...
  Protocol inet, MTU: 4470, Generation: 13, Route table: 0
    Flags: Sendbcst-pkt-to-re
    Input Filters: filter_s_tcp-at-1/1/1.0-i,,,,,
```

2. Verify that the filter is applied to the output for **ge-2/2/2.2**:

```
user@host> show interfaces ge-2/2/2 detail
Physical interface: ge-2/2/2, Enabled, Physical link is Up
  Interface index: 129, SNMP ifIndex: 502, Generation: 132
...
  Logical interface ge-2/2/2.2 (Index 70) (SNMP ifIndex 536) (Generation 135)
    Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPP
...
  Protocol inet, MTU: 4470, Generation: 146, Route table: 0
    Flags: Sendbcst-pkt-to-re
    Output Filters: filter_s_tcp-ge-2/2/2.2-o,,,,,
```

Verifying That the Counters Are Collected Separately by Interface

Purpose Make sure that the **count_s_tcp** counters are collected separately for the two logical interfaces.

Action Run the **show firewall** command.

```
user@host> show firewall filter filter_s_tcp
Filter: filter_s_tcp
Counters:
Name                               Bytes      Packets
count_s_tcp-at-1/1/1.0-i           420         5
count_s_tcp-ge-2/2/2.2-o          8888        101
```

- Related Documentation**
- [Interface-Specific Firewall Filter Instances Overview](#)
 - [Statement Hierarchy for Configuring Interface-Specific Firewall Filters on page 4773](#)
 - [Statement Hierarchy for Applying Interface-Specific Firewall Filters on page 4774](#)

Example: Filtering Packets Received on an Interface Group

This example shows how to configure a standard stateless firewall filter to match packets tagged for a particular interface group.

- [Requirements on page 4634](#)
- [Overview on page 4634](#)
- [Configuration on page 4634](#)
- [Verification on page 4637](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you configure two router or switch interfaces to belong to the interface group. You also configure a stateless firewall filter that matches packets that have been tagged as received on that interface group, contain a source or destination address within a particular prefix, and contain a TCP source or destination port of a specific type and port number. The filter counts, logs, and rejects packets that match this criteria. The filter counts, logs, and rejects all other packets. By applying this firewall filter to only one of the two interfaces in the interface group, you can apply the filtering mechanism to all packets input to the two interfaces.

Topology

You configure the interface group number 1 to consist of the management port **fxp0.0** and the loopback port **lo0.0**.

You configure the firewall filter **filter_if_group** to accept only packets from interface group 1, received from or destined for IP addresses in the 192.168.80.114/32 prefix, and received from or destined for TCP port number 79.

You apply the firewall filter **filter_if_group** to the router's (or switch's) loopback interface.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

- [Configure the Stateless Firewall Filter on page 4635](#)
- [Assign Interfaces to the Interface Group on page 4635](#)
- [Apply the Firewall Filter to the Loopback Interface on page 4636](#)
- [Confirm and Commit Your Candidate Configuration on page 4636](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet filter filter_if_group term term1 from interface-group 1
set firewall family inet filter filter_if_group term term1 from address 192.168.80.114/32
```

```

set firewall family inet filter filter_if_group term term1 from protocol tcp
set firewall family inet filter filter_if_group term term1 from port finger
set firewall family inet filter filter_if_group term term1 then count if_group_counter1
set firewall family inet filter filter_if_group term term1 then log
set firewall family inet filter filter_if_group term term1 then reject
set firewall family inet filter filter_if_group term term2 then count if_group_counter2
set firewall family inet filter filter_if_group term term2 then log
set firewall family inet filter filter_if_group term term2 then accept
set interfaces fxp0 unit 0 family inet filter group 1
set interfaces fxp0 unit 0 family inet address 192.168.5.38/24
set interfaces lo0 unit 0 family inet filter group 1
set interfaces lo0 unit 0 family inet address 10.0.0.1/32
set interfaces lo0 unit 0 family inet address 192.168.77.1/32
set interfaces lo0 unit 0 family inet filter input filter_if_group

```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter `filter_if_group`:

1. Create the stateless firewall filter `filter_if_group`.

```

[edit]
user@host# edit firewall family inet filter filter_if_group

```
2. Configure term `term1` to match packets received on interface group 1, with the source or destination address field in the 192.168.80.114/32 prefix, and with the TCP source or destination port number 79.

```

[edit firewall family inet filter filter_if_group]
user@host# set term term1 from interface-group 1
user@host# set term term1 from address 192.168.80.114/32
user@host# set term term1 from protocol tcp
user@host# set term term1 from port finger

```
3. Configure term `term1` to count, log, and reject matching packets.

```

[edit firewall family inet filter filter_if_group]
user@host# set term term1 then count if_group_counter1
user@host# set term term1 then log
user@host# set term term1 then reject

```
4. Configure the term `term2` to count, log, and accept all other packets.

```

[edit firewall family inet filter filter_if_group]
user@host# set term term2 then count if_group_counter2
user@host# set term term2 then log
user@host# set term term2 then accept

```

Assign Interfaces to the Interface Group

Step-by-Step Procedure

To assign logical interfaces to the interface group number 1 referenced by the firewall filter match term `term1`:

1. Assign the management port to interface group number 1.

```

[edit]
user@host# set interfaces fxp0 unit 0 family inet filter group 1
user@host# set interfaces fxp0 unit 0 family inet address 192.168.5.38/24

```

2. Assign a second logical interface to interface group number 1.

```
[edit]
user@host# set interfaces lo0 unit 0 family inet filter group 1
user@host# set interfaces lo0 unit 0 family inet address 10.0.0.1/32
user@host# set interfaces lo0 unit 0 family inet address 192.168.77.1/32
```

Apply the Firewall Filter to the Loopback Interface

Step-by-Step Procedure

- To apply the firewall filter to the router's (or switch's) loopback interface:

```
[edit]
user@host# set interfaces lo0 unit 0 family inet filter input filter_if_group
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter_if_group {
    term term1 {
      from {
        interface-group 1;
        address {
          192.168.80.114/32;
        }
        protocol tcp;
        port finger;
      }
      then {
        count if_group_counter1;
        log;
        reject;
      }
    }
    term term2 {
      then {
        count if_group_counter2;
        log;
        accept;
      }
    }
  }
}
```

2. Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
```

```

user@host# show interfaces
fxp0 {
  unit 0 {
    family inet {
      filter {
        group 1;
      }
      address 192.168.5.38/24;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      filter {
        input filter_if_group;
        group 1;
      }
      address 10.0.0.1/32;
      address 192.168.77.1/32;
    }
  }
}

```

3. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To display the firewall filter counters, enter the `show firewall filter filter_if_group` operational mode command:

```
user@host> show firewall filter filter_if_group
```

```
Filter: filter_if_group
```

```
Counters:
```

Name	Bytes	Packets
if_group_counter1	0	0
if_group_counter2	6452105	82667

To display the local log of packet headers for packets evaluated by the firewall filter, enter the `show firewall log` operational mode command.

Example: Filtering Packets Received on an Interface Set

This example shows how to configure a standard stateless firewall filter to match packets tagged for a particular interface set.

- [Requirements on page 4638](#)
- [Overview on page 4638](#)
- [Configuration on page 4639](#)
- [Verification on page 4643](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you apply a stateless firewall filter to the input of the router or switch loopback interface. The firewall filter includes a term that matches packets tagged for a particular interface set.

Topology

You create the firewall filter **L2_filter** to apply rate limits to the protocol-independent traffic received on the following interfaces:

- fe-0/0/0.0
- fe-1/0/0.0
- fe-1/1/0.0

NOTE: The interface type in this topic is just an example. The fe- interface type is not supported by EX Series switches.

First, for protocol-independent traffic received on **fe-0/0/0.0**, the firewall filter term **t1** applies policer **p1**.

For protocol-independent traffic received on any other Fast Ethernet interfaces, firewall filter term **t2** applies policer **p2**. To define an interface set that consists of all Fast Ethernet interfaces, you include the **interface-set interface-set-name interface-name** statement at the **[edit firewall]** hierarchy level. To define a packet-matching criteria based on the interface on which a packet arrives to a specified interface set, you configure a term that uses the **interface-set** firewall filter match condition.

Finally, for any other protocol-independent traffic, firewall filter term **t3** applies policer **p3**.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Interfaces for Which the Stateless Firewall Filter Terms Take Rate-Limiting Actions on page 4639](#)
- [Configuring the Stateless Firewall Filter That Rate-Limits Protocol-Independent Traffic Based on the Interfaces on Which Packets Arrive on page 4640](#)
- [Applying the Stateless Firewall Filter to the Routing Engine Input Interface on page 4643](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces fe-0/0/0 unit 0 family inet address 10.1.1.1/30
set interfaces fe-1/0/0 unit 0 family inet address 10.2.2.1/30
set interfaces fe-1/1/0 unit 0 family inet address 10.4.4.1/30
set firewall policer p1 if-exceeding bandwidth-limit 5m
set firewall policer p1 if-exceeding burst-size-limit 10m
set firewall policer p1 then discard
set firewall policer p2 if-exceeding bandwidth-limit 40m
set firewall policer p2 if-exceeding burst-size-limit 100m
set firewall policer p2 then discard
set firewall policer p3 if-exceeding bandwidth-limit 600m
set firewall policer p3 if-exceeding burst-size-limit 1g
set firewall policer p3 then discard
set firewall interface-set ifset fe-*
set firewall family any filter L2_filter term t1 from interface fe-0/0/0.0
set firewall family any filter L2_filter term t1 then count c1
set firewall family any filter L2_filter term t1 then policer p1
set firewall family any filter L2_filter term t2 from interface-set ifset
set firewall family any filter L2_filter term t2 then count c2
set firewall family any filter L2_filter term t2 then policer p2
set firewall family any filter L2_filter term t3 then count c3
set firewall family any filter L2_filter term t3 then policer p3
set interfaces lo0 unit 0 family inet address 1.1.1.157/30
set interfaces lo0 unit 0 filter input L2_filter
```

Configuring the Interfaces for Which the Stateless Firewall Filter Terms Take Rate-Limiting Actions

Step-by-Step Procedure

To configure the interfaces for which the stateless firewall filter terms take rate-limiting actions:

1. Configure the logical interface whose input traffic will be matched by the first term of the firewall filter.

[edit]

user@host# **set interfaces fe-0/0/0 unit 0 family inet address 10.1.1.1/30**

2. Configure the logical interfaces whose input traffic will be matched by the second term of the firewall filter.

```
[edit ]
user@host# set interfaces fe-1/0/0 unit 0 family inet address 10.2.2.1/30
user@host# set interfaces fe-1/1/0 unit 0 family inet address 10.4.4.1/30
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results Confirm the configuration of the router (or switch) transit interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
fe-0/0/0 {
  unit 0 {
    family inet {
      address 10.1.1.1/30;
    }
  }
}
fe-1/0/0 {
  unit 0 {
    family inet {
      address 10.2.2.1/30;
    }
  }
}
fe-1/1/0 {
  unit 0 {
    family inet {
      address 10.4.4.1/30;
    }
  }
}
```

Configuring the Stateless Firewall Filter That Rate-Limits Protocol-Independent Traffic Based on the Interfaces on Which Packets Arrive

Step-by-Step Procedure To configure the standard stateless firewall **L2_filter** that uses policers (**p1**, **p2**, and **p3**) to rate-limit protocol-independent traffic based on the interfaces on which the packets arrive:

1. Configure the firewall statements.

```
[edit]
user@host# edit firewall
```

2. Configure the policer **p1** to discard traffic that exceeds a traffic rate of **5m** bps or a burst size of **10m** bytes.

```
[edit firewall]
```

```

user@host# set policer p1 if-exceeding bandwidth-limit 5m
user@host# set policer p1 if-exceeding burst-size-limit 10m
user@host# set policer p1 then discard

```

3. Configure the policer **p2** to discard traffic that exceeds a traffic rate of **40m** bps or a burst size of **100m** bytes .

```

[edit firewall]
user@host# set policer p2 if-exceeding bandwidth-limit 40m
user@host# set policer p2 if-exceeding burst-size-limit 100m
user@host# set policer p2 then discard

```

4. Configure the policer **p3** to discard traffic that exceeds a traffic rate of **600m** bps or a burst size of **1g** bytes.

```

[edit firewall]
user@host# set policer p3 if-exceeding bandwidth-limit 600m
user@host# set policer p3 if-exceeding burst-size-limit 1g
user@host# set policer p3 then discard

```

5. Define the interface set **ifset** to be the group of all Fast Ethernet interfaces on the router.

```

[edit firewall]
user@host# set interface-set ifset fe-*

```

6. Create the stateless firewall filter **L2_filter**.

```

[edit firewall]
user@host# edit family any filter L2_filter

```

7. Configure filter term **t1** to match IPv4, IPv6, or MPLS packets received on interface **fe-0/0/0.0** and use policer **p1** to rate-limit that traffic.

```

[edit firewall family any filter L2_filter]
user@host# set term t1 from interface fe-0/0/0.0
user@host# set term t1 then count c1
user@host# set term t1 then policer p1

```

8. Configure filter term **t2** to match packets received on interface-set **ifset** and use policer **p2** to rate-limit that traffic.

```

[edit firewall family any filter L2_filter]
user@host# set term t2 from interface-set ifset
user@host# set term t2 then count c2
user@host# set term t2 then policer p2

```

9. Configure filter term **t3** to use policer **p3** to rate-limit all other traffic.

```

[edit firewall family any filter L2_filter]
user@host# set term t3 then count c3
user@host# set term t3 then policer p3

```

10. If you are done configuring the device, commit the configuration.

```

[edit]
user@host# commit

```

Results Confirm the configuration of the stateless firewall filter and the policers referenced as firewall filter actions by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family any {
  filter L2_filter {
    term t1 {
      from {
        interface fe-0/0/0.0;
      }
      then {
        policer p1;
        count c1;
      }
    }
    term t2 {
      from {
        interface-set ifset;
      }
      then {
        policer p2;
        count c2;
      }
    }
    term t3 {
      then {
        policer p3;
        count c3;
      }
    }
  }
}
policer p1 {
  if-exceeding {
    bandwidth-limit 5m;
    burst-size-limit 10m;
  }
  then discard;
}
policer p2 {
  if-exceeding {
    bandwidth-limit 40m;
    burst-size-limit 100m;
  }
  then discard;
}
policer p3 {
  if-exceeding {
    bandwidth-limit 600m;
    burst-size-limit 1g;
  }
  then discard;
}
```

```

interface-set ifset {
  fe-*;
}

```

Applying the Stateless Firewall Filter to the Routing Engine Input Interface

Step-by-Step Procedure

To apply the stateless firewall filter to the Routing Engine input interface:

1. Apply the stateless firewall filter to the Routing Engine interface in the input direction.

```

[edit]
user@host# set interfaces lo0 unit 0 family inet address 1.1.1.157/30
user@host# set interfaces lo0 unit 0 filter input L2_filter

```

2. If you are done configuring the device, commit the configuration.

```

[edit]
user@host# commit

```

Results Confirm the application of the firewall filter to the Routing Engine input interface by entering the **show interfaces** command again. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

user@host# show interfaces
fe-0/0/0 {
  ...
}
fe-1/0/0 {
  ...
}
fe-1/1/0 {
  ...
}
lo0 {
  unit 0 {
    filter {
      input L2_filter;
    }
    family inet {
      address 1.1.1.157/30;
    }
  }
}

```

Verification

To confirm that the configuration is working properly, use the **show firewall filter L2_filter** operational mode command to monitor traffic statistics about the firewall filter and three counters.

Example: Configuring Filter-Based Forwarding on the Source Address

This example shows how to configure filter-based forwarding. The filter classifies packets to determine their forwarding path within the ingress routing device.

- [Requirements on page 4644](#)
- [Overview on page 4644](#)
- [Configuration on page 4646](#)
- [Verification on page 4651](#)

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

Filter-based forwarding is supported for IP version 4 (IPv4) and IP version 6 (IPv6).

Use filter-based forwarding for service provider selection when customers have Internet connectivity provided by different ISPs yet share a common access layer. When a shared media (such as a cable modem) is used, a mechanism on the common access layer looks at Layer 2 or Layer 3 addresses and distinguishes between customers. You can use filter-based forwarding when the common access layer is implemented using a combination of Layer 2 switches and a single router.

With filter-based forwarding, all packets received on an interface are considered. Each packet passes through a filter that has match conditions. If the match conditions are met for a filter and you have created a routing instance, filter-based forwarding is applied to a packet. The packet is forwarded based on the next hop specified in the routing instance. For static routes, the next hop can be a specific LSP.

NOTE: Source-class usage filter matching and unicast reverse-path forwarding checks are not supported on an interface configured with filter-based forwarding (FBF).

To configure filter-based forwarding, perform the following tasks:

- Create a match filter on an ingress router or switch. To specify a match filter, include the **filter filter-name** statement at the **[edit firewall]** hierarchy level. A packet that passes through the filter is compared against a set of rules to classify it and to determine its membership in a set. Once classified, the packet is forwarded to a routing table specified in the accept action in the filter description language. The routing table then forwards the packet to the next hop that corresponds to the destination address entry in the table.
- Create routing instances that specify the routing table(s) to which a packet is forwarded, and the destination to which the packet is forwarded at the **[edit routing-instances]** hierarchy level. For example:

```
[edit]
routing-instances {
  routing-table-name1 {
    instance-type forwarding;
    routing-options {
      static {
        route 0.0.0.0/0 nexthop 10.0.0.1;
      }
    }
  }
  routing-table-name2 {
    instance-type forwarding;
    routing-options {
      static {
        route 0.0.0.0/0 nexthop 10.0.0.2;
      }
    }
  }
}
```

- Create a routing table group that adds interface routes to the forwarding routing instances used in filter-based forwarding (FBF), as well as to the default routing instance inet.0. This part of the configuration resolves the routes installed in the routing instances to directly connected next hops on that interface. Create the routing table group at the **[edit routing-options]** hierarchy level.

NOTE: Specify inet.0 as one of the routing instances that the interface routes are imported into. If the default instance inet.0 is not specified, interface routes are not imported into the default routing instance.

This example shows a packet filter that directs customer traffic to a next-hop router in the domains, SP 1 or SP 2, based on the packet's source address.

If the packet has a source address assigned to an SP 1 customer, destination-based forwarding occurs using the sp1-route-table.inet.0 routing table. If the packet has a source address assigned to an SP 2 customer, destination-based forwarding occurs using the sp2-route-table.inet.0 routing table. If a packet does not match either of these conditions, the filter accepts the packet, and destination-based forwarding occurs using the standard inet.0 routing table.

Figure 96 on page 4646 shows the topology used in this example.

On Device P1, an input filter classifies packets received from Device PE3 and Device PE4. The packets are routed based on the source addresses. Packets with source addresses in the 10.1.1.0/24 and 10.1.2.0/24 networks are routed to Device PE1. Packets with source addresses in the 10.2.1.0/24 and 10.2.2.0/24 networks are routed to Device PE2.

Figure 96: Filter-Based Forwarding

To establish connectivity, OSPF is configured on all of the interfaces. For demonstration purposes, loopback interface addresses are configured on the routing devices to represent networks in the clouds.

The [“CLI Quick Configuration” on page 4646](#) section shows the entire configuration for all of the devices in the topology. The [“Configuring the Routing Instances on the Device P1” on page 4648](#) section shows the step-by-step configuration of the ingress routing device, Device P1.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
Device P1
set firewall filter classify-customers term sp1-customers from source-address 10.1.1.0/24
set firewall filter classify-customers term sp1-customers from source-address 10.1.2.0/24
set firewall filter classify-customers term sp1-customers then log
set firewall filter classify-customers term sp1-customers then routing-instance
  sp1-route-table
set firewall filter classify-customers term sp2-customers from source-address 10.2.1.0/24
set firewall filter classify-customers term sp2-customers from source-address 10.2.2.0/24
set firewall filter classify-customers term sp2-customers then log
set firewall filter classify-customers term sp2-customers then routing-instance
  sp2-route-table
set firewall filter classify-customers term default then accept
set interfaces fe-1/2/0 unit 0 family inet filter input classify-customers
set interfaces fe-1/2/0 unit 0 family inet address 172.16.0.10/30
set interfaces fe-1/2/1 unit 0 family inet address 172.16.0.13/30

set interfaces lo0 unit 0 family inet address 10.2.1.1/32
set interfaces lo0 unit 0 family inet address 10.2.2.1/32
set protocols ospf area 0.0.0.0 interface all
set protocols ospf area 0.0.0.0 interface fxp0.0 disable

```

Configuring the Firewall Filter

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure the firewall filter on the main router or switch:

1. Configure the source addresses for SP1 customers.

```

[edit firewall filter classify-customers term sp1-customers]
user@host# set from source-address 10.1.1.0/24
user@host# set from source-address 10.1.2.0/24

```
2. Configure the actions that are taken when packets are received with the specified source addresses.

To track the action of the firewall filter, a log action is configured. The sp1-route-table.inet.0 routing table on Device P1 routes the packets.

```

[edit firewall filter classify-customers term sp1-customers]
user@host# set then log

```

```
user@host# set then routing-instance sp1-route-table
```

3. Configure the source addresses for SP2 customers.

```
[edit firewall filter classify-customers term sp2-customers]
```

```
user@host# set from source-address 10.2.1.0/24
```

```
user@host# set from source-address 10.2.2.0/24
```

4. Configure the actions that are taken when packets are received with the specified source addresses.

To track the action of the firewall filter, a log action is configured. The sp2-route-table.inet.0 routing table on Device P1 routes the packet.

```
[edit firewall filter classify-customers term sp2-customers]
```

```
user@host# set then log
```

```
user@host# set then routing-instance sp2-route-table
```

5. Configure the action to take when packets are received from any other source address.

All of these packets are simply accepted and routed using the default IPv4 unicast routing table, inet.0.

```
[edit firewall filter classify-customers term default]
```

```
user@host# set then accept
```

Configuring the Routing Instances on the Device P1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure the routing instances:

1. Configure the interfaces.

```
[edit interfaces fe-1/2/0]
```

```
user@host# set unit 0 family inet address 172.16.0.10/30
```

```
[edit interfaces fe-1/2/1]
```

```
user@host# set unit 0 family inet address 172.16.0.13/30
```

```
[edit interfaces fe-1/2/2]
```

```
user@host# set unit 0 family inet address 172.16.0.17/30
```

2. Assign the **classify-customers** firewall filter to router interface fe-1/2/0.0 as an input packet filter.

```
[edit interfaces fe-1/2/0]
```

```
user@host# set unit 0 family inet filter input classify-customers
```

3. Configure connectivity, using either a routing protocol or static routing.

As a best practice, disable routing on the management interface.

```
[edit protocols ospf area 0.0.0.0]
```

```
user@host# set interface all
```

```
user@host# set interface fxp0.0 disable
```

4. Create the routing instances.

These routing instances are referenced in the **classify-customers** firewall filter.

The forwarding instance type provides support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance, in this case Device P1.

```
[edit routing-instances]
user@host# set sp1-route-table instance-type forwarding
```

```
user@host# set sp2-route-table instance-type forwarding
```

5. Resolve the routes installed in the routing instances to directly connected next hops.

```
[edit routing-instances sp1-route-table routing-options]
user@host# set static route 0.0.0.0/0 next-hop 172.16.0.13
```

```
user@host# set static route 0.0.0.0/0 next-hop 172.16.0.17
```

6. Group together the routing tables to form a routing table group.

The first routing table, inet.0, is the primary routing table, and the additional routing tables are the secondary routing tables.

The primary routing table determines the address family of the routing table group, in this case IPv4.

```
[edit routing-options]
user@host# set rib-groups fbf-group import-rib inet.0
user@host# set rib-groups fbf-group import-rib sp1-route-table.inet.0
user@host# set rib-groups fbf-group import-rib sp2-route-table.inet.0
```

7. Apply the routing table group to OSPF.

This causes the OSPF routes to be installed into all the routing tables in the group.

```
[edit protocols ospf]
user@host# set rib-group fbf-group
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show interfaces**, **show firewall**, **show protocols**, **show routing-instances**, and **show routing-options** commands.

```
user@host# show interfaces
fe-1/2/0 {
  unit 0 {
    family inet {
      filter {
        input classify-customers;
      }
      address 172.16.0.10/30;
```

```
    }
  }
}
fe-1/2/1 {
  unit 0 {
    family inet {
      address 172.16.0.13/30;
    }
  }
}
fe-1/2/2 {
  unit 0 {
    family inet {
      address 172.16.0.17/30;
    }
  }
}
}

user@host# show firewall
filter classify-customers {
  term sp1-customers {
    from {
      source-address {
        10.1.1.0/24;
        10.1.2.0/24;
      }
    }
    then {
      log;
      routing-instance sp1-route-table;
    }
  }
  term sp2-customers {
    from {
      source-address {
        10.2.1.0/24;
        10.2.2.0/24;
      }
    }
    then {
      log;
      routing-instance sp2-route-table;
    }
  }
  term default {
    then accept;
  }
}

user@host# show protocols
ospf {
  rib-group fbf-group;
  area 0.0.0.0 {
    interface all;
    interface fxp0.0 {
      disable;
    }
  }
}
```

```

    }
  }
user@host# show routing-instances
sp1-route-table {
  instance-type forwarding;
  routing-options {
    static {
      route 0.0.0.0/0 next-hop 172.16.0.13;
    }
  }
}
sp2-route-table {
  instance-type forwarding;
  routing-options {
    static {
      route 0.0.0.0/0 next-hop 172.16.0.17;
    }
  }
}

user@host# show routing-options
rib-groups {
  fbf-group {
    import-rib [ inet.0 sp1-route-table.inet.0 sp2-route-table.inet.0 ];
  }
}

```

Verification

Confirm that the configuration is working properly.

Pinging with Specified Source Addresses

Purpose Send some ICMP packets across the network to test the firewall filter.

Action 1. Run the **ping** command, pinging the lo0.0 interface on Device PE1.

The address configured on this interface is 1.1.1.1.

Specify the source address 10.1.2.1, which is the address configured on the lo0.0 interface on Device PE3.

```

user@PE3> ping 1.1.1.1 source 10.1.2.1
PING 1.1.1.1 (1.1.1.1): 56 data bytes
64 bytes from 1.1.1.1: icmp_seq=0 ttl=62 time=1.444 ms
64 bytes from 1.1.1.1: icmp_seq=1 ttl=62 time=2.094 ms
^C
--- 1.1.1.1 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.444/1.769/2.094/0.325 ms

```

2. Run the **ping** command, pinging the lo0.0 interface on Device PE2.

The address configured on this interface is 2.2.2.2.

Specify the source address 10.2.1.1, which is the address configured on the lo0.0 interface on Device PE4.

```

user@PE4> ping 2.2.2.2 source 10.2.1.1

```

```

PING 2.2.2.2 (2.2.2.2): 56 data bytes
64 bytes from 2.2.2.2: icmp_seq=0 ttl=62 time=1.473 ms
64 bytes from 2.2.2.2: icmp_seq=1 ttl=62 time=1.407 ms
^C
--- 2.2.2.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.407/1.440/1.473/0.033 ms

```

Meaning Sending these pings activates the firewall filter actions.

Verifying the Firewall Filter

Purpose Make sure the firewall filter actions take effect.

Action 1. Run the **show firewall log** command on Device P1.

```

user@P1> show firewall log
Log :
Time      Filter  Action Interface  Protocol  Src Addr
Dest Addr
13:52:20  pfe      A      fe-1/2/0.0    ICMP      10.2.1.1
2.2.2.2
13:52:19  pfe      A      fe-1/2/0.0    ICMP      10.2.1.1
2.2.2.2
13:51:53  pfe      A      fe-1/2/0.0    ICMP      10.1.2.1
1.1.1.1
13:51:52  pfe      A      fe-1/2/0.0    ICMP      10.1.2.1
1.1.1.1

```

Example: Configuring Filter-Based Forwarding on Logical Systems

This example shows how to configure filter-based forwarding within a logical system. The filter classifies packets to determine their forwarding path within the ingress routing device.

- [Requirements on page 4652](#)
- [Overview on page 4653](#)
- [Configuration on page 4655](#)
- [Verification on page 4661](#)

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

Filter-based forwarding is supported for IP version 4 (IPv4) and IP version 6 (IPv6).

Use filter-based forwarding for service provider selection when customers have Internet connectivity provided by different ISPs yet share a common access layer. When a shared media (such as a cable modem) is used, a mechanism on the common access layer looks at Layer 2 or Layer 3 addresses and distinguishes between customers. You can use filter-based forwarding when the common access layer is implemented using a combination of Layer 2 switches and a single router.

With filter-based forwarding, all packets received on an interface are considered. Each packet passes through a filter that has match conditions. If the match conditions are met for a filter and you have created a routing instance, filter-based forwarding is applied to a packet. The packet is forwarded based on the next hop specified in the routing instance. For static routes, the next hop can be a specific LSP.

NOTE: Source-class usage filter matching and unicast reverse-path forwarding checks are not supported on an interface configured with filter-based forwarding (FBF).

To configure filter-based forwarding, perform the following tasks:

- Create a match filter on an ingress router or switch. To specify a match filter, include the **filter filter-name** statement at the **[edit firewall]** hierarchy level. A packet that passes through the filter is compared against a set of rules to classify it and to determine its membership in a set. Once classified, the packet is forwarded to a routing table specified in the accept action in the filter description language. The routing table then forwards the packet to the next hop that corresponds to the destination address entry in the table.
- Create routing instances that specify the routing table(s) to which a packet is forwarded, and the destination to which the packet is forwarded at the **[edit routing-instances]** or **[edit logical-systems logical-system-name routing-instances]** hierarchy level. For example:

```
[edit]
routing-instances {
  routing-table-name1 {
    instance-type forwarding;
    routing-options {
      static {
        route 0.0.0.0/0 nexthop 10.0.0.1;
      }
    }
  }
  routing-table-name2 {
    instance-type forwarding;
    routing-options {
      static {
        route 0.0.0.0/0 nexthop 10.0.0.2;
      }
    }
  }
}
```

```

    }
  }
}

```

- Create a routing table group that adds interface routes to the forwarding routing instances used in filter-based forwarding (FBF), as well as to the default routing instance **inet.0**. This part of the configuration resolves the routes installed in the routing instances to directly connected next hops on that interface. Create the routing table group at the **[edit routing-options]** or **[edit logical-systems *logical-system-name* routing-options]** hierarchy level.

NOTE: Specify **inet.0** as one of the routing instances that the interface routes are imported into. If the default instance **inet.0** is not specified, interface routes are not imported into the default routing instance.

This example shows a packet filter that directs customer traffic to a next-hop router in the domains, SP 1 or SP 2, based on the packet's source address.

If the packet has a source address assigned to an SP 1 customer, destination-based forwarding occurs using the **sp1-route-table.inet.0** routing table. If the packet has a source address assigned to an SP 2 customer, destination-based forwarding occurs using the **sp2-route-table.inet.0** routing table. If a packet does not match either of these conditions, the filter accepts the packet, and destination-based forwarding occurs using the standard **inet.0** routing table.

One way to make filter-based forwarding work within a logical system is to configure the firewall filter on the logical system that receives the packets. Another way is to configure the firewall filter on the main router or switch and then reference the logical system in the firewall filter. This example uses the second approach. The specific routing instances are configured within the logical system. Because each routing instance has its own routing table, you have to reference the routing instances in the firewall filter, as well. The syntax looks as follows:

```

[edit firewall filter filter-name term term-name]
user@host# set then logical-system logical-system-name routing-instance
routing-instance-name

```

Figure 59 on page 3300 shows the topology used in this example.

On Logical System P1, an input filter classifies packets received from Logical System PE3 and Logical System PE4. The packets are routed based on the source addresses. Packets with source addresses in the 10.1.1.0/24 and 10.1.2.0/24 networks are routed to Logical System PE1. Packets with source addresses in the 10.2.1.0/24 and 10.2.2.0/24 networks are routed to Logical System PE2.

Figure 97: Logical Systems with Filter-Based Forwarding

To establish connectivity, OSPF is configured on all of the interfaces. For demonstration purposes, loopback interface addresses are configured on the routing devices to represent networks in the clouds.

The [“CLI Quick Configuration” on page 3300](#) section shows the entire configuration for all of the devices in the topology. The [“Configuring the Routing Instances on the Logical System P1” on page 3303](#) and [“Configuring the Firewall Filter on the Main Router” on page 3302](#) sections shows the step-by-step configuration of the ingress routing device, Logical System P1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter classify-customers term sp1-customers from source-address 10.1.1.0/24
set firewall filter classify-customers term sp1-customers from source-address 10.1.2.0/24
set firewall filter classify-customers term sp1-customers then log
set firewall filter classify-customers term sp1-customers then logical-system P1
  routing-instance sp1-route-table
set firewall filter classify-customers term sp2-customers from source-address 10.2.1.0/24
set firewall filter classify-customers term sp2-customers from source-address 10.2.2.0/24
set firewall filter classify-customers term sp2-customers then log
set firewall filter classify-customers term sp2-customers then logical-system P1
  routing-instance sp2-route-table
set firewall filter classify-customers term default then accept

```

Configuring the Firewall Filter on the Main Router

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure the firewall filter on the main router or switch:

1. Configure the source addresses for SP1 customers.

```
[edit firewall filter classify-customers term sp1-customers]
user@host# set from source-address 10.1.1.0/24
user@host# set from source-address 10.1.2.0/24
```

2. Configure the actions that are taken when packets are received with the specified source addresses.

To track the action of the firewall filter, a log action is configured. The sp1-route-table.inet.0 routing table on Logical System P1 routes the packets.

```
[edit firewall filter classify-customers term sp1-customers]
user@host# set then log
user@host# set then logical-system P1 routing-instance sp1-route-table
```

3. Configure the source addresses for SP2 customers.

```
[edit firewall filter classify-customers term sp2-customers]
user@host# set from source-address 10.2.1.0/24
user@host# set from source-address 10.2.2.0/24
```

4. Configure the actions that are taken when packets are received with the specified source addresses.

To track the action of the firewall filter, a log action is configured. The sp2-route-table.inet.0 routing table on Logical System P1 routes the packet.

```
[edit firewall filter classify-customers term sp2-customers]
user@host# set then log
user@host# set then logical-system P1 routing-instance sp2-route-table
```

5. Configure the action to take when packets are received from any other source address.

All of these packets are simply accepted and routed using the default IPv4 unicast routing table, inet.0.

```
[edit firewall filter classify-customers term default]
user@host# set then accept
```

Configuring the Routing Instances on the Logical System P1

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure the routing instances on a logical system:

1. Configure the interfaces on the logical system.

```
[edit logical-systems P1 interfaces lt-1/2/0]
user@host# set unit 10 encapsulation ethernet
user@host# set unit 10 peer-unit 9
user@host# set unit 10 family inet address 172.16.0.10/30
```

```
user@host# set unit 13 encapsulation ethernet
user@host# set unit 13 peer-unit 14
user@host# set unit 13 family inet address 172.16.0.13/30
```

```
user@host# set unit 17 encapsulation ethernet
user@host# set unit 17 peer-unit 18
user@host# set unit 17 family inet address 172.16.0.17/30
```

2. Assign the **classify-customers** firewall filter to router interface lt-1/2/0.10 as an input packet filter.

```
[edit logical-systems P1 interfaces lt-1/2/0]
user@host# set unit 10 family inet filter input classify-customers
```

3. Configure connectivity, using either a routing protocol or static routing.

As a best practice, disable routing on the management interface.

```
[edit logical-systems P1 protocols ospf area 0.0.0.0]
user@host# set interface all
user@host# set interface fxp0.0 disable
```

4. Create the routing instances.

These routing instances are referenced in the **classify-customers** firewall filter.

The forwarding instance type provides support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance, in this case Logical System P1.

```
[edit logical-systems P1 routing-instances]
user@host# set sp1-route-table instance-type forwarding
```

```
user@host# set sp2-route-table instance-type forwarding
```

5. Resolve the routes installed in the routing instances to directly connected next hops.

```
[edit logical-systems P1 routing-instances]
user@host# set sp1-route-table routing-options static route 0.0.0.0/0 next-hop
172.16.0.13
```

```
user@host# set sp2-route-table routing-options static route 0.0.0.0/0 next-hop
172.16.0.17
```

6. Group together the routing tables to form a routing table group.

The first routing table, inet.0, is the primary routing table, and the additional routing tables are the secondary routing tables.

The primary routing table determines the address family of the routing table group, in this case IPv4.

```
[edit logical-systems P1 routing-options]
user@host# set rib-groups fbf-group import-rib inet.0
user@host# set rib-groups fbf-group import-rib sp1-route-table.inet.0
user@host# set rib-groups fbf-group import-rib sp2-route-table.inet.0
```

7. Apply the routing table group to OSPF.

This causes the OSPF routes to be installed into all the routing tables in the group.

```
[edit logical-systems P1 protocols ospf]
user@host# set rib-group fbf-group
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show firewall** and **show logical-systems P1** commands.

```
user@host# show firewall
filter classify-customers {
  term sp1-customers {
    from {
      source-address {
        10.1.1.0/24;
        10.1.2.0/24;
      }
    }
    then {
      log;
      logical-system P1 routing-instance sp1-route-table;
    }
  }
}
term sp2-customers {
  from {
    source-address {
      10.2.1.0/24;
      10.2.2.0/24;
    }
  }
  then {
    log;
    logical-system P1 routing-instance sp2-route-table;
  }
}
```

```
}
term default {
  then accept;
}
}

user@host# show logical-systems P1
interfaces {
  lt-1/2/0 {
    unit 10 {
      encapsulation ethernet;
      peer-unit 9;
      family inet {
        filter {
          input classify-customers;
        }
        address 172.16.0.10/30;
      }
    }
    unit 13 {
      encapsulation ethernet;
      peer-unit 14;
      family inet {
        address 172.16.0.13/30;
      }
    }
    unit 17 {
      encapsulation ethernet;
      peer-unit 18;
      family inet {
        address 172.16.0.17/30;
      }
    }
  }
}
protocols {
  ospf {
    rib-group fbf-group;
    area 0.0.0.0 {
      interface all;
      interface fxp0.0 {
        disable;
      }
    }
  }
}
routing-instances {
  sp1-route-table {
    instance-type forwarding;
    routing-options {
      static {
        route 0.0.0.0/0 next-hop 172.16.0.13;
      }
    }
  }
  sp2-route-table {
```

```

instance-type forwarding;
routing-options {
  static {
    route 0.0.0.0/0 next-hop 172.16.0.17;
  }
}
}
routing-options {
  rib-groups {
    fbf-group {
      import-rib [ inet.0 sp1-route-table.inet.0 sp2-route-table.inet.0 ];
    }
  }
}
}

```

Verification

Confirm that the configuration is working properly.

Pinging with Specified Source Addresses

Purpose Send some ICMP packets across the network to test the firewall filter.

Action 1. Log in to Logical System PE3.

```

user@host> set cli logical-system PE3
Logical system: PE3

```

2. Run the **ping** command, pinging the lo0.3 interface on Logical System PE1.

The address configured on this interface is 1.1.1.1.

Specify the source address 10.1.2.1, which is the address configured on the lo0.1 interface on Logical System PE3.

```

user@host:PE3> ping 1.1.1.1 source 10.1.2.1
PING 1.1.1.1 (1.1.1.1): 56 data bytes
64 bytes from 1.1.1.1: icmp_seq=0 ttl=62 time=1.444 ms
64 bytes from 1.1.1.1: icmp_seq=1 ttl=62 time=2.094 ms
^C
--- 1.1.1.1 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.444/1.769/2.094/0.325 ms

```

3. Log in to Logical System PE4.

```

user@host:PE3> set cli logical-system PE4
Logical system: PE4

```

4. Run the **ping** command, pinging the lo0.4 interface on Logical System PE2.

The address configured on this interface is 2.2.2.2.

Specify the source address 10.2.1.1, which is the address configured on the lo0.2 interface on Logical System PE4.

```

user@host:PE4> ping 2.2.2.2 source 10.2.1.1
PING 2.2.2.2 (2.2.2.2): 56 data bytes
64 bytes from 2.2.2.2: icmp_seq=0 ttl=62 time=1.473 ms
64 bytes from 2.2.2.2: icmp_seq=1 ttl=62 time=1.407 ms

```

```
^C
--- 2.2.2.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.407/1.440/1.473/0.033 ms
```

Meaning Sending these pings activates the firewall filter actions.

Verifying the Firewall Filter

Purpose Make sure the firewall filter actions take effect.

Action 1. Log in to Logical System P1.

```
user@host> set cli logical-system P1
Logical system: P1
```

2. Run the **show firewall log** command on Logical System P1.

```
user@host:P1> show firewall log
Log :
Time      Filter  Action Interface  Protocol  Src Addr
Dest Addr
13:52:20  pfe          A      1t-1/2/0.10  ICMP      10.2.1.1
2.2.2.2
13:52:19  pfe          A      1t-1/2/0.10  ICMP      10.2.1.1
2.2.2.2
13:51:53  pfe          A      1t-1/2/0.10  ICMP      10.1.2.1
1.1.1.1
13:51:52  pfe          A      1t-1/2/0.10  ICMP      10.1.2.1
1.1.1.1
```

Understanding Filter-Based Forwarding to a Specific Outgoing Interface or Destination IP Address

Policy-based routing (also known as filter-based forwarding) refers to the use of firewall filters that are applied to an interface to match certain IP header characteristics and to route only those matching packets differently than the packets would normally be routed.

Starting in Junos OS Release 12.2, you can use **then next-interface**, **then next-ip**, or **then next-ip6** as an action in a firewall filter.

For example:

```
from {
  set of match conditions
}
then {
  IP-address (or)
  IPv6-address (or)
  Interface name
}
```

The set of match conditions can be as follows:

- Layer-3 properties (for example, the source or destination IP address or the TOS byte)
- Layer-4 properties (for example, the source or destination port)

The route for the given IPv4 or IPv6 address has to be present in the routing table for policy-based routing to take effect. Similarly, the route through the given interface has to be present in the forwarding table for **next-interface** action to take effect. This can be achieved by configuring an interior gateway protocol (IGP), such as OSPF or IS-IS, to advertise Layer 3 routes.

The firewall filter matches the conditions and forwards the packet to one of the following:

- An IPv4 address (using the **next-ip** firewall filter action)
- An IPv6 address (using the **next-ip6** firewall filter action)
- An interface (using the **next-interface** firewall filter action)

Suppose, for example, that you want to offer services to your customers, and the services reside on different servers. An example of a service might be hosted DNS or hosted FTP. As customer traffic arrives at the Juniper Networks routing device, you can use filter-based forwarding to send traffic to the servers by applying a match condition on a MAC address or an IP address or simply an incoming interface and send the packets to a certain outgoing interface that is associated with the appropriate server. Some of your destinations might be IPv4 or IPv6 addresses, in which case the **next-ip** or **next-ip6** action is useful.

Optionally, you can associate the outgoing interfaces or IP addresses with routing instances.

For example:

```
firewall {
```

```
filter filter1 {
  term t1 {
    from {
      source-address {
        10.1.1.3/32;
      }
    }
    then {
      next-interface {
        xe-0/1/0.1;
        routing-instance rins1;
      }
    }
  }
  term t2 {
    from {
      source-address {
        10.1.1.4/32;
      }
    }
    then {
      next-interface {
        xe-0/1/0.2;
        routing-instance rins2;
      }
    }
  }
}
routing-instances {
  rins1 {
    instance-type virtual-router;
    interface xe-0/1/0.1;
  }
  rins2 {
    instance-type virtual-router;
    interface xe-0/1/0.2;
  }
}
```

Example: Configuring Filter-Based Forwarding to a Specific Outgoing Interface

This example shows how to use **then next-interface** as an action in a firewall filter.

- [Requirements on page 4665](#)
- [Overview on page 4665](#)
- [Configuration on page 4665](#)
- [Verification on page 4668](#)

Requirements

This example has the following hardware and software requirements:

- MX Series 3D Universal Edge Router or an EX Series switch as the routing device with the firewall filter configured.
- Junos OS Release 12.3R2 running on the routing device with the firewall filter configured.
- The filter with the **next-interface** (or **next-ip**) action can only be applied to an interface that is hosted on a Trio MPC. If you apply the filter to an I-chip based DPC, the commit operation fails.
- The outgoing interface referred to in the **next-interface *interface-name*** action can be hosted on a Trio MPC or an I-chip based DPC.

Overview

In this example, Device R1 has two loopback interface addresses configured: 172.16.1.1 and 172.16.2.2.

On Device R2, a firewall filter has multiple terms configured. Each term matches one of the source addresses in incoming traffic, and routes the traffic to specified outgoing interfaces. The outgoing interfaces are configured as VLAN-tagged interfaces between Device R2 and Device R3.

IS-IS is used for connectivity among the devices.

Figure 98 on page 4665 shows the topology used in this example.

Figure 98: Filter-Based Forwarding to Specified Outgoing Interfaces

This example shows the configuration on Device R2.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
Device R2
set interfaces ge-2/1/0 unit 0 family inet filter input filter1
set interfaces ge-2/1/0 unit 0 family inet address 10.0.0.10/30
set interfaces ge-2/1/0 unit 0 description to-R1
set interfaces ge-2/1/0 unit 0 family iso
set interfaces ge-2/1/1 vlan-tagging
set interfaces ge-2/1/1 description to-R3
set interfaces ge-2/1/1 unit 0 vlan-id 1001
```

```
set interfaces ge-2/1/1 unit 0 family inet address 10.0.0.13/30
set interfaces ge-2/1/1 unit 0 family iso
set interfaces ge-2/1/1 unit 1 vlan-id 1002
set interfaces ge-2/1/1 unit 1 family inet address 10.0.0.25/30
set interfaces ge-2/1/1 unit 1 family iso
set interfaces lo0 unit 0 family inet address 10.255.4.4/32
set interfaces lo0 unit 0 family iso address 49.0001.0010.0000.0404.00
set firewall family inet filter filter1 term t1 from source-address 172.16.1.1/32
set firewall family inet filter filter1 term t1 then next-interface ge-2/1/1.0
set firewall family inet filter filter1 term t2 from source-address 172.16.2.2/32
set firewall family inet filter filter1 term t2 then next-interface ge-2/1/1.1
set protocols isis interface all level 1 disable
set protocols isis interface fxp0.0 disable
set protocols isis interface lo0.0
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure Device R2:

1. Configure the interfaces.

```
[edit interfaces]
```

```
user@R2# set ge-2/1/0 unit 0 family inet filter input filter1
user@R2# set ge-2/1/0 unit 0 family inet address 10.0.0.10/30
user@R2# set ge-2/1/0 unit 0 description to-R1
user@R2# set ge-2/1/0 unit 0 family iso
```

```
user@R2# set ge-2/1/1 vlan-tagging
user@R2# set ge-2/1/1 description to-R3
```

```
user@R2# set ge-2/1/1 unit 0 vlan-id 1001
user@R2# set ge-2/1/1 unit 0 family inet address 10.0.0.13/30
user@R2# set ge-2/1/1 unit 0 family iso
```

```
user@R2# set ge-2/1/1 unit 1 vlan-id 1002
user@R2# set ge-2/1/1 unit 1 family inet address 10.0.0.25/30
user@R2# set ge-2/1/1 unit 1 family iso
```

```
user@R2# set lo0 unit 0 family inet address 10.255.4.4/32
user@R2# set lo0 unit 0 family iso address 49.0001.0010.0000.0404.00
```

2. Configure the firewall filter.

```
[edit firewall family inet filter filter1]
```

```
user@R2# set term t1 from source-address 172.16.1.1/32
user@R2# set term t1 then next-interface ge-2/1/1.0
```

```
user@R2# set term t2 from source-address 172.16.2.2/32
user@R2# set term t2 then next-interface ge-2/1/1.1
```

3. Enable IS-IS on the interfaces.

```
[edit protocols is-is]
```

```

user@R2# set interface all level 1 disable
user@R2# set interface fxp0.0 disable
user@R2# set interface lo0.0

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show firewall**, and **show protocols** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@R2# show interfaces
ge-2/1/0 {
  unit 0 {
    description to-R1;
    family inet {
      filter {
        input filter1;
      }
      address 10.0.0.10/30;
    }
    family iso;
  }
}
ge-2/1/1 {
  description to-R3;
  vlan-tagging;
  unit 0 {
    vlan-id 1001;
    family inet {
      address 10.0.0.13/30;
    }
    family iso;
  }
  unit 1 {
    vlan-id 1002;
    family inet {
      address 10.0.0.25/30;
    }
    family iso;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.4.4/32;
    }
    family iso {
      address 49.0001.0010.0000.0404.00;
    }
  }
}
}

user@R2# show firewall
family inet {
  filter filter1 {
    term t1 {
      from {

```

```
        source-address {
            172.16.1.1/32;
        }
    }
    then {
        next-interface {
            ge-2/1/1.0;
        }
    }
}
term t2 {
    from {
        source-address {
            172.16.2.2/32;
        }
    }
    then {
        next-interface {
            ge-2/1/1.1;
        }
    }
}
}
}
}

user@R2# show protocols
isis {
    interface all {
        level 1 disable;
    }
    interface fxp0.0 {
        disable;
    }
    interface lo0.0;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Checking the Paths Used

Purpose Make sure that the expected paths are used when sending traffic from Device R1 to Device R4.

Action On Device R1, enter the **traceroute** command.

```
user@R1> traceroute 10.255.6.6 source 172.16.1.1
traceroute to 10.255.6.6 (10.255.6.6) from 172.16.1.1, 30 hops max, 40 byte packets
 1  10.0.0.10 (10.0.0.10)  0.976 ms  0.895 ms  0.815 ms
 2  10.0.0.14 (10.0.0.14)  0.868 ms  0.888 ms  0.813 ms
 3  10.255.6.6 (10.255.6.6)  1.715 ms  1.442 ms  1.382 ms

user@R1> traceroute 10.255.6.6 source 172.16.2.2
```

```
traceroute to 10.255.6.6 (10.255.6.6) from 172.16.2.2, 30 hops max, 40 byte packets
```

```
 1  10.0.0.10 (10.0.0.10)  0.973 ms  0.907 ms  0.782 ms
 2  10.0.0.26 (10.0.0.26)  0.844 ms  0.890 ms  0.852 ms
 3  10.255.6.6 (10.255.6.6)  1.384 ms  1.516 ms  1.462 ms
```

Meaning The output shows that the second hop changes, depending on the source address used in the **traceroute** command.

To verify this feature, a traceroute operation is performed on Device R1 to Device R4. When the source IP address is 172.16.1.1, packets are forwarded out the ge-2/1/1.0 interface on Device R2. When the source IP address is 172.16.2.2, packets are forwarded out the ge-2/1/1.1 interface on Device R2.

Example: Configuring Statistics Collection for a Standard Firewall Filter

This example shows how to configure and apply a stateless firewall filter that collects data according to parameters specified in an associated accounting profile.

- [Requirements on page 4669](#)
- [Overview on page 4669](#)
- [Configuration on page 4670](#)
- [Verification on page 4673](#)

Requirements

Firewall filter accounting profiles are supported for all traffic types except **family any**.

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you create a firewall filter accounting profile and apply it to a stateless firewall filter. The accounting profile specifies how frequently to collect packet and byte count statistics and the name of the file to which the statistics are written. The profile also specifies that statistics are to be collected for three firewall filter counters.

Topology

The firewall filter accounting profile **filter_acctg_profile** specifies that statistics are collected every 60 minutes, and the statistics are written to the file

`/var/log/ff_accounting_file`. Statistics are collected for counters named `counter1`, `counter2`, and `counter3`.

The IPv4 stateless firewall filter named `my_firewall_filter` increments a counter for each of three filter terms. The filter is applied to logical interface `ge-0/0/1.0`.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure an Accounting Profile on page 4670](#)
- [Configure a Firewall Filter That References the Accounting Profile on page 4671](#)
- [Apply the Firewall Filter to an Interface on page 4671](#)
- [Confirm Your Candidate Configuration on page 4672](#)
- [Clear the Counters and Commit Your Candidate Configuration on page 4673](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the `[edit]` hierarchy level.

```
set accounting-options filter-profile filter_acctg_profile file ff_accounting_file
set accounting-options filter-profile filter_acctg_profile interval 60
set accounting-options filter-profile filter_acctg_profile counters counter1
set accounting-options filter-profile filter_acctg_profile counters counter2
set accounting-options filter-profile filter_acctg_profile counters counter3
set firewall family inet filter my_firewall_filter accounting-profile filter_acctg_profile
set firewall family inet filter my_firewall_filter term term1 from protocol ospf
set firewall family inet filter my_firewall_filter term term1 then count counter1
set firewall family inet filter my_firewall_filter term term1 then discard
set firewall family inet filter my_firewall_filter term term2 from source-address
  10.108.0.0/16
set firewall family inet filter my_firewall_filter term term2 then count counter2
set firewall family inet filter my_firewall_filter term term2 then discard
set firewall family inet filter my_firewall_filter term accept-all then count counter3
set firewall family inet filter my_firewall_filter term accept-all then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input my_firewall_filter
```

Configure an Accounting Profile

Step-by-Step Procedure

To configure an accounting profile:

1. Create the accounting profile `filter_acctg_profile`.

```
[edit]
user@host# edit accounting-options filter-profile filter_acctg_profile
```

2. Configure the accounting profile to filter and collect packet and byte count statistics every 60 minutes and write them to the `/var/log/ff_accounting_file` file.

```
[edit accounting-options filter-profile filter_acctg_profile]
```

```
user@host# set file ff_accounting_file
user@host# set interval 60
```

3. Configure the accounting profile to collect filter profile statistics (packet and byte counts) for three counters.

```
[edit accounting-options filter-profile filter_acctg_profile]
user@host# set counters counter1
user@host# set counters counter2
user@host# set counters counter3
```

Configure a Firewall Filter That References the Accounting Profile

Step-by-Step Procedure

To configure a firewall filter that references the accounting profile:

1. Create the stateless firewall filter **my_firewall_filter**.

```
[edit]
user@host# edit firewall family inet filter my_firewall_filter
```

2. Apply the filter-accounting profile **filter_acctg_profile** to the firewall filter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set accounting-profile filter_acctg_profile
```

3. Configure the first filter term and counter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set term term1 from protocol ospf
user@host# set term term1 then count counter1
user@host# set term term1 then discard
```

4. Configure the second filter term and counter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set term term2 from source-address 10.108.0.0/16
user@host# set term term2 then count counter2
user@host# set term term2 then discard
```

5. Configure the third filter term and counter.

```
[edit firewall family inet filter my_firewall_filter]
user@host# set term accept-all then count counter3
user@host# set term accept-all then accept
```

Apply the Firewall Filter to an Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```
[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30
```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input my_firewall_filter
```

Confirm Your Candidate Configuration

Step-by-Step Procedure

To confirm your candidate configuration:

1. Confirm the configuration of the accounting profile by entering the **show accounting-options** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show accounting-options
filter-profile filter_acctg_profile {
  file ff_accounting_file;
  interval 60;
  counters {
    counter1;
    counter2;
    counter3;
  }
}
```

2. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter my_firewall_filter {
    accounting-profile filter_acctg_profile;
    term term1 {
      from {
        protocol ospf;
      }
      then {
        count counter1;
        discard;
      }
    }
    term term2 {
      from {
        source-address {
          10.108.0.0/16;
        }
      }
      then {
        count counter2;
        discard;
      }
    }
    term accept-all {
```

```

        then {
            count counter3;
            accept;
        }
    }
}

```

3. Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            filter {
                input my_firewall_filter;
            }
            address 10.1.2.3/30;
        }
    }
}

```

Clear the Counters and Commit Your Candidate Configuration

Step-by-Step Procedure

To clear the counters and commit your candidate configuration:

1. From operational command mode, use the **clear firewall all** command to clear the statistics for all firewall filters.

To clear only the counters incremented in this example, include the name of the firewall filter.

```

[edit]
user@host> clear firewall filter my_firewall_filter

```

2. Commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To verify that the filter is applied to the logical interface, run the **show interfaces** command with the **detail** or **extensive** output level.

To verify that the three counters are collected separately, run the **show firewall filter my_firewall_filter** command.

```

user@host> show firewall filter my_firewall_filter

```

```

Filter: my_firewall_filter

```

```

Counters:

```

Name	Bytes	Packets
counter1	0	0

counter2	0	0
counter3	0	0

- [Statement Hierarchy for Applying Firewall Filter Accounting Profiles on page 4784](#)

Example: Configuring Logging for a Stateless Firewall Filter Term

This example shows how to configure a standard stateless firewall filter to log packet headers.

- [Requirements on page 4674](#)
- [Overview on page 4674](#)
- [Configuration on page 4674](#)
- [Verification on page 4677](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you use a stateless firewall filter that logs and counts ICMP packets that have 192.168.207.222 as either their source or destination.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configure the Syslog Messages File for the Firewall Facility on page 4675](#)
- [Configure the Stateless Firewall Filter on page 4675](#)
- [Apply the Stateless Firewall Filter to a Logical Interface on page 4675](#)
- [Confirm and Commit Your Candidate Configuration on page 4676](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set system syslog file messages_firewall_any firewall any
set system syslog file messages_firewall_any archive no-world-readable
set firewall family inet filter icmp_syslog term icmp_match from address
192.168.207.222/32
set firewall family inet filter icmp_syslog term icmp_match from protocol icmp
set firewall family inet filter icmp_syslog term icmp_match then count packets
set firewall family inet filter icmp_syslog term icmp_match then log
```

```

set firewall family inet filter icmp_syslog term icmp_match then accept
set firewall family inet filter icmp_syslog term default_term then accept
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
set interfaces ge-0/0/1 unit 0 family inet filter input icmp_syslog

```

Configure the Syslog Messages File for the Firewall Facility

Step-by-Step Procedure

To configure a syslog messages file for the **firewall** facility:

1. Configure a messages file for all syslog messages generated for the **firewall** facility.

```

user@host# set system syslog file messages_firewall_any firewall any

```

2. Restrict permission to the archived **firewall** facility syslog files to the root user and users who have the Junos OS maintenance permission.

```

user@host# set system syslog file messages_firewall_any archive no-world-readable

```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter **icmp_syslog** that logs and counts ICMP packets that have **192.168.207.222** as either their source or destination:

1. Create the stateless firewall filter **icmp_syslog**.

```

[edit]
user@host# edit firewall family inet filter icmp_syslog

```

2. Configure matching on the ICMP protocol and an address.

```

[edit firewall family inet filter icmp_syslog]
user@host# set term icmp_match from address 192.168.207.222/32
user@host# set term icmp_match from protocol icmp

```

3. Count, log, and accept matching packets.

```

[edit firewall family inet filter icmp_syslog]
user@host# set term icmp_match then count packets
user@host# set term icmp_match then log
user@host# set term icmp_match then accept

```

4. Accept all other packets.

```

[edit firewall family inet filter icmp_syslog]
user@host# set term default_term then accept

```

Apply the Stateless Firewall Filter to a Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to a logical interface:

1. Configure the logical interface to which you will apply the stateless firewall filter.

```

[edit]
user@host# edit interfaces ge-0/0/1 unit 0 family inet

```

2. Configure the interface address for the logical interface.

```

[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set address 10.1.2.3/30

```

3. Apply the stateless firewall filter to the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
user@host# set filter input icmp_syslog
```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the syslog message file for the **firewall** facility by entering the **show system** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show system
syslog {
  file messages_firewall_any {
    firewall any;
    archive no-world-readable;
  }
}
```

2. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter icmp_syslog {
    term icmp_match {
      from {
        address {
          192.168.207.222/32;
        }
        protocol icmp;
      }
      then {
        count packets;
        log;
        accept;
      }
    }
    term default_term {
      then accept;
    }
  }
}
```

3. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
```

```

unit 0 {
    family inet {
        filter {
            input icmp_syslog;
        }
        address 10.1.2.3/30;
    }
}

```

4. If you are done configuring the device, commit your candidate configuration.

```

[edit]
user@host# commit

```

Verification

To confirm that the configuration is working properly, enter the `show log filter` command:

```

user@host> show log messages_firewall_any
Mar 20 08:03:11 hostname feb FW: ge-0/1/0.0   A icmp 192.168.207.222
192.168.207.223      0      0 (1 packets)

```

This output file contains the following fields:

- **Date and Time**—Date and time at which the packet was received (not shown in the default).
- **Filter action**:
 - **A**—Accept (or next term)
 - **D**—Discard
 - **R**—Reject
- **Protocol**—Packet's protocol name or number.
- **Source address**—Source IP address in the packet.
- **Destination address**—Destination IP address in the packet.

NOTE: If the protocol is ICMP, the ICMP type and code are displayed. For all other protocols, the source and destination ports are displayed.

The last two fields (both zero) are the source and destination TCP/UDP ports, respectively, and are shown for TCP or UDP packets only. This log message indicates that only one packet for this match has been detected in about a 1-second interval. If packets arrive faster, the system log function compresses the information so that less output is generated, and displays an output similar to the following:

```

user@host> show log filter
Mar 20 08:08:45 hostname feb FW: ge-0/1/0.0   A icmp 192.168.207.222
192.168.207.223      0      0 (515 packets)

```

Service Filters Configuration

- [Example: Configuring and Applying Service Filters on page 4678](#)

Example: Configuring and Applying Service Filters

This example shows how to configure and apply service filters.

- [Requirements on page 4678](#)
- [Overview on page 4678](#)
- [Configuration on page 4679](#)
- [Verification on page 4682](#)

Requirements

This example use the logical interface **xe-0/1/0.0** on any of the following hardware components:

- Adaptive Services (AS) PIC on an M Series or T Series router
- Multiservices (MS) PIC on an M Series or T Series router
- Multiservices (MS) DPC on an MX Series router
- EX Series switch

Before you begin, make sure that you have:

- Installed your supported router (or switch) and PICs or DPCs and performed the initial router (or switch) configuration.
- Configured basic Ethernet in the topology, and verified that traffic is flowing in the topology and that IPv4 traffic is flowing through logical interface **xe-0/1/0.0**.
- Configured the service set **vrf_svcs** with service input and output rules and default settings for services at a service interface.

For guidelines for configuring service sets, see “*Configuring Service Sets to be Applied to Services Interfaces*” in the *Junos Services Interfaces Configuration Release 11.2*.

Overview

In this example, you create three types of service filters for IPv4 traffic: one input service filter, one postservice input filter, and one output service filter.

Topology

You apply the input service filter and postservice input filter to input traffic at logical interface **xe-0/1/0.0**, and you apply the output service filter to the output traffic at the same logical interface.

- Filtering IPv4 traffic before it is accepted for input service processing—At logical interface **xe-0/1/0.0**, you use the service filter **in_filter_presvc** to filter IPv4 input traffic before the traffic can be accepted for processing by services associated with service set **vrf_svcs**. The **in_filter_presvc** service filter counts packets sent from ICMP port 179, directs these packets to the input services associated with the service set **vrf_svcs**, and discards all other packets.
- Filtering IPv4 traffic after it has completed input service processing—At logical interface **xe-0/1/0.0**, you use the service filter **in_filter_postsvc** to filter traffic that is returning to the services interface after the input service set **in_filter_presvc** is executed. The **in_filter_postsvc** service filter counts packets sent from ICMP port 179 and then discards them.
- Filtering IPv4 traffic before it is accepted for output service processing—At logical interface **xe-0/1/0.0**, you use the service-filter **out_filter_presvc** to filter IPv4 output traffic before the traffic can be accepted for processing by the services associated with service set **vrf_svcs**. The **out_filter_presvc** service filter counts packets destined for TCP port 179 and then directs the packets to the output services associated with the service set **vrf_svcs**.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Three Service Filters on page 4680](#)
- [Applying the Three Service Filters on page 4681](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet service-filter in_filter_presvc term t1 from protocol tcp
set firewall family inet service-filter in_filter_presvc term t1 from source-port bgp
set firewall family inet service-filter in_filter_presvc term t1 then count svc_in_pkts
set firewall family inet service-filter in_filter_postsvc term t2 from protocol tcp
set firewall family inet service-filter in_filter_postsvc term t2 from source-port bgp
set firewall family inet service-filter in_filter_postsvc term t2 then count svc_in_pkts_rtn
set firewall family inet service-filter in_filter_postsvc term t2 then skip
set firewall family inet service-filter out_filter_presvc term t3 from protocol icmp
set firewall family inet service-filter out_filter_presvc term t3 from destination-port bgp
set firewall family inet service-filter out_filter_presvc term t3 then count svc_out_pkts
set firewall family inet service-filter out_filter_presvc term t3 then service
```

```
set interfaces xe-0/1/0 unit 0 family inet service input service-set vrf_svcs service-filter
in_filter_presvc
set interfaces xe-0/1/0 unit 0 family inet service input post-service-filter in_filter_postsvc
set interfaces xe-0/1/0 unit 0 family inet service output service-set vrf_svcs service-filter
out_filter_presvc
```

Configuring the Three Service Filters

Step-by-Step Procedure

To configure the three service filters:

1. Configure the input service filter.

```
[edit]
user@host# edit firewall family inet service-filter in_filter_presvc
```

```
[edit firewall family inet service-filter in_filter_presvc]
user@host# set term t1 from protocol tcp
user@host# set term t1 from source-port bgp
user@host# set term t1 then count svc_in_pkts
user@host# set term t1 then service
```

2. Configure the postservice input filter.

```
[edit]
user@host# edit firewall family inet service-filter in_filter_postsvc
```

```
[edit firewall family inet service-filter in_filter_postsvc]
user@host# set term t2 from protocol tcp
user@host# set term t2 from source-port bgp
user@host# set term t2 then count svc_in_pkts_rtn
user@host# set term t2 then skip
```

3. Configure the output service filter.

```
[edit]
user@host# edit firewall family inet service-filter out_filter_presvc
```

```
[edit firewall family inet service-filter out_filter_presvc]
user@host# set term t3 from protocol icmp
user@host# set term t3 from destination-port bgp
user@host# set term t3 then count svc_out_pkts
user@host# set term t3 then service
```

Results Confirm the configuration of the input and output service filters and the postservice input filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  service-filter in_filter_presvc {
    term t1 {
      from {
        protocol tcp;
        source-port bgp;
      }
    }
  }
}
```

```

        then {
            count svc_in_pkts;
            service;
        }
    }
}
service-filter in_filter_postsvc {
    term t2 {
        from {
            protocol tcp;
            source-port bgp;
        }
        then {
            count svc_in_pkts_rtn;
            skip;
        }
    }
}
service-filter out_filter_presvc {
    term t3 {
        from {
            protocol icmp;
            destination-port bgp;
        }
        then {
            count svc_out_pkts;
            service;
        }
    }
}
}

```

Applying the Three Service Filters

Step-by-Step Procedure

To apply the three service filters:

1. Access the IPv4 protocol on the input interface **xe-0/1/0.0**.

```

[edit]
user@host# edit interfaces xe-0/1/0 unit 0 family inet

```

2. Apply the input service filter and the postservice input filter.

```

[edit interfaces xe-0/1/0 unit 0 family inet]
user@host# set service input service-set vrf_svcs service-filter in_filter_presvc
user@host# set service input post-service-filter in_filter_postsvc
user@host# set service output service-set vrf_svcs service-filter out_filter_presvc

```

Results Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show interfaces
xe-0/1/0 {
    unit 0 {

```

```
family inet {
  service {
    input {
      service-set vrf_svcs service-filter in_filter_presvc;
      post-service-filter in_filter_postsvc;
    }
    output {
      service-set vrf_svcs service-filter out_filter_presvc;
    }
  }
}
```

When you are done configuring the device, commit your candidate configuration.

Verification

Confirm that the configuration is working properly.

- [Verifying That Inbound Traffic Is Filtered Before Input Service on page 4682](#)
- [Verifying That Inbound Traffic Is Filtered After Input Service Processing on page 4682](#)
- [Verifying That Outbound Traffic Is Filtered Before Output Service Processing on page 4682](#)

Verifying That Inbound Traffic Is Filtered Before Input Service

Purpose Verify that inbound packets sent from TCP port 179 are sent for processing by the *input* services associated with the service set **vrf_svcs**.

Action Display the count of packets sent for processing by the *input* services associated with the service set **vrf_svcs**.

[edit]

user@host> show firewall filter in_filter_presvc-vrf_svcs counter svc_in_pkts

Verifying That Inbound Traffic Is Filtered After Input Service Processing

Purpose Verify that inbound packets sent from TCP port 179 are returned from processing by the *input* services associated with the service set **vrf_svcs**.

Action Display the count of packets returned from processing by the *input* services associated with the service set **vrf_svcs**.

[edit]

user@host> show firewall filter in_filter_postsvc-vrf_svcs counter svc_in_pkts_rtn

Verifying That Outbound Traffic Is Filtered Before Output Service Processing

Purpose Verify that outbound packets sent to ICMP port 179 are sent for processing by the *output* services associated with the service set **vrf_svcs**.

Action Display the count of packets sent for processing by the *output* services associated with the service set **vrf_svcs**.

[edit]

```
user@host> show firewall filter out_filter_presvc-vrf_svcs counter svc_out_pkts
```

Simple Filters Configuration

- [Example: Configuring and Applying a Simple Filter on page 4683](#)

Example: Configuring and Applying a Simple Filter

This example shows how to configure a simple filter.

- [Requirements on page 4683](#)
- [Overview on page 4683](#)
- [Configuration on page 4684](#)
- [Verification on page 4686](#)

Requirements

This example uses one of the following hardware components:

- One Gigabit Ethernet intelligent queuing (IQ2) PIC installed on an M120, M320, or T Series router
- One Enhanced Queuing Dense Port Concentrator (EQ DPC) installed on an MX Series router or an EX Series switch

Before you begin, make sure that you have:

- Installed your supported router (or switch) and PIC or DPC and performed the initial router (or switch) configuration.
- Configured basic Ethernet in the topology, and verified that traffic is flowing in the topology and that ingress IPv4 traffic is flowing into logical interface **ge-0/0/1.0**.

Overview

This simple filter sets the loss priority to low for TCP traffic with source address **1.1.1.1**, sets the loss priority to high for HTTP (Web) traffic with source addresses in the **4.0.0.0/8** range, and sets the loss priority to low for all traffic with destination address **6.6.6.6**.

Topology

The simple filter is applied as an input filter (arriving packets are checking for destination address **6.6.6.6**, not queued output packets) on interface **ge-0/0/1.0**.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Simple Firewall Filter on page 4684](#)
- [Applying the Simple Filter to the Logical Interface Input on page 4685](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall family inet simple-filter sf_classify_1 term 1 from source-address 1.1.1.1/32
set firewall family inet simple-filter sf_classify_1 term 1 from protocol tcp
set firewall family inet simple-filter sf_classify_1 term 1 then loss-priority low
set firewall family inet simple-filter sf_classify_1 term 2 from source-address 4.0.0.0/8
set firewall family inet simple-filter sf_classify_1 term 2 from protocol tcp
set firewall family inet simple-filter sf_classify_1 term 2 from source-port http
set firewall family inet simple-filter sf_classify_1 term 2 then loss-priority high
set firewall family inet simple-filter sf_classify_1 term 3 from destination-address
  6.6.6.6/32
set firewall family inet simple-filter sf_classify_1 term 3 then loss-priority low
set firewall family inet simple-filter sf_classify_1 term 3 then forwarding-class best-effort
set interfaces ge-0/0/1 unit 0 family inet simple-filter input sf_classify_1
set interfaces ge-0/0/1 unit 0 family inet address 10.1.2.3/30
```

Configuring the Simple Firewall Filter

Step-by-Step Procedure

To configure the simple filter:

1. Create the simple filter **sf_classify_1**.

```
[edit]
user@host# edit firewall family inet simple-filter sf_classify_1
```

2. Configure classification of TCP traffic based on the source IP address.

```
[edit firewall family inet simple-filter sf_classify_1]
user@host# set term 1 from source-address 1.1.1.1/32
user@host# set term 1 from protocol tcp
user@host# set term 1 then loss-priority low
```

3. Configure classification of HTTP traffic based on the source IP address.

```
[edit firewall family inet simple-filter sf_classify_1]
user@host# set term 2 from source-address 4.0.0.0/8
user@host# set term 2 from protocol tcp
user@host# set term 2 from source-port http
user@host# set term 2 then loss-priority high
```

4. Configure classification of other traffic based on the destination IP address.

```
[edit firewall family inet simple-filter sf_classify_1]
user@host# set term 3 from destination-address 6.6.6.6/32
user@host# set term 3 then loss-priority low
```

```
user@host# set term 3 then forwarding-class best-effort
```

Results Confirm the configuration of the simple filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  simple-filter sf_classify_1 {
    term 1 {
      from {
        source-address {
          1.1.1.1/32;
        }
        protocol {
          tcp;
        }
      }
      then loss-priority low;
    }
    term 2 {
      from {
        source-address {
          4.0.0.0/8;
        }
        source-port {
          http;
        }
        protocol {
          tcp;
        }
      }
      then loss-priority high;
    }
    term 3 {
      from {
        destination-address {
          6.6.6.6/32;
        }
      }
      then {
        loss-priority low;
        forwarding-class best-effort;
      }
    }
  }
}
```

Applying the Simple Filter to the Logical Interface Input

Step-by-Step Procedure To apply the simple filter to the logical interface input:

1. Configure the logical interface to which you will apply the simple filter.

```
[edit]
```

```
user@host# edit interfaces ge-0/0/1 unit 0 family inet
```

2. Configure the interface address for the logical interface.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
```

```
user@host# set address 10.1.2.3/30
```

3. Apply the simple filter to the logical interface input.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
```

```
user@host# set simple-filter input sf_classify_1
```

Results Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      simple-filter {
        input sf_classify_1;
      }
      address 10.1.2.3/30;
    }
  }
}
```

When you are done configuring the device, commit your candidate configuration.

Verification

Confirm that the configuration is working properly.

- [Displaying the Mapping of Forwarding Class Maps and Names to Queue Numbers on page 4686](#)
- [Displaying CoS Queue Counters for the Interface on page 4686](#)
- [Displaying CoS Queue Counter Details for the Physical Interface on page 4687](#)

Displaying the Mapping of Forwarding Class Maps and Names to Queue Numbers

Purpose Display the mapping of forwarding class names to queue numbers.

Action Enter the **show class-of-service forwarding-class** operational mode command.

```
[edit]
```

```
user@host> show class-of-service forwarding-class
```

For information about the command output, see “**show class-of-service forwarding-class**” in the *Junos OS Operational Mode Commands*.

Displaying CoS Queue Counters for the Interface

Purpose Verify that the class-of-service (CoS) queue counters for the interface reflect the simple filter applied to the logical interface.

Action Enter the **show interfaces** command for the physical interface on which the simple filter is applied, and specify **detail** or **extensive** output level.

[edit]

```
user@host> show interfaces ge-0/0/1 detail
```

In the **Physical interface** section, under **Ingress queues**, the **Queue counters** section displays ingress queue counters for each forwarding class.

For more detailed information about the command output, see “[show interfaces \(Gigabit Ethernet\)](#)” or “[show interfaces \(10-Gigabit Ethernet\)](#)” in the *Junos OS Operational Mode Commands*.

Displaying CoS Queue Counter Details for the Physical Interface

Purpose Verify that the CoS queue counter details for the physical interface reflect the simple filter applied to the logical interface.

Action Enter the **show interfaces queue** command for the physical interface on which the simple filter is applied, and specify the **ingress** option.

[edit]

```
user@host> show interfaces queue ge-0/0/1 ingress
```

For information about the command output, see “[show interfaces queue](#)” in the *Junos OS Operational Mode Commands*.

Example: Configuring a Stateless Firewall Filter to Protect a Logical System Against ICMP Floods

This example shows how to configure a stateless firewall filter that protects against ICMP denial-of-service attacks on a logical system.

- [Requirements on page 4687](#)
- [Overview on page 4688](#)
- [Configuration on page 4688](#)
- [Verification on page 4690](#)

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

This example shows a stateless firewall filter called **protect-RE** that polices ICMP packets. The **icmp-policer** limits the traffic rate of the ICMP packets to 1,000,000 bps and the burst size to 15,000 bytes. Packets that exceed the traffic rate are discarded.

The policer is incorporated into the action of a filter term called **icmp-term**.

In this example, a ping is sent from a directly connected physical router to the interface configured on the logical system. The logical system accepts the ICMP packets if they are received at a rate of up to 1 Mbps (bandwidth-limit). The logical system drops all ICMP packets when this rate is exceeded. The **burst-size-limit** statement accepts traffic bursts up to 15 Kbps. If bursts exceed this limit, all packets are dropped. When the flow rate subsides, ICMP packets are again accepted.

Figure 58 on page 3295 shows the topology used in this example.

Figure 99: Logical System with a Stateless Firewall

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet policer input icmp-policer
set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet address 10.0.45.2/30
set logical-systems LS1 firewall family inet filter protect-RE term icmp-term from protocol icmp
set logical-systems LS1 firewall family inet filter protect-RE term icmp-term then policer icmp-policer
set logical-systems LS1 firewall policer icmp-policer if-exceeding bandwidth-limit 1m
set logical-systems LS1 firewall policer icmp-policer if-exceeding burst-size-limit 15k
set logical-systems LS1 firewall policer icmp-policer then discard
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure an ICMP firewall filter on a logical system:

1. Configure the interface on the logical system.

```
[edit]
user@host# set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet address
10.0.45.2/30
```

2. Explicitly enable ICMP packets to be received on the interface.

```
[edit]
user@host# set logical-systems LS1 firewall family inet filter protect-RE term
icmp-term from protocol icmp
user@host# set logical-systems LS1 firewall family inet filter protect-RE term
icmp-term then accept
```

3. Create the policer.

```
[edit]
user@host# set logical-systems LS1 firewall policer icmp-policer if-exceeding
bandwidth-limit 1m
user@host# set logical-systems LS1 firewall policer icmp-policer if-exceeding
burst-size-limit 15k
user@host# set logical-systems LS1 firewall policer icmp-policer then discard
```

4. Apply the policer to a filter term.

```
[edit]
user@host# set logical-systems LS1 firewall family inet filter protect-RE term
icmp-term then policer icmp-policer
```

5. Apply the policer to the logical system interface.

```
[edit]
user@host# set logical-systems LS1 interfaces ge-0/0/2 unit 0 family inet policer
input icmp-policer
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show logical-systems LS1** command.

```
user@host# show logical-systems LS1
interfaces {
  ge-0/0/2 {
    unit 0 {
      family inet {
        policer {
          input icmp-policer;
        }
      }
    }
  }
}
```

```
        address 10.0.45.2/30;
      }
    }
  }
}
firewall {
  family inet {
    filter protect-RE {
      term icmp-term {
        from {
          protocol icmp;
        }
        then {
          policer icmp-policer;
          accept;
        }
      }
    }
  }
}
policer icmp-policer {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 15k;
  }
  then discard;
}
}
```

Verification

Confirm that the configuration is working properly.

Verifying That Ping Works Unless the Limits Are Exceeded

Purpose Make sure that the logical system interface is protected against ICMP-based DoS attacks.

Action Log in to a system that has connectivity to the logical system and run the **ping** command.

```
user@R2> ping 10.0.45.2
PING 10.0.45.2 (10.0.45.2): 56 data bytes
64 bytes from 10.0.45.2: icmp_seq=0 ttl=64 time=1.316 ms
64 bytes from 10.0.45.2: icmp_seq=1 ttl=64 time=1.277 ms
64 bytes from 10.0.45.2: icmp_seq=2 ttl=64 time=1.269 ms

user@R2> ping 10.0.45.2 size 20000
PING 10.0.45.2 (10.0.45.2): 20000 data bytes
^C
--- 10.0.45.2 ping statistics ---
4 packets transmitted, 0 packets received, 100% packet loss
```

Meaning When you send a normal ping, the packet is accepted. When you send a ping packet that exceeds the filter limit, the packet is discarded.

Configuration Statements

- [\[edit firewall\] Hierarchy Level on page 4691](#)

[edit firewall] Hierarchy Level

Several statements in the **[edit firewall]** hierarchy are valid at numerous locations within the hierarchy. To make the complete hierarchy easier to read, the repeated statements are listed in the following sections, which are referenced at the appropriate locations in [“Complete \[edit firewall\] Hierarchy” on page 325](#).

- [Common Firewall Actions on page 4691](#)
- [Common IP Firewall Actions on page 4691](#)
- [Common IPv4 Firewall Actions on page 4692](#)
- [Common IP Firewall Match Conditions on page 4692](#)
- [Common IPv4 Firewall Match Conditions on page 4693](#)
- [Common Layer 2 Firewall Match Conditions on page 4694](#)
- [Complete \[edit firewall\] Hierarchy on page 4695](#)

Common Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family (any | ccc | ethernet-switching | inet | inet6 | mpls | vpls) filter *filter-name* term *term-name* then]**
- **[edit firewall filter *filter-name* term *term-name* then]**

The common firewall actions are as follows:

```
count counter-name;
forwarding-class class-name;
loss-priority (high | low | medium-high | medium-low);
next term;
policer policer-name;
three-color-policer policer-name {
    (single-rate single-rate-policer-name | two-rate two-rate-policer-name);
}
```

Common IP Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family inet filter *filter-name* term *term-name* then]**
- **[edit firewall family inet6 filter *filter-name* term *term-name* then]**
- **[edit firewall filter *filter-name* term *term-name* then]**

The common IP firewall actions are as follows:

```
log;
logical-system logical-system-name <routing-instance routing-instance-name>
  <topology topology-name>;
port-mirror;
port-mirror-instance instance-name;
routing-instance routing-instance-name <topology topology-name>;
sample;
service-filter-hit;
syslog;
topology topology-name;
```

Common IPv4 Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family inet filter *filter-name* term *term-name* then]**
- **[edit firewall filter *filter-name* term *term-name* then]**

The common IP version 4 (IPv4) firewall actions are as follows:

```
(accept | discard <accounting collector-name> | reject <administratively-prohibited |
  bad-host-tos | bad-network-tos | fragmentation-needed | host-prohibited |
  host-unknown | host-unreachable | network-prohibited | network-unknown |
  network-unreachable | port-unreachable | precedence-cutoff | precedence-violation |
  protocol-unreachable | source-host-isolated | source-route-failed | tcp-reset>);
ipsec-sa sa-name;
load-balance sa-name;
next-hop-group group-name;
prefix-action action-name;
```

Common IP Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family inet dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- **[edit firewall family inet filter *filter-name* term *term-name* from]**
- **[edit firewall family inet6 dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- **[edit firewall family inet6 filter *filter-name* term *term-name* from]**
- **[edit firewall filter *filter-name* term *term-name* from]**

The common IP firewall match conditions are as follows:

```
address {
  ip-prefix/prefix-length> <except>;
}
```

```

destination-address {
    ip-prefix</prefix-length> <except>;
}
destination-class [ class-names ] | destination-class-except [ class-names ];
(destination-port [ port-names ] | destination-port-except [ port-names ]);
destination-prefix-list {
    list-name <except>;
}
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);
icmp-code [ codes ] | icmp-code-except [ codes ];
icmp-type [ types ] | icmp-type-except [ types ];
interface interface-name;
interface-group [ group-names ] | interface-group-except [ group-names ];
interface-set set-name;
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(packet-length [ values ] | packet-length-except [ values ]);
(port [ port-names ] | port-except [ port-names ]);
prefix-list {
    list-name <except>;
}
service-filter-hit;
source-address {
    ip-prefix</prefix-length> <except>;
}
(source-class [ class-names ] | source-class-except [ class-names ]);
(source-port [ port-names ] | source-port-except [ port-names ]);
source-prefix-list {
    list-name <except>;
}
tcp-established;
tcp-flags flag;
tcp-initial;

```

Common IPv4 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [\[edit firewall family inet dialer-filter filter-name term term-name from\]](#) (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- [\[edit firewall family inet filter filter-name term term-name from\]](#)
- [\[edit firewall filter filter-name term term-name from\]](#)

The common IPv4 firewall match conditions are as follows:

```

(ah-spi [ values ] | ah-spi-except [ values ]);
(dscp [ code-point-values ] | dscp-except [ code-point-values ]);
(esp-spi [ values ] | esp-spi-except [ values ]);
first-fragment;
fragment-flags flag;
(fragment-offset [ offsets ] | fragment-offset-except [ offsets ]);
(ip-options [ option-names ] | ip-options-except [ option-names ]);
is-fragment;
(precedence [ precedence-names ] | precedence-except [ precedence-names ]);

```

```
(protocol [ protocol-names ] | protocol-except [ protocol-names ] );  
(ttl [ tll-values ] | ttl-except [ tll-values ] );
```

Common Layer 2 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- [edit firewall family ethernet-switching filter *filter-name* term *term-name* from]
- [edit firewall family vpls filter *filter-name* term *term-name* from]

The common Layer 2 firewall match conditions are as follows:

```
destination-mac-address {  
    mac-address <except>;  
}  
(destination-port [ port-names ] | destination-port-except [ port-names ] );  
(dscp [ code-point-values ] | dscp-except [ code-point-values ] );  
(ether-type [ protocol-types ] | ether-type-except [ protocol-types ] );  
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ] );  
(icmp-code [ codes ] | icmp-code-except [ codes ] );  
(icmp-type [ types ] | icmp-type-except [ types ] );  
(interface-group [ group-names ] | interface-group-except [ group-names ] );  
ip-address {  
    ip-prefix </prefix-length> <except>;  
}  
ip-destination-address {  
    ip-prefix </prefix-length> <except>;  
}  
(ip-precedence [ precedence-names ] | ip-precedence-except [ precedence-names ] );  
(ip-protocol [ protocol-names ] | ip-protocol-except [ protocol-names ] );  
ip-source-address ip-prefix </prefix-length>;  
(learn-vlan-lp-priority [ priorities ] | learn-vlan-lp-priority [ priorities ] );  
(learn-vlan-id [ vlan-ids ] | learn-vlan-id-except [ vlan-ids ] );  
(loss-priority [ priorities ] | loss-priority-except [ priorities ] );  
(port [ port-names ] | port-except [ port-names ] );  
source-mac-address {  
    mac-address <except>;  
}  
(source-port [ port-names ] | source-port-except [ port-names ] );  
tcp-flags flag;  
(traffic-type [ broadcast known-unicast multicast unknown-unicast ] |  
    traffic-type-except [ broadcast known-unicast multicast unknown-unicast ] );  
(user-vlan-lp-priority [ priorities ] | user-vlan-lp-priority [ priorities ] );  
(user-vlan-id [ vlan-ids ] | user-vlan-id-except [ vlan-ids ] );  
(vlan-ether-type [ protocol-types ] | vlan-ether-type-except [ protocol-types ] );
```

Firewall Filters Standards

- [Supported Standards for Filtering on page 4703](#)

Supported Standards for Filtering

The Junos OS supports the following RFCs related to filtering:

- RFC 792, *Internet Control Message Protocol*
- RFC 2460, *Internet Protocol, Version 6 (IPv6)*
- RFC 2474, *Definition of the Differentiated Services (DS) Field*

- RFC 2475, *An Architecture for Differentiated Services*
- RFC 2597, *Assured Forwarding PHB Group*
- RFC 3246, *An Expedited Forwarding PHB (Per-Hop Behavior)*
- RFC 4291, *IP Version 6 Addressing Architecture*
- RFC 4443, *Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification*

Firewall Filters Reference

- [Using the CLI Editor in Configuration Mode on page 4704](#)

Using the CLI Editor in Configuration Mode

This topic describes some of the basic commands that you must use to enter configuration mode in the command-line interface (CLI) editor, navigate through the configuration hierarchy, get help, and commit or revert the changes that you make during the configuration session.

Task	Command/Statement	Example
Edit Your Configuration		
Enter configuration mode. When you first log in to the device, the device is in operational mode. You must explicitly enter configuration mode. When you do, the CLI prompt changes from user@host> to user@host# and the hierarchy level appears in square brackets.	configure	user@host> configure [edit] user@host#
Create a statement hierarchy. You can use the edit command to simultaneously create a hierarchy and move to that new level in the hierarchy. You cannot use the edit command to change the value of identifiers.	edit hierarchy-level value	[edit] user@host# edit security zones security-zone myzone [edit security zones security-zone myzone] user@host#
Create a statement hierarchy and set identifier values. The set command is similar to edit except that your current level in the hierarchy does not change.	set hierarchy-level value	[edit] user@host# set security zones security-zone myzone [edit] user@host#

Task	Command/Statement	Example
Navigate the Hierarchy		
Navigate down to an existing hierarchy level.	<code>edit hierarchy-level</code>	<pre>[edit] user@host# edit security zones [edit security zones] user@host#</pre>
Navigate up one level in the hierarchy.	<code>up</code>	<pre>[edit security zones] user@host# up [edit security] user@host#</pre>
Navigate to the top of the hierarchy.	<code>top</code>	<pre>[edit security zones] user@host# top [edit] user@host#</pre>
Commit or Revert Changes		
Commit your configuration.	<code>commit</code>	<pre>[edit] user@host# commit commit complete</pre>
<p>Roll back changes from the current session.</p> <p>Use the rollback command to revert all changes from the current configuration session. When you run the rollback command before exiting your session or committing changes, the software loads the most recently committed configuration onto the device. You must enter the rollback statement at the edit level in the hierarchy.</p>	<code>rollback</code>	<pre>[edit] user@host# rollback load complete</pre>
Exit Configuration Mode		
Commit the configuration and exit configuration mode.	<code>commit and-quit</code>	<pre>[edit] user@host# commit and-quit user@host></pre>
<p>Exit configuration mode without committing your configuration.</p> <p>You must navigate to the top of the hierarchy using the up or top commands before you can exit configuration mode.</p>	<code>exit</code>	<pre>[edit] user@host# exit The configuration has been changed but not committed Exit with uncommitted changes? [yes,no] (yes)</pre>
Get Help		

Task	Command/Statement	Example
Display a list of valid options for the current hierarchy level.	?	<pre>[edit] user@host# edit security zones ?</pre> <p>Possible completions:</p> <pre><[Enter]> Execute this command > functional-zone Functional zone > security-zone Security zones Pipe through a command [edit]</pre>

Standard Firewall Filter Match Conditions for Protocol-Independent Traffic

You can configure a standard stateless firewall filter with match conditions for protocol-independent traffic (**family any**).

NOTE: Protocol-independent standard firewall filters—firewall filters configured at the [edit firewall family any] hierarchy level— are not supported on the router (or switch) loopback interface (lo0).

Table 340 on page 4707 describes the **match-conditions** you can configure at the [edit firewall family any filter *filter-name* term *term-name* from] hierarchy level.

Table 340: Standard Firewall Filter Match Conditions for Protocol-Independent Traffic

Match Condition	Description
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p> <p>For information about forwarding classes and router-internal output queues, see the <i>Junos OS Class of Service Configuration Guide</i>.</p> <p>NOTE: On T4000 Type 5 FPCs, a filter attached at the Layer 2 application point (that is, at the logical interface level) is unable to match with the forwarding class of a packet that is set by a Layer 3 classifier such as DSCP, DSCP V6, inet-precedence, and mpls-exp.</p>
forwarding-class-except <i>class</i>	Do not match on the forwarding class. For details, see the forwarding-class match condition.
interface <i>interface-name</i>	<p>Match the interface on which the packet was received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. For more information, see "Filtering Packets Received on an Interface Set Overview" on page 4515.</p>
packet-length <i>bytes</i>	Match the length of the received packet, in bytes. The length refers only to the IP packet, including the packet header, and does not include any Layer 2 encapsulation overhead.
packet-length-except <i>bytes</i>	Do not match on the received packet length, in bytes. For details, see the packet-length match type.

Standard Firewall Filter Match Conditions for IPv4 Traffic

You can configure a standard stateless firewall filter with match conditions for Internet Protocol version 4 (IPv4) traffic (**family inet**). [Table 341 on page 4707](#) describes the **match-conditions** you can configure at the **[edit firewall family inet filter filter-name term term-name from]** hierarchy level.

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic

Match Condition	Description
address <i>address</i> [except]	Match the IPv4 source or destination address field unless the except option is included. If the option is included, do not match the IPv4 source or destination address field.

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
ah-spi <i>spi-value</i>	(M Series routers, except M120 and M320) Match the IPsec authentication header (AH) security parameter index (SPI) value. NOTE: This match condition is not supported on PTX series packet transport switches.
ah-spi-except <i>spi-value</i>	(M Series routers, except M120 and M320) Do not match the IPsec AH SPI value. NOTE: This match condition is not supported on PTX series packet transport switches.
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
destination-address <i>address</i> [except]	Match the IPv4 destination address field unless the except option is included. If the option is included, do not match the IPv4 destination address field.. You cannot specify both the address and destination-address match conditions in the same term.
destination-class <i>class-names</i>	Match one or more specified destination class names (sets of destination prefixes grouped together and given a class name). For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 4502 . NOTE: This match condition is not supported on PTX series packet transport switches.
destination-class-except <i>class-names</i>	Do not match one or more specified destination class names. For details, see the destination-class match condition. NOTE: This match condition is not supported on PTX series packet transport switches.
destination-port <i>number</i>	Match the UDP or TCP destination port field. You cannot specify both the port and destination-port match conditions in the same term. If you configure this match condition, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port. In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).
destination-port-except <i>number</i>	Do not match the UDP or TCP destination port field. For details, see the destination-port match condition.

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
destination-prefix-list <i>name</i> [except]	<p>Match destination prefixes in the specified list unless the except option is included. If the option is included, do not match the destination prefixes in the specified list.</p> <p>Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p>
dscp <i>number</i>	<p>Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see the <i>Junos OS Class of Service Configuration Guide</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <ul style="list-style-type: none"> • af11 (10), af12 (12), af13 (14) • af21 (18), af22 (20), af23 (22) • af31 (26), af32 (28), af33 (30) • af41 (34), af42 (36), af43 (38)
dscp-except <i>number</i>	Do not match on the DSCP number. For more information, see the dscp match condition.
esp-spi <i>spi-value</i>	<p>Match the IPsec encapsulating security payload (ESP) SPI value. Match on this specific SPI value. You can specify the ESP SPI value in hexadecimal, binary, or decimal form.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
esp-spi-except <i>spi-value</i>	<p>Match the IPsec ESP SPI value. Do not match on this specific SPI value.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
first-fragment	<p>Match if the packet is the first fragment of a fragmented packet. Do not match if the packet is a trailing fragment of a fragmented packet. The first fragment of a fragmented packet has a fragment offset value of 0.</p> <p>This match condition is an alias for the bit-field match condition fragment-offset 0 match condition.</p> <p>To match both first and trailing fragments, you can use two terms that specify different match conditions: first-fragment and is-fragment.</p>
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p> <p>For information about forwarding classes and router-internal output queues, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
forwarding-class-except <i>class</i>	Do not match the forwarding class of the packet. For details, see the forwarding-class match condition.

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
fragment-flags <i>number</i>	<p>(Ingress only) Match the three-bit IP fragmentation flags field in the IP header.</p> <p>In place of the numeric field value, you can specify one of the following keywords (the field values are also listed): dont-fragment (0x4), more-fragments (0x2), or reserved (0x8).</p>
fragment-offset <i>value</i>	<p>Match the 13-bit fragment offset field in the IP header. The value is the offset, in 8-byte units, in the overall datagram message to the data fragment. Specify a numeric value, a range of values, or a set of values. An offset value of 0 indicates the first fragment of a fragmented packet.</p> <p>The first-fragment match condition is an alias for the fragment-offset 0 match condition.</p> <p>To match both first and trailing fragments, you can use two terms that specify different match conditions (first-fragment and is-fragment).</p>
fragment-offset-except <i>number</i>	Do not match the 13-bit fragment offset field.
icmp-code <i>number</i>	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol icmp match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type <i>message-type</i> match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip-header-bad (0), required-option-missing (1) redirect: redirect-for-host (1), redirect-for-network (0), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) unreachable: communication-prohibited-by-filtering (13), destination-host-prohibited (10), destination-host-unknown (7), destination-network-prohibited (9), destination-network-unknown (6), fragmentation-needed (4), host-precedence-violation (14), host-unreachable (1), host-unreachable-for-TOS (12), network-unreachable (0), network-unreachable-for-TOS (11), port-unreachable (3), precedence-cutoff-in-effect (15), protocol-unreachable (2), source-host-isolated (8), source-route-failed (5)
icmp-code-except <i>message-code</i>	Do not match the ICMP message code field. For details, see the icmp-code match condition.
icmp-type <i>number</i>	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol icmp match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply (0), echo-request (8), info-reply (16), info-request (15), mask-request (17), mask-reply (18), parameter-problem (12), redirect (5), router-advertisement (9), router-solicit (10), source-quench (4), time-exceeded (11), timestamp (13), timestamp-reply (14), or unreachable (3).</p>

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
icmp-type-except <i>message-type</i>	Do not match the ICMP message type field. For details, see the icmp-type match condition.
interface <i>interface-name</i>	<p>Match the interface on which the packet was received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-group <i>group-number</i>	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For <i>group-number</i>, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group <i>group-number</i>, specify the <i>group-number</i> at the [interfaces interface-name unit number family family filter group] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 4514.</p>
interface-group-except <i>group-number</i>	<p>Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For more information, see “Filtering Packets Received on an Interface Set Overview” on page 4515.</p>

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
ip-options values	<p>Match the 8-bit IP option field, if present, to the specified value or list of values.</p> <p>In place of a numeric value, you can specify one of the following text synonyms (the option values are also listed): loose-source-route (131), record-route (7), router-alert (148), security (130), stream-id (136), strict-source-route (137), or timestamp (68).</p> <p>To match <i>any</i> value for the IP option, use the text synonym any. To match on <i>multiple</i> values, specify the list of values within square brackets ('[' and ']'). To match a <i>range</i> of values, use the value specification [<i>value1-value2</i>].</p> <p>For example, the match condition ip-options [0-147] matches on an IP options field that contains the loose-source-route, record-route, or security values, or any other value from 0 through 147. However, this match condition does not match on an IP options field that contains only the router-alert value (148).</p> <p>For most interfaces, a filter term that specifies an ip-option match on one or more <i>specific</i> IP option values (a value other than any) causes packets to be sent to the Routing Engine so that the kernel can parse the IP option field in the packet header.</p> <ul style="list-style-type: none"> For a firewall filter term that specifies an ip-option match on one or more specific IP option values, you cannot specify the count, log, or syslog nonterminating actions <i>unless</i> you also specify the discard terminating action in the same term. This behavior prevents double-counting of packets for a filter applied to a transit interface on the router or switch. Packets processed on the kernel might be dropped in case of a system bottleneck. To ensure that matched packets are instead sent to the Packet Forwarding Engine (where packet processing is implemented in hardware), use the ip-options any match condition. <p>The 10-Gigabit Ethernet Modular Port Concentrator (MPC), 100-Gigabit Ethernet MPC, 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, and 60-Gigabit Ethernet Enhanced Queuing MPC on MX Series routers (and EX Series switches) are capable of parsing the IP option field of the IPv4 packet header. For interfaces configured on those MPCs, <i>all</i> packets that are matched using the ip-options match condition are sent to the Packet Forwarding Engine for processing.</p> <p>NOTE: On M and T series routers, firewall filters cannot count ip-options packets on a per option type and per interface basis. A limited work around is to use the show pfe statistics ip options command to see ip-options statistics on a per PFE basis. See <i>show pfe statistics ip</i> for sample output.</p>
ip-options-except values	<p>Do not match the IP option field to the specified value or list of values. For details about specifying the values, see the ip-options match condition.</p>
is-fragment	<p>Match if the packet is a trailing fragment of a fragmented packet. Do not match the first fragment of a fragmented packet.</p> <p>NOTE: To match both first and trailing fragments, you can use two terms that specify different match conditions (first-fragment and is-fragment).</p>

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
loss-priority level	<p>Match the packet loss priority (PLP) level.</p> <p>Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers.</p> <p>For IP traffic on M320, MX Series and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For information about the tri-color statement and for information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
loss-priority-except level	<p>Do not match the PLP level. For details, see the loss-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
packet-length bytes	Match the length of the received packet, in bytes. The length refers only to the IP packet, including the packet header, and does not include any Layer 2 encapsulation overhead.
packet-length-except bytes	Do not match the length of the received packet, in bytes. For details, see the packet-length match type.
port number	<p>Match the UDP or TCP source or destination port field.</p> <p>If you configure this match condition, you cannot configure the destination-port match condition or the source-port match condition in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed under destination-port.</p>
port-except number	Do not match the UDP or TCP source or destination port field. For details, see the port match condition.
precedence ip-precedence-value	<p>Match the IP precedence field.</p> <p>In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00). You can specify precedence in hexadecimal, binary, or decimal form.</p>

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
precedence-except ip-precedence-value	Do not match the IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00). You can specify precedence in hexadecimal, binary, or decimal form.
prefix-list name	Match the prefixes of the source or destination address fields to the prefixes in the specified list unless the except option is included. If the option is included, do not match the prefixes of the source or destination address fields to the prefixes in the specified list. The prefix list is defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.
protocol number	Match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).
protocol-except number	Do not match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).
rat-type tech-type-value	Match the radio-access technology (RAT) type specified in the 8-bit Tech-Type field of Proxy Mobile IPv4 (PMIPv4) access technology type extension. The technology type specifies the access technology through which the mobile device is connected to the access network. Specify a single value, a range of values, or a set of values. You can specify a technology type as a numeric value from 0 through 255 or as a system keyword. <ul style="list-style-type: none"> The following numeric values are examples of well-known technology types: <ul style="list-style-type: none"> Numeric value 1 matches IEEE 802.3. Numeric value 2 matches IEEE 802.11a/b/g. Numeric value 3 matches IEEE 802.16e Numeric value 4 matches IEEE 802.16m. Text string eutran matches 4G. Text string geran matches 2G. Text string utran matches 3G.
rat-type-except tech-type-value	Do not match the RAT Type.
service-filter-hit	Match a packet received from a filter where a service-filter-hit action was applied. NOTE: This match condition is not supported on PTX series packet transport switches.
source-address address [except]	Match the IPv4 address of the source node sending the packet unless the except option is included. If the option is included, do not match the IPv4 address of the source node sending the packet. You cannot specify both the address and source-address match conditions in the same term.

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
source-class <i>class-names</i>	<p>Match one or more specified source class names (sets of source prefixes grouped together and given a class name). For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 4502.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
source-class-except <i>class-names</i>	<p>Do not match one or more specified source class names. For details, see the source-class match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
source-port <i>number</i>	<p>Match the UDP or TCP source port field.</p> <p>You cannot specify the port and source-port match conditions in the same term.</p> <p>If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port <i>number</i> match condition.</p>
source-port-except <i>number</i>	Do not match the UDP or TCP source port field. For details, see the source-port match condition.
source-prefix-list <i>name</i> [except]	<p>Match source prefixes in the specified list unless the except option is included. If the option is included, do not match the source prefixes in the specified list.</p> <p>Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p>
tcp-established	<p>Match TCP packets of an established TCP session (packets other than the first packet of a connection). This is an alias for tcp-flags "(ack rst)".</p> <p>This match condition does not implicitly check that the protocol is TCP. To check this, specify the protocol tcp match condition.</p>

Table 341: Standard Firewall Filter Match Conditions for IPv4 Traffic (*continued*)

Match Condition	Description
tcp-flags value	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-established and tcp-initial match conditions.</p> <p>If you configure this match condition, we recommend that you also configure the protocol tcp match statement in the same term to specify that the TCP protocol is being used on the port.</p> <p>For IPv4 traffic only, this match condition does not implicitly check whether the datagram contains the first fragment of a fragmented packet. To check for this condition for IPv4 traffic only, use the first-fragment match condition.</p>
tcp-initial	<p>Match the initial packet of a TCP connection. This is an alias for tcp-flags "(lack & syn)".</p> <p>This condition does not implicitly check that the protocol is TCP. If you configure this match condition, we recommend that you also configure the protocol tcp match condition in the same term.</p>
ttl number	<p>Match the IPv4 time-to-live number. Specify a TTL value or a range of TTL values. For number, you can specify one or more values from 0 through 255. This match condition is supported only on M120, M320, MX Series, and T Series routers.</p>
ttl-except number	<p>Do not match on the IPv4 TTL number. For details, see the ttl match condition.</p>

Standard Firewall Filter Match Conditions for IPv6 Traffic

You can configure a standard stateless firewall filter with match conditions for Internet Protocol version 6 (IPv6) traffic (**family inet6**). [Table 342 on page 4717](#) describes the **match-conditions** you can configure at the **[edit firewall family inet6 filter filter-name term term-name from]** hierarchy level.

Table 342: Standard Firewall Filter Match Conditions for IPv6 Traffic

Match Condition	Description
address <i>address</i> [except]	Match the IPv6 source or destination address field unless the except option is included. If the option is included, do not match the IPv6 source or destination address field.
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
destination-address <i>address</i> [except]	Match the IPv6 destination address field unless the except option is included. If the option is included, do not match the IPv6 destination address field. You cannot specify both the address and destination-address match conditions in the same term.
destination-class <i>class-names</i>	Match one or more specified destination class names (sets of destination prefixes grouped together and given a class name). NOTE: This match condition is not supported on PTX series packet transport switches. For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 4502 .
destination-class-except <i>class-names</i>	Do not match one or more specified destination class names. For details, see the destination-class match condition. NOTE: This match condition is not supported on PTX series packet transport switches.
destination-port <i>number</i>	Match the UDP or TCP destination port field. You cannot specify both the port and destination-port match conditions in the same term. If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port. In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).
destination-port-except <i>number</i>	Do not match the UDP or TCP destination port field. For details, see the destination-port match condition.
destination-prefix-list <i>prefix-list-name</i> [except]	Match the IPv6 destination prefix to the specified list unless the except option is included. If the option is included, do not match the IPv6 destination prefix to the specified list. The prefix list is defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.

Table 342: Standard Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p> <p>For information about forwarding classes and router-internal output queues, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
forwarding-class-except <i>class</i>	Do not match the forwarding class of the packet. For details, see the forwarding-class match condition.
hop-limit <i>hop-limit</i>	Match the hop limit to the specified hop limit or set of hop limits. For hop-limit , specify a single value or a range of values from 0 through 255..
hop-limit-except <i>message-code</i>	Do not match the hop limit to the specified hop limit or set of hop limits. For details, see the hop-limit match condition.
icmp-code <i>message-code</i>	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: administratively-prohibited (1), address-unreachable (3), no-route-to-destination (0), port-unreachable (4)
icmp-code-except <i>message-code</i>	Do not match the ICMP message code field. For details, see the icmp-code match condition.
icmp-type <i>message-type</i>	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): destination-unreachable (1), echo-reply (129), echo-request (128), membership-query (130), membership-report (131), membership-termination (132), neighbor-advertisement (136), neighbor-solicit (135), node-information-reply (140), node-information-request (139), packet-too-big (2), parameter-problem (4), redirect (137), router-advertisement (134), router-renumbering (138), router-solicit (133), or time-exceeded (3).</p>
icmp-type-except <i>message-type</i>	Do not match the ICMP message type field. For details, see the icmp-type match condition.

Table 342: Standard Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
interface <i>interface-name</i>	<p>Match the interface on which the packet was received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-group group-number	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For group-number, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group group-number, specify the group-number at the [interfaces interface-name unit number family family filter group] hierarchy level.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 4514.</p>
interface-group-except group-number	<p>Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
interface-set interface-set-name	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For more information, see “Filtering Packets Received on an Interface Set Overview” on page 4515.</p>
loss-priority level	<p>Match the packet loss priority (PLP) level.</p> <p>Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, T Series routers and EX Series switches with Enhanced II Flexible PIC Concentrators (FPCs), you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For information about the tri-color statement and for information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
loss-priority-except level	<p>Do not match the PLP level. For details, see the loss-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>

Table 342: Standard Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
next-header <i>header-type</i>	<p>Match the 8-bit Next Header field that identifies the type of header between the IPv6 header and payload.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), no-next-header (59), ospf (89), pim (103), routing (43), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).</p> <p>NOTE: next-header icmp6 and next-header icmpv6 match conditions perform the same function. next-header icmp6 is the preferred option. next-header icmpv6 is hidden in the Junos OS CLI.</p>
next-header-except <i>header-type</i>	Do not match the 8-bit Next Header field that identifies the type of header between the IPv6 header and payload. For details, see the next-header match type.
packet-length <i>bytes</i>	Match the length of the received packet, in bytes. The length refers only to the IP packet, including the packet header, and does not include any Layer 2 encapsulation overhead.
packet-length-except <i>bytes</i>	Do not match the length of the received packet, in bytes. For details, see the packet-length match type.
payload-protocol <i>protocol-type</i>	<p>Match the payload protocol type.</p> <p>In place of the protocol-type numeric value, you can specify one of the following text synonyms (the field values are also listed): specify one or a set of of the following: ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), igmp (2), ipip (4), ipv6 (41), no-next-header, ospf (89), pim (103), routing, rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).</p>
payload-protocol-except <i>protocol-type</i>	Do not match the payload protocol type. For details, see the payload-protocol match type.
port <i>number</i>	<p>Match the UDP or TCP source or destination port field.</p> <p>If you configure this match condition, you cannot configure the destination-port match condition or the source-port match condition in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed under destination-port.</p>
port-except <i>number</i>	Do not match the UDP or TCP source or destination port field. For details, see the port match condition.
prefix-list <i>prefix-list-name</i> [except]	<p>Match the prefixes of the source or destination address fields to the prefixes in the specified list unless the except option is included. If the option is included, do not match the prefixes of the source or destination address fields to the prefixes in the specified list.</p> <p>The prefix list is defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p>

Table 342: Standard Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
service-filter-hit	<p>Match a packet received from a filter where a service-filter-hit action was applied.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
source-address <i>address</i> [except]	<p>Match the IPv6 address of the source node sending the packet unless the except option is included. If the option is included, do not match the IPv6 address of the source node sending the packet.</p> <p>You cannot specify both the address and source-address match conditions in the same term.</p>
source-class <i>class-names</i>	<p>Match one or more specified source class names (sets of source prefixes grouped together and given a class name).</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For more information, see “Firewall Filter Match Conditions Based on Address Classes” on page 4502.</p>
source-class-except <i>class-names</i>	<p>Do not match one or more specified source class names. For details, see the source-class match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
source-port <i>number</i>	<p>Match the UDP or TCP source port field.</p> <p>You cannot specify the port and source-port match conditions in the same term.</p> <p>If you configure this match condition, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port number match condition.</p>
source-port-except <i>number</i>	<p>Do not match the UDP or TCP source port field. For details, see the source-port match condition.</p>
source-prefix-list <i>name</i> [except]	<p>Match the IPv6 address prefix of the packet source field unless the except option is included. If the option is included, do not match the IPv6 address prefix of the packet source field.</p> <p>Specify a prefix list name defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p>
tcp-established	<p>Match TCP packets other than the first packet of a connection. This is a text synonym for tcp-flags "(ack rst)" (0x14).</p> <p>NOTE: This condition does not implicitly check that the protocol is TCP. To check this, specify the protocol tcp match condition.</p> <p>If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term.</p>

Table 342: Standard Firewall Filter Match Conditions for IPv6 Traffic (*continued*)

Match Condition	Description
tcp-flags flags	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-established and tcp-initial match conditions.</p> <p>If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term to specify that the TCP protocol is being used on the port.</p>
tcp-initial	<p>Match the initial packet of a TCP connection. This is a text synonym for tcp-flags "(!ack & syn)".</p> <p>This condition does not implicitly check that the protocol is TCP. If you configure this match condition, we recommend that you also configure the next-header tcp match condition in the same term.</p>
traffic-class number	<p>Match the 8-bit field that specifies the class-of-service (CoS) priority of the packet.</p> <p>This field was previously used as the type-of-service (ToS) field in IPv4.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <ul style="list-style-type: none"> • af11 (10), af12 (12), af13 (14) • af21 (18), af22 (20), af23 (22) • af31 (26), af32 (28), af33 (30) • af41 (34), af42 (36), af43 (38)
traffic-class-except number	<p>Do not match the 8-bit field that specifies the CoS priority of the packet. For details, see the traffic-class match description.</p>

NOTE: If you specify an IPv6 address in a match condition (the *address*, *destination-address*, or *source-address* match conditions), use the syntax for text representations described in RFC 2373, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see “IPv6 Overview” and “IPv6 Standards” in the *Junos OS Routing Protocols Configuration Guide*.

Standard Firewall Filter Match Conditions for MPLS Traffic

You can configure a standard stateless firewall filter with match conditions for MPLS traffic (*family mpls*).

NOTE: The input-list *filter-names* and output-list *filter-names* statements for firewall filters for the *mpls* protocol family are supported on all interfaces with the exception of management interfaces and internal Ethernet interfaces (fxp or em0), loopback interfaces (lo0), and USB modem interfaces (umd).

Table 270 on page 3566 describes the *match-conditions* you can configure at the [edit firewall family mpls filter *filter-name* term *term-name* from] hierarchy level.

Table 343: Standard Firewall Filter Match Conditions for MPLS Traffic

Match Condition	Description
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
exp <i>number</i>	Experimental (EXP) bit number or range of bit numbers in the MPLS header. For <i>number</i> , you can specify one or more values from 0 through 7 in decimal, binary, or hexadecimal format. NOTE: This match condition is not supported on PTX series packet transport switches.
exp-except <i>number</i>	Do not match on the EXP bit number or range of bit numbers in the MPLS header. For <i>number</i> , you can specify one or more values from 0 through 7. NOTE: This match condition is not supported on PTX series packet transport switches.
forwarding-class <i>class</i>	Forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .
forwarding-class-except <i>class</i>	Do not match on the forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .

Table 343: Standard Firewall Filter Match Conditions for MPLS Traffic (*continued*)

Match Condition	Description
interface <i>interface-name</i>	<p>Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For more information, see “Filtering Packets Received on an Interface Set Overview” on page 4515.</p>
ip-version <i>number</i>	<p>(Interfaces on Enhanced Scaling flexible PIC concentrators [FPCs] on supported T Series routers only) Inner IP version. To match MPLS-tagged IPv4 packets, match on the text synonym ipv4.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
loss-priority <i>level</i>	<p>Match the packet loss priority (PLP) level.</p> <p>Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement and for information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
loss-priority-except <i>level</i>	<p>Do not match the PLP level. For details, see the loss-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>

Standard Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic

This topic covers the following information:

- [Matching on IPv4 or IPv6 Packet Header Address or Port Fields in MPLS Flows on page 4725](#)
- [IP Address Match Conditions for MPLS Traffic on page 4726](#)
- [IP Port Match Conditions for MPLS Traffic on page 4726](#)

Matching on IPv4 or IPv6 Packet Header Address or Port Fields in MPLS Flows

To support network-based service in a core network, you can configure a standard firewall filter that matches Internet Protocol version 4 (IPv4) or version 6 (IPv6) packet header fields in MPLS traffic (**family mpls**). The firewall filter can match IPv4 or IPv6 packets as an inner payload of an MPLS packet that has a single MPLS label or up to five MPLS labels stacked together. You can configure match conditions based on IPv4 addresses and IPv4 port numbers or IPv6 addresses and IPv6 port numbers in the header.

Standard firewall filters based on MPLS-tagged IPv4 headers are supported for interfaces on Enhanced Scaling flexible PIC concentrators (FPCs) on T320, T640, T1600, TX Matrix, and TX Matrix Plus routers only. However, the standard firewall filters based on MPLS-tagged IPv6 headers are supported for interfaces on the Type 5 FPC on T4000 Core Routers only. The feature is not supported for the router loopback interface (**lo0**), the router management interface (**fxp0** or **em0**), or USB modem interfaces (**umd**).

To configure a stateless firewall filter term that matches an address or port fields in the Layer 4 header of packets in an MPLS flow, you use the **ip-version ipv4** match condition to specify that the term is to match packets based on inner IP fields:

- To match an MPLS-tagged IPv4 packet on the source or destination address field in the IPv4 header, specify the match condition at the **[edit firewall family mpls filter filter-name term term-name from ip-version ipv4]** hierarchy level.
- To match an MPLS-tagged IPv4 packet on the source or destination port field in the Layer 4 header, specify the match condition at the **[edit firewall family mpls filter filter-name term term-name from ip-version ipv4 protocol (udp | tcp)]** hierarchy level.

To configure a stateless firewall filter term that matches an address or port fields in the IPv6 header of packets in an MPLS flow, you use the **ip-version ipv6** match condition to specify that the term is to match packets based on inner IP fields:

- To match an MPLS-tagged IPv6 packet on the source or destination address field in the IPv6 header, specify the match condition at the **[edit firewall family mpls filter filter-name term term-name from ip-version ipv6]** hierarchy level.
- To match an MPLS-tagged IPv6 packet on the source or destination port field in the Layer 4 header, specify the match condition at the **[edit firewall family mpls filter filter-name term term-name from ip-version ipv6 protocol (udp | tcp)]** hierarchy level.

IP Address Match Conditions for MPLS Traffic

Table 344 on page 4726 describes the IP address-specific match conditions you can configure at the `[edit firewall family mpls filter filter-name term term-name from ip-version ip-version]` hierarchy level.

Table 344: IP Address-Specific Firewall Filter Match Conditions for MPLS Traffic

Match Condition	Description
<code>destination-address <i>address</i></code>	Match the address of the destination node to receive the packet.
<code>destination-address <i>address</i> except</code>	Do not match the address of the destination node to receive the packet.
<code>protocol <i>number</i></code>	Match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): <code>ah</code> (51), <code>dstopts</code> (60), <code>egp</code> (8), <code>esp</code> (50), <code>fragment</code> (44), <code>gre</code> (47), <code>hop-by-hop</code> (0), <code>icmp</code> (1), <code>icmp6</code> (58), <code>icmpv6</code> (58), <code>igmp</code> (2), <code>ipip</code> (4), <code>ipv6</code> (41), <code>ospf</code> (89), <code>pim</code> (103), <code>rsvp</code> (46), <code>sctp</code> (132), <code>tcp</code> (6), <code>udp</code> (17), or <code>vrrp</code> (112).
<code>source-address <i>address</i></code>	Match the address of the source node sending the packet.
<code>source-address <i>address</i> except</code>	Do not match the address of the source node sending the packet.

IP Port Match Conditions for MPLS Traffic

Table 345 on page 4727 describes the IP port-specific *match-conditions* you can configure at the `[edit firewall family mpls filter filter-name term term-name from ip-version ip-version protocol (udp | tcp)]` hierarchy level.

Table 345: IP Port-Specific Firewall Filter Match Conditions for MPLS Traffic

Match Condition	Description
destination-port <i>number</i>	<p>Match on the UDP or TCP destination port field.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nnntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xmcp (177).</p>
destination-port-except <i>number</i>	<p>Do not match on the UDP or TCP destination port field.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port match condition.</p>
source-port <i>number</i>	<p>Match on the TCP or UDP source port field.</p> <p>In place of the numeric field, you can specify one of the text synonyms listed under destination-port.</p>
source-port-except <i>number</i>	Do not match on the TCP or UDP source port field.

Standard Firewall Filter Match Conditions for VPLS Traffic

In the **from** statement in the VPLS filter term, you specify conditions that the packet must match for the action in the **then** statement to be taken. All conditions in the **from** statement must match for the action to be taken. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify no match conditions in a term, that term matches all packets.

An individual condition in a **from** statement can contain a list of values. For example, you can specify numeric ranges. You can also specify multiple source addresses or destination addresses. When a condition defines a list of values, a match occurs if one of the values in the list matches the packet.

Individual conditions in a **from** statement can be negated. When you negate a condition, you are defining an explicit mismatch. For example, the negated match condition for **forwarding-class** is **forwarding-class-except**. If a packet matches a negated condition, it is immediately considered not to match the **from** statement, and the next term in the filter is evaluated, if there is one. If there are no more terms, the packet is discarded.

You can configure a standard firewall filter with match conditions for Virtual Private LAN Service (VPLS) traffic (**family vpls**). [Table 346 on page 4728](#) describes the **match-conditions** you can configure at the **[edit firewall family vpls filter *filter-name* term *term-name* from]** hierarchy level.

NOTE: Not all match conditions for VPLS traffic are supported on all routing platforms or switching platforms. A number of match conditions for VPLS traffic are supported only on MX Series 3D Universal Edge Routers.

In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Table 346: Standard Firewall Filter Match Conditions for VPLS Traffic

Match Condition	Description
destination-mac-address address	Match the destination media access control (MAC) address of a VPLS packet.
destination-port number	<p>(MX Series routers and EX Series switches only) Match the UDP or TCP destination port field.</p> <p>You cannot specify both the port and destination-port match conditions in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>
destination-port-except number	<p>(MX Series routers and EX Series switches only) Do not match on the TCP or UDP destination port field. You cannot specify both the port and destination-port match conditions in the same term.</p>
destination-prefix-list name	<p>(MX Series routers and EX Series switches only) Match destination prefixes in the specified list. Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>
destination-prefix-list name except	<p>(MX Series routers and EX Series switches only) Do not match destination prefixes in the specified list. For more information, see the destination-prefix-list match condition.</p>

Table 346: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
dscp number	<p>(MX Series routers and EX Series switches only) Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see the <i>Junos OS Class of Service Configuration Guide</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <p>af11 (10), af12 (12), af13 (14),</p> <p>af21 (18), af22 (20), af23 (22),</p> <p>af31 (26), af32 (28), af33 (30),</p> <p>af41 (34), af42 (36), af43 (38)</p>
dscp-except number	<p>(MX Series routers and EX Series switches only) Do not match on the DSCP. For details, see the dscp match condition.</p>
ether-type values	<p>Match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>You can specify decimal or hexadecimal values from 0 through 65535 (0xFFFF). A value from 0 through 1500 (0x05DC) specifies the length of an Ethernet Version 1 frame. A value from 1536 (0x0600) through 65535 specifies the EtherType (nature of the MAC client protocol) of an Ethernet Version 2 frame.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): aarp (0x80F3), appletalk (0x809B), arp (0x0806), ipv4 (0x0800), ipv6 (0x86DD), mpls-multicast (0x8848), mpls-unicast (0x8847), oam (0x8902), ppp (0x880B), pppoe-discovery (0x8863), pppoe-session (0x8864), or sna (0x80D5).</p>
ether-type-except values	<p>Do not match the 2-octet Length/EtherType field to the specified value or list of values.</p> <p>For details about specifying the values, see the ether-type match condition.</p>
forwarding-class class	<p>Match the forwarding class. Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p>
forwarding-class-except class	<p>Do not match the forwarding class. For details, see the forwarding-class match condition.</p>

Table 346: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
icmp-code message-code	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except message-code	Do not match the ICMP message code field. For details, see the icmp-code match condition.
icmp-code number	<p>(MX Series routers and EX Series switches only) Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp or ip-protocol icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except number	(MX Series routers and EX Series switches only) Do not match on the ICMP code field. For details, see the icmp-code match condition.
icmp-type number	<p>(MX Series routers and EX Series switches only) Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp, ip-protocol icmp6, or ip-protocol icmpv6 match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): destination-unreachable (1), echo-reply (129), echo-request (128), membership-query (130), membership-report (131), membership-termination (132), neighbor-advertisement (136), neighbor-solicit (135), node-information-reply (140), node-information-request (139), packet-too-big (2), parameter-problem (4), redirect (137), router-advertisement (134), router-renumbering (138), router-solicit (133), or time-exceeded (3).</p>

Table 346: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
icmp-type-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match the ICMP message type field. For details, see the icmp-type match condition.
interface <i>interface-name</i>	Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received. NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.
interface-group <i>group-number</i>	Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For <i>group-number</i> , specify a single value or a range of values from 0 through 255. To assign a logical interface to an interface group <i>group-number</i> , specify the <i>group-number</i> at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter group] hierarchy level. For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 4514. NOTE: This match condition is not supported on T4000 Type 5 FPCs.
interface-group-except <i>group-name</i>	Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition. NOTE: This match condition is not supported on T4000 Type 5 FPCs.
interface-set <i>interface-set-name</i>	Match the interface on which the packet was received to the specified interface set. To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. For more information, see “Filtering Packets Received on an Interface Set Overview” on page 4515.
ip-address <i>address</i>	(MX Series routers and EX Series switches only) 32-bit address that supports the standard syntax for IPv4 addresses.
ip-destination-address <i>address</i>	(MX Series routers and EX Series switches only) 32-bit address that is the final destination node address for the packet.
ip-precedence <i>ip-precedence-field</i>	(MX Series routers and EX Series switches only) IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00).
ip-precedence-except <i>ip-precedence-field</i>	(MX Series routers and EX Series switches only) Do not match on the IP precedence field.
ip-protocol <i>number</i>	(MX Series routers and EX Series switches only) IP protocol field.
ip-protocol-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the IP protocol field.
ip-source-address <i>address</i>	(MX Series routers and EX Series switches only) IP address of the source node sending the packet.

Table 346: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
learn-vlan-1p-priority <i>number</i>	<p>(MX Series routers and EX Series switches only) Match on the IEEE 802.1p learned VLAN priority bits in the provider VLAN tag (the only tag in a single-tag frame with 802.1Q VLAN tags or the outer tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the user-vlan-1p-priority match condition.</p>
learn-vlan-1p-priority-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p learned VLAN priority bits. For details, see the learn-vlan-1p-priority match condition.
learn-vlan-dei	(MX Series routers and EX Series switches only) Match the user VLAN ID drop eligibility indicator (DEI) bit.
learn-vlan-dei-except	(MX Series routers and EX Series switches only) Do not match the user VLAN ID DEI bit.
learn-vlan-id <i>number</i>	(MX Series routers and EX Series switches only) VLAN identifier used for MAC learning.
learn-vlan-id-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the VLAN identifier used for MAC learning.
loss-priority <i>level</i>	<p>Packet loss priority (PLP) level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement and about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
loss-priority-except <i>level</i>	<p>Do not match on the packet loss priority level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
port <i>number</i>	(MX Series routers and EX Series switches only) TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.
port-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.

Table 346: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
prefix-list <i>name</i>	<p>(MX Series routers and EX Series switches only) Match the destination or source prefixes in the specified list. Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>
prefix-list <i>name</i> except	<p>(MX Series routers and EX Series switches only) Do not match the destination or source prefixes in the specified list. For more information, see the destination-prefix-list match condition.</p>
source-mac-address <i>address</i>	Source MAC address of a VPLS packet.
source-port <i>number</i>	<p>(MX Series routers and EX Series switches only) TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.</p>
source-port-except <i>number</i>	<p>(MX Series routers and EX Series switches only) Do not match on the TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.</p>
source-prefix-list <i>name</i>	<p>(MX Series routers and EX Series switches only) Match the source prefixes in the specified prefix list. Specify a prefix list name defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>
source-prefix-list <i>name</i> except	<p>(MX Series routers and EX Series switches only) Do not match the source prefixes in the specified prefix list. For more information, see the source-prefix-list match condition.</p>
tcp-flags <i>flags</i>	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>If you configure this match condition for IPv6 traffic, we recommend that you also configure the next-header tcp match condition in the same term to specify that the TCP protocol is being used on the port.</p>
traffic-type <i>type-name</i>	<p>(MX Series routers and EX Series switches only) Traffic type. Specify broadcast, multicast, unknown-unicast, or known-unicast.</p>

Table 346: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
traffic-type-except <i>type-name</i>	(MX Series routers and EX Series switches only) Do not match on the traffic type. Specify broadcast , multicast , unknown-unicast , or known-unicast .
user-vlan-1p-priority <i>number</i>	(MX Series routers and EX Series switches only) Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7. Compare with the learn-vlan-1p-priority match condition.
user-vlan-1p-priority-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p user priority bits. For details, see the user-vlan-1p-priority match condition.
user-vlan-id <i>number</i>	(MX Series routers and EX Series switches only) Match the first VLAN identifier that is part of the payload.
user-vlan-id-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the first VLAN identifier that is part of the payload.
vlan-ether-type <i>value</i>	VLAN Ethernet type field of a VPLS packet.
vlan-ether-type-except <i>value</i>	Do not match on the VLAN Ethernet type field of a VPLS packet.

Standard Firewall Filter Match Conditions for Layer 2 CCC Traffic

You can configure a standard stateless firewall filter with match conditions for Layer 2 circuit cross-connect (CCC) traffic (**family ccc**).

The following restrictions apply to firewall filters for Layer 2 CCC traffic:

- The **input-list** *filter-names* and **output-list** *filter-names* statements for firewall filters for the **ccc** protocol family are supported on all interfaces with the exception of management interfaces and internal Ethernet interfaces (**fxp** or **em0**), loopback interfaces (**lo0**), and USB modem interfaces (**umd**).
- Only on MX Series routers and EX Series switches, you cannot apply a Layer 2 CCC stateless firewall filter (a firewall filter configured at the **[edit firewall filter family ccc]** hierarchy level) as an output filter. On MX Series routers and EX Series switches, firewall filters configured for the **family ccc** statement can be applied only as input filters.

[Table 347 on page 4735](#) describes the *match-conditions* you can configure at the **[edit firewall family ccc filter filter-name term term-name from]** hierarchy level.

Table 347: Standard Firewall Filter Match Conditions for Layer 2 CCC Traffic

Match Condition	Description
apply-groups	Specify which groups to inherit configuration data from. You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.
apply-groups-except	Specify which groups not to inherit configuration data from. You can specify more than one group name.
destination-mac-address address	<p>(MX Series routers and EX Series switches only) Match the destination media access control (MAC) address of a virtual private LAN service (VPLS) packet.</p> <p>To have packets correctly evaluated by this match condition when applied to egress traffic flowing over a CCC circuit from a logical interface on an I-chip DPC in a Layer 2 virtual private network (VPN) routing instance, you must make a configuration change to the Layer 2 VPN routing instance. You must explicitly disable the use of a control word for traffic flowing out over a Layer 2 circuit. The use of a control word is enabled by default for Layer 2 VPN routing instances to support the emulated virtual circuit (VC) encapsulation for Layer 2 circuits.</p> <p>To explicitly disable the use of a control word for Layer 2 VPNs, include the no-control-word statement at either of the following hierarchy levels:</p> <ul style="list-style-type: none"> • [edit routing-instances <i>routing-instance-name</i> protocols l2vpn] • [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols l2vpn] <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For more information, see “Disabling the Control Word for Layer 2 VPNs” in the <i>Junos OS VPNs Configuration Guide</i>.</p>
forwarding-class class	Forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .
forwarding-class-except class	Do not match on the forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .
interface-group group-number	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For <i>group-number</i>, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group <i>group-number</i>, specify the <i>group-number</i> at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter group] hierarchy level.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 4514.</p>
interface-group-except number	<p>Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>

Table 347: Standard Firewall Filter Match Conditions for Layer 2 CCC Traffic (*continued*)

Match Condition	Description
learn-vlan-1p-priority <i>number</i>	<p>(MX Series routers and EX Series switches only) Match on the IEEE 802.1p learned VLAN priority bits in the provider VLAN tag (the only tag in a single-tag frame with 802.1Q VLAN tags or the outer tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the user-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
learn-vlan-1p-priority-except <i>number</i>	<p>(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p learned VLAN priority bits. For details, see the learn-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
loss-priority <i>level</i>	<p>Packet loss priority (PLP) level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement and for information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
loss-priority-except <i>level</i>	<p>Do not match on the packet loss priority level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
user-vlan-1p-priority <i>number</i>	<p>(MX Series routers and EX Series switches only) Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the learn-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>
user-vlan-1p-priority-except <i>number</i>	<p>(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p user priority bits. For details, see the user-vlan-1p-priority match condition.</p> <p>NOTE: This match condition is not supported on PTX series packet transport switches.</p>

Standard Firewall Filter Match Conditions for Layer 2 Bridging Traffic

Only on MX Series routers and EX Series switches, you can configure a standard stateless firewall filter with match conditions for Layer 2 bridging traffic (**family bridge**).

[Table 348 on page 4737](#) describes the **match-conditions** you can configure at the **[edit firewall family bridge filter filter-name term term-name from]** hierarchy level.

Table 348: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series 3D Universal Edge Routers and EX Series switches Only)

Match Condition	Description
destination-mac-address address	Destination media access control (MAC) address of a Layer 2 packet in a bridging environment.
destination-port number	TCP or UDP destination port field. You cannot specify both the port and destination-port match conditions in the same term.
destination-port-except	Do not match the TCP/UDP destination port.
destination-prefix-list	Match the IP destination prefixes in a named list.
dscp number	<p>Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see the <i>Junos OS Class of Service Configuration Guide</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <p>af11 (10), af12 (12), af13 (14),</p> <p>af21 (18), af22 (20), af23 (22),</p> <p>af31 (26), af32 (28), af33 (30),</p> <p>af41 (34), af42 (36), af43 (38)</p>
dscp-except number	Do not match on the DSCP number. For more information, see the dscp-except match condition.

Table 348: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series 3D Universal Edge Routers and EX Series switches Only) (continued)

Match Condition	Description
ether-type value	<p>Match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>You can specify decimal or hexadecimal values from 0 through 65535 (0xFFFF). A value from 0 through 1500 (0x05DC) specifies the length of an Ethernet Version 1 frame. A value from 1536 (0x0600) through 65535 specifies the EtherType (nature of the MAC client protocol) of an Ethernet Version 2 frame.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): aarp (0x80F3), appletalk (0x809B), arp (0x0806), ipv4 (0x0800), ipv6 (0x86DD), mpls-multicast (0x8848), mpls-unicast (0x8847), oam (0x8902), ppp (0x880B), pppoe-discovery (0x8863), pppoe-session (0x8864), sna (0x80D5).</p>
ether-type-except value	<p>Do not match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>For details about specifying the values, see the ether-type match condition.</p>
forwarding class class	Forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .
forwarding-class-except class	Ethernet type field of a Layer 2 packet environment. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .
icmp-code message-code	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp, ip-protocol icmp6, or ip-protocol icmpv6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except message-code	Do not match the ICMP message code field. For details, see the icmp-code match condition.

Table 348: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series 3D Universal Edge Routers and EX Series switches Only) (*continued*)

Match Condition	Description
icmp-type <i>message-type</i>	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp, ip-protocol icmp6, or ip-protocol icmpv6 match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): destination-unreachable (1), echo-reply (129), echo-request (128), membership-query (130), membership-report (131), membership-termination (132), neighbor-advertisement (136), neighbor-solicit (135), node-information-reply (140), node-information-request (139), packet-too-big (2), parameter-problem (4), redirect (137), router-advertisement (134), router-renumbering (138), router-solicit (133), or time-exceeded (3).</p>
icmp-type-except <i>message-type</i>	Do not match the ICMP message type field. For details, see the icmp-type match condition.
interface <i>interface-name</i>	<p>Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-group <i>group-number</i>	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For <i>group-number</i>, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group <i>group-number</i>, specify the <i>group-number</i> at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter <i>group</i>] hierarchy level.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 4514.</p>
interface-group-except <i>number</i>	Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition.
interface-set <i>interface-set-name</i>	<p>Match the interface on which the packet was received to the specified interface set.</p> <p>To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. For more information, see “Filtering Packets Received on an Interface Set Overview” on page 4515.</p>
ip-address <i>address</i>	32-bit address that supports the standard syntax for IPv4 addresses.
ip-destination-address <i>address</i>	32-bit address that is the final destination node address for the packet.
ip-precedence <i>ip-precedence-field</i>	<p>IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00).</p>
ip-precedence-except <i>ip-precedence-field</i>	Do not match on the IP precedence field.

Table 348: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series 3D Universal Edge Routers and EX Series switches Only) (*continued*)

Match Condition	Description
ip-protocol <i>number</i>	IP protocol field.
ip-protocol-except	Do not match the IP protocol type.
ip-source-address <i>address</i>	IP address of the source node sending the packet.
isid <i>number</i>	(Supported with Provider Backbone Bridging [PBB]) Match internet service identifier.
isid-dei <i>number</i>	(Supported with PBB) Match the Internet service identifier drop eligibility indicator (DEI) bit.
isid-dei-except <i>number</i>	(Supported with PBB) Do not match the Internet service identifier DEI bit.
isid-priority-code-point <i>number</i>	(Supported with PBB) Match the Internet service identifier priority code point.
isid-priority-code-point-except <i>number</i>	(Supported with PBB) Do not match the Internet service identifier priority code point.
learn-vlan-1p-priority <i>value</i>	(MX Series routers and EX Series switches only) Match on the IEEE 802.1p learned VLAN priority bits in the provider VLAN tag (the only tag in a single-tag frame with 802.1Q VLAN tags or the outer tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7. Compare with the user-vlan-1p-priority match condition.
learn-vlan-1p-priority-except <i>value</i>	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p learned VLAN priority bits. For details, see the learn-vlan-1p-priority match condition.
learn-vlan-dei <i>number</i>	(Supported with bridging) Match user virtual LAN (VLAN) identifier DEI bit.
learn-vlan-dei-except <i>number</i>	(Supported with bridging) Do not match user VLAN identifier DEI bit.
learn-vlan-id <i>number</i>	VLAN identifier used for MAC learning.
learn-vlan-id-except <i>number</i>	Do not match on the VLAN identifier used for MAC learning.

Table 348: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series 3D Universal Edge Routers and EX Series switches Only) (*continued*)

Match Condition	Description
loss-priority <i>level</i>	<p>Packet loss priority (PLP) level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers and EX Series switches.</p> <p>For IP traffic on M320, MX Series, T Series routers with Enhanced II Flexible PIC Concentrators (FPCs), and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement and for information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
loss-priority-except <i>level</i>	<p>Do not match on the packet loss priority level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
port <i>number</i>	TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match conditions in the same term.
source-mac-address <i>address</i>	Source MAC address of a Layer 2 packet.
source-port <i>number</i>	TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.
source-port-except	Do not match the TCP/UDP source port.
tcp-flags <i>flags</i>	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>Configuring the tcp-flags match condition requires that you configure the next-header-tcp match condition.</p>
traffic-type <i>type</i>	Traffic type. Specify broadcast , multicast , unknown-unicast , or known-unicast .

Table 348: Standard Firewall Filter Match Conditions for Layer 2 Bridging (MX Series 3D Universal Edge Routers and EX Series switches Only) (*continued*)

Match Condition	Description
traffic-type-except <i>type</i>	Do not match on the traffic type.
user-vlan-1p-priority <i>value</i>	(MX Series routers and EX Series switches only) Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7. Compare with the learn-vlan-1p-priority match condition.
user-vlan-1p-priority-except <i>value</i>	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p user priority bits. For details, see the user-vlan-1p-priority match condition.
user-vlan-id <i>number</i>	(MX Series routers and EX Series switches only) Match the first VLAN identifier that is part of the payload.
user-vlan-id-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the first VLAN identifier that is part of the payload.
vlan-ether-type <i>value</i>	VLAN Ethernet type field of a Layer 2 bridging packet.
vlan-ether-type-except <i>value</i>	Do not match on the VLAN Ethernet type field of a Layer 2 bridging packet.

Standard Firewall Filter Terminating Actions

Standard stateless firewall filters support different sets of terminating actions for each protocol family.

NOTE: You cannot configure the next term action with a *terminating* action in the same filter term. However, you can configure the next term action with another *nonterminating* action in the same filter term.

[Table 349 on page 4743](#) describes the terminating actions you can specify in a standard firewall filter term.

Table 349: Terminating Actions for Standard Firewall Filters

Terminating Action	Description	Protocols
accept	Accept the packet.	<ul style="list-style-type: none"> • family any • family inet • family inet6 • family mpls • family vpls • family ccc • family bridge <p>family ethernet-switching (for EX Series switches only)</p>
discard	Discard a packet silently, without sending an Internet Control Message Protocol (ICMP) message. Discarded packets are available for logging and sampling.	<ul style="list-style-type: none"> • family any • family inet • family inet6 • family mpls • family vpls • family ccc • family bridge <p>family ethernet-switching (for EX Series switches only)</p>
logical-system <i>logical-system-name</i>	Direct the packet to the specified logical system. NOTE: This action is not supported on PTX series packet transport switches.	<ul style="list-style-type: none"> • family inet • family inet6
reject <i>message-type</i>	Reject the packet and return an ICMPv4 or ICMPv6 message: <ul style="list-style-type: none"> • If no <i>message-type</i> is specified, a destination unreachable message is returned by default. • If tcp-reset is specified as the <i>message-type</i>, tcp-reset is returned only if the packet is a TCP packet. Otherwise, the administratively-prohibited message, which has a value of 13, is returned. • If any other <i>message-type</i> is specified, that message is returned. <p>NOTE: Rejected packets can be sampled or logged if you configure the sample or syslog action.</p> <p>The <i>message-type</i> can be one of the following values: address-unreachable, administratively-prohibited, bad-host-tos, bad-network-tos, beyond-scope, fragmentation-needed, host-prohibited, host-unknown, host-unreachable, network-prohibited, network-unknown, network-unreachable, no-route, port-unreachable, precedence-cutoff, precedence-violation, protocol-unreachable, source-host-isolated, source-route-failed, or tcp-reset.</p>	<ul style="list-style-type: none"> • family inet • family inet6

Table 349: Terminating Actions for Standard Firewall Filters (*continued*)

Terminating Action	Description	Protocols
routing-instance <i>routing-instance-name</i>	Direct the packet to the specified routing instance. NOTE: This action is not supported on PTX series packet transport switches.	<ul style="list-style-type: none"> family inet family inet6
topology <i>topology-name</i>	Direct the packet to the specified topology. NOTE: This action is not supported on PTX series packet transport switches. Each routing instance (master or virtual-router) supports one default topology to which all forwarding classes are forwarded. For Multitopology Routing, you can configure a firewall filter on the ingress interface to match a specific forwarding class, such as expedited forwarding, with a specific topology. The traffic that matches the specified forwarding class is then added to the routing table for that topology.	<ul style="list-style-type: none"> family inet family inet6

Standard Firewall Filter Match Conditions and Actions on ACX Series Routers Overview

On ACX Series Universal Access Routers, you can configure firewall filters to filter packets and to perform an action on packets that match the filter. The match conditions specified to filter the packets are specific to the type of traffic being filtered.

NOTE: On ACX Series routers, the filter for the exiting traffic (egress filter) can be applied only for interface-specific instances of the firewall filter.

[Table 351 on page 4751](#) describes the types of traffic for which you can configure standard stateless firewall filters.

Table 351: Standard Firewall Filter Match Conditions by Protocol Family for ACX Series Routers

Traffic Type	Hierarchy Level at Which Match Conditions Are Specified
Protocol-independent	<p>[edit firewall family any filter <i>filter-name</i> term <i>term-name</i>]</p> <p>No match conditions are supported for this traffic type on ACX Series routers.</p>
IPv4	<p>[edit firewall family inet filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Standard Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers” on page 4752.</p>
MPLS	<p>[edit firewall family mpls filter <i>filter-name</i> term <i>term-name</i>]</p> <p>For the complete list of match conditions, see “Standard Firewall Filter Match Conditions for MPLS Traffic on ACX Series Routers” on page 4756.</p>
Layer 2 CCC	<p>[edit firewall family ccc filter <i>filter-name</i> term <i>term-name</i>]</p> <p>No match conditions are supported for this traffic type on ACX Series routers.</p>

Under the **then** statement for a standard stateless firewall filter term, you can specify the actions to be taken on a packet that matches the term.

[Table 352 on page 4752](#) summarizes the types of actions you can specify in a standard stateless firewall filter term.

Table 352: Standard Firewall Filter Action Categories for ACX Series Routers

Type of Action	Description	Comment
Terminating	<p>Halts all evaluation of a firewall filter for a specific packet. The router performs the specified action, and no additional terms are used to examine the packet.</p> <p>You can specify only one <i>terminating action</i> in a standard firewall filter. You can, however, specify one terminating action with one or more <i>nonterminating actions</i> in a single term. For example, within a term, you can specify accept with count and syslog.</p>	See “ Standard Firewall Filter Terminating Actions on ACX Series Routers ” on page 4756.
Nonterminating	Performs other functions on a packet (such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality), but any additional terms are used to examine the packet.	See “ Standard Firewall Filter Nonterminating Actions on ACX Series Routers ” on page 4757.

Standard Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers

On ACX Series routers, you can configure a standard stateless firewall filter with match conditions for IP version 4 (IPv4) traffic (**family inet**). [Table 353 on page 4752](#) describes the match conditions you can configure at the **[edit firewall family inet filter *filter-name* term *term-name* from]** hierarchy level.

Table 353: Standard Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers

Match Condition	Description
destination-address <i>address</i>	<p>Match the IPv4 destination address field.</p> <p>NOTE: On ACX Series routers, you can specify only one destination address. A list of IPv4 destination addresses is not supported.</p>

Table 353: Standard Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers (*continued*)

Match Condition	Description
destination-port <i>number</i>	<p>Match the UDP or TCP destination port field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>NOTE: On ACX Series routers, you can specify only one destination port number. A list of port numbers is not supported.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xmcp (177).</p>
dscp <i>number</i>	<p>Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see the <i>Junos OS Class of Service Configuration Guide</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> • RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). • RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <ul style="list-style-type: none"> • af11 (10), af12 (12), af13 (14) • af21 (18), af22 (20), af23 (22) • af31 (26), af32 (28), af33 (30) • af41 (34), af42 (36), af43 (38)
fragment-flags <i>number</i>	<p>(Ingress only) Match the three-bit IP fragmentation flags field in the IP header.</p> <p>In place of the numeric field value, you can specify one of the following keywords (the field values are also listed): dont-fragment (0x4), more-fragments (0x2), or reserved (0x8).</p>

Table 353: Standard Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers (*continued*)

Match Condition	Description
icmp-code <i>number</i>	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol icmp match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type <i>message-type</i> match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip-header-bad (0), required-option-missing (1) redirect: redirect-for-host (1), redirect-for-network (0), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) unreachable: communication-prohibited-by-filtering (13), destination-host-prohibited (10), destination-host-unknown (7), destination-network-prohibited (9), destination-network-unknown (6), fragmentation-needed (4), host-precedence-violation (14), host-unreachable (1), host-unreachable-for-TOS (12), network-unreachable (0), network-unreachable-for-TOS (11), port-unreachable (3), precedence-cutoff-in-effect (15), protocol-unreachable (2), source-host-isolated (8), source-route-failed (5)
icmp-type <i>number</i>	<p>Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol icmp match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply (0), echo-request (8), info-reply (16), info-request (15), mask-request (17), mask-reply (18), parameter-problem (12), redirect (5), router-advertisement (9), router-solicit (10), source-quench (4), time-exceeded (11), timestamp (13), timestamp-reply (14), or unreachable (3).</p>
ip-options <i>values</i>	<p>Match the 8-bit IP option field, if present, to the specified value.</p> <p>ACX Series routers support only the ip-options_any match condition, which ensures that the packets are sent to the Packet Forwarding Engine for processing.</p> <p>NOTE: On ACX Series routers, you can specify only one IP option value. Configuring multiple values is not supported.</p>
precedence ip-precedence-field	<p>Match the IP precedence field.</p> <p>In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00). You can specify precedence in hexadecimal, binary, or decimal form.</p>

Table 353: Standard Firewall Filter Match Conditions for IPv4 Traffic on ACX Series Routers (*continued*)

Match Condition	Description
protocol <i>number</i>	Match the IP protocol type field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).
source-address <i>address</i>	Match the IPv4 address of the source node sending the packet.
source-port <i>number</i>	Match the UDP or TCP source port field. If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port. In place of the numeric value, you can specify one of the text synonyms listed with the destination-port <i>number</i> match condition.
tcp-flags <i>value</i>	Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header. To specify individual bit fields, you can specify the following text synonyms or hexadecimal values: <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-initial match conditions.</p> <p>If you configure this match condition, we recommend that you also configure the protocol tcp match statement in the same term to specify that the TCP protocol is being used on the port.</p>
tcp-initial	Match the initial packet of a TCP connection. This is an alias for tcp-flags "(ack & syn)" . This condition does not implicitly check that the protocol is TCP. If you configure this match condition, we recommend that you also configure the protocol tcp match condition in the same term.
ttl <i>number</i>	Match the IPv4 time-to-live number. Specify a TTL value or a range of TTL values. For <i>number</i> , you can specify one or more values from 2 through 255.

Standard Firewall Filter Match Conditions for MPLS Traffic on ACX Series Routers

On ACX Series routers, you can configure a standard stateless firewall filter with match conditions for MPLS traffic (**family mpls**).

NOTE: The input-list *filter-names* and output-list *filter-names* statements for firewall filters for the mpls protocol family are supported on all interfaces with the exception of management interfaces and internal Ethernet interfaces (fxp or em0), loopback interfaces (lo0), and USB modem interfaces (umd).

[Table 354 on page 4756](#) describes the match conditions you can configure at the `[edit firewall family mpls filter filter-name term term-name from]` hierarchy level.

Table 354: Standard Firewall Filter Match Conditions for MPLS Traffic on ACX Series Routers

Match Condition	Description
<i>exp number</i>	Experimental (EXP) bit number or range of bit numbers in the MPLS header. For <i>number</i> , you can specify one or more values from 0 through 7 in decimal, binary, or hexadecimal format.

Standard Firewall Filter Terminating Actions on ACX Series Routers

Standard stateless firewall filters support different sets of terminating actions for each protocol family.

NOTE: ACX Series routers do not support the `next term` action.

[Table 355 on page 4757](#) describes the terminating actions you can specify in a standard firewall filter term.

Table 355: Terminating Actions for Standard Firewall Filters on ACX Series Routers

Terminating Action	Description	Protocols
accept	Accept the packet.	<ul style="list-style-type: none"> family any family inet family mpls family ccc
discard	Discard a packet silently, without sending an Internet Control Message Protocol (ICMP) message. Discarded packets are available for logging and sampling.	<ul style="list-style-type: none"> family any family inet family mpls family ccc
reject <i>message-type</i>	<p>Reject the packet and return an ICMPv4 or ICMPv6 message:</p> <ul style="list-style-type: none"> If no message type is specified, a destination-unreachable message is returned by default. If tcp-reset is specified as the message type, tcp-reset is returned only if the packet is a TCP packet. Otherwise, the administratively-prohibited message, which has a value of 13, is returned. If any other message type is specified, that message is returned. <p>NOTE:</p> <ul style="list-style-type: none"> Rejected packets can be sampled or logged if you configure the sample or syslog action. This action is supported on ingress only. <p>The message-type option can have one of the following values: address-unreachable, administratively-prohibited, bad-host-tos, bad-network-tos, beyond-scope, fragmentation-needed, host-prohibited, host-unknown, host-unreachable, network-prohibited, network-unknown, network-unreachable, no-route, port-unreachable, precedence-cutoff, precedence-violation, protocol-unreachable, source-host-isolated, source-route-failed, or tcp-reset.</p>	family inet
routing-instance <i>routing-instance-name</i>	Direct the packet to the specified routing instance.	<ul style="list-style-type: none"> family inet

Standard Firewall Filter Nonterminating Actions on ACX Series Routers

Standard stateless firewall filters support different sets of nonterminating actions for each protocol family.

NOTE: ACX Series routers do not support the next term action.

Table 356 on page 4758 describes the nonterminating actions you can configure for a standard firewall filter term.

Table 356: Nonterminating Actions for Standard Firewall Filters on ACX Series Routers

Nonterminating Action	Description	Protocol Families
count <i>counter-name</i>	Count the packet in the named counter.	<ul style="list-style-type: none"> family any family inet family mpls family ccc
forwarding-class <i>class-name</i>	Classify the packet based on the specified forwarding class: <ul style="list-style-type: none"> assured-forwarding best-effort expedited-forwarding network-control <p>NOTE: This action is supported on ingress only.</p>	<ul style="list-style-type: none"> family inet family any family mpls family ccc
log	Log the packet header information in a buffer within the Packet Forwarding Engine. You can access this information by issuing the show firewall log command at the command-line interface (CLI). <p>NOTE: This action is supported on ingress only.</p>	family inet

Table 356: Nonterminating Actions for Standard Firewall Filters on ACX Series Routers (*continued*)

Nonterminating Action	Description	Protocol Families
loss-priority (high medium-high low)	<p>Set the packet loss priority (PLP) level.</p> <p>You cannot also configure the three-color-policer nonterminating action for the same firewall filter term. These two nonterminating actions are mutually exclusive.</p> <p>You must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can configure only the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement and for information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p> <p>NOTE: This action is supported on ingress only.</p>	<ul style="list-style-type: none"> • family any • family inet • family mpls • family ccc
policer <i>policer-name</i>	Name of policer to use to rate-limit traffic.	<ul style="list-style-type: none"> • family any • family inet • family mpls • family ccc
port-mirror	<p>Port-mirror the packet based on the specified family.</p> <p>NOTE: This action is supported on ingress only.</p>	family inet
syslog	<p>Log the packet to the system log file.</p> <p>NOTE: This action is supported on ingress only.</p>	family inet

Table 356: Nonterminating Actions for Standard Firewall Filters on ACX Series Routers (*continued*)

Nonterminating Action	Description	Protocol Families
three-color-policer (single-rate two-rate) <i>policer-name</i>	Police the packet using the specified single-rate or two-rate three-color policer. You cannot also configure the loss-priority action for the same firewall filter term. These two actions are mutually exclusive.	<ul style="list-style-type: none"> • family any • family inet • family mpls • family ccc

Service Filter Match Conditions for IPv4 or IPv6 Traffic

Service filters support only a subset of the stateless firewall filter match conditions for IPv4 and IPv6 traffic. [Table 357 on page 4760](#) describes the service filter match conditions.

Table 357: Service Filter Match Conditions for IPv4 or IPv6 Traffic

Match Condition	Description	Protocol Families	
address <i>address</i>	Match the IP source or destination address field.	family inet	family inet6
address <i>address</i> except	Do not match the IP source or destination address field.	family inet	family inet6
ah-spi <i>spi-value</i>	(M Series routers, except M120 and M320) Match on the IPsec authentication header (AH) security parameter index (SPI) value.	family inet	—
ah-spi-except <i>spi-value</i>	(M Series routers, except M120 and M320) Do not match on the IPsec AH SPI value.	family inet	—
destination-address <i>address</i>	Match the IP destination address field. You cannot specify both the address and destination-address match conditions in the same term.	family inet	family inet6

Table 357: Service Filter Match Conditions for IPv4 or IPv6 Traffic (continued)

Match Condition	Description	Protocol Families	
destination-address address address	Do not match the IP destination address field. You cannot specify both the address and destination-address match conditions in the same term.	family inet	family inet6
destination-port number	Match the UDP or TCP destination port field. You cannot specify both the port and destination-port match conditions in the same term. If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port. If you configure this match condition for IPv6 traffic, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port. In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobileip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinet (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xmcp (177).	family inet	family inet6
destination-port-except number	Do not match the UDP or TCP destination port field. For details, see the destination-port match description.	family inet	family inet6
destination-prefix-list name	Match the list of destination prefixes. The prefix list is defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.	family inet	family inet6
esp-spi value	Match the IPsec encapsulating security payload (ESP) SPI value. Specify a single value or a range of values. You can specify a <i>value</i> in hexadecimal, binary, or decimal form. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.	family inet	family inet6
esp-spi-except value	Do not match the IPsec ESP SPI value or range of values. For details, see the esp-spi match condition.	family inet	family inet6

Table 357: Service Filter Match Conditions for IPv4 or IPv6 Traffic (*continued*)

Match Condition	Description	Protocol Families	
first-fragment	<p>Match if the packet is the first fragment of a fragmented packet. Do not match if the packet is a trailing fragment of a fragmented packet. The first fragment of a fragmented packet has a fragment offset value of 0.</p> <p>This match condition is an alias for the bit-field match condition fragment-offset 0 match condition.</p> <p>To match both first and trailing fragments, you can use two terms that specify different match conditions: first-fragment and is-fragment.</p>	family inet	—
fragment-flags <i>number</i>	<p>(Ingress only) Match the three-bit IP fragmentation flags field in the IP header.</p> <p>In place of the numeric field value, you can specify one of the following keywords (the field values are also listed): dont-fragment (0x4), more-fragments (0x2), or reserved (0x8).</p>	family inet	—
fragment-offset <i>number</i>	<p>Match the 13-bit fragment offset field in the IP header. The value is the offset, in 8-byte units, in the overall datagram message to the data fragment. Specify a numeric value, a range of values, or a set of values. An offset value of 0 indicates the first fragment of a fragmented packet.</p> <p>The first-fragment match condition is an alias for the fragment-offset 0 match condition.</p> <p>To match both first and trailing fragments, you can use two terms that specify different match conditions (first-fragment and is-fragment).</p>	family inet	—
fragment-offset-except <i>number</i>	Do not match the 13-bit fragment offset field.	family inet	—
interface-group <i>group-number</i>	<p>Match the interface group (set of one or more logical interfaces) on which the packet was received. For <i>group-number</i>, specify a value from 0 through 255.</p> <p>For information about configuring interface groups, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 4514.</p>	family inet	family inet6
interface-group-except <i>group-number</i>	Do not match the interface group on which the packet was received. for details, see the interface-group match condition.	family inet	family inet6

Table 357: Service Filter Match Conditions for IPv4 or IPv6 Traffic (*continued*)

Match Condition	Description	Protocol Families
ip-options values	<p>Match the 8-bit IP option field, if present, to the specified value or list of values.</p> <p>In place of a numeric value, you can specify one of the following text synonyms (the option values are also listed): loose-source-route (131), record-route (7), router-alert (148), security (130), stream-id (136), strict-source-route (137), or timestamp (68).</p> <p>To match <i>any</i> value for the IP option, use the text synonym any. To match on <i>multiple</i> values, specify the list of values within square brackets ('[' and ']'). To match a <i>range</i> of values, use the value specification [<i>value1-value2</i>].</p> <p>For example, the match condition ip-options [0-147] matches on an IP options field that contains the loose-source-route, record-route, or security values, or any other value from 0 through 147. However, this match condition does not match on an IP options field that contains only the router-alert value (148).</p> <p>For most interfaces, a filter term that specifies an ip-option match on one or more <i>specific</i> IP option values (a value other than any) causes packets to be sent to the Routing Engine so that the kernel can parse the IP option field in the packet header.</p> <ul style="list-style-type: none"> For a firewall filter term that specifies an ip-option match on one or more specific IP option values, you cannot specify the count, log, or syslog nonterminating actions <i>unless</i> you also specify the discard terminating action in the same term. This behavior prevents double-counting of packets for a filter applied to a transit interface on the router (or switch). Packets processed on the kernel might be dropped in case of a system bottleneck. To ensure that matched packets are instead sent to the Packet Forwarding Engine (where packet processing is implemented in hardware), use the ip-options any match condition. <p>The 10-Gigabit Ethernet Modular Port Concentrator (MPC), 60-Gigabit Ethernet MPC, 60-Gigabit Queuing Ethernet MPC, 60-Gigabit Ethernet Enhanced Queuing MPC on MX Series routers and EX Series switches are capable of parsing the IP option field of the IPv4 packet header. This capability is supported on EX Series switches also. For interfaces configured on those MPCs, <i>all</i> packets that are matched using the ip-options match condition are sent to the Packet Forwarding Engine for processing.</p>	family inet —
ip-options-except values	Do not match the IP option field to the specified value or list of values. For details about specifying the values , see the ip-options match condition.	family inet —
is-fragment	<p>Match if the packet is a trailing fragment of a fragmented packet. Do not match the first fragment of a fragmented packet.</p> <p>This match condition is an alias for the bit-field match condition fragment-offset 0 except bits.</p> <p>NOTE: To match both first and trailing fragments, you can use two terms that specify different match conditions (first-fragment and is-fragment).</p>	family inet —

Table 357: Service Filter Match Conditions for IPv4 or IPv6 Traffic (*continued*)

Match Condition	Description	Protocol Families	
port number	<p>Match the UDP or TCP source or destination port field.</p> <p>If you configure this match condition, you cannot configure the destination-port match condition or the source-port match condition in the same term.</p> <p>If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>If you configure this match condition for IPv6 traffic, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed under destination-port.</p>	family inet	family inet6
port-except number	Do not match the UDP or TCP source or destination port field. For details, see the port match condition.	family inet	family inet6
prefix-list prefix-list-name	Match the prefixes of the source or destination address fields to the prefixes in the specified list. The prefix list is defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.	family inet	family inet6
protocol number	<p>Match the IP protocol type field.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).</p>	family inet	—
protocol-except number	Do not match the IP protocol type field. For details, see the protocol match condition.	family inet	—
source-address address	<p>Match the IP source address.</p> <p>You cannot specify both the address and source-address match conditions in the same term.</p>	family inet	family inet6
source-address address except	<p>Do not match the IP source address.</p> <p>You cannot specify both the address and source-address match conditions in the same term.</p>	family inet	family inet6

Table 357: Service Filter Match Conditions for IPv4 or IPv6 Traffic (*continued*)

Match Condition	Description	Protocol Families	
source-port <i>number</i>	<p>Match the UDP or TCP source port field.</p> <p>You cannot specify the port and source-port match conditions in the same term.</p> <p>If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol udp or protocol tcp match statement in the same term to specify which protocol is being used on the port.</p> <p>If you configure this match condition for IPv6 traffic, we recommend that you also configure the next-header udp or next-header tcp match condition in the same term to specify which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the text synonyms listed with the destination-port <i>number</i> match condition.</p>	family inet	family inet6
source-port-except <i>number</i>	Do not match the UDP or TCP source port field. For details, see the source-port match condition.	family inet	family inet6
source-prefix-list <i>name</i>	Match source prefixes in the specified list. Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.	family inet	family inet6
tcp-flags <i>value</i>	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>For combined bit-field match conditions, see the tcp-established and tcp-initial match conditions.</p> <p>If you configure this match condition for IPv4 traffic, we recommend that you also configure the protocol tcp match statement in the same term to specify that the TCP protocol is being used on the port.</p> <p>If you configure this match condition for IPv6 traffic, we recommend that you also configure the next-header tcp match condition in the same term to specify that the TCP protocol is being used on the port.</p>	family inet	family inet6

NOTE: If you specify an IPv6 address in a match condition (the address, destination-address, or source-address match conditions), use the syntax for text representations described in RFC 2373, *IP Version 6 Addressing Architecture*. For more information about IPv6 addresses, see “IPv6 Overview” and “IPv6 Standards” in the *Junos OS Routing Protocols Configuration Guide*.

Reference Information for Firewall Filters in Logical Systems

- [Unsupported Firewall Filter Statements for Logical Systems on page 4767](#)
- [Unsupported Actions for Firewall Filters in Logical Systems on page 4769](#)

Unsupported Firewall Filter Statements for Logical Systems

Table 360 on page 4768 shows statements that are supported at the `[edit firewall]` hierarchy level but not at the `[edit logical-systems logical-system-name firewall]` hierarchy level.

Table 360: Unsupported Firewall Statements for Logical Systems

Statement	Example	Description
accounting-profile	<pre>[edit] logical-systems { ls1 { firewall { family inet { filter myfilter { accounting-profile fw-profile; ... } } } } }</pre>	In this example, the accounting-profile statement is not allowed because the accounting profile fw-profile is configured under the [edit accounting-options] hierarchy.
hierarchical-policer	<pre>[edit] logical-systems { lr1 { firewall { hierarchical-policer { ... } } } }</pre>	In this example, the hierarchical policer statement requires a class-of-service configuration, which is not supported under logical systems.
load-balance-group	<pre>[edit] logical-systems { ls1 { firewall { load-balance-group lb-group { next-hop-group nh-group; } } } }</pre>	<p>This configuration is not allowed because the next-hop-group nh-group statement must be configured at the [edit forwarding-options next-hop-group] hierarchy level—outside the [edit logical-systems logical-system-name firewall] hierarchy.</p> <p>Currently, the forwarding-options dhcp-relay statement is the only forwarding option supported for logical systems.</p>

Table 360: Unsupported Firewall Statements for Logical Systems (*continued*)

Statement	Example	Description
virtual-channel	<pre>[edit] logical-systems { ls1 { firewall { family inet { filter foo { term one { from { source-address 10.1.0.0/16; } then { virtual-channel sammy; } } } } } } }</pre>	<p>This configuration is not allowed because the virtual channel sammy refers to an object defined at the [edit class-of-service] hierarchy level, and class of service is not supported for logical systems.</p> <p>NOTE:</p> <p>The virtual-channel statement is supported for J Series devices only, provided the firewall filter is configured outside of a logical-system.</p>

Unsupported Actions for Firewall Filters in Logical Systems

[Table 361 on page 4769](#) describes the firewall filter actions that are supported at the **[edit firewall]** hierarchy level, but not supported at the **[edit logical-systems logical-system-name firewall]** hierarchy level.

Table 361: Unsupported Actions for Firewall Filters in Logical Systems

Firewall Filter Action	Example	Description
------------------------	---------	-------------

Terminating Actions Not Supported in a Logical System

Table 361: Unsupported Actions for Firewall Filters in Logical Systems (*continued*)

Firewall Filter Action	Example	Description
logical-system	<pre>[edit] logical-systems { ls1 { firewall { family inet { filter foo { term one { from { source-address 10.1.0.0/16; } then { logical-system fred; } } } } } } }</pre>	Because the logical-system action refers to fred —a logical system defined outside the local logical system—, this action is not supported.

Nonterminating Actions Not Supported in a Logical System

ipsec-sa	<pre>[edit] logical-systems { ls1 { firewall { family inet { filter foo { term one { from { source-address 10.1.0.0/16; } then { ipsec-sa barney; } } } } } } }</pre>	Because the ipsec-sa action modifier references barney —a security association defined outside the local logical system—this action is not supported.
-----------------	---	---

Table 361: Unsupported Actions for Firewall Filters in Logical Systems (*continued*)

Firewall Filter Action	Example	Description
next-hop-group	<pre> [edit] logical-systems { ls1 { firewall { family inet { filter foo { term one { from { source-address 10.1.0.0/16; } then { next-hop-group fred; } } } } } } } </pre>	Because the next-hop-group action refers to fred —an object defined at the [edit forwarding-options next-hop-group] hierarchy level—this action is not supported.
port-mirror	<pre> [edit] logical-systems { ls1 { firewall { family inet { filter foo { term one { from { source-address 10.1.0.0/16; } then { port-mirror; } } } } } } } </pre>	Because the port-mirror action relies on a configuration defined at the [edit forwarding-options port-mirroring] hierarchy level, this action is not supported.

Table 361: Unsupported Actions for Firewall Filters in Logical Systems (*continued*)

Firewall Filter Action	Example	Description
sample	<pre> [edit] logical-systems { ls1 { firewall { family inet { filter foo { term one { from { source-address 10.1.0.0/16; } then { sample; } } } } } } } </pre>	<p>In this example, the sample action depends on the sampling configuration defined under the [edit forwarding-options] hierarchy. Therefore, the sample action is not supported.</p>
syslog	<pre> [edit] logical-systems { ls1 { firewall { family inet { filter icmp-syslog { term icmp-match { from { address { 192.168.207.222/32; } protocol icmp; } then { count packets; syslog; accept; } } term default { then accept; } } } } } } </pre>	<p>In this example, there must be at least one system log (system syslog file filename) with the firewall facility enabled for the icmp-syslog filter's logs to be stored.</p> <p>Because this firewall configuration relies on a configuration outside the logical system, the syslog action modifier is not supported.</p>

Statement Hierarchy for Configuring Interface-Specific Firewall Filters

To enable interface-specific instances for stateless firewall filters, include the **interface-specific** statement in the **filter** *filter-name* or **service-filter** *service-filter-name* stanza. Any counters specified as actions in an interface-specific filter are maintained separately per filter instance. Any policers specified as actions in an interface-specific filter are applied per filter instance.

```

firewall {
  family family-name {
    (filter filter-name | service-filter service-filter-name) {
      ...
      interface-specific;
      ...
      term term-name {
        from {
          match-conditions;
        }
        then {
          count counter-name;
          policer policer-name;
        }
      }
      ...
    }
  }
}

```

```
]
```

You can include the firewall configuration at one of the following hierarchy levels:

- `[edit]`
- `[edit logical-systems logical-system-name]`

**Related
Documentation**

- *Interface-Specific Firewall Filter Instances Overview*

- *Example: Configuring Interface-Specific Firewall Filter Counters*

Statement Hierarchy for Applying Interface-Specific Firewall Filters

To apply an interface-specific stateless firewall filter to a logical interface, include the **input *filter-name*** or **output *filter-name*** statement in the **filter** or **service-filter** stanza of the interfaces configuration:

```
interfaces {  
  interface-name {  
    unit unit-number {  
      family family-name {  
        filter {  
          input filter-name-1;  
          output filter-name-2;  
        }  
        service-filter {  
          input service-filter-name-1;  
          output service-filter-name-2;  
        }  
      }  
    }  
  }  
}
```

You can include the interface configuration at one of the following hierarchy levels:

- `[edit]`
- `[edit logical-systems logical-system-name]`

Statement Hierarchy for Assigning Interfaces to Interface Groups

To assign a logical interface to an interface group, specify the group number by including the **group *interface-group-number*** statement in the **filter** stanza:

```
interfaces {  
  interface-name {  
    unit unit-number {
```

```

family ( inet | inet6 | vpls | ccc | bridge ) {
  filter {
    group interface-group-number;
  }
}

```

NOTE: The number 0 is not a valid number for an interface group.

You can configure the firewall filter at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

Related Documentation

- [Filtering Packets Received on a Set of Interface Groups Overview on page 4514](#)
- [Statement Hierarchy for Configuring a Filter to Match on a Set of Interface Groups on page 4775](#)
- [Example: Filtering Packets Received on an Interface Group on page 4634](#)

Statement Hierarchy for Configuring a Filter to Match on a Set of Interface Groups

You can configure a standard stateless firewall filter or a service filter term that matches packets tagged for a specified interface group or set of interface groups.

To configure a standard stateless firewall filter that matches packets tagged for a specified interface group or set of interface groups, configure a filter term that uses the **interface-group** *interface-group-number* match condition:

```

firewall {
  family (inet | inet6 | vpls | ccc | bridge) {
    filter filter-name {
      term term-name {
        from {
          interface-group interface-group-number;
        }
        then {
          filter-actions;
        }
      }
    }
  }
}

```

To configure a service filter that matches packets tagged for a specified interface group or set of interface groups, configure a filter term that uses the **interface-group** *interface-group-name* match condition:

```

firewall {
  family (inet | inet6) {
    service-filter filter-name {

```

```
term term-name {  
  from {  
    interface-group interface-group-number;  
  }  
  then {  
    service-filter-actions;  
  }  
}  
}  
}
```

You can configure the firewall filter at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

**Related
Documentation**

- [Filtering Packets Received on a Set of Interface Groups Overview on page 4514](#)

- [Example: Filtering Packets Received on an Interface Group on page 4634](#)

Statement Hierarchy for Applying Filters to an Interface Group

To apply a standard stateless firewall filter to an interface group, include the input *filter-name* or output *filter-name* in the filter stanza:

```
interfaces {  
  interface-name {  
    unit unit-number {  
      family family-name {  
        ...  
        filter {  
          input filter-name;  
          output filter-name;  
        }  
      }  
    }  
  }  
}
```

You can include the interface configuration at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

**Related
Documentation**

- [Statement Hierarchy for Assigning Interfaces to Interface Groups on page 4774](#)
- [Statement Hierarchy for Configuring a Filter to Match on a Set of Interface Groups on page 4775](#)
- [Example: Filtering Packets Received on an Interface Group on page 4634](#)

Statement Hierarchy for Defining an Interface Set

To configure a named group of interfaces that can be referenced in a stateless firewall filter match condition, use the **interface-set** statement to define the interface-set name and two or more interfaces:

```
firewall {
  interface-set interface-set-name {
    interface-name;
  }
}
```

You can include the statements at one of the following hierarchy levels:

- [\[edit firewall\]](#)
- [\[edit logical-systems logical-system-name firewall\]](#)

To specify that the interface set contains all interfaces of a particular type, you can use the '*' (asterisk) wildcard character. For example, use **fe-*** to specify all Fast Ethernet interfaces.

Statement Hierarchy for Configuring a Filter to Match on an Interface Set

To configure a standard stateless firewall filter that matches packets tagged for a specified interface group or set of interface groups, configure a filter term that uses the **interface-group interface-group-name** match condition:

```
firewall {
  family (any | inet | inet6 | mpls | vpls | bridge) {
    filter filter-name {
      term term-name {
        from {
          interface-set interface-set-name;
        }
        then {
          filter-actions;
        }
      }
    }
  }
}
```

Statement Hierarchy for Configuring FBF for IPv4 or IPv6 Traffic

You can configure stateless firewall filters for filter-based forwarding by configuring filter terms that specify the **forwarding-class** *class-name* nonterminating action or the **routing-instance** *routing-instance-name* terminating action:

```
firewall {  
  family (inet | inet6) {  
    filter filter-name {  
      term term-name {  
        from {  
          ipv4-or-ipv6-match-conditions;  
        }  
        then {  
          forwarding-class class-name; #optional  
          other-optional-nonterminating-actions;  
          routing-instance routing-instance-name <topology topology-name>;  
        }  
      }  
    }  
  }  
}
```

You can include the firewall configuration at one of the following hierarchy levels:

- [edit]
- [edit logical-systems *logical-system-name*]

Statement Hierarchy for Configuring FBF for IPv4 Traffic on ACX Series Routers

On ACX Series routers, you can configure stateless firewall filters for filter-based forwarding (FBF) by configuring filter terms that specify the optional nonterminating actions or the **routing-instance** *routing-instance-name* terminating action:

```
firewall {  
  family inet {  
    filter filter-name {  
      term term-name {  
        from {  
          ipv4-match-conditions;  
        }  
        then {  
          optional-nonterminating-actions;  
          routing-instance routing-instance-name ;  
        }  
      }  
    }  
  }  
}
```

```

    }
  }
}

```

You can include the firewall configuration at the **[edit]** hierarchy level:

The **[edit logical-systems *logical-system-name*]** hierarchy level is not supported on the ACX Series routers.

Matching on IPv4 Address and TCP/UDP Port Fields

To configure a firewall filter term that matches on IP source and destination address fields, and TCP and UDP ports in the IPv4 header of packets in an MPLS flow, you can specify supported match conditions as shown here:

```

[edit]
interfaces {
  interface-name {
    unit logical-unit-number {
      family family {
        address ip-address;
      }
      family mpls {
        filter {
          input filter-name;
        }
      }
    }
  }
}
firewall {
  family mpls {
    filter filter-name {
      term term-name {
        from {
          ip-version ipv4 {
            destination-address {

```

```
        ip-address;
      }
      source-address {
        ip-address;
      }
      protocol tcp {
        destination-port tcp-port;
        destination-port-except tcp-port;
        source-port tcp-port;
        source-port-except tcp-port;
      }
      protocol udp {
        destination-port udp-port;
        destination-port-except udp-port;
        source-port udp-port;
        source-port-except udp-port;
      }
    }
  }
  then {
    ...
  }
}
}
```

Configuration Example

```
interfaces {
  ge-6/0/0 {
    unit 0 {
      family inet {
        address 20.20.20.1/30;
      }
      family mpls {
        filter {
          input mpls-ipv4-filter1;
        }
      }
    }
  }
}
firewall {
  family mpls {
    filter mpls-ipv4-filter1 {
      term term1 {
        from {
          ip-version ipv4 {
            source-address {
              10.0.0.1/32;
            }
          }
          protocol tcp {
            destination-port ftp;
          }
        }
      }
    }
  }
}
```

```

    }
    then {
        count counter1;
        discard;
    }
}
}
}
}
}

```

Related Documentation

Statement Hierarchy for Configuring Routing Instances for FBF

A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

To configure a routing instance for filter-based forwarding:

1. The **instance-type** must be **forwarding**. The **forwarding** routing instance type supports filter-based forwarding, where interfaces are not associated with instances. For this instance type, there is no one-to-one mapping between an interface and a routing instance. All interfaces belong to the default instance **inet.0**.
2. The name of the routing instance name must be the one referenced in the firewall filter action.

NOTE: In Junos OS Release 9.0 and later, you can no longer specify a routing-instance name of **default** or include special characters within the name of a routing instance.

You must also create a routing table group that adds interface routes to the following routing instances:

- Routing instance named in the action
- Default routing table **inet.0**

You create a routing table group to resolve the routes installed in the routing instance to directly connected next hops on that interface. For more information on routing table groups and interface routes, see the *Junos OS Routing Protocols Configuration Guide*.

```

routing-instances {
    routing-table-name {
        instance-type forwarding;
    }
}

```

```
routing-options {
  static {
    route destination-prefix nexthop address;
  }
}
```

You can include the **forwarding** routing instance at one of the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

- [Example: Configuring Filter-Based Forwarding on the Source Address on page 4644](#)

Statement Hierarchy for Applying FBF Filters to Interfaces

To apply filter-based forwarding to a logical interface, include the **input** or **output** statement in the **filter** stanza.

NOTE: An interface configured with filter-based forwarding does not support source-class usage (SCU) filter matching and unicast reverse-path forwarding (RPF) check filters.

```
interfaces {
  interface-name {
    unit unit-number {
      family (inet | inet6 | mpls) {
        filter {
          input filter-name;
          output filter-name;
        }
        address address;
      }
    }
  }
}
```

You can include the interfaces configuration at one of the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

- Related Documentation**

 - [Statement Hierarchy for Configuring Routing Instances for FBF on page 4781](#)
 - [Example: Configuring Filter-Based Forwarding on the Source Address on page 4644](#)

Statement Hierarchy for Configuring Firewall Filter Accounting Profiles

To configure an accounting profile that you can apply to a firewall filter, include the **filter-profile** *filter-profile-name* statement in the **accounting-options** stanza.

```
accounting-options {
  filter-profile filter-profile-name {
    file log-filename {
      archive-sites {
        site-urls;
      }
      files number;
      size bytes;
      start-time time;
      transfer-interval minutes;
    }
    interval minutes;
    counters {
      counter-name-1;
      counter-name-2;
    }
  }
}
```

You can include the accounting options configuration at one of the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

To specify the name of the accounting data log file in the **/var/log** directory to be used in conjunction with the accounting profile, include the **file *log-filename*** statement.

To specify how often statistics are collected for the accounting profile, include the **interval *minutes*** statement.

To specify the names of the firewall filter counters for which filter profile statistics are collected, include the **counters** statement.

- Related Documentation**
- [Accounting for Standard Firewall Filters Overview on page 4517](#)
 - [Statement Hierarchy for Applying Firewall Filter Accounting Profiles on page 4784](#)
 - [Example: Configuring Statistics Collection for a Standard Firewall Filter on page 4669](#)

Statement Hierarchy for Applying Firewall Filter Accounting Profiles

You can apply an accounting profile to a standard stateless firewall filter for any supported protocol family except **family any**.

To apply a filter-accounting profile to a stateless firewall filter, include the **accounting-profile *accounting-profile-name*** statement at the firewall **filter** stanza:

```
firewall {  
  family family-name {  
    filter filter-name {  
      accounting-profile accounting-profile-name;  
      interface-specific;  
      physical-interface-policer;  
      term {  
        filter filter-profile-name;  
      }  
      term term-name {  
        from {  
          match-conditions;  
        }  
        then {  
          actions;  
        }  
      }  
    }  
  }  
}
```

You can include the firewall configuration at one of the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

Summary of Firewall Filters Configuration Statements

accounting-profile

Syntax	<code>accounting-profile <i>name</i>;</code>
Hierarchy Level	<code>[edit firewall family <i>family-name</i> filter <i>filter-name</i>]</code>
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Enable collection of accounting data for the specified filter.
Options	<i>name</i> —Name assigned to the accounting profile.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Accounting for Standard Firewall Filters Overview on page 4517

destination-address

Syntax	<code>destination-address <i>address</i>;</code>
Hierarchy Level	<code>[edit firewall family <i>family-name</i> filter <i>filter-name</i> term <i>term-name</i> from ip-version <i>ip-version</i>]</code>
Release Information	Statement introduced in Junos OS Release 10.1R1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure the IPv4 or IPv6 address of the destination node that receives the packet.
Required Privilege Level	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Standard Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic on page 4725

destination-port

Syntax	<code>destination-port <destination-port>;</code>
Hierarchy Level	[edit firewall family <i>family-name</i> filter <i>filter-name</i> term <i>term-name</i> from ip-version <i>ip-version</i> protocol (tcp udp)]
Release Information	Statement introduced in Junos OS Release 10.1R1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure the destination port of the Layer 4 header.
Options	<i>destination-port</i> —The destination port of the Layer 4 header. Range: 0 through 65,535
Required Privilege Level	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Standard Firewall Filter Match Conditions for MPLS-Tagged IPv4 or IPv6 Traffic on page 4725

enhanced-mode

Syntax	enhanced-mode;

Hierarchy Level [edit [firewall](#)],
 [edit logical-systems *logical-system-name* [firewall](#)]

Release Information Statement introduced before Junos OS Release 7.4.
 Logical systems support introduced in Junos OS Release 9.3.
 simple-filter statement introduced in Junos OS Release 7.6.
 any family type introduced in Junos OS Release 8.0.
 bridge family type introduced in Junos OS Release 8.4 (MX Series routers only).
 Statement introduced in Junos OS Release 12.3R2 for EX Series switches.

Description Configure a firewall filter for IP version 4 (IPv4) or IP version 6 (IPv6) traffic. Only on MX Series routers and EX Series switches, configure a firewall filter for Layer 2 traffic in a bridging environment.

Options *family-name*—Version or type of addressing protocol:

- **any**—Protocol-independent match conditions.
- **bridge**—(MX Series routers only) Layer 2 packets that are part of bridging domain.
- **ethernet-switching**—(EX Series switches) Filter Layer 2 (Ethernet) packets and Layer 3 (IP) packets.
- **ccc**—Layer 2 switching cross-connects.

- **inet**—IPv4 addressing protocol.
- **inet6**—IPv6 addressing protocol.
- **mpls**—MPLS.
- **vpls**—Virtual private LAN service (VPLS).

The remaining statements are explained separately.

NOTE: The packet lengths that a policer considers depends on the address family of the firewall filter. See [“Understanding the Frame Length for Policing Packets” on page 4811](#).

Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

Congestion Management for IP Traffic Flows

Traffic policing, also known *rate limiting*, is an essential component of network access security that is designed to thwart denial-of-service (DoS) attacks. Traffic policing enables you to control the maximum rate of IP traffic sent or received on an interface and also to partition network traffic into multiple priority levels, also known as *classes of service*. A policer defines a set of traffic rate limits and sets consequences for traffic that does not conform to the configured limits. Packets in a traffic flow that does not conform to traffic limits are either discarded or marked with a different forwarding class or packet loss priority (PLP) level.

With the exception of policers configured to rate-limit aggregate traffic (all protocol families and logical interfaces configured on a physical interface), you can apply a policer to all IP packets in a Layer 2 or Layer 3 traffic flow at a logical interface.

With the exception of policers configured to rate-limit based on physical interface media rate, you can apply a policer to specific IP packets in a Layer 3 traffic flow at a logical interface by using a stateless firewall filter.

You can apply a policer to inbound or outbound interface traffic. Policers applied to inbound traffic help to conserve resources by dropping traffic that does not need to be routed through a network. Dropping inbound traffic also helps to thwart denial-of-service (DoS) attacks. Policers applied to outbound traffic control the bandwidth used.

NOTE: Traffic policers are instantiated on a per-PIC basis. Traffic policing does not work when the traffic for one local policy decision function (L-PDF) subscriber is distributed over multiple Multiservices PICs in an AMS group.

Traffic Limits

Junos[®] OS policers use the *token-bucket* algorithm to enforce a limit on average transmit or receive rate of IP traffic at an interface while allowing bursts of traffic up to a maximum value based on the overall traffic load. The token-bucket algorithm offers more flexibility than the *leaky-bucket* algorithm in that you can allow a specified amount of bursting before starting to discard packets or apply a penalty to packet output-queuing priority or packet drop priority.

In the token-bucket model, the bucket represents the policing function. Tokens are added to the bucket at a fixed rate, but only up to the specified depth of the bucket. Each token represents a “credit” for some number of bits, and tokens in the bucket are “cashed in” for the ability to transmit or receive traffic at the interface. When sufficient tokens are present in the bucket, a traffic flow continues unrestricted. Otherwise, packets might be dropped or else re-marked with a lower forwarding class, a higher packet loss priority (PLP) level, or both.

- The rate at which tokens are added to the bucket represents the highest average transmit or receive rate in bits per second allowed for a given service level. You specify

this highest average traffic rate as the *bandwidth limit* of the policer. If the traffic arrival rate is so high that at some point insufficient tokens are present in the bucket, then the traffic flow is no longer conforming to the traffic limit.

- The depth of the bucket in bytes controls the amount of back-to-back bursting allowed. You specify this factor as the *burst-size limit* of the policer. This second limit affects the average transmit or receive rate by limiting the number of bytes permitted in a transmission burst for a given interval of time. Bursts exceeding the current burst-size limit are dropped until there are sufficient tokens available to permit the burst to proceed.

Figure 100: Network Traffic and Burst Rates

As shown in the figure above, a UPC bar code is a good facsimile of what traffic looks like on the line; an interface is either transmitting (bursting at full rate) or it is not. The black lines represent periods of data transmission and the white space represents periods of silence when the token bucket can replenish.

Depending on the type of policer used, packets in a policed traffic flow that surpasses the defined limits might be implicitly set to a higher PLP level, assigned to a configured forwarding class or set to a configured PLP level (or both), or simply discarded. If packets encounter downstream congestion, packets with a **low** PLP level are less likely to be discarded than those with a **medium-low**, **medium-high**, or **high** PLP level.

Traffic Color Marking

Based on the particular set of traffic limits configured, a policer identifies a traffic flow as belonging to one of either two or three categories that are similar to the colors of a traffic light used to control automobile traffic.

A *two-color-marking* policer categorizes traffic as either conforming to the traffic limits (green) or violating the traffic limits (red):

- **Green**—Two-color-marking policers implicitly set the packets in a green flow to the low PLP level, and you cannot configure any policer actions for conforming traffic.
- **Red**—Two-color-marking policers do not perform any implicit actions on packets in a red flow. Instead, those packets are handled according to the actions specified in the policer configuration. You can configure a two-color-marking policer to simply discard packets if the traffic flow is red. Alternatively, you can configure a two-color-marking policer to handle the packets in a red flow by setting the PLP level to either **low** or **high**, assigning the packets to any forwarding class already configured, or both.

On MX Series, M120, and M320 routers and M7i and M10i routers with the Enhanced CFEB (CFEB-E) and EX Series switches only, you can specify two additional PLP levels for packets in a red flow: **medium-low** or **medium-high**.

Three-color-marking policers categorize traffic as conforming to the traffic limits (green), violating the traffic limits (red), or exceeding the traffic limits but within an allowed range (yellow):

- **Green**—Like two-color-marking policers, three-color-marking policers implicitly set the packets in a green flow to the low PLP level, and you cannot configure any policer actions for conforming traffic.
- **Yellow**—Unlike two-color-marking policers, three-color-marking policers categorize a second type of nonconforming traffic: yellow.

Single-rate three-color policing categorizes as yellow traffic that exceeds the traffic limits while conforming to a second defined burst-size limit. Two-rate three-color policing categorizes as yellow traffic that exceeds the traffic limits while conforming to both a second defined burst-size limit and a second defined bandwidth limit.

Three-color-marking policers implicitly set the packets in a yellow flow to the medium-high PLP level so that the packets incur a less severe penalty than those in a red flow. You cannot configure any policer actions for yellow traffic.

- **Red**—Unlike two-color-marking policers, three-color-marking policers implicitly set the packets in a red flow to the high PLP level, which is the highest PLP value. You can also configure a three-color-marking policer to discard the packets in a red flow instead of forwarding them with a high PLP setting.

Two-color-marking policers allows bursts of traffic for short periods, whereas three-color-marking policers allow more sustained bursts of traffic.

Forwarding Classes and PLP Levels

A packet's forwarding class assignment and PLP level are used by the Junos OS class of service (CoS) features. The Junos CoS features include a set of mechanisms that you can use to provide differentiated services when best-effort traffic delivery is insufficient. For router (and switch) interfaces that carry IPv4, IPv6, and MPLS traffic, you can configure CoS features to take in a single flow of traffic entering at the edge of your network and provide different levels of service across the network—internal forwarding and scheduling (queuing) for output—based on the forwarding class assignments and PLP levels of the individual packets.

NOTE: Forwarding-class or loss-priority assignments performed by a policer or a stateless firewall filter override any such assignments performed on the ingress by the CoS default IP precedence classification at all logical interfaces or by any configured behavior aggregate (BA) classifier that is explicitly mapped to a logical interface.

Based on CoS configurations, packets of a given forwarding class are transmitted through a specific output queue, and each output queue is associated with a transmission service level defined in a *scheduler*.

Based on other CoS configurations, when packets in an output queue encounter congestion, packets with higher loss-priority values are more likely to be dropped by the random early detection (RED) algorithm. Packet loss priority values affect the scheduling of a packet without affecting the packet's relative ordering within the traffic flow.

Policer Application to Traffic

After you have defined and named a policer, it is stored as a template. You can later use the same policer name to provide the same policer configuration each time you want to use it. This eliminates the need to define the same policer values more than once.

You can apply a policer to a traffic flow in either of two ways:

- You can configure a standard stateless firewall filter that specifies the **policer *policer-name*** nonterminating action or the **three-color-policer (single-rate | two-rate) *policer-name*** nonterminating action. When you apply the standard filter to the input or output at a logical interface, the policer is applied to all packets of the filter-specific protocol family that match the conditions specified in the filter configuration.

With this method of applying a policer, you can define specific classes of traffic on an interface and apply traffic rate-limiting to each class.

- You can apply a policer directly to an interface so that traffic rate-limiting applies to all traffic on that interface, regardless of protocol family or any match conditions.

You can configure policers at the queue, logical interface, or Layer 2 (MAC) level. Only a single policer is applied to a packet at the egress queue, and the search for policers occurs in this order:

- Queue level
- Logical interface level
- Layer 2 (MAC) level

Traffic Policer Types

This topic covers the following information:

- [Single-Rate Two-Color Policers on page 4807](#)
- [Three-Color Policers on page 4808](#)
- [Two-Color and Three-Color Policer Options on page 4808](#)

Single-Rate Two-Color Policers

You can use a single-rate two-color policer, or “policer” when used without qualification, to rate-limit a traffic flow to an average bits-per-second arrival rate (specified by the single specified bandwidth limit) while allowing bursts of traffic for short periods (controlled by the single specified burst-size limit). This type of policer categorizes a traffic flow as either green (conforming) or red (nonconforming). Packets in a green flow are implicitly set to a **low** loss priority and then transmitted. Packets in a red flow are handled according to actions specified in the policer configuration. Packets in a red flow can be marked—set to a specified forwarding class, set to a specified loss priority, or both—or they can be discarded.

A single-rate two-color policer is most useful for metering traffic at the port (physical interface) level.

Basic Single-Rate Two-Color Policer

You can apply a basic single-rate two-color policer to Layer 3 traffic in either of two ways: as an interface policer or as a firewall filter policer. You can apply the policer as an *interface policer*, meaning that you apply the policer directly to a logical interface at the protocol family level. If you want to apply the policer to selected packets only, you can apply the policer as a *firewall filter policer*, meaning that you reference the policer in a stateless firewall filter term and then apply the filter to a logical interface at the protocol family level.

Bandwidth Policer

A bandwidth policer is simply a single-rate two-color policer that is defined using a bandwidth limit specified as a percentage value rather than as an absolute number of bits per second. When you apply the policer (as an interface policer or as a firewall filter policer) to a logical interface at the protocol family level, the effective bandwidth limit is calculated based on either the physical interface media rate or the logical interface configured shaping rate.

Logical Bandwidth Policer

A logical bandwidth policer is a bandwidth policer for which the effective bandwidth limit is calculated based on the logical interface configured shaping rate. You can apply the policer as a firewall filter policer only, and the firewall filter must be configured as an interface-specific filter. When you apply an interface-specific filter to multiple logical interfaces on supported routing platforms, any **count** or **policer** actions act on the traffic stream entering or exiting each individual interface, regardless of the sum of traffic on the multiple interfaces.

Three-Color Policers

The Junos OS supports two types of three-color policers: single-rate and two-rate. The main difference between a single-rate and a two-rate policer is that the single-rate policer allows bursts of traffic for short periods, while the two-rate policer allows more sustained bursts of traffic. Single-rate policing is implemented using a single token-bucket model, so that periods of relatively low traffic must occur between traffic bursts to allow the token bucket to refill. Two-rate policing is implemented using a dual token-bucket model, which allows bursts of traffic for longer periods.

Single-Rate Three-Color Policers

The single-rate three-color type of policer is defined in RFC 2697, *A Single Rate Three Color Marker*. You use this type of policer to rate-limit a traffic flow to a single rate and three traffic categories (green, yellow, and red). A single-rate three-color policer defines a *committed* bandwidth limit and burst-size limit plus an excess burst-size limit. Traffic that conforms to the committed traffic limits is categorized as green (conforming). Traffic that conforms to the bandwidth limit while allowing bursts of traffic as controlled by the excess burst-size limit is categorized as yellow. All other traffic is categorized as red.

A single-rate three-color policer is most useful when a service is structured according to packet length, not peak arrival rate.

Two-Rate Three-Color Policers

The two-rate three-color type of policer is defined in RFC 2698, *A Two Rate Three Color Marker*. You use this type of policer to rate-limit a traffic flow to two rates and three traffic categories (green, yellow, and red). A two-rate three-color policer defines a *committed* bandwidth limit and burst-size limit plus a *peak* bandwidth limit and burst-size limit. Traffic that conforms to the committed traffic limits is categorized as green (conforming). Traffic that exceeds the committed traffic limits but remains below the peak traffic limits is categorized as yellow. Traffic that exceeds the peak traffic limits is categorized as red.

A two-rate three-color policer is most useful when a service is structured according to arrival rates and not necessarily packet length.

Two-Color and Three-Color Policer Options

Both two-color and three-color policers can be configured with the following options:

- [Logical Interface \(Aggregate\) Policers on page 4809](#)
- [Physical Interface Policers on page 4809](#)
- [Policers Applied to Layer 2 Traffic on page 4809](#)
- [Multifield Classification on page 4809](#)

Logical Interface (Aggregate) Policers

A logical interface policer can be a two-color policer, not a three-color policer. When you apply a logical interface policer to multiple protocol families on the same logical interface, multiple instances of the policer are created, meaning that traffic for each protocol family is policed separately. You apply a logical interface policer directly to a logical interface configuration (and not by referencing the policer in a stateless firewall filter and then applying the filter to the logical interface).

- You can apply the policer at the interface logical unit level to rate-limit all traffic types, regardless of the protocol family.

When applied in this manner, the logical interface policer will be used by all traffic types (inet, inet6, etc.) and across all layers (layer 2, layer 3) no matter where the policer is attached on the logical interface.

- You can also apply the policer at the logical interface protocol family level, to rate-limit traffic for a specific protocol family.

You can apply a logical interface policer to unicast traffic only. For information about configuring a stateless firewall filter for flooded traffic, see “*Applying Filters to Forwarding Tables*” in the “Traffic Sampling, Forwarding, and Monitoring” section of the *Routing Policy Configuration Guide*.

Physical Interface Policers

A physical interface policer can be a two-color or three-color policer. When you apply physical interface policer, to different protocol families on the same logical interface, the protocol families share the same policer instance. This means that rate limiting is performed aggregately for the protocol families for which the policer is applied. This feature enables you to use a single policer instance to perform aggregate policing for different protocol families on the same physical interface. If you want a policer instance to be associated with a protocol family, the corresponding physical interface filter needs to be applied to that protocol family. The policer is not automatically applied to all protocol families configured on the physical interface.

In contrast, with logical interface policers there are multiple separate policer instances.

Policers Applied to Layer 2 Traffic

In addition to hierarchical policing, you can also apply single-rate two-color policers and three-color policers (both single-rate and two-rate) to Layer 2 input or output traffic. You must configure the two-color or three-color policer as a logical interface policer and reference the policer in the interface configuration at the logical unit level, and not at the protocol level. You cannot apply a two-color or three-color policer to Layer 2 traffic as a stateless firewall filter action.

Multifield Classification

Like behavior aggregate (BA) classification, which is sometimes referred to as class-of-service (CoS) value traffic classification, multifield classification is a method of classifying incoming traffic by associating each packet with a forwarding class, a packet loss priority level, or both. The CoS scheduling configuration assigns packets to output queues based on forwarding class. The CoS random early detection (RED) process uses

the drop probability configuration, output queue fullness percentage, and packet loss priority to drop packets as needed to control congestion at the output stage.

BA classification and multifield classification use different fields of a packet to perform traffic classification. BA classification is based on a *CoS value* in the IP packet header. Multifield classification can be based on *multiple fields* in the IP packet header, including CoS values. Multifield classification is used instead of BA classification when you need to classify packets based on information in the packet other than the CoS values only. Multifield classification is configured using a stateless firewall filter term that matches on any packet header fields and associates matched packets with a forwarding class, a loss priority, or both. The forwarding class or loss priority can be set by a firewall filter action or by a policer referenced as a firewall filter action.

Order of Policer and Firewall Filter Operations

You can apply both a traffic policer and a stateless firewall filter (with or without policing actions) to a single logical interface at the same time. In this case, the order of precedence of operations is such that policers applied directly to the logical interface are evaluated before input filters but after output filters.

- If an input firewall filter is configured on the same logical interface as a policer, the policer is executed first.
- If an output firewall filter is configured on the same logical interface as a policer, the firewall filter is executed first.

[Figure 101 on page 4810](#) illustrates the order of policer and firewall filter processing at the same interface.

Guidelines for Applying Traffic Policers

The following general guidelines pertain to applying traffic policers:

- Only one type of policer can be applied to the input or output of the same physical or logical interface. For example, you are not allowed to apply a policer and a hierarchical policer in the same direction at the same logical interface.
- Chaining of policers—that is, applying policers to both a port and the logical interfaces of that port—is not allowed.
- A maximum of 64 policers is supported per physical or logical interface, provided no behavior aggregate (BA) classification—traffic classification based on CoS values in the packet headers—is applied to the logical interface.
- The policer should be independent of BA classification. Without BA classification, all traffic on an interface is treated either as expedited forwarding (EF) or non-EF, based on the configuration. With BA classification, a physical or logical interface can support up to 64 policers. The interface might be a physical interface or logical interface.
- With BA classification, the miscellaneous traffic (the traffic *not* matching any of the BA classification DSCP/EXP bits) is policed as non-EF traffic. No separate policers are installed for this traffic.
- Policers can be applied to unicast packets only. For information about configuring a filter for flooded traffic, see “*Applying Filters to Forwarding Tables*” in the “Traffic Sampling, Forwarding, and Monitoring” section of the *Routing Policy Configuration Guide*.

Policer Bandwidth and Burst-Size Limits

[Table 365 on page 4822](#) lists each of the Junos OS policer types supported. For each policer type, the table summarizes the bandwidth limits and burst-size limits used to rate-limit traffic.

Table 365: Policer Bandwidth Limits and Burst-Size Limits

Policer Type	Bandwidth Limits	Burst-Size Limits
Single-Rate Two-Color Policer		
Defines a single rate limit: a bandwidth limit and an allowed burst size for conforming traffic.	bandwidth-limit <i>bps</i>; M, MX, T Series routers and EX Series switches: 8000..500000000000	burst-size-limit <i>bytes</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000
For a single-rate two-color policer only, you can specify the bandwidth limit as a percentage value from 1 through 100 instead of as an absolute number of bits per second. The effective bandwidth limit is calculated as a percentage of either the physical interface media rate or the logical interface configured shaping rate.	bandwidth-percent 1..100 percent	
Single-Rate Three-Color Policer		
Defines a single rate limit: a bandwidth limit and an allowed burst size for conforming traffic.	committed-information-rate <i>bps</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000	committed-burst-size <i>bytes</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000
Also defines a second, larger burst size. This second burst size is used to differentiate between two categories of nonconforming traffic (yellow or red).		excess-burst-size <i>bytes</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000
Two-Rate Three-Color Policer		
Defines a committed rate limit: a bandwidth limit and an allowed burst size for conforming traffic.	committed-information-rate <i>bps</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000	committed-burst-size <i>bytes</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000
Also defines a peak rate limit: a second, larger burst size and a second, higher bandwidth limit. These additional rate-limit components are used to differentiate between two categories of nonconforming traffic (yellow or red).	peak-information-rate <i>bps</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000	peak-burst-size <i>bytes</i>; M, MX, T Series routers, and EX Series switches: 1500..100000000000

Single Token Bucket Algorithm

This topic covers the following information:

- [Token Bucket Concepts on page 4825](#)
- [Single Token Bucket Algorithm on page 4825](#)
- [Conformance Measurement for Two-Color Marking on page 4826](#)

Token Bucket Concepts

When you apply traffic policing to the input or output traffic at an interface, the rate limits and actions specified in the policer configuration are used to enforce a limit on the average throughput rate at the interface while also allowing bursts of traffic up to a maximum number of bytes based on the overall traffic load. Junos OS policers measure traffic-flow conformance to a policing rate limit by using a *token bucket algorithm*:

- The *bucket* represents a rate-limiting function of the policer on the interface input or output traffic.
- Each *token* in the bucket represents a “credit” for some number of *bits*, and tokens in the bucket are “cashed in” for the ability to receive or transmit traffic that conforms to a rate limit configured for the policer.
- The *token arrival rate* is the fixed *bits-per-second* rate at which tokens are added to the token bucket, but only up to the specified depth of the bucket.
- The *token bucket depth* defines the capacity of the bucket in *bytes*.

An algorithm based on a single token bucket allows burst of traffic for short periods, whereas an algorithm based dual token buckets allows more sustained bursts of traffic.

Single Token Bucket Algorithm

A single-rate two-color policer limits traffic throughput at an interface based on how the traffic conforms to rate-limit values specified in the policer configuration. Similarly, a hierarchical policer limits traffic throughput at an interface based on how aggregate and premium traffic subflows conform to aggregate and premium rate-limit values specified in the policer configuration. For both two-color policer types, packets in a conforming traffic flow are categorized as *green*, and packets in a non-conforming traffic flow are categorized as *red*.

The single token bucket algorithm measures traffic-flow conformance to a two-color policer rate limit as follows:

- The token arrival rate represents the single *bandwidth limit* configured for the policer. You can specify the bandwidth limit as an absolute number of bits per second by including the **bandwidth-limit *bps*** statement. Alternatively, for single-rate two-color policers only, you can use the **bandwidth-percent *percentage*** statement to specify the bandwidth limit as a percentage of either the physical interface port speed or the configured logical interface shaping rate.
- The token bucket depth represents the single *burst size* configured for the policer. You specify the burst size by including the **burst-size-limit *bytes*** statement.
- If the bucket is filled to capacity, arriving tokens “overflow” the bucket and are lost.

When the bucket contains insufficient tokens for receiving or transmitting the traffic at the interface, packets might be dropped or else re-marked with a lower forwarding class, a higher packet loss priority (PLP) level, or both.

Conformance Measurement for Two-Color Marking

In two-color-marking policing, a traffic flow whose average arrival or departure rate does not exceed the token arrival rate (bandwidth limit) is considered *conforming traffic*. Packets in a conforming traffic flow (categorized as green traffic) are implicitly marked with a packet loss priority (PLP) level of **low** and then passed through the interface.

For a traffic flow whose average arrival or departure rate exceeds the token arrival rate, conformance to a two-color policer rate limit depends on the tokens in the bucket. If sufficient tokens remain in the bucket, the flow is considered conforming traffic. If the bucket does not contain sufficient tokens, the flow is considered *non-conforming traffic*. Packets in a non-conforming traffic flow (categorized as red traffic) are handled according to policing actions. Depending on the configuration of the two-color policer, packets might be implicitly discarded; or the packets might be re-marked with a specified forwarding class, a specified PLP, or both, and then passed through the interface.

NOTE: The number of tokens remaining in the bucket at any given time is a function of the token bucket depth and the overall traffic load.

The token bucket is initially filled to capacity, and so the policer allows an initial traffic burst (back-to-back traffic at average rates that exceed the token arrival rate) up to the size of the token bucket depth.

During periods of relatively low traffic (traffic that arrives at or departs from the interface at average rates below the token arrival rate), unused tokens accumulate in the bucket, but only up to the configured token bucket depth.

Token Bucket Concepts

When you apply traffic policing to the input or output traffic at an interface, the rate limits and actions specified in the policer configuration are used to enforce a limit on the average throughput rate at the interface while also allowing bursts of traffic up to a maximum number of bytes based on the overall traffic load. Junos OS policers measure traffic-flow conformance to a policing rate limit by using a *token bucket algorithm*:

- The *bucket* represents a rate-limiting function of the policer on the interface input or output traffic.
- Each *token* in the bucket represents a “credit” for some number of *bits*, and tokens in the bucket are “cashed in” for the ability to receive or transmit traffic that conforms to a rate limit configured for the policer.
- The *token arrival rate* is the fixed *bits-per-second* rate at which tokens are added to the token bucket, but only up to the specified depth of the bucket.
- The *token bucket depth* defines the capacity of the bucket in *bytes*.

An algorithm based on a single token bucket allows burst of traffic for short periods, whereas an algorithm based dual token buckets allows more sustained bursts of traffic.

Guaranteed Bandwidth for Three-Color Marking

A committed information rate (CIR) defines the guaranteed bandwidth for traffic arriving at or departing from the interface under normal line conditions. A flow of traffic at an average rate that conforms to the CIR is categorized green, and packets in a green flow are implicitly marked with **low** packet loss priority (PLP) and then passed through the interface. During periods of relatively low traffic (traffic that arrives at or departs from the interface at average rates below the CIR), any unused bandwidth capacity accumulates in the first token bucket, but only up to a configured number of bytes. If any unused bandwidth capacity overflows the first bucket, the excess accumulates in a second token bucket.

The committed burst size (CBS) defines the maximum number of bytes for which unused amounts of the guaranteed bandwidth can be accumulated in the first token bucket. A burst of traffic at an average rate that exceeds the CIR is also categorized as green provided that sufficient unused bandwidth capacity is available in the first token bucket.

Nonconformance Measurement for Single-Rate Three-Color Marking

Single-rate three-color policer configurations specify a second burst size—the excess burst size (EBS)—that defines the maximum number of bytes for which the second token bucket can accumulate unused bandwidth that overflows from the first bucket.

A traffic flow is categorized yellow if its average rate exceeds the CIR and the available bandwidth capacity accumulated in the first bucket if sufficient unused bandwidth capacity is available in the second token bucket. Packets in a yellow flow are implicitly marked with **medium-high** PLP and then passed through the interface.

A traffic flow is categorized red its average rate exceeds the CIR and the available bandwidth capacity accumulated in the second bucket. Packets in a red flow are implicitly marked with **high** PLP and then either passed through the interface or optionally discarded.

Nonconformance Measurement for Two-Rate Three-Color Marking

Two-rate three-color policer configurations include a second rate limit—the peak-information-rate (PIR)—that you set to the expected average data rate for traffic arriving at or departing from the interface under peak conditions.

Two-rate three-color policer configurations also include a second burst size—the peak burst size (PBS)—that defines the maximum number of bytes for which the second token bucket can accumulate unused peak bandwidth capacity. During periods of relatively little peak traffic (traffic that arrives at or departs from the interface at average rates that exceed the PIR), any unused peak bandwidth capacity accumulates in the second token bucket, but only up to the maximum number of bytes specified by the PBS.

A traffic flow is categorized yellow if it exceeds the CIR and the available committed bandwidth capacity accumulated in the first token bucket but conforms to the PIR. Packets in a yellow flow are implicitly marked with **medium-high** PLP and then passed through the interface.

A traffic flow is categorized red if it exceeds the PIR and the available peak bandwidth capacity accumulated in the second token bucket. Packets in a red flow are implicitly marked with **high** PLP and then either passed through the interface or optionally discarded.

Policer Implementation Overview

Traffic policing enables you to control the maximum rate of traffic sent or received on an interface and also to partition network traffic into multiple priority levels, also known as classes of service. A policer defines a set of traffic rate limits and sets consequences for traffic that does not conform to the configured limits. Packets in a traffic flow that do not conform to traffic limits are either discarded or marked with a different forwarding class or packet loss priority (PLP) level.

You can apply a policer to inbound or outbound traffic. Policers applied to inbound traffic help to conserve resources by dropping traffic that does not need to be routed through a network. Policers applied to outbound traffic control the bandwidth used.

The Juniper Networks® Junos® operating system (Junos OS) supports three types of policers:

- *Single-rate two-color policer* — The most common policer. Single-rate means that there is only a single bandwidth and burst rate referenced in the policer. The two colors associated with this policer are red (nonconforming) and green (conforming).
- *Single-rate three-color policer* — Similar to the single-rate two-color policer with the addition of the color yellow. This type also introduces the *committed information rate* (CIR) and a *committed burst rate* (CBR).
- *Two-rate three-color policer* — Builds off of the single-rate three-color policer by adding a second rate tier. *Two-rate* means there is an upper bandwidth limit and associated burst size as well as a *peak information rate* (PIR) and a *peak burst rate* (PBS).

NOTE: The remainder of this topic covers the single-rate two-color policer. For more information about the other types of policers, see the *Junos OS Traffic Policers Configuration Guide*.

Junos OS policers use a *token bucket algorithm* to enforce a limit on an average transmit or receive rate of traffic at an interface while allowing bursts of traffic up to a maximum value based on the configured bandwidth limit and configured burst size. The token bucket algorithm offers more flexibility than a *leaky bucket algorithm* in that you can allow a specified traffic burst before starting to discard packets or apply a penalty such as packet output-queuing priority or packet-drop priority.

There are two types of token bucket algorithms that can be used, depending on the type of policer that is applied to network traffic. Single-rate two-color policers use the *single token bucket algorithm* to measure traffic flow conformance to a two-color policer rate limit. Single-rate three-color policers and two-rate three-color policers both use the *dual token bucket algorithm* to measure traffic flow conformance to a three-color policer rate. The main difference between these two token bucket algorithms is that the single token bucket algorithm allows bursts of traffic for short periods, whereas the dual token bucket algorithm allows more sustained bursts of traffic.

NOTE: The remainder of this topic discusses the single token bucket algorithm. For more information about the dual token bucket algorithm, see the *Junos OS Traffic Policers Configuration Guide*.

Following are the main components of the token bucket algorithm:

- The *bucket* represents a rate-limiting function of the policer on the interface input or output traffic.
- Each *token* in the bucket represents a “credit” for some number of *bits*, and tokens in the bucket are “cashed in” for the ability to receive or transmit traffic that conforms to a rate limit configured for the policer.

- The *token arrival rate* is a periodic allocation of tokens into the token bucket that is calculated from the configured bandwidth limit.
- The *token bucket depth* defines the capacity of the bucket in *bytes*. Tokens that are allocated after the bucket reaches capacity are not able to be stored and used.

In the token bucket model, the bucket represents the policing function. Tokens are added to the bucket at a fixed rate, but once the specified depth of the bucket is reached, tokens allocated after cannot be stored and used. Each token represents a “credit” for some number of bits, and the tokens in the bucket are “cashed in” for the ability to transmit or receive traffic at the interface. When sufficient tokens are present in the bucket, a traffic flow continues unrestricted.

- The rate at which tokens are added to the bucket represents the highest average transmit or receive rate in bits per second allowed for a given service level. You specify this highest average traffic rate as the *bandwidth limit* of the policer. If the traffic arrival rate is so high that at some point insufficient tokens are present in the bucket, then the traffic flow is no longer conforming to the traffic limit. During periods of relatively low traffic (traffic that arrives at or departs from the interface at average rates below the token arrival rate), unused tokens accumulate in the bucket.
- The depth of the bucket in bytes controls the amount of back-to-back bursting allowed. You specify this factor as the *burst-size limit* of the policer. This second limit affects the average transmit or receive rate by limiting the number of bytes permitted in a transmission burst for a given interval of time. Bursts exceeding the current burst-size limit are dropped until there are sufficient tokens available to permit the burst to proceed.

To configure a policer, you need to set two parameters:

- Bandwidth limit configured in bps (using the **bandwidth-limit** statement)
- Burst size configured in bytes (using the **burst-size-limit** statement)

NOTE: For single-rate two-color policers only, you can also specify the bandwidth limit as a percentage of either the physical interface port speed or the configured logical interface shaping rate by using the **bandwidth-percent *percentage*** statement. You cannot configure a policer to use bandwidth percentage for aggregate, tunnel, or software interfaces.

Use the following command to set the policer conditions:

```
user@router# set firewall policer <policer name> if-exceeding ?
Possible completions:
  <[Enter]>          Execute this command
+ apply-groups       Groups from which to inherit configuration data
+ apply-groups-except Don't inherit configuration data from these groups
  bandwidth-limit    Bandwidth limit (8000..1000000000000 bits per second)
  bandwidth-percent  Bandwidth limit in percentage (1..100 percent)
  burst-size-limit    Burst size limit (1500..1000000000000 bytes)
  |                  Pipe through a command
```

The bandwidth limit parameter is used to determine the average rate limit applied to the traffic, while the burst-size parameter is used to allow for short periods of traffic bursting (back-to-back traffic at average rates that exceed the configured bandwidth limit). Once you apply a set of policer configuration settings (bandwidth limit and burst size), the configured values are adjusted to hardware programmable values. The conversion adjustment introduced is normally less than 1 percent of the configured bandwidth limit. This adjustment is needed because the software allows you to configure the bandwidth limit and burst size to any value within the specified ranges, but those values must be adjusted to the nearest value that can be programmed in the hardware.

The policer bandwidth limit configuration in the hardware is represented by two values: the *credit update frequency* and the *credit size*. The credit update frequency is used by the hardware to determine how frequently tokens (bits of unused bandwidth) are added to the token bucket. The credit size is based on the number of tokens that can fit in the token bucket. The MX Series, M120, M320 routers, and EX Series switches contain a set of credit update frequencies instead of having a single credit update frequency to minimize the adjustment difference from the configured bandwidth limit and to support a wide range of policer bandwidth rates (from 40 Kbps to 40 Gbps). One of the frequencies is used to program the policer (bandwidth limit and burst size) in the hardware.

The burst size is based on the overall traffic load and allows bursts of traffic to exceed the configured bandwidth limit. A policer with a large burst size effectively disables the configured bandwidth limit function, so the burst size must be relative to the configured bandwidth limit. You need to consider the traffic patterns in your network before determining the burst size. For more information about determining burst size, see [“Determining Proper Burst Size for Traffic Policers” on page 4834](#).

The configured burst size is adjusted in the hardware to a value that is based on the configured bandwidth limit. The burst size extends the configured bandwidth limit for bursty traffic that exceeds the configured bandwidth limit.

When a policer is applied to the traffic at an interface, the initial capacity for traffic bursting is equal to the number of bytes specified in the **burst-size-limit** statement.

[Figure 102 on page 4832](#) represents how a policer is implemented using the token bucket algorithm. The token allocator allocates tokens to the policer based on the configured bandwidth limit, which is the token size multiplied by the token arrival rate.

token size x token arrival rate = policer rate (configured bandwidth limit)

Figure 102: Token Bucket Algorithm

When a packet arrives at an interface configured with a policer, tokens that represent the number of bits that correspond to the length of the packet are used (or “cached in”) from the token bucket. If the token arrival rate is higher than the rate of traffic so that there are tokens not being used, the token bucket is filled to capacity, and arriving tokens “overflow” the bucket and are lost. The token bucket depth represents the single user-configured burst size for the policer.

If there are tokens in the token bucket and the incoming traffic rate is higher than the token rate (the configured policer rate, bandwidth limit), the traffic can use the tokens until the bucket is empty. The token consumption rate can be as high as the incoming traffic rate, which creates the burst of traffic shown in [Figure 103 on page 4832](#).

By using the token bucket algorithm, the average bandwidth rate being allowed is close to the configured bandwidth limit while simultaneously supporting bursty traffic, as shown in [Figure 103 on page 4832](#).

Figure 103: Traffic Behavior Using Policer and Burst Size

NOTE: The measured length of a packet changes according to the family type that the policer applies to. If the policer is applied under the family inet hierarchy, the policer considers only the IPv4 packet length. If the policer is applied under the family vpls hierarchy, the entire Ethernet frame (including the Ethernet MAC header) is included in the packet length.

The major factor that affects the policer shaping result is not the conversion adjustment, but the traffic pattern since most network traffic is not consistent and is not sent at a constant rate. Due to the fluctuation of the incoming traffic rate, some of the allocated tokens are not used. As a result, the shaped traffic rate is lower than you might expect, and the TCP connection behavior discussed in “[Understanding the Benefits of Policers and Token Bucket Algorithms](#)” on page 4833 is a typical example of this. To alleviate this effect of the lower shaped traffic rate, a proper burst size configuration is required.

Understanding the Benefits of Policers and Token Bucket Algorithms

This topic describes some scenarios that demonstrate how difficult it is to control traffic that comes into your network without the help of policers and the token bucket algorithm. These scenarios assume that traffic is coming from a TCP-based connection. Depending on the number of TCP connections, policers can have different affects on rate limits.

This topic presents the following scenarios:

- [Scenario 1: Single TCP Connection on page 4833](#)
- [Scenario 2: Multiple TCP Connections on page 4834](#)

Scenario 1: Single TCP Connection

[Figure 104 on page 4833](#) shows the traffic loading on an interface with a policer configured. When the traffic rate reaches the configured bandwidth limit (which results in a packet drop), a TCP slow-start mechanism reduces the traffic rate down to half of what it was. When the traffic rate rises again, the same cycle repeats.

Figure 104: Policer Behavior With a Single TCP Connection

The problem presented in this scenario is that some bandwidth is available, but it is not being used by the traffic. The unused bandwidth shown in [Figure 104 on page 4833](#) is the result of an overall data throughput that is lower than the configured bandwidth value. This example is an extreme case because there is only a single TCP connection.

Scenario 2: Multiple TCP Connections

With multiple TCP connections or some background non-TCP-based traffic, there is less unused bandwidth, as depicted in [Figure 105 on page 4834](#). However, the same issue of unused bandwidth still exists if all the TCP connections experience a drop when the aggregated traffic rate exceeds the configured bandwidth limit.

Figure 105: Policer Behavior With Background Traffic (Multiple TCP Connections)

To reduce the problem of unused bandwidth in your network, you can configure a burst size.

Determining Proper Burst Size for Traffic Policers

A policer burst-size limit controls the number of bytes of traffic that can pass unrestricted through a policed interface when a burst of traffic pushes the average transmit or receive rate above the configured bandwidth limit. The actual number of bytes of bursty traffic allowed to pass through a policed interface can vary from zero to the configured burst-size limit, depending on the overall traffic load.

By configuring a proper burst size, the effect of a lower shaped rate is alleviated. Use the **burst-size-limit** statement to configure the burst size.

NOTE: If you set the burst-size limit too low, too many packets will be subjected to rate limiting. If you set the burst-size limit too high, too few packets will be rate-limited.

Consider these two main factors when determining the burst size to use:

- The allowed duration of a blast of traffic on the line.

- The burst size is large enough to handle the maximum transmission unit (MTU) size of the packets.

The following general guidelines apply to choosing a policer burst-size limit:

- A burst-size limit should not be set lower than 10 times the MTU of the traffic on the interface to be policed.
- The amount of time to allow a burst of traffic at the full line rate of a policed interface should not be lower than 5 ms.
- The minimum and maximum values you can specify for a policer burst-size limit depends on the policer type (two-color or three-color).

BEST PRACTICE: The preferred method for choosing a burst-size limit is based on the line rate of the interface on which you apply the policer and the amount of time you want to allow a burst of traffic at the full line rate.

Bursty traffic requires a relatively large burst size so that extra tokens can be allocated into the token bucket for upcoming traffic to use. [Figure 106 on page 4835](#) shows an extreme case of bursty traffic where the opportunity to allocate tokens is missed, and the bandwidth goes unused because a large burst size is not configured.

Figure 106: Bursty Traffic Without Configured Burst Size (Excessive Unused Bandwidth)

[Figure 107 on page 4836](#) depicts how bandwidth usage changes when a large burst size is configured to handle bursty traffic. The large burst size minimizes the amount of unused bandwidth because tokens are being allocated in between the bursts of traffic that can be used during traffic peaks. The burst size determines the depth of the token bucket.

Figure 107: Bursty Traffic With Configured Burst Size (Less Unused Bandwidth)

Configuring a large burst size for the unused tokens creates another issue. If the burst size is set to a very large value, the burst of traffic can be transmitted from the interface at line rate until all the accumulated tokens in the token bucket are used up. This means that configuring a large burst size can allow too many packets to avoid rate limiting, which can lead to a traffic rate that exceeds the bandwidth limit for an extended period of time.

If the average rate is considered within 1 second, the rate is still below the configured bandwidth limit. However, the downstream device might not be able to handle bursty traffic, so some packets might be dropped. As a result, the way to determine the best burst size configuration is to perform experimental configurations, since one burst size is not suitable for every traffic pattern.

To program the burst size on the MX Series, M120, M320 routers, and EX Series switches, the user-configured burst size value is restricted to 1 ms through 600 ms of the policer rate (configured bandwidth limit).

Before performing burst size test configurations, select the initial burst size value using one of the following:

- The recommended formula for calculating burst size for bandwidth described as bits per second is: **burst size = bandwidth x allowable time for burst traffic / 8** (5 ms of the policer rate)
- For policers where the interface bandwidth is unknown, use the MTU method of calculating burst size: **burst size = interface MTU x 10**

[Figure 108 on page 4837](#) depicts a comparison between the two methods.

Figure 108: Comparing Burst Size Configuration Methods: 5 ms V.S. 10 MTU

In [Figure 108 on page 4837](#), with the 5 ms method, the burst size decreases with the policer rate (the configured bandwidth limit). As a result, the burst size can become so small that it might not be able to hold 2 MTU packets. This can severely affect the policer performance, which makes the 10 MTU method appear to be a better choice.

For example, with a 100 Kbps bandwidth limit configured on a Gigabit Ethernet interface and a burst size configured to 100 ms, the burst size becomes **100 Kbps x 100 ms = 1250 bytes**. This burst size is smaller than one standard MTU payload size on an Ethernet-type interface. A 10 MTU burst size provides a burst size of **1500 bytes x 10 = 15000 bytes**. However, since the maximum burst size is 600 ms of the bandwidth limit, the maximum configured burst size is **100 Kbps x 600 ms = 7500 bytes**. On the Gigabit Ethernet interface, the burst duration is **7500 bytes / 1 Gbps = 60 μs** at Gigabit Ethernet line rate. If the burst size is too large for the downstream device, the burst size can be further reduced until the result is acceptable.

However, if the bandwidth limit is very high, the 10 MTU method might not be able to create a token bucket large enough to accommodate the unused credits. As a result, the average bandwidth limit is lower than what you configured. In this case, the 5 ms method is the better choice for configuring the burst size.

If a 200 Mbps bandwidth limit is configured with a 5 ms burst size, the calculation becomes **200 Mbps x 5 ms = 125 Kbytes**, which is approximately 83 1500-byte packets. If the 200 Mbps bandwidth limit is configured on a Gigabit Ethernet interface, the burst duration is **125000 bytes / 1 Gbps = 1 ms** at the Gigabit Ethernet line rate.

If a large burst size is configured at 600 ms with the bandwidth limit configured at 200 Mbps, the calculation becomes **200 Mbps x 600 ms = 15 Mbytes**. This creates a burst duration of 120 ms at the Gigabit Ethernet line rate. The average bandwidth rate in 1 second becomes **200 Mbps + 15 Mbytes = 320 Mbps**, which is much higher than the configured bandwidth limit at 200 Mbps. This example shows that a larger burst size can affect the measured bandwidth rate.

Single-Rate Two-Color Policer Overview

Single-rate two color policing enforces a configured rate of traffic flow for a particular service level by applying implicit or configured actions to traffic that does not conform to the limits. When you apply a single-rate two-color policer to the input or output traffic at an interface, the policer meters the traffic flow to the rate limit defined by the following components:

- **Bandwidth limit**—The average number of bits per second permitted for packets received or transmitted at the interface. You can specify the bandwidth limit as an absolute number of bits per second or as a percentage value from 1 through 100. If a percentage value is specified, the effective bandwidth limit is calculated as a percentage of either the physical interface media rate or the logical interface configured shaping rate.
- **Burst-size limit**—The maximum size permitted for bursts of data.

For a traffic flow that conforms to the configured limits (categorized as green traffic), packets are implicitly marked with a packet loss priority (PLP) level of **low** and are allowed to pass through the interface unrestricted.

For a traffic flow that exceeds the configured limits (categorized as red traffic), packets are handled according to the traffic-policing actions configured for the policer. The action might be to discard the packet, or the action might be to re-mark the packet with a specified forwarding class, a specified PLP, or both, and then transmit the packet.

To rate-limit Layer 3 traffic, you can apply a two-color policer in the following ways:

- Directly to a logical interface, at a specific protocol level.
- As the action of a standard stateless firewall filter that is applied to a logical interface, at a specific protocol level.

To rate-limit Layer 2 traffic, you can apply a two-color policer as a *logical interface policer* only. You cannot apply a two-color policer to Layer 2 traffic through a firewall filter.

Example: Configuring a Single-Rate Two-Color Policer

This example shows how to configure a single-rate two-color policer that you apply to a logical interface as a firewall filter action.

- [Requirements on page 4839](#)
- [Overview on page 4839](#)
- [Configuration on page 4839](#)
- [Verification on page 4844](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

To set the maximum burst size of the policer, you should know the line rate of the interface (preferred) or else the maximum transmission unit (MTU) of the traffic on the target interface.

Overview

In this example, you configure a single-rate two-color policer and then use an IPv4 firewall filter to apply the policer to all traffic except for BGP messages. You apply the firewall filter to the input and output of the same logical interface.

Topology

Assume that you know the traffic flow needs to be rate-limited to an average bandwidth of 9 Mbps. Also assume that you do not know the line rate of the target interface, but you do know that the MTU of traffic on the interface is 4700 bytes. As described in [“Determining Proper Burst Size for Traffic Policers” on page 4834](#), you can estimate a starting value of 10 times the MTU.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Logical Interface and Monitoring the Traffic Rate Without Policing on page 4840](#)
- [Configuring the Basic Single-Rate Two-Color Policer on page 4841](#)

- [Referencing the Policer from a Term in a Stateless Firewall Filter on page 4842](#)
- [Applying the Firewall Filter to the Input and Output of the Logical Interface on page 4843](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces so-1/3/0 unit 0 family inet address 10.39.1.1/16
set firewall policer p-9m-47k-discard if-exceeding bandwidth-limit 9m
set firewall policer p-9m-47k-discard if-exceeding burst-size-limit 47k
set firewall policer p-9m-47k-discard then discard
set firewall family inet filter rate-limit-in term t1 from protocol tcp
set firewall family inet filter rate-limit-in term t1 from port bgp
set firewall family inet filter rate-limit-in term t1 then accept
set firewall family inet filter rate-limit-in term t2 then policer p-9m-47k-discard
set firewall family inet filter rate-limit-in term t2 then accept
set interfaces so-1/3/0 unit 0 family inet filter input rate-limit-in
set interfaces so-1/3/0 unit 0 family inet filter output rate-limit-in
```

Configuring the Logical Interface and Monitoring the Traffic Rate Without Policing**Step-by-Step Procedure**

To configure the logical interface and monitor the traffic rate:

1. Configure IPv4 on the logical interface.

```
[edit]
user@host# edit interfaces so-1/3/0 unit 0 family inet address 10.39.1.1/16
```

2. Commit the configuration.

```
[edit]
user@host# commit
```

3. Monitor the traffic flow at the interface (press 'q' to terminate monitoring).

```
[edit]
user@host# run monitor interface so-1/3/0.0
```

The traffic statistics report the input and output rates before applying interface rate limiting.

Results

Confirm the configuration of the logical interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
so-3/3/0 {
  unit 0 {
    family inet {
      address 10.39.1.1/16
    }
  }
}
```

*Configuring the Basic Single-Rate Two-Color Policer***Step-by-Step
Procedure**

To configure the basic single-rate two-color policer:

1. Enable configuration of a single-rate two-color policer.

[edit]

user@host# edit **firewall policer** p-9m-47k-discard

**NOTE:**

This example illustrates a basic two-color policer, which does not require any of the following statements:

- **filter-specific**—You can include this statement so that, when this policer is applied as a firewall filter policer, a single instance of the policer is used by all terms within the same firewall filter.
- **logical-bandwidth-policer**—Include this statement only if the policer bandwidth limit is specified as a percentage value (using the **bandwidth-percent percent** statement) and you want the bandwidth limit to be based on the configured shaping rate for the target logical interface.
- **logical-interface-policer**—Include this statement only if you apply the policer directly to a physical or logical interface to rate-limit traffic for any configured protocol family based on the physical interface media rate.
- **physical-interface-policer**—Include this statement if you apply the policer to packets filtered by a standard stateless firewall filter term and you want the policer to meter the aggregate traffic (all protocol families and logical interfaces configured on the underlying physical interface).

2. Configure the policer to rate-limit to an average bandwidth of 9 Mbps and a burst size of 47 KB.

[edit firewall policer p-9m-47k-discard]

user@host# set **if-exceeding bandwidth-limit** 9m

user@host# set **if-exceeding burst-size-limit** 47k

For information about configuring the burst size, see [“Determining Proper Burst Size for Traffic Policers”](#) on page 4834.

When the traffic flow conforms to these limits, the flow is categorized as green. For a single-rate two-color policer, packets in a green flow are implicitly set to a **low** packet loss priority (PLP) level.

3. Configure the policer to discard packets in a red traffic flow.

[edit firewall policer p-9m-47k-discard]

user@host# set **then discard**

Instead of discarding the traffic that exceeds the traffic limits, you can set the PLP level, the forwarding class assignment, or both.

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer p-9m-47k-discard {
  if-exceeding {
    bandwidth-limit 9m;
    burst-size-limit 47k;
  }
  then discard;
}
```

Referencing the Policer from a Term in a Stateless Firewall Filter

Step-by-Step Procedure To reference the policer from a term in a stateless firewall filter:

1. Enable configuration of the stateless firewall filter.

```
[edit]
user@host# edit firewall family inet filter rate-limit-in
```

2. Configure the first term to accept all BGP traffic.

BGP messages are transported over TCP port 179.

```
[edit firewall family inet filter rate-limit-in]
user@host# set term t1 from protocol tcp
user@host# set term t1 from port bgp
user@host# set term t1 then accept
```

The BGP traffic is not rate-limited to avoid having the BGP session time out because the packet is discarded by the policer.

3. Configure the second term to rate-limit all other traffic using the policer.

```
[edit firewall family inet filter rate-limit-in]
user@host# set term t2 then policer p-9m-47k-discard
user@host# set term t2 then accept
```

Results Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter rate-limit-in {
    term t1 {
      from {
        protocol tcp;
        port bgp;
      }
    }
  }
}
```

```

        then accept;
    }
    term t2 {
        then {
            policer p-9m-47k-discard;
            accept;
        }
    }
}
policer p-9m-47k-discard {
    if-exceeding {
        bandwidth-limit 9m;
        burst-size-limit 47k;
    }
    then discard;
}

```

Applying the Firewall Filter to the Input and Output of the Logical Interface

Step-by-Step Procedure

To apply the stateless firewall filter to the input and output of the logical interface:

1. Enable configuration of IPv4 on the logical interface.

```

[edit]
user@host# edit interfaces so-1/3/0 unit 0 family inet

```

2. Apply the stateless firewall filter.

```

[edit interfaces so-1/3/0 unit 0 family inet]
user@host# set filter input rate-limit-in
user@host# set filter output rate-limit-in

```

Results

Confirm the configuration of the logical interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

[edit]
user@host# show interfaces
so-3/3/0 {
    unit 0 {
        family inet {
            filter {
                input rate-limit-in;
                output rate-limit-in;
            }
            address 10.39.1.1/16;
        }
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Monitoring and Adjusting Policing of the Logical Interface on page 4844](#)
- [Displaying the Number of Packets Processed by the Policer at the Logical Interface on page 4844](#)

Monitoring and Adjusting Policing of the Logical Interface

Purpose Ensure that the traffic limits configured in the policer are throttling the input and output rate as you intended.

Action To ensure that the configured traffic limits are throttling the traffic rate as intended:

1. Monitor the traffic flow at the interface (press 'q' to terminate monitoring).

[edit]

```
user@host# run monitor interface so-1/3/0.0
```

The traffic statistics report the input and output rate after applying interface rate limiting.

2. Adjust the burst-size limit if necessary.

If the policer appears to be throttling the input and output rate more than you intended, increase the burst size (possibly doubling it) and then check again.

Displaying the Number of Packets Processed by the Policer at the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show firewall** operational mode command for the filter you applied to the logical interface:

[edit]

```
user@host# run show firewall filter rate-limit-in
```

```
Filter: rate-limit-in
```

```
Policers:
```

Name	Packets
p-9m-47k-discard-t2	32863

The command output displays the name of policer (**p-9m-47k-discard**), the name of the filter term (**t2**) under which the policer action is specified, and the number of packets that matched the filter term. This is only the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.

Example: Configuring Interface and Firewall Filter Policers at the Same Interface

This example shows how to configure three single-rate two-color policers and apply the policers to the IPv4 input traffic at the same single-tag virtual LAN (VLAN) logical interface.

- [Requirements on page 4845](#)
- [Overview on page 4845](#)
- [Configuration on page 4846](#)
- [Verification on page 4852](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you configure three single-rate two-color policers and apply the policers to the IPv4 input traffic at the same single-tag VLAN logical interface. Two policers are applied to the interface through a firewall filter, and one policer is applied directly to the interface.

You configure one policer, named **p-all-1m-5k-discard**, to rate-limit traffic to 1 Mbps with a burst size of 5000 bytes. You apply this policer directly to IPv4 input traffic at the logical interface. When you apply a policer directly to protocol-specific traffic at a logical interface, the policer is said to be applied as an *interface policer*.

You configure the other two policers to allow burst sizes of 500 KB, and you apply these policers to IPv4 input traffic at the logical interface by using an IPv4 standard stateless firewall filter. When you apply a policer to protocol-specific traffic at a logical interface through a firewall filter action, the policer is said to be applied as a *firewall-filter policer*.

- You configure the policer named **p-icmp-500k-500k-discard** to rate-limit traffic to 500 Kbps with a burst size of 500 K bytes by discarding packets that do not conform to these limits. You configure one of the firewall filter terms to apply this policer to Internet Control Message Protocol (ICMP) packets.
- You configure the policer named **p-ftp-10p-500k-discard** to rate-limit traffic to a 10 percent bandwidth with a burst size of 500 KB by discarding packets that do not conform to these limits. You configure another firewall-filter term to apply this policer to File Transfer Protocol (FTP) packets.

A policer that you configure with a bandwidth limit expressed as a percentage value (rather than as an absolute bandwidth value) is called a *bandwidth policer*. Only single-rate two-color policers can be configured with a percentage bandwidth specification. By default, a bandwidth policer rate-limits traffic to the specified percentage of the line rate of the physical interface underlying the target logical interface.

Topology

You configure the target logical interface as a single-tag VLAN logical interface on a Fast Ethernet interface operating at 100 Mbps. This means that the policer you configure with

the 10-percent bandwidth-limit (the policer that you apply to FTP packets) rate-limits the FTP traffic on this interface to 10 Mbps.

NOTE: In this example, you do not configure the bandwidth policer as a *logical-bandwidth policer*. Therefore, the percentage is based on the physical media rate rather than on the configured shaping rate of the logical interface.

The firewall filter that you configure to reference two of the policers must be configured as an *interface-specific filter*. Because the policer that is used to rate-limit FTP packets specifies the bandwidth limit as a percentage value, the firewall filter that references this policer must be configured as an interface-specific filter. Thus, if this firewall filter were to be applied to multiple interfaces instead of just the Fast Ethernet interface in this example, unique policers and counters would be created for each interface to which the filter is applied.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Single-Tag VLAN Logical Interface on page 4847](#)
- [Configuring the Three Policers on page 4848](#)
- [Configuring the IPv4 Firewall Filter on page 4849](#)
- [Applying the Interface Policer and Firewall Filter Policers to the Logical Interface on page 4851](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces fe-0/1/1 vlan-tagging
set interfaces fe-0/1/1 unit 0 vlan-id 100
set interfaces fe-0/1/1 unit 0 family inet address 10.20.15.1/24
set interfaces fe-0/1/1 unit 1 vlan-id 101
set interfaces fe-0/1/1 unit 1 family inet address 10.20.240.1/24
set firewall policer p-all-1m-5k-discard if-exceeding bandwidth-limit 1m
set firewall policer p-all-1m-5k-discard if-exceeding burst-size-limit 5k
set firewall policer p-all-1m-5k-discard then discard
set firewall policer p-ftp-10p-500k-discard if-exceeding bandwidth-percent 10
set firewall policer p-ftp-10p-500k-discard if-exceeding burst-size-limit 500k
set firewall policer p-ftp-10p-500k-discard then discard
set firewall policer p-icmp-500k-500k-discard if-exceeding bandwidth-limit 500k
set firewall policer p-icmp-500k-500k-discard if-exceeding burst-size-limit 500k
set firewall policer p-icmp-500k-500k-discard then discard
set firewall family inet filter filter-ipv4-with-limits interface-specific
set firewall family inet filter filter-ipv4-with-limits term t-ftp from protocol tcp
set firewall family inet filter filter-ipv4-with-limits term t-ftp from port ftp
set firewall family inet filter filter-ipv4-with-limits term t-ftp from port ftp-data
```

```

set firewall family inet filter filter-ipv4-with-limits term t-ftp then policer
  p-ftp-10p-500k-discard
set firewall family inet filter filter-ipv4-with-limits term t-icmp from protocol icmp
set firewall family inet filter filter-ipv4-with-limits term t-icmp then policer
  p-icmp-500k-500k-discard
set firewall family inet filter filter-ipv4-with-limits term catch-all then accept
set interfaces fe-0/1/1 unit 1 family inet filter input filter-ipv4-with-limits
set interfaces fe-0/1/1 unit 1 family inet policer input p-all-1m-5k-discard

```

Configuring the Single-Tag VLAN Logical Interface

Step-by-Step Procedure To configure the single-tag VLAN logical interface:

1. Enable configuration of the Fast Ethernet interface.

```

[edit]
user@host# edit interfaces fe-0/1/1

```
2. Enable single-tag VLAN framing.

```

[edit interfaces fe-0/1/1]
user@host# set vlan-tagging

```
3. Bind VLAN IDs to the logical interfaces.

```

[edit interfaces fe-0/1/1]
user@host# set unit 0 vlan-id 100
user@host# set unit 1 vlan-id 101

```
4. Configure IPv4 on the single-tag VLAN logical interfaces.

```

[edit interfaces fe-0/1/1]
user@host# set unit 0 family inet address 10.20.15.1/24
user@host# set unit 1 family inet address 10.20.240.1/24

```

Results Confirm the configuration of the VLAN by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

[edit]
user@host# show interfaces
fe-0/1/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 10.20.15.1/24;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      address 10.20.240.1/24;
    }
  }
}

```

Configuring the Three Policers

Step-by-Step Procedure

To configure the three policers:

1. Enable configuration of a two-color policer that discards packets that do not conform to a bandwidth of 1 Mbps and a burst size of 5000 bytes.

NOTE: You apply this policer directly to all IPv4 input traffic at the single-tag VLAN logical interface, so the packets will not be filtered before being subjected to rate limiting.

[edit]

user@host# edit **firewall policer p-all-1m-5k-discard**

2. Configure the first policer.

[edit firewall policer p-all-1m-5k-discard]

user@host# set **if-exceeding bandwidth-limit 1m**

user@host# set **if-exceeding burst-size-limit 5k**

user@host# set then discard

3. Enable configuration of a two-color policer that discards packets that do not conform to a bandwidth specified as "10 percent" and a burst size of 500,000 bytes.

You apply this policer only to the FTP traffic at the single-tag VLAN logical interface.

You apply this policer as the action of an IPv4 firewall filter term that matches FTP packets from TCP.

[edit firewall policer p-all-1m-5k-discard]

user@host# up

[edit]

user@host# edit **firewall policer p-ftp-10p-500k-discard**

4. Configure policing limits and actions.

[edit firewall policer p-ftp-10p-500k-discard]

user@host# set **if-exceeding bandwidth-percent 10**

user@host# set **if-exceeding burst-size-limit 500k**

user@host# set then discard

Because the bandwidth limit is specified as a percentage, the firewall filter that references this policer must be configured as an interface-specific filter.

NOTE: If you wanted this policer to rate-limit to 10 percent of the logical interface configured shaping rate (rather than to 10 percent of the physical interface media rate), you would need to include the **logical-bandwidth-policer** statement at the [edit firewall policer p-all-1m-5k-discard] hierarchy level. This type of policer is called a *logical-bandwidth policer*.

5. Enable configuration of the IPv4 firewall filter policer for ICMP packets.

```
[edit firewall policer p-ftp-10p-500k-discard]
user@host# up

[edit]
user@host# edit firewall policer p-icmp-500k-500k-discard
```

6. Configure policing limits and actions.

```
[edit firewall policer p-icmp-500k-500k-discard]
user@host# set if-exceeding bandwidth-limit 500k
user@host# set if-exceeding burst-size-limit 500k
user@host# set then discard
```

Results Confirm the configuration of the policers by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer p-all-1m-5k-discard {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 5k;
  }
  then discard;
}
policer p-ftp-10p-500k-discard {
  if-exceeding {
    bandwidth-percent 10;
    burst-size-limit 500k;
  }
  then discard;
}
policer p-icmp-500k-500k-discard {
  if-exceeding {
    bandwidth-limit 500k;
    burst-size-limit 500k;
  }
  then discard;
}
```

Configuring the IPv4 Firewall Filter

Step-by-Step Procedure To configure the IPv4 firewall filter:

1. Enable configuration of the IPv4 firewall filter.

```
[edit]
user@host# edit firewall family inet filter filter-ipv4-with-limits
```

2. Configure the firewall filter as interface-specific.

```
[edit firewall family inet filter filter-ipv4-with-limits]
user@host# set interface-specific
```

The firewall filter must be interface-specific because one of the policers referenced is configured with a bandwidth limit expressed as a percentage value.

3. Enable configuration of a filter term to rate-limit FTP packets.

```
[edit firewall family inet filter filter-ipv4-with-limits]
user@host# edit term t-ftp
```

```
[edit firewall family inet filter filter-ipv4-with-limits term t-ftp]
user@host# set from protocol tcp
user@host# set from port [ ftp ftp-data ]
```

FTP messages are sent over TCP port 20 (**ftp**) and received over TCP port 21 (**ftp-data**).

4. Configure the filter term to match FTP packets.

```
[edit firewall family inet filter filter-ipv4-with-limits term t-ftp]
user@host# set then policer p-ftp-10p-500k-discard
```

5. Enable configuration of a filter term to rate-limit ICMP packets.

```
[edit firewall family inet filter filter-ipv4-with-limits term t-ftp]
user@host# up
```

```
[edit firewall family inet filter filter-ipv4-with-limits]
user@host# edit term t-icmp
```

6. Configure the filter term for ICMP packets

```
[edit firewall family inet filter filter-ipv4-with-limits term t-icmp]
user@host# set from protocol icmp
user@host# set then policer p-icmp-500k-500k-discard
```

7. Configure a filter term to accept all other packets without policing.

```
[edit firewall family inet filter filter-ipv4-with-limits term t-icmp]
user@host# up
```

```
[edit firewall family inet filter filter-ipv4-with-limits]
user@host# set term catch-all then accept
```

Results Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter-ipv4-with-limits {
    interface-specific;
    term t-ftp {
      from {
        protocol tcp;
        port [ ftp ftp-data ];
      }
      then policer p-ftp-10p-500k-discard;
    }
  }
}
```

```

term t-icmp {
    from {
        protocol icmp;
    }
    then policer p-icmp-500k-500k-discard;
}
term catch-all {
    then accept;
}
}
}
policer p-all-1m-5k-discard {
    if-exceeding {
        bandwidth-limit 1m;
        burst-size-limit 5k;
    }
    then discard;
}
policer p-ftp-10p-500k-discard {
    if-exceeding {
        bandwidth-percent 10;
        burst-size-limit 500k;
    }
    then discard;
}
policer p-icmp-500k-500k-discard {
    if-exceeding {
        bandwidth-limit 500k;
        burst-size-limit 500k;
    }
    then discard;
}
}

```

Applying the Interface Policer and Firewall Filter Policers to the Logical Interface

Step-by-Step Procedure

To apply the three policers to the VLAN:

1. Enable configuration of IPv4 on the logical interface.

```
[edit]
user@host# edit interfaces fe-0/1/1 unit 1 family inet
```
2. Apply the firewall filter policers to the interface.

```
[edit interfaces fe-0/1/1 unit 1 family inet]
user@host# set filter input filter-ipv4-with-limits
```
3. Apply the interface policer to the interface.

```
[edit interfaces fe-0/1/1 unit 1 family inet]
user@host# set policer input p-all-1m-5k-discard
```

Input packets at **fe-0/1/1.0** are evaluated against the interface policer before they are evaluated against the firewall filter policers. For more information, see [“Order of Policer and Firewall Filter Operations” on page 4810](#).

Results Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
fe-0/1/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 10.20.15.1/24;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      filter {
        input filter-ipv4-with-limits;
      }
      policer {
        input p-all-1m-5k-discard;
      }
      address 10.20.240.1/24;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying Policers Applied Directly to the Logical Interface on page 4852](#)
- [Displaying Statistics for the Policer Applied Directly to the Logical Interface on page 4853](#)
- [Displaying the Policers and Firewall Filters Applied to an Interface on page 4853](#)
- [Displaying Statistics for the Firewall Filter Policers on page 4854](#)

Displaying Policers Applied Directly to the Logical Interface

Purpose Verify that the interface policer is evaluated when packets are received on the logical interface.

Action Use the **show interfaces policers** operational mode command for logical interface **fe-0/1/1.1**. The command output section for the **Proto** column and **Input Policer** column shows that the policer **p-all-1m-5k-discard** is evaluated when packets are received on the logical interface.

```
user@host> show interfaces policers fe-0/1/1.1
Interface      Admin Link Proto Input Policer      Output Policer
fe-0/1/1.1     up    up
```

```
inet p-all-1m-5k-discard-fe-0/1/1.1-inet-i
```

In this example, the interface policer is applied to logical interface traffic in the input direction only.

Displaying Statistics for the Policer Applied Directly to the Logical Interface

Purpose Verify the number of packets evaluated by the interface policer.

Action Use the `show policer` operational mode command and optionally specify the name of the policer. The command output displays the number of packets evaluated by each configured policer (or the specified policer), in each direction.

```
user@host> show policer p-all-1m-5k-discard-fe-0/1/1.1-inet-i
Policers:
Name                                     Bytes      Packets
p-all-1m-5k-discard-fe-0/1/1.1-inet-i    200         5
```

Displaying the Policers and Firewall Filters Applied to an Interface

Purpose Verify that the firewall filter `filter-ipv4-with-limits` is applied to the IPv4 input traffic at logical interface `fe-0/1/1.1`.

Action Use the `show interfaces statistics` operational mode command for logical interface `fe-0/1/1.1`, and include the `detail` option. Under the **Protocol inet** section of the command output section, the **Input Filters** and **Policer** lines display the names of filter and policer applied to the logical interface in the input direction.

```
user@host> show interfaces statistics fe-0/1/1.1 detail
Logical interface fe-0/1/1.1 (Index 83) (SNMP ifIndex 545) (Generation 153)
Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x8100.100 ] Encapsulation: ENET2
Traffic statistics:
  Input bytes : 0
  Output bytes : 46
  Input packets: 0
  Output packets: 1
Local statistics:
  Input bytes : 0
  Output bytes : 46
  Input packets: 0
  Output packets: 1
Transit statistics:
  Input bytes : 0 0 bps
  Output bytes : 0 0 bps
  Input packets: 0 0 pps
  Output packets: 0 0 pps
Protocol inet, MTU: 1500, Generation: 176, Route table: 0
Flags: Sendbcst-pkt-to-re
Input Filters: filter-ipv4-with-limits-fe-0/1/1.1-i
Policer: Input: p-all-1m-5k-discard-fe-0/1/1.1-inet-i
Addresses, Flags: Is-Preferred Is-Primary
Destination: 10.20.130/24, Local: 10.20.130.1, Broadcast: 10.20.130.255,
```

Generation: 169

In this example, the two firewall filter policers are applied to logical interface traffic in the input direction only.

Displaying Statistics for the Firewall Filter Policers

Purpose Verify the number of packets evaluated by the firewall filter policers.

Action Use the **show firewall** operational mode command for the filter you applied to the logical interface.

[edit]

```
user@host> show firewall filter filter-ipv4-with-limits-fe-0/1/1.1-i
```

Filter: filter-ipv4-with-limits-fe-0/1/1.1-i

Policers:

Name	Bytes	Packets
p-ftp-10p-500k-discard-t-ftp-fe-0/1/1.1-i	0	0
p-icmp-500k-500k-discard-t-icmp-fe-0/1/1.1-i	0	0

The command output displays the names of the policers (**p-ftp-10p-500k-discard** and **p-icmp-500k-500k-discard**), combined with the names of the filter terms (**t-ftp** and **t-icmp**, respectively) under which the policer action is specified. The policer-specific output lines display the number of packets that matched the filter term. This is only the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.

Bandwidth Policer Overview

For a single-rate two-color policer only, you can specify the bandwidth limit as a percentage value from 1 through 100 instead of as an absolute number of bits per second. This type of two-color policer, called a *bandwidth policer*, rate-limits traffic to a bandwidth limit that is calculated as a percentage of either the physical interface media rate or the logical interface configured shaping rate.

Guidelines for Configuring a Bandwidth Policer

The following guidelines apply to configuring a bandwidth policer:

- To specify a percentage bandwidth limit, you include the **bandwidth-percent *percentage*** statement in place of the **bandwidth-limit *bps*** statement.
- By default, a bandwidth policer calculates the percentage bandwidth limit based on the physical interface port speed. To configure a bandwidth policer to calculate the percentage bandwidth limit based on the configured logical interface shaping rate instead, include the **logical-bandwidth-policer** statement at the **[edit firewall policer *policer-name*]** hierarchy level. This type of bandwidth policer is called a *logical bandwidth policer*.

You can configure a logical interface shaping rate by including the **shaping-rate *bps*** statement at the **[edit class-of-service interfaces interface *interface-name* unit *logical-unit-number*]** hierarchy level. A logical interface shaping rate causes the specified amount of bandwidth to be allocated to the logical interface.

NOTE: If you configure a logical-bandwidth policer and then apply the policer to a logical interface that is not configured with a shaping rate, then the policer rate-limits traffic on that logical interface to calculate the percentage bandwidth limit based on the physical interface port speed, even if you include the **logical-bandwidth-policer** statement in the bandwidth policer configuration.

- If you reference a bandwidth policer from a stateless firewall filter term, you must include the **interface-specific** statement in the firewall filter configuration.

Guidelines for Applying a Bandwidth Policer

The following guidelines pertain to applying a bandwidth policer to traffic:

- You can use a bandwidth policer to rate-limit protocol-specific traffic (not **family any**) at the input or output of a logical interface.
- You can apply a bandwidth policer directly to protocol-specific input or output traffic at a logical interface.
- To send only selected packets to a bandwidth policer, you can reference the bandwidth policer from a stateless firewall filter term and then apply the filter to logical interface traffic for a specific protocol family.
 - To reference a *logical bandwidth policer* from a firewall filter, you must include the **interface-specific** statement in the firewall filter configuration.
 - You cannot use a bandwidth policer for forwarding-table filters.
- You cannot apply a bandwidth policer to an aggregate interface, a tunnel interface, or a software interface.

Example: Configuring a Logical Bandwidth Policer

This example shows how to configure a logical bandwidth policer.

- [Requirements on page 4856](#)
- [Overview on page 4856](#)
- [Configuration on page 4857](#)
- [Verification on page 4861](#)

Requirements

Before you begin, make sure that you have two logical units available on a Gigabit Ethernet interface.

Overview

In this example, you configure a single-rate two-color policer that specifies the bandwidth limit as a percentage value rather than as an absolute number of bits per second. This type of policer is called a *bandwidth policer*. By default, a bandwidth policer enforces a bandwidth limit based on the line rate of the underlying physical interface. As an option, you can configure a bandwidth policer to enforce a bandwidth limit based on the configured shaping rate of the logical interface. To configure this type of bandwidth policer, called a *logical bandwidth policer*, you include the [logical-bandwidth-policer](#) statement in the policer configuration.

To configure a logical interface shaping rate, include the **shaping-rate bps** statement at the **[edit class-of-service interfaces interface *interface-name* unit *logical-unit-number*]** hierarchy level. This class-of-service (CoS) configuration statement causes the specified amount of bandwidth to be allocated to the logical interface.

NOTE: If you configure a policer bandwidth limit as a percentage but a shaping rate is not configured for the target logical interface, the policer bandwidth limit is calculated as a percentage of the physical interface media rate, even if you enable the logical-bandwidth policing feature.

To apply a logical bandwidth policer to a logical interface, you can apply the policer directly to the logical interface at the protocol family level or (if you only need to rate-limit filtered packets) you can reference the policer from a stateless firewall filter configured to operate in *interface-specific* mode.

Topology

In this example, you configure two logical interfaces on a single Gigabit Ethernet interface and configure a shaping rate on each logical interface. On logical interface **ge-1/3/0.0**, you allocate 4 Mbps of bandwidth. On logical interface **ge-1/3/0.1**, you allocate 2 Mbps of bandwidth.

You also configure a logical bandwidth policer with a bandwidth limit of 50 percent and a maximum burst size of 125,000 bytes, and then you apply the policer to input and output traffic at the logical units configured on **ge-1/3/0.0**. For logical interface **ge-1/3/0.0**,

the policer rate-limits to a bandwidth limit of 2 Mbps (50 percent of the 4 Mbps shaping rate configured for the logical interface). For logical interface **ge-1/3/0.1**, the policer rate-limits traffic to a bandwidth limit of 1 Mbps (50 percent of the 2 Mbps shaping rate configured for the logical interface).

If no shaping rate is configured for a target logical interface, the policer rate-limits to a bandwidth limit calculated as 50 percent of the physical interface media rate. For example, if you apply a 50 percent bandwidth policer to input or output traffic at a Gigabit Ethernet logical interface without rate shaping, the policer applies a bandwidth limit of 500 Mbps (50 percent of 1000 Mbps).

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Logical Interfaces on page 4857](#)
- [Configuring Traffic Rate-Shaping by Specifying the Amount of Bandwidth to be Allocated to the Logical Interface on page 4858](#)
- [Configuring the Logical Bandwidth Policar on page 4859](#)
- [Applying the Logical Bandwidth Policers to the Logical Interfaces on page 4860](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-1/3/0 per-unit-scheduler
set interfaces ge-1/3/0 vlan-tagging
set interfaces ge-1/3/0 unit 0 vlan-id 100
set interfaces ge-1/3/0 unit 0 family inet address 172.1.1.1/30
set interfaces ge-1/3/0 unit 1 vlan-id 200
set interfaces ge-1/3/0 unit 1 family inet address 172.2.1.1/30
set class-of-service interfaces ge-1/3/0 unit 0 shaping-rate 4m
set class-of-service interfaces ge-1/3/0 unit 1 shaping-rate 2m
set firewall policer LB-policer logical-bandwidth-policer
set firewall policer LB-policer if-exceeding bandwidth-percent 50
set firewall policer LB-policer if-exceeding burst-size-limit 125k
set firewall policer LB-policer then discard
set interfaces ge-1/3/0 unit 0 family inet policer input LB-policer
set interfaces ge-1/3/0 unit 0 family inet policer output LB-policer
set interfaces ge-1/3/0 unit 1 family inet policer input LB-policer
set interfaces ge-1/3/0 unit 1 family inet policer output LB-policer
```

Configuring the Logical Interfaces

Step-by-Step Procedure

To configure the logical interfaces:

1. Enable configuration of the physical interface.

```
[edit]
user@host# edit interfaces ge-1/3/0
```

```
[edit interfaces ge-1/3/0]
user@host# set per-unit-scheduler
user@host# set vlan-tagging
```

2. Configure the first logical interface.

```
[edit interfaces ge-1/3/0]
user@host# set unit 0 vlan-id 100
user@host# set unit 0 family inet address 172.1.1.1/30
```

3. Configure the second logical interface.

```
[edit interfaces ge-1/3/0]
user@host# set unit 1 vlan-id 200
user@host# set unit 1 family inet address 172.2.1.1/30
```

Results Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/0 {
  per-unit-scheduler;
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 172.1.1.1/30;
    }
  }
  unit 1 {
    vlan-id 200;
    family inet {
      address 172.2.1.1/30;
    }
  }
}
```

Configuring Traffic Rate-Shaping by Specifying the Amount of Bandwidth to be Allocated to the Logical Interface

Step-by-Step Procedure To configure rate shaping by specifying the bandwidth to be allocated to the logical interface:

1. Enable CoS configuration on the physical interface.

```
[edit]
user@host# edit class-of-service interfaces ge-1/3/0
```

2. Configure rate shaping for the logical interfaces.

```
[edit]
user@host# set unit 0 shaping-rate 4m
user@host# set unit 1 shaping-rate 2m
```

These statements allocate 4 Mbps of bandwidth to logical unit **ge-1/3/0.0** and 2 Mbps of bandwidth to logical unit **ge-1/3/0.1**.

Results Confirm the configuration of the rate shaping by entering the **show class-of-service** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show class-of-service
interfaces {
  ge-1/3/0 {
    unit 0 {
      shaping-rate 4m;
    }
    unit 1 {
      shaping-rate 2m;
    }
  }
}
```

Configuring the Logical Bandwidth Policer

Step-by-Step Procedure To configure the logical bandwidth policer:

1. Enable configuration of a single-rate two-color policer.

```
[edit]
user@host# edit firewall policer LB-policer
```

2. Configure the policer as a logical-bandwidth policer.

```
[edit firewall policer LB-policer]
user@host# set logical-bandwidth-policer
```

This applies the rate-limiting to logical interfaces.

3. Configure the policer traffic limits and actions.

```
[edit firewall policer LB-policer]
user@host# set if-exceeding bandwidth-percent 50
user@host# set if-exceeding burst-size-limit 125k
user@host# set then discard
```

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer LB-policer {
  logical-bandwidth-policer;
  if-exceeding {
    bandwidth-percent 50;
    burst-size-limit 125k;
  }
  then discard;
```

```
}
```

Applying the Logical Bandwidth Policers to the Logical Interfaces

Step-by-Step Procedure

To configure the logical bandwidth policers to the logical interfaces:

1. Enable configuration of the interface.

```
[edit]
user@host# edit interfaces ge-1/3/0
```

2. Apply the logical bandwidth policer to the first logical interface.

```
[edit interfaces ge-1/3/0]
user@host# set unit 0 family inet policer input LB-policer
user@host# set unit 0 family inet policer output LB-policer
```

3. Apply the policing to the second logical interface.

```
[edit interfaces ge-1/3/0]
user@host# set unit 1 family inet policer input LB-policer
user@host# set unit 1 family inet policer output LB-policer
```

Results Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/0 {
  per-unit-scheduler;
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      policer {
        input LB-policer;
        output LB-policer;
      }
    }
    address 172.1.1.1/30;
  }
}
unit 1 {
  vlan-id 200;
  family inet {
    policer {
      input LB-policer;
      output LB-policer;
    }
  }
  address 172.2.1.1/30;
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying Traffic Statistics and Policers for the Logical Interface on page 4861](#)
- [Displaying Statistics for the Policer on page 4862](#)

Displaying Traffic Statistics and Policers for the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show interfaces** operational mode command for logical interfaces **ge-1/3/0.0** and **ge-1/3/0.1**, and include the **detail** or **extensive** option. The command output section for **Traffic statistics** lists the number of bytes and packets received and transmitted on the logical interface, and the **Protocol inet** section contains a **Policer** field that lists the policer **LB-policer** as an input or output policer as follows:

- **Input:** LB-policer-ge-1/3/0.0-inet-i
- **Output:** LB-policer-ge-1/3/0.0-inet-o

In this example, the policer is applied to logical interface traffic in both the input and output directions.

```
user@host> show interfaces ge-1/3/0.0 detail
Logical interface ge-1/3/0.0 (Index 80) (SNMP ifIndex 154) (Generation 150)
  Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x8100.100 ] Encapsulation: ENET2

```

Displaying Statistics for the Policer

Purpose Verify the number of packets evaluated by the policer.

Action Use the [show policer](#) operational mode command and optionally specify the name of the policer. The command output displays the number of packets evaluated by each configured policer (or the specified policer), in each direction. For the policer **LB-policer**, the input and output policer names are displayed as follows:

- **LB-policer-ge-1/3/0.0-inet-i**
- **LB-policer-ge-1/3/0.0-inet-o**
- **LB-policer-ge-1/3/0.1-inet-i**
- **LB-policer-ge-1/3/0.1-inet-o**

The **-inet-i** suffix denotes a policer applied to logical interface input traffic, while the **-inet-o** suffix denotes a policer applied to logical interface output traffic. In this example, the policer is applied to both input and output traffic on logical interface **ge-1/3/0.0** and logical interface **ge-1/3/0.1**.

```

user@host> show policer
Policers:
Name                                     Packets
__default_arp_policer__                 0
LB-policer-ge-1/3/0.0-inet-i            0
LB-policer-ge-1/3/0.0-inet-o            0
LB-policer-ge-1/3/0.1-inet-i            0
LB-policer-ge-1/3/0.1-inet-o            0

```

Filter-Specific Policer Overview

By default, a policer operates in *term-specific* mode so that, for a given firewall filter, the Junos OS creates a separate policer instance for every filter term that references the policer. As an option, you can configure a policer to operate in *filter-specific* mode so that a single policer instance is used by all terms (within the same firewall filter) that reference the policer.

For an IPv4 firewall filter with multiple terms that reference the same policer, configuring the policer to operate in filter-specific mode enables you to count and monitor the activity of the policer at the firewall filter level.

NOTE: Term-specific mode and filter-specific mode also apply to prefix-specific policer sets.

To enable a single-rate two-color policer to operate in filter-specific mode, you can include the **filter-specific** statement at the following hierarchy levels:

- **[edit firewall policer *policer-name*]**
- **[edit logical-systems *logical-system-name* firewall policer *policer-name*]**

You can reference filter-specific policers from IPv4 (**family inet**) firewall filters only.

Example: Configuring a Stateless Firewall Filter to Protect Against TCP and ICMP Floods

This example shows how to create a stateless firewall filter that protects against TCP and ICMP denial-of-service attacks.

- [Requirements on page 4863](#)
- [Overview on page 4864](#)
- [Configuration on page 4865](#)
- [Verification on page 4869](#)

Requirements

No special configuration beyond device initialization is required before configuring stateless firewall filters.

Overview

In this example, you create a stateless firewall filter called **protect-RE** that polices TCP and ICMP packets. This example includes the following policers:

- **tcp-connection-policer**—Limits the traffic rate of the TCP packets to 500,000 bps and the burst size to 15,000 bytes. Packets that exceed the traffic rate are discarded.
- **icmp-policer**—Limits the traffic rate of the ICMP packets to 1,000,000 bps and the burst size to 15,000 bytes. Packets that exceed the traffic rate are discarded.

When specifying limits, the bandwidth limit can be from 32,000 bps to 32,000,000,000 bps and the burst-size limit can be from 1,500 bytes through 100,000,000 bytes. Use the following abbreviations when specifying limits: k (1,000), m (1,000,000), and g (1,000,000,000).

Each policer is incorporated into the action of a filter term. This example includes the following terms:

- **tcp-connection-term**—Policies certain TCP packets with a source address of 192.168.0.0/24 or 10.0.0.0/24. These addresses are defined in the **trusted-addresses** prefix list.

Filtered packets include **tcp-established** packets. The **tcp-established** match condition is an alias for the bit-field match condition **tcp-flags "(ack | rst)"**, which indicates an established TCP session, but not the first packet of a TCP connection.

- **icmp-term**—Policies ICMP packets. All ICMP packets are counted in the **icmp-counter** counter.

NOTE: You can move terms within the firewall filter by using the **insert** command. See *insert* in the *CLI User Guide*.

You can apply a stateless firewall to the input or output sides, or both, of an interface. To filter packets transiting the device, apply the firewall filter to any non-Routing Engine interface. To filter packets originating from, or destined for, the Routing Engine, apply the firewall filter to the loopback (lo0) interface.

Figure 95 on page 4601 shows the sample network.

Figure 109: Firewall Filter to Protect Against TCP and ICMP Floods

Because this firewall filter limits Routing Engine traffic to TCP packets, routing protocols that use other transport protocols for Layer 4 cannot successfully establish sessions when this filter is active. To demonstrate, this example sets up OSPF between Device R1 and Device R2.

“CLI Quick Configuration” on page 4602 shows the configuration for all of the devices in Figure 95 on page 4601.

The section “Step-by-Step Procedure” on page 4603 describes the steps on Device R2.

Configuration

CLI Quick Configuration To quickly configure the stateless firewall filter, copy the following commands to a text file, remove any line breaks, and then paste the commands into the CLI.

Device R1

```

set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.1/30
set interfaces lo0 unit 0 family inet address 192.168.0.1/32 primary
set interfaces lo0 unit 0 family inet address 172.16.0.1/32
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext peer-as 200
set protocols bgp group ext neighbor 10.0.0.2
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set policy-options policy-statement send-direct term 1 from protocol direct
set policy-options policy-statement send-direct term 1 then accept
set routing-options router-id 192.168.0.1
set routing-options autonomous-system 100

```

Device R2

```

set interfaces fe-1/2/0 unit 0 family inet address 10.0.0.2/30
set interfaces lo0 unit 0 family inet filter input protect-RE
set interfaces lo0 unit 0 family inet address 192.168.0.2/32 primary
set interfaces lo0 unit 0 family inet address 172.16.0.2/32
set protocols bgp group ext type external
set protocols bgp group ext export send-direct
set protocols bgp group ext neighbor 10.0.0.1 peer-as 100
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-1/2/0.0
set policy-options prefix-list trusted-addresses 10.0.0.0/24
set policy-options prefix-list trusted-addresses 192.168.0.0/24
set policy-options policy-statement send-direct term 1 from protocol direct

```

```
set policy-options policy-statement send-direct term 1 then accept
set routing-options router-id 192.168.0.2
set routing-options autonomous-system 200
set firewall family inet filter protect-RE term tcp-connection-term from source-prefix-list
trusted-addresses
set firewall family inet filter protect-RE term tcp-connection-term from protocol tcp
set firewall family inet filter protect-RE term tcp-connection-term from tcp-established
set firewall family inet filter protect-RE term tcp-connection-term then policer
tcp-connection-policer
set firewall family inet filter protect-RE term tcp-connection-term then accept
set firewall family inet filter protect-RE term icmp-term from source-prefix-list
trusted-addresses
set firewall family inet filter protect-RE term icmp-term from protocol icmp
set firewall family inet filter protect-RE term icmp-term then policer icmp-policer
set firewall family inet filter protect-RE term icmp-term then count icmp-counter
set firewall family inet filter protect-RE term icmp-term then accept
set firewall policer tcp-connection-policer filter-specific
set firewall policer tcp-connection-policer if-exceeding bandwidth-limit 1m
set firewall policer tcp-connection-policer if-exceeding burst-size-limit 15k
set firewall policer tcp-connection-policer then discard
set firewall policer icmp-policer filter-specific
set firewall policer icmp-policer if-exceeding bandwidth-limit 1m
set firewall policer icmp-policer if-exceeding burst-size-limit 15k
set firewall policer icmp-policer then discard
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure stateless firewall filter policers:

1. Configure the device interfaces.

```
[edit interfaces fe-1/2/0 unit 0 family inet ]
user@R2# set address 10.0.0.2/30
```

```
[edit interfaces lo0 unit 0 family inet]
user@R2# set address 192.168.0.2/32 primary
user@R2# set address 172.16.0.2/32
```

2. Configure the BGP peering session.

```
[edit protocols bgp group ext]
user@R2# set type external
user@R2# set export send-direct
user@R2# set neighbor 10.0.0.1 peer-as 100
```

3. Configure the autonomous system (AS) number and router ID.

```
[edit routing-options]
user@R2# set autonomous-system 200
user@R2# set router-id 192.168.0.2
```

4. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@R2# set interface lo0.0 passive
```

```
user@R2# set interface fe-1/2/0.0
```

5. Define the list of trusted addresses.

```
[edit policy-options prefix-list trusted-addresses]
user@R2# set 10.0.0.0/24
user@R2# set 192.168.0.0/24
```

6. Configure a policy to advertise direct routes.

```
[edit policy-options policy-statement send-direct term 1]
user@R2# set from protocol direct
user@R2# set then accept
```

7. Configure the TCP policer.

```
[edit firewall policer tcp-connection-policer]
user@R2# set filter-specific
user@R2# set if-exceeding bandwidth-limit 1m
user@R2# set if-exceeding burst-size-limit 15k
user@R2# set then discard
```

8. Create the ICMP policer.

```
[edit firewall policer icmp-policer]
user@R2# set filter-specific
user@R2# set if-exceeding bandwidth-limit 1m
user@R2# set if-exceeding burst-size-limit 15k
user@R2# set then discard
```

9. Configure the TCP filter rules.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# set from source-prefix-list trusted-addresses
user@R2# set from protocol tcp
user@R2# set from tcp-established
user@R2# set then policer tcp-connection-policer
user@R2# set then accept
```

10. Configure the ICMP filter rules.

```
[edit firewall family inet filter protect-RE term icmp-term]
user@R2# set from source-prefix-list trusted-addresses
user@R2# set from protocol icmp
user@R2# set then policer icmp-policer
user@R2# set then count icmp-counter
user@R2# set then accept
```

11. Apply the filter to the loopback interface.

```
[edit interfaces lo0 unit 0]
user@R2# set family inet filter input protect-RE
```

Results Confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-options**, and **show firewall** commands from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
```

```
fe-1/2/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      filter {
        input protect-RE;
      }
      address 192.168.0.2/32 {
        primary;
      }
      address 172.16.0.2/32;
    }
  }
}

user@R2# show protocols
bgp {
  group ext {
    type external;
    export send-direct;
    neighbor 10.0.0.1 {
      peer-as 100;
    }
  }
}
ospf {
  area 0.0.0.0 {
    interface lo0.0 {
      passive;
    }
    interface fe-1/2/0.0;
  }
}

user@R2# show policy-options
prefix-list trusted-addresses {
  10.0.0.0/24;
  192.168.0.0/24;
}
policy-statement send-direct {
  term 1 {
    from protocol direct;
    then accept;
  }
}

user@R2# show routing-options
router-id 192.168.0.2;
autonomous-system 200;

user@R2# show firewall
```

```

family inet {
  filter protect-RE {
    term tcp-connection-term {
      from {
        source-prefix-list {
          trusted-addresses;
        }
        protocol tcp;
        tcp-established;
      }
      then {
        policer tcp-connection-policer;
        accept;
      }
    }
    term icmp-term {
      from {
        source-prefix-list {
          trusted-addresses;
        }
        protocol icmp;
      }
      then {
        policer icmp-policer;
        count icmp-counter;
        accept;
      }
    }
  }
}
policer tcp-connection-policer {
  filter-specific;
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 15k;
  }
  then discard;
}
policer icmp-policer {
  filter-specific;
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 15k;
  }
  then discard;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

NOTE: To verify the TCP policer, you can use a packet generation tool. This task is not shown here.

- [Displaying Stateless Firewall Filter That Are in Effect on page 4870](#)
- [Using telnet to Verify the tcp-established Condition in the TCP Firewall Filter on page 4870](#)
- [Using telnet to Verify the Trusted Prefixes Condition in the TCP Firewall Filter on page 4871](#)
- [Using OSPF to Verify the TCP Firewall Filter on page 4872](#)
- [Verifying the ICMP Firewall Filter on page 4873](#)

Displaying Stateless Firewall Filter That Are in Effect

Purpose Verify the configuration of the firewall filter.

Action From operational mode, enter the **show firewall** command.

```
user@R2> show firewall
Filter: protect-RE
Counters:
Name                               Bytes      Packets
icmp-counter                        0           0
Policers:
Name                               Bytes      Packets
icmp-policer                       0           0
tcp-connection-policer             0           0
```

Meaning The output shows the filter, the counter, and the policers that are in effect on Device R2.

Using telnet to Verify the tcp-established Condition in the TCP Firewall Filter

Purpose Make sure that telnet traffic works as expected.

Action Verify that the device can establish only TCP sessions with hosts that meet the **from tcp-established** condition..

1. From Device R2, make sure that the BGP session with Device R1 is established.

```
user@R2> show bgp summary | match down
Groups: 1 Peers: 1 Down peers: 0
```

2. From Device R2, telnet to Device R1.

```
user@R2> telnet 192.168.0.1
Trying 192.168.0.1...
Connected to R1.acme.net.
Escape character is '^['.
```

```
R1 (ttyp4)
```

```
login:
```

3. From Device R1, telnet to Device R2.

```
user@R1> telnet 192.168.0.2
```

```
Trying 192.168.0.2...
telnet: connect to address 192.168.0.2: Operation timed out
telnet: Unable to connect to remote host
```

4. On Device R2, deactivate the **from tcp-established** match condition.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# deactivate from tcp-established
user@R2# commit
```

5. From Device R1, try again to telnet to Device R2.

```
user@R1> telnet 192.168.0.1
Trying 192.168.0.2...
Connected to R2.acme.net.
Escape character is '^['.
```

```
R2 (ttyp4)
```

```
login:
```

Meaning Verify the following information:

- As expected, the BGP session is established. The **from tcp-established** match condition is not expected to block BGP session establishment.
- From Device R2, you can telnet to Device R1. Device R1 has no firewall filter configured, so this is the expected behavior.
- From Device R1, you cannot telnet to Device R2. Telnet uses TCP as the transport protocol, so this result might be surprising. The cause for the lack of telnet connectivity is the **from tcp-established** match condition. This match condition limits the type of TCP traffic that is accepted of Device R2. After this match condition is deactivated, the telnet session is successful.

Using telnet to Verify the Trusted Prefixes Condition in the TCP Firewall Filter

Purpose Make sure that telnet traffic works as expected.

Action Verify that the device can establish only telnet sessions with a host at an IP address that matches one of the trusted source addresses. For example, log in to the device with the **telnet** command from another host with one of the trusted address prefixes. Also, verify that telnet sessions with untrusted source addresses are blocked.

1. From Device R1, telnet to Device R2 from an untrusted source address.

```
user@R1> telnet 172.16.0.2 source 172.16.0.1
Trying 172.16.0.2...
^C
```

2. From Device R2, add 172.16/16 to the list of trusted prefixes.

```
[edit policy-options prefix-list trusted-addresses]
user@R2# set 172.16.0.0/16
user@R2# commit
```

3. From Device R1, try again to telnet to Device R2.

```
user@R1> telnet 172.16.0.2 source 172.16.0.1
```

```
Trying 172.16.0.2...
Connected to R2.acme.net.
Escape character is '^['.
```

```
R2 (ttyp4)
```

```
login:
```

Meaning Verify the following information:

- From Device R1, you cannot telnet to Device R2 with an untrusted source address. After the 172.16/16 prefix is added to the list of trusted prefixes, the telnet request from source address 172.16.0.1 is accepted.
- OSPF session establishment is blocked. OSPF does not use TCP as its transport protocol. After the **from protocol tcp** match condition is deactivated, OSPF session establishment is not blocked.

Using OSPF to Verify the TCP Firewall Filter

Purpose Make sure that OSPF traffic works as expected.

Action Verify that the device cannot establish OSPF connectivity.

1. From Device R1, check the OSPF sessions.

```
user@R1> show ospf neighbor
Address      Interface      State    ID          Pri  Dead
10.0.0.2     fe-1/2/0.0    Init    192.168.0.2 128   34
```

2. From Device R2, check the OSPF sessions.

```
user@R2> show ospf neighbor
```

3. From Device R2, remove the **from protocol tcp** match condition.

```
[edit firewall family inet filter protect-RE term tcp-connection-term]
user@R2# deactivate from protocol
user@R2# commit
```

4. From Device R1, recheck the OSPF sessions.

```
user@R1> show ospf neighbor
Address      Interface      State    ID          Pri  Dead
10.0.0.2     fe-1/2/0.0    Full    192.168.0.2 128   36
```

5. From Device R2, recheck the OSPF sessions.

```
user@R2> show ospf neighbor
Address      Interface      State    ID          Pri  Dead
10.0.0.1     fe-1/2/0.0    Full    192.168.0.1 128   39
```

Meaning Verify the following information:

- ## Verifying the ICMP Firewall Filter

Action 1. Undo the configuration changes made in previous verification steps.

2. From Device R1, ping the loopback interface on Device R2.

```
pinground-trip min/avg/max/stddev = 2.976/3.405/42.380/2.293 ms
```

- 0

- 14 packets transmitted, 0 packets received, 100% packet loss

4873

- The ICMP packet counter is incrementing, and the icmp-policer is incrementing.
- Device R2 does not send ICMP responses to the **ping 172.16.0.2 source 172.16.0.1** command.

Prefix-Specific Counting and Policing Overview

This topic covers the following information:

- [Separate Counting and Policing for Each IPv4 Address Range on page 4874](#)
- [Prefix-Specific Action Configuration on page 4875](#)
- [Counter and Policer Set Size and Indexing on page 4876](#)

Separate Counting and Policing for Each IPv4 Address Range

Prefix-specific counting and policing enables you to configure an IPv4 firewall filter term that matches on a source or destination address, applies a single-rate two-color policer as the term action, but associates the matched packet with a specific counter and policer instance based on the source or destination in the packet header. You can implicitly create a separate counter or policer instance for a single address or for a group of addresses.

NOTE: J Series Services Routers do not support prefix-specific counting and policing.

Prefix-specific counting and policing uses a *prefix-specific action* configuration that specifies the name of the policer you want to apply, whether prefix-specific counting is to be enabled, and a source or destination address prefix range.

The prefix range specifies between 1 and 16 sequential set bits of an IPv4 address mask. The length of the prefix range determines the size of the counter and policer set, which consists of as few as 2 or as many as 65,536 counter and policer instances. The position of the bits of the prefix range determines the indexing of filter-matched packets into the set of instances.

NOTE: A prefix-specific action is specific to a source or destination *prefix range*, but it is not specific to a particular source or destination *address range*, and it is not specific to a particular interface.

To apply a prefix-specific action to the traffic at an interface, you configure a firewall filter term that matches on source or destination addresses, and then you apply the firewall filter to the interface. The flow of filtered traffic is rate-limited using prefix-specific counter and policer instances that are selected per packet based on the source or destination address in the header of the filtered packet.

Prefix-Specific Action Configuration

To configure a prefix-specific action, you specify the following information:

- Prefix-specific action name—Name that can be referenced as the action of an IPv4 standard firewall filter term that matches packets on source or destination addresses.
- Policer name—Name of a single-rate two-color policer for which you want to implicitly create prefix-specific instances.

NOTE: For aggregated Ethernet interfaces, you can configure a prefix-specific action that references a logical interface policer (also called an aggregate policer). You can reference this type of prefix-specific action from an IPv4 standard firewall filter and then apply the filter at the aggregate level of the interface.

- Counting option—Option to include if you want to enable prefix-specific counters.
- Filter-specific option—Option to include if you want a single counter and policer set to be shared across all terms in the firewall filter. A prefix-specific action that operates in this way is said to operate in *filter-specific* mode. If you do not enable this option, the prefix-specific action operates in *term-specific* mode, meaning that a separate counter and policer set is created for each filter term that references the prefix-specific action.
- Source address prefix length—Length of the address prefix, from 0 through 32, to be used with a packet matched on the source address.
- Destination address prefix length—Length of the address prefix, from 0 through 32, to be used with a packet matched on the destination address.
- Subnet prefix length—Length of the subnet prefix, from 0 through 32, to be used with a packet matched on either the source or destination address.

You must configure source and destination address prefix lengths to be from 1 to 16 bits longer than the subnet prefix length. If you configure source or destination address prefix lengths to be more than 16 bits beyond the configured subnet prefix length, an error occurs when you try to commit the configuration.

Counter and Policer Set Size and Indexing

The number of prefix-specific actions (counters or policers) implicitly created for a prefix-specific action is determined by the length of the address prefix and the length of the subnet prefix:

$$\text{Size of Counter and Policer Set} = 2^{(\text{source-or-destination-prefix-length} - \text{subnet-prefix-length})}$$

Table 367 on page 4876 shows examples of counter and policer set size and indexing.

Table 367: Examples of Counter and Policer Set Size and Indexing

Example Prefix Lengths Specified in the Prefix-Specific Action	Calculation of Counter or Policer Set Size	Indexing of Instances	
$\text{source-prefix-length} = 32$ $\text{subnet-prefix-length} = 16$	Size = $2^{(32-16)} = 2^{16} = 65,536$ instances NOTE: This calculation shows the largest counter or policer set size supported.	Instance 0:	x.x.0.0
		Instance 1:	x.x.0.1
		Instance 65535:	x.x.255.255
$\text{source-prefix-length} = 32$ $\text{subnet-prefix-length} = 24$	Size = $2^{(32-24)} = 2^8 = 256$ instances	Instance 0:	x.x.x.0
		Instance 1:	x.x.x.1
		Instance 255:	x.x.x.255
$\text{source-prefix-length} = 32$ $\text{subnet-prefix-length} = 25$	Size = $2^{(32-25)} = 2^7 = 128$ instances	Instance 0:	x.x.x.0
		Instance 1:	x.x.x.1
		Instance 127:	x.x.x.127
$\text{source-prefix-length} = 24$ $\text{subnet-prefix-length} = 20$	Size = $2^{(24-20)} = 2^4 = 16$ instances	Instance 0:	x.x.0.x
		Instance 1:	x.x.1.x
		Instance 15:	x.x.15.x

Filter-Specific Counter and Policer Set Overview

By default, a prefix-specific policer set operates in *term-specific* mode so that, for a given firewall filter, the Junos OS creates a separate counter and policer set for every filter term that references the prefix-specific action. As an option, you can configure a prefix-specific policer set to operate in *filter-specific* mode so that a single prefix-specific policer set is used by all terms (within the same firewall filter) that reference the policer.

For an IPv4 firewall filter with multiple terms that reference the same prefix-specific policer set, configuring the policer set to operate in filter-specific mode enables you to count and monitor the activity of the policer set at the firewall filter level.

NOTE: Term-specific mode and filter-specific mode also apply to policers. See [“Filter-Specific Policer Overview” on page 4863](#).

To enable a prefix-specific policer set to operate in filter-specific mode, you can include the **filter-specific** statement at following the hierarchy levels:

- [edit firewall family inet prefix-action *prefix-action-name*]
- [edit logical-systems *logical-system-name* firewall family inet prefix-action *prefix-action-name*]

You can reference filter-specific, prefix-specific policer sets from IPv4 (**family inet**) firewall filters only.

Example: Configuring Prefix-Specific Counting and Policing

This example shows how to configure prefix-specific counting and policing.

- [Requirements on page 4877](#)
- [Overview on page 4877](#)
- [Configuration on page 4878](#)
- [Verification on page 4882](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, you configure prefix-specific counting and policing based on the last octet of the source address field in packets matched by an IPv4 firewall filter.

The single-rate two-color policer named **1Mbps-policer** rate-limits traffic to a bandwidth of 1,000,000 bps and a burst-size limit of 63,000 bytes, discarding any packets in a traffic flow that exceeds the traffic limits.

Independent of the IPv4 addresses contained in any packets passed from a firewall filter, the prefix-specific action named **psa-1Mbps-per-source-24-32-256** specifies a set of 256 counters and policers, numbered from 0 through 255. For each packet, the last octet of the source address field is used to index into the associated prefix-specific counter and policer in the set:

- Packets with a source address ending with the octet 0x0000 0000 index the first counter and policer in the set.
- Packets with a source address ending with the octet 0x0000 0001 index the second counter and policer in the set.
- Packets with a source address ending with the octet 0x1111 1111 index the last counter and policer in the set.

The **limit-source-one-24** firewall filter contains a single term that matches all packets from the /24 subnet of source address **10.10.10.0**, passing these packets to the prefix-specific action **psa-1Mbps-per-source-24-32-256**.

Topology

In this example, because the filter term matches the /24 subnet of a single source address, each counting and policing instance in the prefix-specific set is used for only one source address.

- Packets with a source address **10.10.10.0** index the first counter and policer in the set.
- Packets with a source address **10.10.10.1** index the second counter and policer in the set.
- Packets with a source address **10.10.10.255** index the last counter and policer in the set.

This example shows the simplest case of prefix-specific actions, in which the filter term matches on one address with a prefix length that is the same as the prefix length specified in the prefix-specific action for indexing into the set of prefix-specific counters and policers.

For descriptions of other configurations for prefix-specific counting and policing, see [“Prefix-Specific Counting and Policing Configuration Scenarios” on page 4883](#).

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring a Policer for Prefix-Specific Counting and Policing on page 4879](#)
- [Configuring a Prefix-Specific Action Based on the Policer on page 4879](#)
- [Configuring an IPv4 Filter That References the Prefix-Specific Action on page 4880](#)
- [Applying the Firewall Filter to IPv4 Input Traffic at a Logical Interface on page 4881](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall policer 1Mbps-policer if-exceeding bandwidth-limit 1m
set firewall policer 1Mbps-policer if-exceeding burst-size-limit 63k
set firewall policer 1Mbps-policer then discard
set firewall family inet prefix-action psa-1Mbps-per-source-24-32-256 policer
  1Mbps-policer
set firewall family inet prefix-action psa-1Mbps-per-source-24-32-256 count
set firewall family inet prefix-action psa-1Mbps-per-source-24-32-256
  subnet-prefix-length 24
set firewall family inet prefix-action psa-1Mbps-per-source-24-32-256 source-prefix-length
  32
set firewall family inet filter limit-source-one-24 term one from source-address
  10.10.10.0/24
```

```

set firewall family inet filter limit-source-one-24 term one then prefix-action
  psa-1Mbps-per-source-24-32-256
set interfaces so-0/0/2 unit 0 family inet filter input limit-source-one-24
set interfaces so-0/0/2 unit 0 family inet address 10.39.1.1/16

```

Configuring a Policer for Prefix-Specific Counting and Policing

Step-by-Step Procedure

To configure a policer to be used for prefix-specific counting and policing:

1. Enable configuration of a single-rate two-color policer.

```

[edit]
user@host# edit firewall policer 1Mbps-policer

```

2. Define the traffic limit.

```

[edit firewall policer 1Mbps-policer]
user@host# set if-exceeding bandwidth-limit 1m
user@host# set if-exceeding burst-size-limit 63k

```

Packets in a traffic flow that conforms to this limit are passed with the PLP set to **low**.

3. Define the actions for nonconforming traffic.

```

[edit firewall policer 1Mbps-policer]
user@host# set then discard

```

Packets in a traffic flow that exceeds this limit are discarded. Other configurable actions for a single-rate two-color policer are to set the forwarding class and to set the PLP level.

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

[edit]
user@host# show firewall
policer 1Mbps-policer {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 63k;
  }
  then discard;
}

```

Configuring a Prefix-Specific Action Based on the Policer

Step-by-Step Procedure

To configure a prefix-specific action that references the policer and specifies a portion of a source address prefix:

1. Enable configuration of a prefix-specific action.

```

[edit]
user@host# edit firewall family inet prefix-action psa-1Mbps-per-source-24-32-256

```

Prefix-specific counting and policing can be defined for IPv4 traffic only.

2. Reference the policer for which a prefix-specific set is to be created.

```
[edit firewall family inet prefix-action psa-1Mbps-per-source-24-32-256]
user@host# set policer 1Mbps-policer
user@host# set count
```

NOTE: For aggregated Ethernet interfaces, you can configure a prefix-specific action that references a logical interface policer (also called an aggregate policer). You can reference this type of prefix-specific action from an IPv4 standard firewall filter and then apply the filter at the aggregate level of the interface.

3. Specify the prefix range on which IPv4 addresses are to be indexed to the counter and policer set.

```
[edit firewall family inet prefix-action psa-1Mbps-per-source-24-32-256]
user@host# set source-prefix-length 32
user@host# set subnet-prefix-length 24
```

Results Confirm the configuration of the prefix-specific action by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer 1Mbps-policer {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 63k;
  }
  then discard;
}
family inet {
  prefix-action psa-1Mbps-per-source-24-32-256 {
    policer 1Mbps-policer;
    subnet-prefix-length 24;
    source-prefix-length 32;
  }
}
```

Configuring an IPv4 Filter That References the Prefix-Specific Action

Step-by-Step Procedure To configure an IPv4 standard firewall filter that references the prefix-specific action:

1. Enable configuration of the IPv4 standard firewall filter.

```
[edit]
user@host# edit firewall family inet filter limit-source-one-24
```

Prefix-specific counting and policing can be defined for IPv4 traffic only.

2. Configure the filter term to match on the packet source address or destination address.

```
[edit firewall family inet filter limit-source-one-24]
user@host# set term one from source-address 10.10.10.0/24
```

3. Configure the filter term to reference the prefix-specific action.

```
[edit firewall family inet filter limit-source-one-24]
user@host# set term one then prefix-action psa-1Mbps-per-source-24-32-256
```

You could also use the **next term** action to configure all Hypertext Transfer Protocol (HTTP) traffic to each host to transmit at 500 Kbps and have the total HTTP traffic limited to 1 Mbps.

Results Confirm the configuration of the prefix-specific action by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer 1Mbps-policer {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 63k;
  }
  then discard;
}
family inet {
  prefix-action psa-1Mbps-per-source-24-32-256 {
    policer 1Mbps-policer;
    subnet-prefix-length 24;
    source-prefix-length 32;
  }
  filter limit-source-one-24 {
    term one {
      from {
        source-address {
          10.10.10.0/24;
        }
      }
      then prefix-action psa-1Mbps-per-source-24-32-256;
    }
  }
}
```

Applying the Firewall Filter to IPv4 Input Traffic at a Logical Interface

Step-by-Step Procedure To apply the firewall filter to IPv4 input traffic at a logical interface:

1. Enable configuration of IPv4 on the logical interface.

```
[edit]
user@host# edit interfaces so-0/0/2 unit 0 family inet
```

2. Configure an IP address.

```
[edit interfaces so-0/0/2 unit 0 family inet]
user@host# set address 10.39.1.1/16
```

3. Apply the IPv4 standard stateless firewall filter.

```
[edit interfaces so-0/0/2 unit 0 family inet]
user@host# set filter input limit-source-one-24
```

Results Confirm the configuration of the prefix-specific action by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
so-0/0/2 {
  unit 0 {
    family inet {
      filter {
        input limit-source-one-24;
      }
      address 10.39.1.1/16;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying the Firewall Filters Applied to an Interface on page 4882](#)
- [Displaying Prefix-Specific Actions Statistics for the Firewall Filter on page 4883](#)

Displaying the Firewall Filters Applied to an Interface

Purpose Verify that the firewall filter **limit-source-one-24** is applied to the IPv4 input traffic at logical interface **so-0/0/2.0**.

Action Use the **show interfaces statistics** operational mode command for logical interface **so-0/0/2.0**, and include the **detail** option. In the command output section for **Protocol inet**, the **Input Filters** field displays **limit-source-one-24**, indicating that the filter is applied to IPv4 traffic in the input direction:

```
user@host> show interfaces statistics so-0/0/2.0 detail
Logical interface so-0/0/2.0 (Index 79) (SNMP ifIndex 510) (Generation 149)
Flags: Hardware-Down Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPP
Protocol inet, MTU: 4470, Generation: 173, Route table: 0
Flags: Sendbcast-pkt-to-re, Protocol-Down
Input Filters: limit-source-one-24
Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
Destination: 10.39/16, Local: 10.39.1.1, Broadcast: 10.39.255.255,
Generation: 163
```

Displaying Prefix-Specific Actions Statistics for the Firewall Filter

Purpose Verify the number of packets evaluated by the policer.

Action Use the `show firewall prefix-action-stats filter filter-name prefix-action name` operational mode command to display statistics about a prefix-specific action configured on a firewall filter.

As an option, you can use the `from set-index to set-index` command option to specify the starting and ending counter or policer to be displayed. A policer set is indexed from 0 through 65535.

The command output displays the specified filter name followed by a listing of the number of bytes and packets processed by each policer in the policer set.

For a term-specific policer, each policer in the set is identified as follows:

prefix-specific-action-name-term-name-set-index

For a filter-specific policer, each policer is identified in the command output as follows:

prefix-specific-action-name-set-index

Because the example prefix-specific action `psa-1Mbps-per-source-24-32-256` is referenced by only one term of the example filter `limit-source-one-24`, the example policer `1Mbps-policer` is configured as term-specific. In the `show firewall prefix-action-stats` command output, the policer statistics are displayed as `psa-1Mbps-per-source-24-32-256-one-0`, `psa-1Mbps-per-source-24-32-256-one-1`, and so on through `psa-1Mbps-per-source-24-32-256-one-255`.

```
user@host> show firewall prefix-action-stats filter limit-source-one-24 prefix-action
psa-1Mbps-per-source-24-32-256 from 0 to 9
```

```
Filter: limit-source-one-24
```

```
Counters:
```

Name	Bytes	Packets
psa-1Mbps-per-source-24-32-256-one-0	0	0
psa-1Mbps-per-source-24-32-256-one-1	0	0
psa-1Mbps-per-source-24-32-256-one-2	0	0
psa-1Mbps-per-source-24-32-256-one-3	0	0
psa-1Mbps-per-source-24-32-256-one-4	0	0
psa-1Mbps-per-source-24-32-256-one-5	0	0
psa-1Mbps-per-source-24-32-256-one-6	0	0
psa-1Mbps-per-source-24-32-256-one-7	0	0
psa-1Mbps-per-source-24-32-256-one-8	0	0
psa-1Mbps-per-source-24-32-256-one-9	0	0

Prefix-Specific Counting and Policing Configuration Scenarios

This topic covers the following information:

- [Prefix Length of the Action and Prefix Length of Addresses in Filtered Packets on page 4884](#)
- [Scenario 1: Firewall Filter Term Matches on Multiple Addresses on page 4885](#)

- [Scenario 2: Subnet Prefix Is Longer Than the Prefix in the Filter Match Condition on page 4886](#)
- [Scenario 3: Subnet Prefix Is Shorter Than the Prefix in the Firewall Filter Match Condition on page 4888](#)

Prefix Length of the Action and Prefix Length of Addresses in Filtered Packets

[Table 368 on page 4884](#) describes the relationship between the prefix length specified in the prefix-specific action and the prefix length of the addresses matched by the firewall filter term that references the prefix-specific action.

Table 368: Summary of Prefix-Specific Action Scenarios

Counter and Policer Set	Packet-Filtering Criteria	Indexing of Instances	
Prefix-specific action scenario: "Example: Configuring Prefix-Specific Counting and Policing" on page 4877			
<i>source-prefix-length</i> = 32 <i>subnet-prefix-length</i> = 24 Set size: 2^8 = 256 Instance numbers: 0 - 255	<i>source-address</i> = 10.10.10.0/24	Instance 0	10.10.10.0
		Instance 1:	10.10.10.1
	
		Instance 255:	10.10.10.255
Prefix-specific action scenario: "Scenario 1: Firewall Filter Term Matches on Multiple Addresses" on page 4885			
<i>source-prefix-length</i> = 32 <i>subnet-prefix-length</i> = 24 Set size: 2^8 = 256 Instance numbers: 0 - 255	<i>source-address</i> = 10.10.10.0/24	Instance 0	10.10.10.0, 10.11.x.0
	<i>source-address</i> = 10.11.0.0/16	Instance 1:	10.10.10.1, 10.11.x.1
	
		Instance 255:	10.10.10.255, 10.11.x.255
For addresses in the /16 subnet, x ranges from 0 through 255.			
Prefix-specific action scenario: "Scenario 2: Subnet Prefix Is Longer Than the Prefix in the Filter Match Condition" on page 4886			
<i>source-prefix-length</i> = 32 <i>subnet-prefix-length</i> = 25 Set size: 2^7 = 128 Instance numbers: 0 - 127	<i>source-address</i> = 10.10.10.0/24	Instance 0	10.10.10.0, 10.10.10.128
		Instance 1:	10.10.10.1, 10.10.10.120
	

Table 368: Summary of Prefix-Specific Action Scenarios (*continued*)

Counter and Policer Set	Packet-Filtering Criteria	Indexing of Instances	
		Instance 127:	10.10.10.255, 10.10.10.127
Prefix-specific action scenario: "Scenario 3: Subnet Prefix Is Shorter Than the Prefix in the Firewall Filter Match Condition" on page 4888			
<i>source-prefix-length</i> = 32 <i>subnet-prefix-length</i> = 24 Set size: $2^8 = 256$ Instance numbers: 0 - 255	<i>source-address</i> = 10.10.10.0/25 NOTE: Only packets with source addresses ranging from 10.10.10.0 through 10.10.10.127 are passed to the prefix-specific action.	Instance 0	10.10.10.0
		Instance 1:	10.10.10.1
	
		Instance 127:	10.10.10.127
		Instances 128 – 255: unused	

Scenario 1: Firewall Filter Term Matches on Multiple Addresses

The complete example, "Example: Configuring Prefix-Specific Counting and Policing" on page 4877, shows the simplest case of prefix-specific actions, in which a single-term firewall filter matches on one address with a prefix length that is the same as the subnet prefix length specified in the prefix-specific action. Unlike the example, this scenario describes a configuration in which a single-term firewall filter matches on two IPv4 source addresses. In addition, the additional condition matches on a source address with a prefix length that is different from the subnet prefix length defined in the prefix-specific action. In this case, the additional condition matches on the /16 subnet of the source address 10.11.0.0.

NOTE: Unlike packets that match the source address 10.10.10.0/24, packets that match the source address 10.11.0.0/16 are in a many-to-one correspondence with the instances in the counter and policer set.

The filter-matched packets that are passed to the prefix-specific action index into the counter and policer set in such a way that the counting and policing instances are shared by packets that contain source addresses across the 10.10.10.0/24 and 10.11.0.0/16 subnets as follows:

- The first counter and policer in the set are indexed by packets with source addresses 10.10.10.0 and 10.11.x.0, where x ranges from 0 through 255.
- The second counter and policer in the set are indexed by packets with source addresses 10.10.10.1 and 10.11.x.1, where x ranges from 0 through 255.
- The 256th (last) counter and policer in the set are indexed by packets with source addresses 10.10.10.255 and 10.11.x.255, where x ranges from 0 through 255.

The following configuration shows the statements for configuring the single-rate two-color policer, the prefix-specific action that references the policer, and the IPv4 standard stateless firewall filter that references the prefix-specific action:

```
[edit]
firewall {
  policer 1Mbps-policer {
    if-exceeding {
      bandwidth-limit 1m;
      burst-size-limit 63k;
    }
    then discard;
  }
  family inet {
    prefix-action psa-1Mbps-per-source-24-32-256 {
      policer 1Mbps-policer;
      subnet-prefix-length 24;
      source-prefix-length 32;
    }
    filter limit-source-two-24-16 {
      term one {
        from {
          source-address {
            10.10.10.0/24;
            10.11.0.0/16;
          }
        }
        then prefix-action psa-1Mbps-per-source-24-32-256;
      }
    }
  }
}
interfaces {
  so-0/0/2 {
    unit 0 {
      family inet {
        filter {
          input limit-source-two-24-16;
        }
        address 10.39.1.1/16;
      }
    }
  }
}
```

Scenario 2: Subnet Prefix Is Longer Than the Prefix in the Filter Match Condition

The complete example, [“Example: Configuring Prefix-Specific Counting and Policing” on page 4877](#), shows the simplest case of prefix-specific actions, in which the single-term firewall filter matches on one address with a prefix length that is the same as the subnet prefix length specified in the prefix-specific action. Unlike the example, this scenario describes a configuration in which the prefix-specific action defines a subnet prefix length that is longer than the prefix of the source address matched by the firewall filter. In this case, the prefix-specific action defines a subnet-prefix value of **25**, while the firewall filter matches on a source address in the **/24** subnet.

NOTE: The firewall filter passes the prefix-specific action packets with source addresses that range from 10.10.10.0 through 10.10.10.255, while the prefix-specific action specifies a set of only 128 counters and policers, numbered from 0 through 127.

The filter-matched packets that are passed to the prefix-specific action index into the counter and policer set in such a way that the counting and policing instances are shared by packets that contain either of two source addresses within the **10.10.10.0/24** subnet:

- The first counter and policer in the set are indexed by packets with source addresses **10.10.10.0** and **10.10.10.128**.
- The second counter and policer in the set are indexed by packets with source addresses **10.10.10.1** and **10.10.10.129**.
- The 128th (last) counter and policer in the set are indexed by packets with source addresses **10.10.10.127** and **10.10.10.255**.

The following configuration shows the statements for configuring the single-rate two-color policer, the prefix-specific action that references the policer, and the IPv4 standard stateless firewall filter that references the prefix-specific action:

```
[edit]
firewall {
  policer 1Mbps-policer {
    if-exceeding {
      bandwidth-limit 1m;
      burst-size-limit 63k;
    }
    then discard;
  }
  family inet {
    prefix-action psa-1Mbps-per-source-25-32-128 {
      policer 1Mbps-policer;
      subnet-prefix-length 25;
      source-prefix-length 32;
    }
    filter limit-source-one-24 {
      term one {
        from {
          source-address {
            10.10.10.0/24;
          }
        }
        then prefix-action psa-1Mbps-per-source-25-32-128;
      }
    }
  }
}
interfaces {
  so-0/0/2 {
    unit 0 {
      family inet {
```

```

    filter {
        input limit-source-one-24;
    }
    address 10.39.1.1/16;
}
}
}
}
}

```

Scenario 3: Subnet Prefix Is Shorter Than the Prefix in the Firewall Filter Match Condition

The complete example, “[Example: Configuring Prefix-Specific Counting and Policing](#)” on [page 4877](#), shows the simplest case of prefix-specific actions, in which the single-term firewall filter matches on one address with a prefix length that is the same as the subnet prefix length specified in the prefix-specific action. Unlike the example, this scenario describes a configuration in which the prefix-specific action defines a subnet prefix length that is shorter than the prefix of the source address matched by the firewall filter. In this case, the filter term matches on the /25 subnet of the source address 10.10.10.0.

NOTE: The firewall filter passes the prefix-specific action only packets with source addresses that range from 10.10.10.0 through 10.10.10.127, while the prefix-specific action specifies a set of 256 counters and policers, numbered from 0 through 255.

The matched packets that are passed to the prefix-specific action index into the lower half of the counter and policer set only:

- The first counter and policer in the set are indexed by packets with source address 10.10.10.0.
- The second counter and policer in the set are indexed by packets with source address 10.10.10.1 and 10.10.10.129.
- The 128th counter and policer in the set are indexed by packets with source address 10.10.10.127.
- The upper half of the set (instances numbered from 128 through 255) are not indexed by packets passed to the prefix-specific action from this particular firewall filter.

The following configuration shows the statements for configuring the single-rate two-color policer, the prefix-specific action that references the policer, and the IPv4 standard stateless firewall filter that references the prefix-specific action:

```

[edit]
firewall {
    policer 1Mbps-policer {
        if-exceeding {
            bandwidth-limit 1m;
            burst-size-limit 63k;
        }
        then discard;
    }
    family inet {

```

```

prefix-action psa-1Mbps-per-source-24-32-256 {
  policer 1Mbps-policer;
  subnet-prefix-length 24;
  source-prefix-length 32;
}
filter limit-source-one-25 {
  term one {
    from {
      source-address {
        10.10.10.0/25;
      }
    }
    then prefix-action psa-1Mbps-per-source-24-32-256;
  }
}
}
}
interfaces {
  so-0/0/2 {
    unit 0 {
      family inet {
        filter {
          input limit-source-one-25;
        }
        address 10.39.1.1/16;
      }
    }
  }
}
}

```

Multifield Classification Overview

This topic covers the following information:

- [Forwarding Classes and PLP Levels on page 4890](#)
- [Multifield Classification and BA Classification on page 4890](#)
- [Multifield Classification Used In Conjunction with Policers on page 4890](#)

Forwarding Classes and PLP Levels

You can configure the Junos OS class of service (CoS) features to classify incoming traffic by associating each packet with a forwarding class, a packet loss priority (PLP) level, or both:

- Based on the associated forwarding class, each packet is assigned to an output queue, and the router services the output queues according to the associated scheduling you configure.
- Based on the associated PLP, each packet carries a lower or higher likelihood of being dropped if congestion occurs. The CoS random early detection (RED) process uses the drop probability configuration, output queue fullness percentage, and packet PLP to drop packet as needed to control congestion at the output stage.

Multifield Classification and BA Classification

The Junos OS supports two general types of packet classification: behavior aggregate (BA) classification and multifield classification:

- BA classification, or CoS value traffic classification, refers to a method of packet classification that uses a CoS configuration to set the forwarding class or PLP of a packet based on the *CoS value* in the IP packet header. The CoS value examined for BA classification purposes can be the Differentiated Services code point (DSCP) value, DSCP IPv6 value, IP precedence value, MPLS EXP bits, and IEEE 802.1p value. The default classifier is based on the IP precedence value.
- Multifield classification refers to a method of packet classification that uses a standard stateless firewall filter configuration to set the forwarding class or PLP for each packet entering or exiting the interface based on *multiple fields* in the IP packet header, including the DSCP value (for IPv4 only), the IP precedence value, the MPLS EXP bits, and the IEEE 802.1p bits. Multifield classification commonly matches on IP address fields, the IP protocol type field, or the port number in the UDP or TCP pseudoheader field. Multifield classification is used instead of BA classification when you need to classify packets based on information in the packet information other than the CoS values only.

With multifield classification, a firewall filter term can specify the packet classification actions for matching packets through the use of the **forwarding-class *class-name*** or **loss-priority (*high* | *medium-high* | *medium-low* | *low*)** nonterminating actions in the term's **then** clause. For more information about these actions, see .

NOTE: BA classification of a packet can be overridden by the stateless firewall filter actions **forwarding-class** and **loss-priority**.

Multifield Classification Used In Conjunction with Policers

To configure multifield classification in conjunction with rate limiting, a firewall filter term can specify the packet classification actions for matching packets through the use of a **policer** nonterminating action that references a single-rate two-color policer.

When multifield classification is configured to perform classification through a policer, the filter-matched packets in the traffic flow are rate-limited to the policer-specified traffic limits. Packets in a conforming flow of filter-matched packets are implicitly set to a **low** PLP. Packets in a nonconforming traffic flow can be discarded, or the packets can be set to a specified forwarding class, set to a specified PLP level, or both, depending on the type of policer and how the policer is configured to handle nonconforming traffic.

NOTE: Before you apply a firewall filter that performs multifield classification and also a policer to the same logical interface and for the same traffic direction, make sure that you consider the order of policer and firewall filter operations.

As an example, consider the following scenario:

- You configure a firewall filter that performs multifield classification (acts on matched packets by setting the forwarding class, the PLP, or both) based on the packet's existing forwarding class or PLP. You apply the firewall filter at the input of a logical interface.
- You also configure a single-rate two-color policer that acts on a red traffic flow by re-marking (setting the forwarding class, the PLP, or both) rather than discarding those packets. You apply the policer as an interface policer at the input of the same logical interface to which you apply the firewall filter.

Because of the order of policer and firewall operations, the input policer is executed before the input firewall filter. This means that the multifield classification specified by the firewall filter is performed on input packets that have already been re-marked once by policing actions. Consequently, any input packet that matches the conditions specified in a firewall filter term is then subject to a second re-marking according to the forwarding-class or loss-priority nonterminating actions also specified in that term.

Multifield Classification Requirements and Restrictions

This topic covers the following information:

- [Supported Platforms on page 4891](#)
- [CoS Tricolor Marking Requirement on page 4892](#)
- [Restrictions on page 4892](#)

Supported Platforms

The **loss-priority** firewall filter action is supported on the following routing and switching platforms only:

- EX Series switches
- M7i and M10i routers with the Enhanced CFEB (CFEB-E)
- M120 and M320 routers

- MX Series routers
- T Series routers with Enhanced II Flexible PIC Concentrators (FPCs)

CoS Tricolor Marking Requirement

The **loss-priority** firewall filter action has platform-specific requirements dependencies on the CoS tricolor marking feature, as defined in RFC 2698:

- On an M320 router, you cannot commit a configuration that includes the **loss-priority** firewall filter action unless you enable the CoS tricolor marking feature.
- On all routing platforms that support the **loss-priority** firewall filter action, you cannot set the **loss-priority** firewall filter action to **medium-low** or **medium-high** unless you enable the CoS tricolor marking feature. .

To enable the CoS tricolor marking feature, include the **tri-color** statement at the **[edit class-of-service]** hierarchy level.

Restrictions

You cannot configure the **loss-priority** and **three-color-policer** nonterminating actions for the same firewall filter term. These two nonterminating actions are mutually exclusive.

Multifield Classification Limitations on M Series Routers

This topic covers the following information:

- [Problem: Output-Filter Matching on Input-Filter Classification on page 4892](#)
- [Workaround: Configure All Actions in the Ingress Filter on page 4893](#)

Problem: Output-Filter Matching on Input-Filter Classification

On M Series routers (except M120 routers), you cannot classify packets with an output filter match based on the ingress classification that is set with an input filter applied to the same IPv4 logical interface.

For example, in the following configuration, the filter called **ingress** assigns all incoming IPv4 packets to the **expedited-forwarding** class. The filter called **egress** counts all packets that were assigned to the **expedited-forwarding** class in the **ingress** filter. This configuration does not work on most M Series routers. It works on all other routing platforms, including M120 routers, MX Series routers, and T Series routers, and EX Series switches.

```
[edit]
user@host # show firewall
family inet {
  filter ingress {
    term 1 {
      then {
        forwarding-class expedited-forwarding;
        accept;
      }
    }
    term 2 {
      then accept;
    }
  }
}
```

```

}
filter egress {
  term 1 {
    from {
      forwarding-class expedited-forwarding;
    }
    then count ef;
  }
  term 2 {
    then accept;
  }
}
}

```

```

[edit]
user@host# show interfaces
ge-1/2/0 {
  unit 0 {
    family inet {
      filter {
        input ingress;
        output egress;
      }
    }
  }
}

```

Workaround: Configure All Actions in the Ingress Filter

As a workaround, you can configure all of the actions in the ingress filter.

```

user@host # show firewall
family inet {
  filter ingress {
    term 1 {
      then {
        forwarding-class expedited-forwarding;
        accept;
        count ef;
      }
    }
    term 2 {
      then accept;
    }
  }
}

```

```

[edit]
user@host# show interfaces
ge-1/2/0 {
  unit 0 {
    family inet {
      filter {
        input ingress;
      }
    }
  }
}

```

```
}
```

Example: Configuring Multifield Classification

This example shows how to configure multifield classification of IPv4 traffic by using firewall filter actions and two firewall filter policers.

- [Requirements on page 4894](#)
- [Overview on page 4895](#)
- [Configuration on page 4896](#)
- [Verification on page 4900](#)

Requirements

Before you begin, make sure that your environment supports the features shown in this example:

1. The **loss-priority** firewall filter action must be supported on the router and configurable to all four values.
 - a. To be able to set a **loss-priority** firewall filter action, configure this example on logical interface **ge-1/2/0.0** on one of the following routing or switching platforms:
 - EX Series switch
 - MX Series router
 - M120 or M320 router
 - M7i or M10i router with the Enhanced CFEB (CFEB-E)
 - T Series router with Enhanced II Flexible PIC Concentrator (FPC)
 - b. To be able to set a **loss-priority** firewall filter action to **medium-low** or **medium-high**, make sure that the CoS tricolor marking feature is enabled. To enable the CoS tricolor marking feature, include the **tri-color** statement at the **[edit class-of-service]** hierarchy level.
2. The **expedited-forwarding** and **assured-forwarding** forwarding classes must be scheduled on the underlying physical interface **ge-1/2/0**.
 - a. Make sure that the following forwarding classes are assigned to output queues:
 - **expedited-forwarding**
 - **assured-forwarding**

NOTE: You cannot commit a configuration that assigns the same forwarding class to two different queues.

- b. Make sure that the output queues to which the forwarding classes are assigned are associated with schedulers. A scheduler defines the amount of interface bandwidth assigned to the queue, the size of the memory buffer allocated for storing packets, the priority of the queue, and the random early detection (RED) drop profiles associated with the queue.
 - You configure output queue schedulers at the **[edit class-of-service schedulers]** hierarchy level.
 - You associate output queue schedulers with forwarding classes by means of a scheduler map that you configure at the **[edit class-of-service scheduler-maps map-name]** hierarchy level.
- c. Make sure that output-queue scheduling is applied to the physical interface **ge-1/2/0**.

You apply a scheduler map to a physical interface at the **[edit class-of-service interfaces ge-1/2/0 scheduler-map map-name]** hierarchy level.

Overview

In this example, you apply multifield classification to the input IPv4 traffic at a logical interface by using stateless firewall filter actions and two firewall filter policers that are referenced from the firewall filter. Based on the source address field, packets are either set to the **low** loss priority or else policed. Neither of the policers discards nonconforming traffic. Packets in nonconforming flows are marked for a specific forwarding class (**expedited-forwarding** or **assured-forwarding**), set to a specific loss priority, and then transmitted.

NOTE: Single-rate two-color policers always transmit packets in a conforming traffic flow after implicitly setting a low loss priority.

Topology

In this example, you apply multifield classification to the IPv4 traffic on logical interface **ge-1/2/0.0**. The classification rules are specified in the IPv4 stateless firewall filter **mfc-filter** and two single-rate two-color policers, **ef-policer** and **af-policer**.

The IPv4 standard stateless firewall filter **mfc-filter** defines three filter terms:

- **isp1-customers**—The first filter term matches packets with the source address 10.1.1.0/24 or 10.1.2.0/24. Matched packets are assigned to the **expedited-forwarding** forwarding class and set to the **low** loss priority.
- **isp2-customers**—The second filter term matches packets with the source address 10.1.3.0/24 or 10.1.4.0/24. Matched packets are passed to **ef-policer**, a policer that rate-limits traffic to a bandwidth limit of 300 Kbps with a burst-size limit of 50 KB. This policer specifies that packets in a nonconforming flow are marked for the **expedited-forwarding** forwarding class and set to the **high** loss priority.
- **other-customers**—The third and final filter term passes all other packets to **af-policer**, a policer that rate-limits traffic to a bandwidth limit of 300 Kbps and a burst-size limit

of 50 KB (the same traffic limits as defined by **ef-policer**). This policer specifies that packets in a nonconforming flow are marked for the **assured-forwarding** forwarding class and set to the **medium-high** loss priority.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring Policers to Rate-Limit Expedited-Forwarding and Assured-Forwarding Traffic on page 4896](#)
- [Configuring a Multifield Classification Filter That Also Applies Policing on page 4897](#)
- [Applying Multifield Classification Filtering and Policing to the Logical Interface on page 4899](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall policer ef-policer if-exceeding bandwidth-limit 300k
set firewall policer ef-policer if-exceeding burst-size-limit 50k
set firewall policer ef-policer then loss-priority high
set firewall policer ef-policer then forwarding-class expedited-forwarding
set firewall policer af-policer if-exceeding bandwidth-limit 300k
set firewall policer af-policer if-exceeding burst-size-limit 50k
set firewall policer af-policer then loss-priority high
set firewall policer af-policer then forwarding-class assured-forwarding
set firewall family inet filter mfc-filter term isp1-customers from source-address 10.1.1.0/24
set firewall family inet filter mfc-filter term isp1-customers from source-address 10.1.2.0/24
set firewall family inet filter mfc-filter term isp1-customers then loss-priority low
set firewall family inet filter mfc-filter term isp1-customers then forwarding-class
  expedited-forwarding
set firewall family inet filter mfc-filter term isp2-customers from source-address
  10.1.3.0/24
set firewall family inet filter mfc-filter term isp2-customers from source-address
  10.1.4.0/24
set firewall family inet filter mfc-filter term isp2-customers then policer ef-policer
set firewall family inet filter mfc-filter term other-customers then policer af-policer
set interfaces ge-1/2/0 unit 0 family inet address 192.168.1.1/24
set interfaces ge-1/2/0 unit 0 family inet filter input mfc-filter
```

Configuring Policers to Rate-Limit Expedited-Forwarding and Assured-Forwarding Traffic

Step-by-Step Procedure

To configure policers to rate-limit expedited-forwarding and assured-forwarding traffic:

1. Define traffic limits for expedited-forwarding traffic.

```
[edit]
user@host# edit firewall policer ef-policer
[edit firewall policer ef-policer]
user@host# set if-exceeding bandwidth-limit 300k
user@host# set if-exceeding burst-size-limit 50k
```

```

user@host# set then loss-priority high
user@host# set then forwarding-class expedited-forwarding

```

2. Configure a policer for assured-forwarding traffic.

```

[edit firewall policer ef-policer]
user@host# up

[edit firewall]
user@host# edit policer af-policer

[edit firewall policer af-policer]
user@host# set if-exceeding bandwidth-limit 300k
user@host# set if-exceeding burst-size-limit 50k
user@host# set then loss-priority high
user@host# set then forwarding-class assured-forwarding

```

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

[edit]
user@host# show firewall
policer af-policer {
  if-exceeding {
    bandwidth-limit 300k;
    burst-size-limit 50k;
  }
  then {
    loss-priority high;
    forwarding-class assured-forwarding;
  }
}
policer ef-policer {
  if-exceeding {
    bandwidth-limit 300k;
    burst-size-limit 50k;
  }
  then {
    loss-priority high;
    forwarding-class expedited-forwarding;
  }
}

```

Configuring a Multifield Classification Filter That Also Applies Policing

Step-by-Step Procedure To configure a multifield classification filter that additionally applies policing:

1. Enable configuration of a firewall filter term for IPv4 traffic.

```

[edit]
user@host# edit firewall family inet filter mfc-filter

```

2. Configure the first term to match on source addresses and then classify the matched packets.

```

[edit firewall family inet filter mfc-filter]

```

```
user@host# set term isp1-customers from source-address 10.1.1.0/24
user@host# set term isp1-customers from source-address 10.1.2.0/24
user@host# set term isp1-customers then loss-priority low
user@host# set term isp1-customers then forwarding-class expedited-forwarding
```

3. Configure the second term to match on different source addresses and then police the matched packets.

```
[edit firewall family inet filter mfc-filter]
user@host# set term isp2-customers from source-address 10.1.3.0/24
user@host# set term isp2-customers from source-address 10.1.4.0/24
user@host# set term isp2-customers then policer ef-policer
```

4. Configure the third term to police all other packets to a different set of traffic limits and actions.

```
[edit firewall family inet filter mfc-filter]
user@host# set term other-customers then policer af-policer
```

Results Confirm the configuration of the filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter mfc-filter {
    term isp1-customers {
      from {
        source-address 10.1.1.0/24;
        source-address 10.1.2.0/24;
      }
      then {
        loss-priority low;
        forwarding-class expedited-forwarding;
      }
    }
    term isp2-customers {
      from {
        source-address 10.1.3.0/24;
        source-address 10.1.4.0/24;
      }
      then {
        policer ef-policer;
      }
    }
    term other-customers {
      then {
        policer af-policer;
      }
    }
  }
}
policer af-policer {
  if-exceeding {
    bandwidth-limit 300k;
```

```

        burst-size-limit 50k;
    }
    then discard;
}
policer ef-policer {
    if-exceeding {
        bandwidth-limit 200k;
        burst-size-limit 50k;
    }
    then {
        loss-priority high;
        forwarding-class expedited-forwarding;
    }
}
}

```

Applying Multifield Classification Filtering and Policing to the Logical Interface

Step-by-Step Procedure To apply multifield classification filtering and policing to the logical interface:

1. Enable configuration of IPv4 on the logical interface.

```

[edit]
user@host# edit interfaces ge-1/2/0 unit 0 family inet

```

2. Configure an IP address for the logical interface.

```

[edit interfaces ge-1/2/0 unit 0 family inet ]
user@host# set address 192.168.1.1/24

```

3. Apply the firewall filter to the logical interface input.

```

[edit interfaces ge-1/2/0 unit 0 family inet ]
user@host# set filter input mfc-filter

```

NOTE: Because the policer is executed before the filter, if an input policer is also configured on the logical interface, it cannot use the forwarding class and PLP of a multifield classifier associated with the interface.

Results Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```

[edit]
user@host# show interfaces
ge-1/2/0 {
    unit 0 {
        family inet {
            filter {
                input mfc-filter;
            }
            address 192.168.1.1/24;
        }
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Displaying the Number of Packets Processed by the Policer at the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show firewall** operational mode command for the filter you applied to the logical interface.

```
user@host> show firewall filter rate-limit-in
Filter: rate-limit-in
Policers:
Name                                     Packets
ef-policer-isp2-customers                32863
af-policer-other-customers                3870
```

The command output lists the policers applied by the firewall filter **rate-limit-in**, and the number of packets that matched the filter term.

NOTE: The packet count includes the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.

The policer name is displayed concatenated with the name of the firewall filter term in which the policer is referenced as an action.

Example: Configuring and Applying a Firewall Filter for a Multifield Classifier

This example shows how to configure a firewall filter to classify traffic using a multifield classifier. The classifier detects packets of interest to CoS as they arrive on an interface.

- [Requirements on page 4900](#)
- [Overview on page 4901](#)
- [Configuration on page 4901](#)
- [Verification on page 4904](#)

Requirements

Before you begin, review how to create and configure a firewall. See [“Guidelines for Configuring Standard Firewall Filters” on page 4478](#).

NOTE: On T4000 Type 5 FPCs, a filter attached at the Layer 2 application point (that is, at the logical interface level) is unable to match with the forwarding class of a packet that is set by a Layer 3 classifier such as DSCP, DSCP V6, inet-precedence, and mpls-exp.

Overview

One common way to detect packets of CoS interest is by source or destination address. The destination address is used in this example, but many other matching criteria for packet detection are available to firewall filters.

In this example, you configure the firewall filter `mf-classifier`. You create and name the assured forwarding traffic class, set the match condition, and specify the destination address as `192.168.44.55`. You create the forwarding class for assured forwarding DiffServ traffic as `af-class` and set the loss priority to low.

Then you create and name the expedited forwarding traffic class, set the match condition, for the expedited forwarding traffic class, and specify the destination address as `192.168.66.77`. You then create the forwarding class for expedited forwarding DiffServ traffic as `ef-class` and set the policer to `ef-policer`. Then you create and name the network-control traffic class and set the match condition.

You then create and name the forwarding class for the network control traffic class as `nc-class`. You create and name the forwarding class for the best-effort traffic class as `be-class`. Finally, you apply the multifield classifier firewall filter as an input filter on each customer-facing or host-facing that needs the filter. In this example, the interface is `ge-0/0/0`.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall filter mf-classifier interface-specific
set firewall filter mf-classifier term assured-forwarding from destination-address
  192.168.44.55
set firewall filter mf-classifier term assured-forwarding then forwarding-class af-class
set firewall filter mf-classifier term assured-forwarding then loss-priority low
set firewall filter mf-classifier term expedited-forwarding from destination-address
  192.168.66.77
set firewall filter mf-classifier term expedited-forwarding then forwarding-class ef-class
set firewall filter mf-classifier term expedited-forwarding then policer ef-policer
set firewall filter mf-classifier term network-control from precedence net-control
set firewall filter mf-classifier term network-control then forwarding-class nc-class
set firewall filter mf-classifier term best-effort then forwarding-class be-class
set interfaces ge-0/0/0 unit 0 family inet filter input mf-classifier
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure a firewall filter for a multifield classifier for a device:

1. Create and name the multifield classifier filter.

```
[edit]
user@host# edit firewall filter mf-classifier
```

user@host# set interface-specific

2. Create and name the term for the assured forwarding traffic class.

[edit firewall filter mf-classifier]

user@host# edit term assured-forwarding

3. Specify the destination address for assured forwarding traffic.

[edit firewall filter mf-classifier term assured-forwarding]

user@host# set from destination-address 192.168.44.55

4. Create the forwarding class and set the loss priority for the assured forwarding traffic class.

[edit firewall filter mf-classifier term assured-forwarding]

user@host# set then forwarding-class af-class

user@host# set then loss-priority low

5. Create and name the term for the expedited forwarding traffic class.

[edit]

user@host# edit firewall filter mf-classifier

user@host# edit term expedited-forwarding

6. Specify the destination address for the expedited forwarding traffic.

[edit firewall filter mf-classifier term expedited-forwarding]

user@host# set from destination-address 192.168.66.77

7. Create the forwarding class and apply the policer for the expedited forwarding traffic class.

[edit firewall filter mf-classifier term expedited-forwarding]

user@host# set then forwarding-class ef-class

user@host# set then policer ef-policer

8. Create and name the term for the network control traffic class.

[edit]

user@host# edit firewall filter mf-classifier

user@host# edit term network-control

9. Create the match condition for the network control traffic class.

[edit firewall filter mf-classifier term network-control]

user@host# set from precedence net-control

10. Create and name the forwarding class for the network control traffic class.

[edit firewall filter mf-classifier term network-control]

user@host# set then forwarding-class nc-class

11. Create and name the term for the best-effort traffic class.

[edit]

user@host# edit firewall filter mf-classifier

user@host# edit term best-effort

12. Create and name the forwarding class for the best-effort traffic class.

[edit firewall filter mf-classifier term best-effort]

user@host# set then forwarding-class be-class

NOTE: Because this is the last term in the filter, it has no match condition.

13. Apply the multifield classifier firewall filter as an input filter.

[edit]

```
user@host# set interfaces ge-0/0/0 unit 0 family inet filter input mf-classifier
```

Results From configuration mode, confirm your configuration by entering the **show firewall filter mf-classifier** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

[edit]

```
user@host# show firewall filter mf-classifier
interface-specific;
term assured-forwarding {
  from {
    destination-address {
      192.168.44.55/32;
    }
  }
  then {
    loss-priority low;
    forwarding-class af-class;
  }
}
term expedited-forwarding {
  from {
    destination-address {
      192.168.66.77/32;
    }
  }
  then {
    policer ef-policer;
    forwarding-class ef-class;
  }
}
term network-control {
  from {
    precedence net-control;
  }
  then forwarding-class nc-class;
}
term best-effort {
  then forwarding-class be-class;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying a Firewall Filter for a Multifield Classifier Configuration on page 4904](#)

Verifying a Firewall Filter for a Multifield Classifier Configuration

Purpose Verify that a firewall filter for a multifield classifier is configured properly on a device.

Action From configuration mode, enter the **show firewall filter mf-classifier** command.

Policer Overhead to Account for Rate Shaping in the Traffic Manager

- [Policer Overhead to Account for Rate Shaping Overview on page 4904](#)
- [Example: Configuring Policer Overhead to Account for Rate Shaping on page 4905](#)

Policer Overhead to Account for Rate Shaping Overview

If you configure ingress or egress traffic-shaping overhead values for an interface, the traffic manager cannot apply these values to any rate-limiting also applied to the interface. To enable the router to account for the additional Ethernet frame length when policing actions are being determined, you must configure the ingress or egress overhead values for policers separately.

NOTE: When a policer overhead value is changed, the PIC or DPC goes offline and then comes back online.

For Gigabit Ethernet Intelligent Queuing 2 (IQ2) and Enhanced IQ2 (IQ2E) PICs or interfaces on Dense Port Concentrators (DPCs) in MX Series routers, you can control the rate of traffic that passes through all interfaces on the PIC or DPC by configuring a *policer overhead*. You can configure a policer ingress overhead and a policer egress overhead,

each with values from 0 through 255 bytes. The policer overhead values are added to the length of the final Ethernet frame when determining ingress and egress policer actions.

Example: Configuring Policer Overhead to Account for Rate Shaping

This example shows how to configure overhead values for policers when rate-shaping overhead is configured.

- [Requirements on page 4905](#)
- [Overview on page 4905](#)
- [Configuration on page 4906](#)
- [Verification on page 4911](#)

Requirements

Before you begin, make sure that interface for which you are applying ingress or egress policer overhead is hosted on one of the following:

- Gigabit Ethernet IQ2 PIC
- IQ2E PIC
- DPCs in MX Series routers

Overview

This example shows how to configure policer overhead values for all physical interfaces on a supported PIC or MPC so that the rate shaping value configured on a logical interface is accounted for in any policing on that logical interface.

Topology

The router hosts a Gigabit Ethernet IQ2 PIC, installed in PIC location 3 of the Flexible PIC Concentrator (FPC) in slot number 1. The physical interface on port 1 on that PIC is configured to receive traffic on logical interface 0 and send it back out on logical interface 1. Class-of-service scheduling includes 100 Mbps of traffic rate-shaping overhead for the output traffic. A policer egress overhead of 100 bytes is configured on the entire PIC so that, for any policers applied to the output traffic, 100 bytes are added to the final Ethernet frame length when determining ingress and egress policer actions.

NOTE:

Traffic rate-shaping and corresponding policer overhead are configured separately:

- You configure rate shaping at the `[edit class-of-service interfaces interface-name unit unit-number]` hierarchy level.
- You configure policer overhead at the `[edit chassis fpc slot-number pic pic-number]` hierarchy level.

When a policer overhead value is changed, the PIC or DPC goes offline and then comes back online.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Logical Interfaces on page 4906](#)
- [Configuring Traffic Rate-Shaping on the Logical Interface That Carries Output Traffic on page 4908](#)
- [Configuring Policer Overhead on the PIC or MPC That Hosts the Rate-Shaped Logical Interface on page 4909](#)
- [Applying a Policer to the Logical Interface That Carries Input Traffic on page 4910](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-1/3/1 per-unit-scheduler
set interfaces ge-1/3/1 vlan-tagging
set interfaces ge-1/3/1 unit 0 vlan-id 100
set interfaces ge-1/3/1 unit 0 family inet address 10.10.10.1/30
set interfaces ge-1/3/1 unit 1 vlan-id 101
set interfaces ge-1/3/1 unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac
  00:00:11:22:33:44
set class-of-service schedulers be transmit-rate percent 5
set class-of-service schedulers ef transmit-rate percent 30
set class-of-service schedulers af transmit-rate percent 30
set class-of-service schedulers nc transmit-rate percent 35
set class-of-service scheduler-maps my-map forwarding-class best-effort scheduler be
set class-of-service scheduler-maps my-map forwarding-class expedited-forwarding
  scheduler ef
set class-of-service scheduler-maps my-map forwarding-class network-control scheduler
  nc
set class-of-service scheduler-maps my-map forwarding-class assured-forwarding
  scheduler af
set class-of-service interfaces ge-1/3/1 unit 1 scheduler-map my-map
set class-of-service interfaces ge-1/3/1 unit 1 shaping-rate 100m
set firewall policer 500Kbps logical-interface-policer
set firewall policer 500Kbps if-exceeding bandwidth-limit 500k
set firewall policer 500Kbps if-exceeding burst-size-limit 625k
set firewall policer 500Kbps then discard
set chassis fpc 1 pic 3 ingress-policer-overhead 100
set chassis fpc 1 pic 3 egress-policer-overhead 100
set interfaces ge-1/3/1 unit 0 family inet policer input 500Kbps
```

Configuring the Logical Interfaces

Step-by-Step Procedure

To configure the logical interfaces:

1. Enable configuration of the interface

[edit]

```
user@host# edit interfaces ge-1/3/1
```

2. Enable multiple queues for each logical interface (so that you can associate an output scheduler with each logical interface).

```
[edit interfaces ge-1/3/1]
user@host# set per-unit scheduler
user@host# set vlan-tagging
```

NOTE: For Gigabit Ethernet IQ2 PICs only, use the **shared-scheduler** statement to enable shared schedulers and shapers on a physical interface.

3. Configure logical interface **ge-1/3/1.0**.

```
[edit interfaces ge-1/3/1]
user@host# set unit 0 vlan-id 100
user@host# set unit 0 family inet address 10.10.10.1/30
```

4. Configure logical interface **ge-1/3/1.1**.

```
[edit interfaces ge-1/3/1]
user@host# set unit 1 vlan-id 101
user@host# set unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac
00:00:11:22:33:44
```

Results Confirm the configuration of the interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/1 {
  per-unit-scheduler;
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 10.10.10.1/30;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      address 20.20.20.1/30 {
        arp 20.20.20.2 mac 00:00:11:22:33:44;
      }
    }
  }
}
```

*Configuring Traffic Rate-Shaping on the Logical Interface That Carries Output Traffic***Step-by-Step Procedure**

To configure traffic rate-shaping on the logical interface that carries output traffic:

1. Enable configuration of class-of-service features.

```
[edit]
user@host# edit class-of-service
```

2. Configure packet scheduling on logical interface **ge-1/3/1.0**.

- a. Configure schedulers that specify the percentage of transmission capacity.

```
[edit class-of-service]
user@host# edit schedulers
```

```
[edit class-of-service schedulers]
user@host# set be transmit-rate percent 5
user@host# set ef transmit-rate percent 30
user@host# set af transmit-rate percent 30
user@host# set nc transmit-rate percent 35
```

A percentage of zero drops all packets in the queue. When the **rate-limit** option is specified, the transmission rate is limited to the rate-controlled amount. In contrast with the **exact** option, a scheduler with the **rate-limit** option shares unused bandwidth above the rate-controlled amount.

- b. Configure a scheduler map to associate each scheduler with a forwarding class.

```
[edit class-of-service]
user@host# edit scheduler-maps my-map

[edit class-of-service scheduler-maps my-map]
user@host# set forwarding-class best-effort scheduler be
user@host# set forwarding-class expedited-forwarding scheduler ef
user@host# set forwarding-class network-control scheduler nc
user@host# set forwarding-class assured-forwarding scheduler af
```

- c. Associate the scheduler map with logical interface **ge-1/3/1.0**.

```
[edit class-of-service]
user@host# edit interfaces ge-1/3/1 unit 1
```

```
[edit class-of-service interfaces ge-1/3/1 unit 1]
user@host# set scheduler-map my-map
```

3. Configure 100 Mbps of traffic rate-shaping overhead on logical interface **ge-1/3/1.1**.

```
[edit class-of-service interfaces ge-1/3/1 unit 1]
user@host# set shaping-rate 100
```

Alternatively, you can configure a shaping rate for a logical interface and oversubscribe the physical interface by including the **shaping-rate** statement at the **[edit class-of-service traffic-control-profiles]** hierarchy level. With this configuration approach, you can independently control the delay-buffer rate.

Results Confirm the configuration of the class-of-service features (including the 100 Mbp of shaping of the egress traffic) by entering the **show class-of-service** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show class-of-service
interfaces {
  ge-1/3/1 {
    unit 1 {
      scheduler-map my-map;
      shaping-rate 100m;
    }
  }
}
scheduler-maps {
  my-map {
    forwarding-class best-effort scheduler be;
    forwarding-class expedited-forwarding scheduler ef;
    forwarding-class network-control scheduler nc;
    forwarding-class assured-forwarding scheduler af;
  }
}
schedulers {
  be {
    transmit-rate percent 5;
  }
  ef {
    transmit-rate percent 30;
  }
  af {
    transmit-rate percent 30;
  }
  nc {
    transmit-rate percent 35;
  }
}
```

Configuring Policer Overhead on the PIC or MPC That Hosts the Rate-Shaped Logical Interface

Step-by-Step Procedure To configure policer overhead on the PIC or MPC that hosts the rate-shaped logical interface:

1. Enable configuration of the supported PIC or MPC.

```
[edit]
user@host# set chassis fpc 1 pic 3
```

2. Configure 100 bytes of policer overhead on the supported PIC or MPC.

```
[edit]
user@host# set ingress-policer-overhead 100
user@host# set egress-policer-overhead 100
```

NOTE: These values are added to the length of the final Ethernet frame when determining ingress and egress policer actions for all physical interfaces on the PIC or MPC.

You can specify policer overhead with values from 0 through 255 bytes.

Results Confirm the configuration of the policer overhead on the physical interface to account for rate-shaping by entering the **show chassis** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show chassis
chassis {
  fpc 1 {
    pic 3 {
      egress-policer-overhead 100;
      ingress-policer-overhead 100;
    }
  }
}
```

Applying a Policer to the Logical Interface That Carries Input Traffic

Step-by-Step Procedure To apply a policer to the logical interface that carries input traffic:

1. Configure the logical interface (aggregate) policer.

```
[edit]
user@host# edit firewall policer 500Kbps

[edit firewall policer 500Kbps]
user@host# set logical-interface-policer
user@host# set if-exceeding bandwidth-limit 500k
user@host# set if-exceeding burst-size-limit 625k
user@host# set then discard
```

2. Apply the policer to Layer 3 input on the IPv4 logical interface.

```
[edit]
user@host# set interfaces ge-1/3/1 unit 0 family inet policer input 500Kbps
```

NOTE: The 100 Mbps policer overhead is added to the length of the final Ethernet frame when determining ingress and egress policer actions,

Results Confirm the configuration of the policer with rate-shaping overhead by entering the **show firewall** and **show interfaces** configuration mode commands. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer 500Kbps {
  logical-interface-policer;
  if-exceeding {
    bandwidth-limit 500k;
    burst-size-limit 625k;
  }
  then discard;
}
[edit]
user@host# show interfaces
ge-1/3/1 {
  per-unit-scheduler;
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    layer2-policer {
      input-policer 500Kbps;
    }
    family inet {
      address 10.10.10.1/30;
    }
  }
  unit 0 {
    vlan-id 101;
    family inet {
      address 20.20.20.1/30 {
        arp 20.20.20.2 mac 00:00:11:22:33:44;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying Traffic Statistics and Policers for the Logical Interface on page 4911](#)
- [Displaying Statistics for the Policer on page 4912](#)

Displaying Traffic Statistics and Policers for the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show interfaces** operational mode command for logical interface **ge-1/3/1.0**, and include the **detail** or **extensive** option. The command output section for **Traffic statistics** lists the number of bytes and packets received and transmitted on the logical interface, and the **Protocol inet** section contains a **Policer** field that would list the policer **500Kbps** as an input or output policer as follows:

- **Input: 500Kbps-ge-1/3/1.0-log_int-i**
- **Output: 500Kbps-ge-1/3/1.0-log_int-o**

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to Input traffic only.

Displaying Statistics for the Policer

Purpose Verify the number of packets evaluated by the policer.

Action Use the **show policer** operational mode command and optionally specify the name of the policer. The command output displays the number of packets evaluated by each configured policer (or the specified policer), in each direction. For the policer **500Kbps**, the input and output policer names are displayed as follows:

- **500Kbps-ge-1/3/1.0-log_int-i**
- **500Kbps-ge-1/3/1.0-log_int-o**

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to input traffic only.

Configuring Three-Color Policers

- [Three-Color Policer Configuration Guidelines on page 4912](#)
- [Basic Single-Rate Three-Color Policers on page 4915](#)
- [Basic Two-Rate Three-Color Policers on page 4921](#)

Three-Color Policer Configuration Guidelines

- [Platforms Supported for Three-Color Policers on page 4913](#)
- [Color Modes for Three-Color Policers on page 4913](#)
- [Naming Conventions for Three-Color Policers on page 4914](#)

Platforms Supported for Three-Color Policers

Three-color policers are supported on the following Juniper Networks routers and switch:

- EX Series switches
- M120 Multiservice Edge Routers
- M320 Multiservice Edge Routers and T Series Core Routers with Enhanced II Flexible PIC Concentrators (FPCs)
- MX Series 3D Universal Edge Routers
- T640 Core Routers with Enhanced Scaling FPC4
- T4000 Core Routers with FPC5

On MX Series and M120 routers and EX Series switches, you can apply three-color policers to aggregated interfaces.

The **discard** action for a tricolor marking policer for a firewall filter is supported on the M120 routers, M320 routers with Enhanced-III FPCs, M7i and M10i routers with the Enhanced CFEB (CFEB-E), and MX Series routers with Trio MPCs and EX Series switches, so it is not necessary to include the **logical-interface-policer** statement for them.

Color Modes for Three-Color Policers

Three-color policers—both single-rate and two-rate three-color policer schemes—can operate in either of two modes:

- [Color-Blind Mode on page 4913](#)
- [Color-Aware Mode on page 4913](#)

Color-Blind Mode

In *color-blind* mode, the three-color policer assumes that all packets examined have not been previously marked or metered. If you configure a three-color policer to be color-blind instead of color-aware, the policer ignores preexisting color markings that might have been set for a packet by another traffic policer configured at a previous network node.

Color-Aware Mode

In *color-aware* mode, the three-color policer assumes that all packets examined have been previously marked or metered. In other words, the three-color policer takes into account any coloring markings that might have been set for a packet by another traffic policer configured at a previous network node. At the node where color-aware policing is configured, any preexisting color markings are used in determining the appropriate policing action for the packet.

In color-aware mode, the three-color policer can increase the packet loss priority (PLP) level of a packet, but never decrease it. For example, if a color-aware three-color policer meters a packet with a medium PLP marking, it can raise the PLP level to high, but cannot reduce the PLP level to low.

For two-rate, three-color policing, the Junos OS uses two token buckets to manage bandwidth based on the two rates of traffic. For example, two-rate policing might be

configured on a node upstream in the network. The two-rate policer has marked a packet as yellow (loss priority medium-low). The color-aware policer takes this yellow marking into account when determining the appropriate policing action. In color-aware policing, the yellow packet would never receive the action associated with either the green packets or red packets. This way, tokens for violating packets are never taken from the metering token buckets at the color-aware policing node.

NOTE: For a three-color policer operating in color-aware mode and when the PLP of the input packet is medium-low, the color of the input packet to the policer is mapped to the color yellow.

In such a scenario, if the color of the input packet remains unchanged, the policer operates in the following way:

- On a T1600 Enhanced Scaling Type 4 FPC (T1600-FPC4-ES), the PLP of the output packet remains medium-low.
- On a T4000 Type 5 FPC (T4000-FPC5-3D), the PLP of the output packet is marked as medium-high.

Because of this difference, for any applications (such as rewrite and WRED selection on egress interface) that use PLP, the packets are treated differently for the same flow depending on the FPC type (T1600 Enhanced Scaling FPC4 (T1600-FPC4-ES) or T4000 FPC5 (T4000-FPC5-3D)) on which the policer is applied.

Naming Conventions for Three-Color Policers

Because policers can be numerous and must be applied correctly to work, a simple naming convention makes it easier to apply the policers properly.

We recommend that you name your policer using a convention that identifies the basic components of the policer:

- Three-color policer type—Where **srTCM** identifies a *single-rate* three-color policer and **trTCM** identifies a *two-rate* three-color policer.
- Three-color policer color mode—Where **ca** identifies a *color-aware* three-color policer and **cb** identifies a *color-blind three-color policer*.

NOTE:

TCM stands for tricolor marking.

Table 369 on page 4915 describes a recommended naming convention for policers.

Table 369: Recommended Naming Convention for Policers

Three-Color Policer Type	Naming Convention	Example Names
Single-rate three-color, color-aware	<i>srTCMnumber-ca</i>	srTCM1-ca, srTCM2-ca, srTCM3-ca, ...
Single-rate three-color, color-blind	<i>srTCMnumber-cb</i>	srTCM1-cb, srTCM2-cb, srTCM3-cb, ...
Two-rate three-color, color-aware	<i>trTCMnumber-ca</i>	trTCM1-ca, trTCM2-ca, trTCM3-ca, ...
Two-rate three-color, color-blind	<i>trTCMnumber-cb</i>	trTCM1-cb, trTCM2-cb, trTCM3-cb, ...

Basic Single-Rate Three-Color Policers

- [Single-Rate Three-Color Policer Overview on page 4915](#)
- [Example: Configuring a Single-Rate Three-Color Policer on page 4916](#)

Single-Rate Three-Color Policer Overview

A single-rate three-color policer defines a bandwidth limit and a maximum burst size for guaranteed traffic and a second burst size for peak traffic. A single-rate three-color policer is most useful when a service is structured according to packet length and not peak arrival rate.

Single-rate three-color policing meters a traffic stream based on the following configured traffic criteria:

- Committed information rate (CIR)—Bandwidth limit for guaranteed traffic.
- Committed burst size (CBS)—Maximum packet size permitted for bursts of data that exceed the CIR.
- Excess burst size (EBS)—Maximum packet size permitted for peak traffic.

Single-rate tricolor marking (single-rate TCM) classifies traffic as belonging to one of three color categories and performs congestion-control actions on the packets based on the color marking:

- Green—Traffic that conforms to *either* the bandwidth limit *or* the burst size for guaranteed traffic (CIR and CBS). For a green traffic flow, single-rate marks the packets with an implicit loss priority of **low** and transmits the packets.
- Yellow—Traffic that exceeds *both* the bandwidth limit *and* the burst size for guaranteed traffic (CIR or CBS) but not the burst size for peak traffic (EBS). For a yellow traffic flow, single-rate marks the packets with an implicit loss priority of **medium-high** and transmits the packets.
- Red—Traffic that exceeds the burst size for peak traffic (EBS), single-rate marks packets with an implicit loss priority of **high** and, optionally, discards the packets.

If congestion occurs downstream, the packets with higher loss priority are more likely to be discarded.

NOTE: For both single-rate and two-rate three-color policers, the only *configurable* action is to discard packets in a red traffic flow.

The **discard** action for a tricolor marking policer for a firewall filter is supported on the M120 routers, M320 routers with Enhanced-III FPCs, M7i and M10i routers with the Enhanced CFEB (CFEB-E), and MX Series routers with Trio MPCs and EX Series switches, so it is not necessary to include the **logical-interface-policer** statement for them.

Example: Configuring a Single-Rate Three-Color Policer

This example shows how to configure a single-rate three-color policer.

- [Requirements on page 4916](#)
- [Overview on page 4916](#)
- [Configuration on page 4917](#)
- [Verification on page 4920](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

A single-rate three-color policer meters a traffic flow against a bandwidth limit and burst-size limit for guaranteed traffic, plus a second burst-size limit for excess traffic. Traffic that conforms to the limits for guaranteed traffic is categorized as green, and nonconforming traffic falls into one of two categories:

- Nonconforming traffic that does not exceed the burst size for excess traffic is categorized as yellow.

- Nonconforming traffic that exceeds the burst size for excess traffic is categorized as red.

Each category is associated with an action. For green traffic, packets are implicitly set with a loss-priority value of **low** and then transmitted. For yellow traffic, packets are implicitly set with a loss-priority value of **medium-high** and then transmitted. For red traffic, packets are implicitly set with a loss-priority value of **high** and then transmitted. If the policer configuration includes the optional **action** statement (**action loss-priority high then discard**), then packets in a red flow are discarded instead.

You can apply a three-color policer to Layer 3 traffic as a firewall filter policer only. You reference the policer from a stateless firewall filter term, and then you apply the filter to the input or output of a logical interface at the protocol level.

Topology

In this example, you apply a color-aware, single-rate three-color policer to the input IPv4 traffic at logical interface **ge-2/0/5.0**. The IPv4 firewall filter term that references the policer does not apply any packet-filtering. The filter is used only to apply the three-color policer to the interface.

You configure the policer to rate-limit traffic to a bandwidth limit of 40 Mbps and a burst-size limit of 100 KB for green traffic but also allow an excess burst-size limit of 200 KB for yellow traffic. Only nonconforming traffic that exceeds the peak burst-size limit is categorized as red. In this example, you configure the three-color policer action **loss-priority high then discard**, which overrides the implicit marking of red traffic to a **high** loss priority.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring a Single-Rate Three-Color Policer on page 4918](#)
- [Configuring an IPv4 Stateless Firewall Filter That References the Policer on page 4919](#)
- [Applying the Filter to the Logical Interface on page 4919](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set firewall three-color-policer srTCM1-ca single-rate color-aware
set firewall three-color-policer srTCM1-ca single-rate committed-information-rate 40m
set firewall three-color-policer srTCM1-ca single-rate committed-burst-size 100k
set firewall three-color-policer srTCM1-ca single-rate excess-burst-size 200k
set firewall three-color-policer srTCM1-ca action loss-priority high then discard
set firewall family inet filter filter-srTCM1ca-all term 1 then three-color-policer single-rate
srTCM1-ca
set class-of-service interfaces ge-2/0/5 unit 0 forwarding-class af
set interfaces ge-2/0/5 unit 0 family inet address 10.20.130.1/24
set interfaces ge-2/0/5 unit 0 family inet filter input filter-srTCM1ca-all
```

Configuring a Single-Rate Three-Color Policer

Step-by-Step Procedure

To configure a single-rate three-color policer:

1. Enable configuration of a three-color policer.

```
[edit]  
user@host# edit firewall three-color-policer srTCM1-ca
```
2. Configure the color mode of the single-rate three-color policer.

```
[edit firewall three-color-policer srTCM1-ca]  
user@host# set single-rate color-aware
```
3. Configure the single-rate guaranteed traffic limits.

```
[edit firewall three-color-policer srTCM1-ca]  
user@host# set single-rate committed-information-rate 40m  
user@host# set single-rate committed-burst-size 100k
```
4. Configure the single-rate burst-size limit that is used to classify nonconforming traffic.

```
[edit firewall three-color-policer srTCM1-ca]  
user@host# set single-rate excess-burst-size 200k
```
5. (Optional) Configure the action for nonconforming traffic.

```
[edit firewall three-color-policer srTCM1-ca]  
user@host# set action loss-priority high then discard
```

For three-color policers, the only configurable action is to discard packets in a red traffic flow. In this example, packets in a red traffic flow have been implicitly marked with a **high** packet loss priority (PLP) level because the traffic flow exceeded the rate-limiting defined by the single rate-limit (specified by the **committed-information-rate 40m** statement) and the larger burst-size limit (specified by the **excess-burst-size 200k** statement). Because the optional **action** statement is included, this example takes the more severe action of discarding packets in a red traffic flow.

Results Confirm the configuration of the hierarchical policer by entering the **show firewall** configuration command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
three-color-policer srTCM1-ca {  
  action {  
    loss-priority high then discard;  
  }  
  single-rate {  
    color-aware;  
    committed-information-rate 40m;  
    committed-burst-size 100k;  
    excess-burst-size 200k;  
  }  
}
```

*Configuring an IPv4 Stateless Firewall Filter That References the Policier***Step-by-Step Procedure**

To configure a standard stateless firewall filter that references the policier:

1. Enable configuration of an IPv4 standard stateless firewall filter.

```
[edit]
user@host# edit firewall family inet filter filter-srtcm1ca-all
```

2. Specify the filter term that references the policier.

```
[edit firewall family inet filter filter-srtcm1ca-all]
user@host# set term 1 then three-color-policer single-rate srTCM1-ca
```

Note that the term does not specify any match conditions. The firewall filter passes all packets to the policier.

Results

Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter-srtcm1ca-all {
    term 1 {
      then {
        three-color-policer {
          single-rate srTCM1-ca;
        }
      }
    }
  }
}
three-color-policer srTCM1-ca {
  action {
    loss-priority high then discard;
  }
  single-rate {
    color-aware;
    committed-information-rate 40m;
    committed-burst-size 100k;
    excess-burst-size 200k;
  }
}
```

*Applying the Filter to the Logical Interface***Step-by-Step Procedure**

To apply the filter to the logical interface:

1. (MX Series routers and EX Series switches only) (Optional) Reclassify all incoming packets on the logical interface **ge-2/0/5.0** to assured forwarding, regardless of any preexisting classification.

```
[edit]
user@host# set class-of-service interfaces ge-2/0/5 unit 0 forwarding-class af
```

The classifier name can be a configured classifier or one of the default classifiers.

2. Enable configuration of the logical interface.

```
[edit]
user@host# edit interfaces ge-2/0/5 unit 0 family inet
```

3. Configure an IP address.

```
[edit interfaces ge-2/0/5 unit 0 family inet]
user@host# set address 10.20.130.1/24
```

4. Reference the filter as an input filter.

```
[edit interfaces ge-2/0/5 unit 0 family inet]
user@host# set filter input filter-srtcm1ca-all
```

Results Confirm the configuration of the interface by entering the **show class-of-service** and **show interfaces** configuration mode commands. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show class-of-service
interfaces {
  ge-2/0/5 {
    unit 0 {
      forwarding-class af;
    }
  }
}
[edit]
user@host# show interfaces
ge-2/0/5 {
  unit 0 {
    family inet {
      filter {
        input filter-srtcm1ca-all;
      }
      address 10.20.130.1/24;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Displaying the Firewall Filters Applied to the Logical Interface

Purpose Verify that the firewall filter is applied to IPv4 input traffic at the logical interface.

Action Use the **show interfaces** operational mode command for the logical interface **ge-2/0/5.0**, and specify **detail** mode. The **Protocol inet** section of the command output displays IPv4

information for the logical interface. Within that section, the **Input Filters** field displays the name of the firewall filter applied to IPv4 input traffic at the logical interface.

```
user@host> show interfaces ge-2/0/5.0 detail

- [Example: Configuring a Two-Rate Three-Color Policer on page 4922](#)

Two-Rate Three-Color Policer Overview

A two-rate three-color policer defines two bandwidth limits (one for guaranteed traffic and one for peak traffic) and two burst sizes (one for each of the bandwidth limits). A two-rate three-color policer is most useful when a service is structured according to arrival rates and not necessarily packet length.

Two-rate three-color policing meters a traffic stream based on the following configured traffic criteria:

- Committed information rate (CIR)—Bandwidth limit for guaranteed traffic.
- Committed burst size (CBS)—Maximum packet size permitted for bursts of data that exceed the CIR.

- Peak information rate (PIR)—Bandwidth limit for peak traffic.
- Peak burst size (PBS)—Maximum packet size permitted for bursts of data that exceed the PIR.

Two-rate tricolor marking (two-rate TCM) classifies traffic as belonging to one of three color categories and performs congestion-control actions on the packets based on the color marking:

- Green—Traffic that conforms to the bandwidth limit and burst size for guaranteed traffic (CIR and CBS). For a green traffic flow, two-rate TCM marks the packets with an implicit loss priority of **low** and transmits the packets.
- Yellow—Traffic that exceeds the bandwidth limit or burst size for guaranteed traffic (CIR or CBS) but not the bandwidth limit and burst size for peak traffic (PIR and PBS). For a yellow traffic flow, two-rate TCM marks packets with an implicit loss priority of **medium-high** and transmits the packets.
- Red—Traffic that exceeds the bandwidth limit and burst size for peak traffic (PIR and PBS). For a red traffic flow, two-rate TCM marks packets with an implicit loss priority of **high** and, optionally, discards the packets.

If congestion occurs downstream, the packets with higher loss priority are more likely to be discarded.

NOTE: For both single-rate and two-rate three-color policers, the only *configurable* action is to discard packets in a red traffic flow.

For a tricolor marking policer referenced by a firewall filter term, the **discard** policing action is supported on the following routing and switching platforms:

- EX Series switches
- M7i and M10i routers with the Enhanced CFEB (CFEB-E)
- M120 and M320 routers with Enhanced-III FPCs
- MX Series routers with Trio MPCs

To apply a tricolor marking policer on these routing platforms, it is not necessary to include the **logical-interface-policer** statement.

Example: Configuring a Two-Rate Three-Color Policer

This example shows how to configure a two-rate three-color policer.

- [Requirements on page 4923](#)
- [Overview on page 4923](#)
- [Configuration on page 4923](#)
- [Verification on page 4926](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

A two-rate three-color policer meters a traffic flow against a bandwidth limit and burst-size limit for guaranteed traffic, plus a bandwidth limit and burst-size limit for peak traffic. Traffic that conforms to the limits for guaranteed traffic is categorized as green, and nonconforming traffic falls into one of two categories:

- Nonconforming traffic that does not exceed peak traffic limits is categorized as yellow.
- Nonconforming traffic that exceeds peak traffic limits is categorized as red.

Each category is associated with an action. For green traffic, packets are implicitly set with a loss-priority value of **low** and then transmitted. For yellow traffic, packets are implicitly set with a loss-priority value of **medium-high** and then transmitted. For red traffic, packets are implicitly set with a loss-priority value of **high** and then transmitted. If the policer configuration includes the optional **action** statement (**action loss-priority high then discard**), then packets in a red flow are discarded instead.

You can apply a three-color policer to Layer 3 traffic as a firewall filter policer only. You reference the policer from a stateless firewall filter term, and then you apply the filter to the input or output of a logical interface at the protocol level.

Topology

In this example, you apply a color-aware, two-rate three-color policer to the input IPv4 traffic at logical interface **fe-0/1/1.0**. The IPv4 firewall filter term that references the policer does not apply any packet-filtering. The filter is used only to apply the three-color policer to the interface.

You configure the policer to rate-limit traffic to a bandwidth limit of 40 Mbps and a burst-size limit of 100 KB for green traffic, and you configure the policer to also allow a peak bandwidth limit of 60 Mbps and a peak burst-size limit of 200 KB for yellow traffic. Only nonconforming traffic that exceeds the peak traffic limits is categorized as red. In this example, you configure the three-color policer action **loss-priority high then discard**, which overrides the implicit marking of red traffic to a **high** loss priority.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring a Two-Rate Three-Color Policer on page 4924](#)
- [Configuring an IPv4 Stateless Firewall Filter That References the Policer on page 4925](#)
- [Applying the Filter to a Logical Interface at the Protocol Family Level on page 4926](#)

CLI Quick Configuration To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the [edit] hierarchy level.

```
set firewall three-color-policer trTCM1-ca two-rate color-aware
set firewall three-color-policer trTCM1-ca two-rate committed-information-rate 40m
set firewall three-color-policer trTCM1-ca two-rate committed-burst-size 100k
set firewall three-color-policer trTCM1-ca two-rate peak-information-rate 60m
set firewall three-color-policer trTCM1-ca two-rate peak-burst-size 200k
set firewall three-color-policer trTCM1-ca action loss-priority high then discard
set firewall family inet filter filter-trtcm1ca-all term 1 then three-color-policer two-rate
trTCM1-ca
set interfaces ge-2/0/5 unit 0 family inet address 10.10.10.1/30
set interfaces ge-2/0/5 unit 0 family inet filter input filter-trtcm1ca-all
set class-of-service interfaces ge-2/0/5 forwarding-class af
```

Configuring a Two-Rate Three-Color Policer

Step-by-Step Procedure To configure a two-rate three-color policer:

1. Enable configuration of a three-color policer.

```
[edit]
user@host# set firewall three-color-policer trTCM1-ca
```

2. Configure the color mode of the two-rate three-color policer.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set two-rate color-aware
```

3. Configure the two-rate guaranteed traffic limits.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set two-rate committed-information-rate 40m
user@host# set two-rate committed-burst-size 100k
```

Traffic that does not exceed both of these limits is categorized as green. Packets in a green flow are implicitly set to **low** loss priority and then transmitted.

4. Configure the two-rate peak traffic limits.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set two-rate peak-information-rate 60m
user@host# set two-rate peak-burst-size 200k
```

Nonconforming traffic that does not exceed both of these limits is categorized as yellow. Packets in a yellow flow are implicitly set to **medium-high** loss priority and then transmitted. Nonconforming traffic that exceeds both of these limits is categorized as red. Packets in a red flow are implicitly set to **high** loss priority.

5. (Optional) Configure the policer action for red traffic.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set action loss-priority high then discard
```

For three-color policers, the only configurable action is to discard red packets. Red packets are packets that have been assigned high loss priority because they exceeded the peak information rate (PIR) and the peak burst size (PBS).

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
three-color-policer trTCM1-ca {
  action {
    loss-priority high then discard;
  }
  two-rate {
    color-aware;
    committed-information-rate 40m;
    committed-burst-size 100k;
    peak-information-rate 60m;
    peak-burst-size 200k;
  }
}
```

Configuring an IPv4 Stateless Firewall Filter That References the Policer

Step-by-Step Procedure To configure an IPv4 stateless firewall filter that references the policer:

1. Enable configuration of an IPv4 standard stateless firewall filter.

```
[edit]
user@host# set firewall family inet filter filter-trtcm1ca-all
```

2. Specify the filter term that references the policer.

```
[edit firewall family inet filter filter-trtcm1ca-all]
user@host# set term 1 then three-color-policer two-rate trTCM1-ca
```

Note that the term does not specify any match conditions. The firewall filter passes all packets to the policer.

Results Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter-trtcm1ca-all {
    term 1 {
      then {
        three-color-policer {
          two-rate trTCM1-ca;
        }
      }
    }
  }
}
three-color-policer trTCM1-ca {
  action {
    loss-priority high then discard;
  }
}
```

```
two-rate {  
  color-aware;  
  committed-information-rate 40m;  
  committed-burst-size 100k;  
  peak-information-rate 60m;  
  peak-burst-size 200k;  
}  
}
```

Applying the Filter to a Logical Interface at the Protocol Family Level

Step-by-Step Procedure

To apply the filter to the logical interface at the protocol family level:

1. Enable configuration of an IPv4 firewall filter.

```
[edit]  
user@host# edit interfaces ge-2/0/5 unit 0 family inet
```

2. Apply the policer to the logical interface at the protocol family level.

```
[edit interfaces ge-2/0/5 unit 0 family inet]  
user@host# set address 10.10.10.1/30  
user@host# set filter input filter-trtcm1ca-all
```

3. (MX Series routers and EX Series switches only) (Optional) For input policers, you can configure a fixed classifier. A fixed classifier reclassifies all incoming packets, regardless of any preexisting classification.

```
[edit]  
user@host# set class-of-service interfaces ge-2/0/5 forwarding-class af
```

The classifier name can be a configured classifier or one of the default classifiers.

Results Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]  
user@host# show interfaces  
ge-2/0/5 {  
  unit 0 {  
    family inet {  
      address 10.10.10.1/30;  
      filter {  
        input filter-trtcm1ca-all;  
      }  
    }  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying the Firewall Filters Applied to the Logical Interface on page 4927](#)

Displaying the Firewall Filters Applied to the Logical Interface

Purpose Verify that the firewall filter is applied to IPv4 input traffic at the logical interface.

Action Use the **show interfaces** operational mode command for the logical interface **ge-2/0/5.0**, and specify **detail** mode. The **Protocol inet** section of the command output displays IPv4 information for the logical interface. Within that section, the **Input Filters** field displays the name of IPv4 firewall filters associated with the logical interface.

```
user@host> show interfaces ge-2/0/5.0 detail
Logical interface ge-2/0/5.0 (Index 105) (SNMP ifIndex 556) (Generation 170)
  Flags: Device-Down SNMP-Traps 0x4004000 Encapsulation: ENET2

Logical Interface (Aggregate) Policer Overview

A *logical interface policer*—also called an *aggregate policer*—is a two-color or three-color policer that defines traffic rate limiting that you can apply to input or output traffic for multiple protocol families on the same logical interface without creating multiple instances of the policer.

To configure a single-rate two-color logical interface policer, include the **logical-interface-policer** statement at one of the following hierarchy levels:

- [edit **firewall policer** *policer-name*]
- [edit logical-systems *logical-system-name* **firewall policer** *policer-name*]

To configure a single-rate or two-rate three-color logical interface policer, include the **logical-interface-policer** statement at one of the following hierarchy levels:

- [edit **firewall three-color-policer** *name*]
- [edit logical-systems *logical-system-name* **firewall three-color-policer** *name*]

NOTE: A three-color policer can be applied to Layer 2 traffic as a logical interface policer only. You cannot apply a three-color policer to Layer 2 traffic as a physical interface policer (through a firewall filter).

You apply a logical interface policer to Layer 3 traffic directly to the interface configuration at the logical unit level (to rate-limit all traffic types, regardless of the protocol family) or at the protocol family level (to rate-limit traffic of a specific protocol family). You cannot reference a logical interface policer from a stateless firewall filter term and then apply the filter to a logical interface.

You can apply a logical interface policer to unicast traffic only. For information about configuring a stateless firewall filter for flooded traffic, see “*Applying Filters to Forwarding Tables*” in the “Traffic Sampling, Forwarding, and Monitoring” section of the *Routing Policy Configuration Guide*.

To display a logical interface policer on a particular interface, issue the **show interfaces policers** operational mode command.

Example: Configuring a Two-Color Logical Interface (Aggregate) Policer

This example shows how to configure a single-rate two-color policer as a logical interface policer and apply it to incoming IPv4 traffic on a logical interface.

- [Verification on page 4933](#)

Requirements

Before you begin, make sure that the logical interface to which you apply the two-color logical interface policer is hosted on a Gigabit Ethernet interface (**ge-**) or a 10-Gigabit Ethernet interface (**xe-**).

Overview

In this example, you configure the single-rate two-color policer **policer_IFL** as a logical interface policer and apply it to incoming IPv4 traffic at logical interface **ge-1/3/1.0**.

Topology

If the input IPv4 traffic on the physical interface **ge-1/3/1** exceeds the bandwidth limit equal to 90 percent of the media rate with a 300 KB burst-size limit, then the logical interface policer **policer_IFL** rate-limits the input IPv4 traffic on the logical interface **ge-1/3/1.0**. Configure the policer to mark nonconforming traffic by setting packet loss priority (PLP) levels to **high** and classifying packets as **best-effort**.

As the incoming IPv4 traffic rate on the physical interface slows and conforms to the configured limits, Junos OS stops marking the incoming IPv4 packets at the logical interface.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Logical Interfaces on page 4930](#)
- [Configuring the Single-Rate Two-Color Policer as a Logical Interface Policer on page 4931](#)
- [Applying the Logical Interface Policer to Input IPv4 Traffic at a Logical Interface on page 4932](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-1/3/1 vlan-tagging
set interfaces ge-1/3/1 unit 0 vlan-id 100
set interfaces ge-1/3/1 unit 0 family inet address 10.10.10.1/30
set interfaces ge-1/3/1 unit 1 vlan-id 101
set interfaces ge-1/3/1 unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac
00:00:11:22:33:44
set firewall policer policer_IFL logical-interface-policer
set firewall policer policer_IFL if-exceeding bandwidth-percent 90
set firewall policer policer_IFL if-exceeding burst-size-limit 300k
set firewall policer policer_IFL then loss-priority high
set firewall policer policer_IFL then forwarding-class best-effort
set interfaces ge-1/3/1 unit 0 family inet policer input policer_IFL
```

Configuring the Logical Interfaces

Step-by-Step Procedure

To configure the logical interfaces:

1. Enable configuration of the interface.

[edit]
user@host# edit interfaces ge-1/3/1
2. Configure single tagging.

[edit interfaces ge-1/3/1]
user@host# set vlan-tagging
3. Configure logical interface **ge-1/3/1.0**.

[edit interfaces ge-1/3/1]
user@host# set unit 0 vlan-id 100
user@host# set unit 0 family inet address 10.10.10.1/30
4. Configure logical interface **ge-1/3/1.0**.

[edit interfaces ge-1/3/1]
user@host# set unit 1 vlan-id 101
user@host# set unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac 00:00:11:22:33:44

Results Confirm the configuration of the logical interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 10.10.10.1/30;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      address 20.20.20.1/30 {
        arp 20.20.20.2 mac 00:00:11:22:33:44;
      }
    }
  }
}
```

*Configuring the Single-Rate Two-Color Policer as a Logical Interface Policer***Step-by-Step Procedure**

To configure a single-rate two-color policer as a logical interface policer:

1. Enable configuration of a single-rate two-color policer.

```
[edit]
user@host# edit firewall policer policer_IFL
```

2. Specify that the policer is a logical interface (aggregate) policer.

```
[edit firewall policer policer_IFL]
user@host# set logical-interface-policer
```

A logical interface policer rate-limits traffic based on a percentage of the media rate of the physical interface underlying the logical interface to which the policer is applied. The policer is applied directly to the interface rather than referenced by a firewall filter.

3. Specify the policer traffic limits.

- a. Specify the bandwidth limit.

- To specify the bandwidth limit as an absolute rate, from 8,000 bits per second through 50,000,000,000 bits per second, include the **bandwidth-limit *bps*** statement.
- To specify the bandwidth limit as a percentage of the physical port speed on the interface, include the **bandwidth-percent *percent*** statement.

In this example, the CLI commands and output are based on a bandwidth limit specified as a percentage rather than as an absolute rate.

```
[edit firewall policer policer_IFL]
user@host# set if-exceeding bandwidth-percent 90
```

- b. Specify the burst-size limit, from 1,500 bytes through 100,000,000,000 bytes, which is the maximum packet size to be permitted for bursts of data that exceed the specified bandwidth limit.

```
[edit firewall policer policer_IFL]
user@host# set if-exceeding burst-size-limit 300k
```

4. Specify the policer actions to be taken on traffic that exceeds the configured rate limits.

- To discard the packet, include the **discard** statement.
- To set the loss-priority value of the packet, include the **loss-priority (*low* | *medium-low* | *medium-high* | *high*)** statement.
- To classify the packet to a forwarding class, include the **forwarding-class (*forwarding-class* | *assured-forwarding* | *best-effort* | *expedited-forwarding* | *network-control*)** statement.

In this example, the CLI commands and output are based on both setting the packet loss priority level and classifying the packet.

```
[edit firewall policer policer_IFL]
user@host# set then loss-priority high
user@host# set then forwarding-class best-effort
```

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer policer_IFL {
  logical-interface-policer;
  if-exceeding {
    bandwidth-percent 90;
    burst-size-limit 300k;
  }
  then {
    loss-priority high;
    forwarding-class best-effort;
  }
}
```

Applying the Logical Interface Policer to Input IPv4 Traffic at a Logical Interface

Step-by-Step Procedure To apply the two-color logical interface policer to input IPv4 traffic a logical interface:

1. Enable configuration of the logical interface.

```
[edit]
user@host# edit interfaces ge-1/3/1 unit 0
```
2. Apply the policer to all traffic types or to a specific traffic type on the logical interface.
 - To apply the policer to all traffic types, regardless of the protocol family, include the **policer (input | output) *policer-name*** statement at the **[edit interfaces *interface-name* unit *number*]** hierarchy level.
 - To apply the policer to traffic of a specific protocol family, include the **policer (input | output) *policer-name*** statement at the **[edit interfaces *interface-name* unit *unit-number* family *family-name*]** hierarchy level.

To apply the logical interface policer to incoming packets, use the **policer input *policer-name*** statement. To apply the logical interface policer to outgoing packets, use the **policer output *policer-name*** statement.

In this example, the CLI commands and output are based on rate-limiting the IPv4 input traffic at logical interface **ge-1/3/1.0**.

```
[edit interfaces ge-1/3/1 unit 0]
user@host# set family inet policer input policer_IFL
```

Results Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      policer input policer_IFL;
      address 10.10.10.1/30;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      address 20.20.20.1/30 {
        arp 20.20.20.2 mac 00:00:11:22:33:44;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying Traffic Statistics and Policers for the Logical Interface on page 4933](#)
- [Displaying Statistics for the Policer on page 4934](#)

Displaying Traffic Statistics and Policers for the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show interfaces** operational mode command for logical interface **ge-1/3/1.0**, and include the **detail** or **extensive** option. The command output section for **Traffic statistics** lists the number of bytes and packets received and transmitted on the logical interface. The **Protocol inet** subsection contains a **Policer** field that would list the policer **policer_IFL** as an input or output logical interface policer as follows:

- **Input:** policer_IFL-ge-1/3/1.0-log_int-i
- **Output:** policer_IFL-ge-1/3/1.0-log_int-o

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to input traffic only.

Displaying Statistics for the Policer

Purpose Verify the number of packets evaluated by the policer.

Action Use the **show policer** operational mode command and optionally specify the name of the policer. The command output displays the number of packets evaluated by each configured policer (or the specified policer), in each direction. For the policer **policer_IFL**, the input and output policer names are displayed as follows:

- **policer_IFL-ge-1/3/1.0-log_int-i**
- **policer_IFL-ge-1/3/1.0-log_int-o**

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to input traffic only.

Example: Configuring a Three-Color Logical Interface (Aggregate) Policer

This example shows how to configure a two-rate three-color color-blind policer as a logical interface (aggregate) policer and apply the policer directly to Layer 2 input traffic at a supported logical interface.

- [Requirements on page 4934](#)
- [Overview on page 4934](#)
- [Configuration on page 4935](#)
- [Verification on page 4939](#)

Requirements

Before you begin, make sure that the logical interface to which you apply the three-color logical interface policer is hosted on a Gigabit Ethernet interface (**ge-**) or a 10-Gigabit Ethernet interface (**xe-**) on an MX Series router and EX Series switch.

Overview

A two-rate three-color policer meters a traffic flow against a bandwidth limit and burst-size limit for guaranteed traffic, plus a second set of bandwidth and burst-size limits for peak traffic. Traffic that conforms to the limits for guaranteed traffic is categorized as green, and nonconforming traffic falls into one of two categories:

- Nonconforming traffic that does not exceed the bandwidth and burst-size limits for peak traffic is categorized as yellow.
- Nonconforming traffic that exceeds the bandwidth and burst-size limits for peak traffic is categorized as red.

A logical interface policer defines traffic rate-limiting rules that you can apply to multiple protocol families on the same logical interface without creating multiple instances of the policer.

NOTE: You apply a logical interface policer directly to a logical interface at the logical unit level, and not by referencing the policer in a stateless firewall filter and then applying the filter to the logical interface at the protocol family level.

Topology

In this example, you configure the two-rate three-color policer **trTCM2-cb** as a color-blind logical interface policer and apply the policer to incoming Layer 2 traffic on logical interface **ge-1/3/1.0**.

NOTE: When using a three-color policer to rate-limit Layer 2 traffic, color-aware policing can be applied to egress traffic only.

The policer defines guaranteed traffic rate limits such that traffic that conforms to the bandwidth limit of 40 Mbps with a 100 KB allowance for traffic bursting (based on the token-bucket formula) is categorized as green. As with any policed traffic, the packets in a green flow are implicitly set to a **low** loss priority and then transmitted.

Nonconforming traffic that falls within the peak traffic limits of a 60 Mbps bandwidth limit and a 200 KB allowance for traffic bursting (based on the token-bucket formula) is categorized as yellow. The packets in a yellow traffic flow are implicitly set to a **medium-high** loss priority and then transmitted.

Nonconforming traffic that exceeds the peak traffic limits are categorized as red. The packets in a red traffic flow are implicitly set to a **high** loss priority. In this example, the optional policer action for red traffic (**loss-priority high then discard**) is configured, so packets in a red traffic flow are discarded instead of transmitted.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Logical Interfaces on page 4936](#)
- [Configuring the Two-Rate Three-Color Policer as a Logical Interface Policer on page 4937](#)
- [Applying the Three-Color Policer to the Layer 2 Input at the Logical Interface on page 4938](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-1/3/1 vlan-tagging
set interfaces ge-1/3/1 unit 0 vlan-id 100
set interfaces ge-1/3/1 unit 0 family inet address 10.10.10.1/30
set interfaces ge-1/3/1 unit 1 vlan-id 101
```

```
set interfaces ge-1/3/1 unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac
00:00:11:22:33:44
set firewall three-color-policer trTCM2-cb logical-interface-policer
set firewall three-color-policer trTCM2-cb two-rate color-blind
set firewall three-color-policer trTCM2-cb two-rate committed-information-rate 40m
set firewall three-color-policer trTCM2-cb two-rate committed-burst-size 100k
set firewall three-color-policer trTCM2-cb two-rate peak-information-rate 60m
set firewall three-color-policer trTCM2-cb two-rate peak-burst-size 200k
set firewall three-color-policer trTCM2-cb action loss-priority high then discard
set interfaces ge-1/3/1 unit 0 layer2-policer input-three-color trTCM2-cb
```

Configuring the Logical Interfaces

Step-by-Step Procedure

To configure the logical interfaces:

1. Enable configuration of the interface.

```
[edit]
user@host# edit interfaces ge-1/3/1
```

2. Configure single tagging.

```
[edit interfaces ge-1/3/1]
user@host# set vlan-tagging
```

3. Configure logical interface **ge-1/3/1.0**.

```
[edit interfaces ge-1/3/1]
user@host# set unit 0 vlan-id 100
user@host# set unit 0 family inet address 10.10.10.1/30
```

4. Configure logical interface **ge-1/3/1.0**.

```
[edit interfaces ge-1/3/1]
user@host# set unit 1 vlan-id 101
user@host# set unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac
00:00:11:22:33:44
```

Results Confirm the configuration of the logical interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 10.10.10.1/30;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      address 20.20.20.1/30 {
        arp 20.20.20.2 mac 00:00:11:22:33:44;
      }
    }
  }
}
```

```

    }
  }
}

```

Configuring the Two-Rate Three-Color Policer as a Logical Interface Policer

Step-by-Step Procedure

To configure the two-rate three-color policer as a logical interface policer:

1. Enable configuration of a three-color policer.

```

[edit]
user@host# edit firewall three-color-policer trTCM2-cb

```

2. Specify that the policer is a logical interface (aggregate) policer.

```

[edit firewall three-color-policer trTCM2-cb]
user@host# set logical-interface-policer

```

A logical interface policer rate-limits traffic based on a percentage of the media rate of the physical interface underlying the logical interface to which the policer is applied, and the policer is applied directly to the interface rather than referenced by a firewall filter.

3. Specify that the policer is two-rate and color-blind.

```

[edit firewall three-color-policer trTCM2-cb]
user@host# set two-rate color-blind

```

A color-aware three-color policer takes into account any coloring markings that might have been set for a packet by another traffic policer configured at a previous network node, and any preexisting color markings are used in determining the appropriate policing action for the packet.

Because you are applying this three-color policer applied to input at Layer 2, you must configure the policer to be color-blind.

4. Specify the policer traffic limits used to classify a green traffic flow.

```

[edit firewall three-color-policer trTCM2-cb]
user@host# set two-rate committed-information-rate 40m
user@host# set two-rate committed-burst-size 100k

```

5. Specify the additional policer traffic limits used to classify a yellow or red traffic flow.

```

[edit firewall three-color-policer trTCM2-cb]
user@host# set two-rate peak-information-rate 60m
user@host# set two-rate peak-burst-size 200k

```

6. (Optional) Specify the configured policer action for packets in a red traffic flow.

```

[edit firewall three-color-policer trTCM2-cb]
user@host# set action loss-priority high then discard

```

In color-aware mode, the three-color policer configured action can increase the packet loss priority (PLP) level of a packet, but never decrease it. For example, if a color-aware three-color policer meters a packet with a medium PLP marking, it can raise the PLP level to high, but cannot reduce the PLP level to low.

Results Confirm the configuration of the three-color policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
three-color-policer trTCM2-cb {
  logical-interface-policer;
  action {
    loss-priority high then discard;
  }
  two-rate {
    color-blind;
    committed-information-rate 40m;
    committed-burst-size 100k;
    peak-information-rate 60m;
    peak-burst-size 200k;
  }
}
```

Applying the Three-Color Policer to the Layer 2 Input at the Logical Interface

Step-by-Step Procedure To apply the three-color policer to the Layer 2 input at the logical interface:

1. Enable application of Layer 2 logical interface policers.

```
[edit]
user@host# edit interfaces ge-1/3/1 unit 0
```

2. Apply the three-color logical interface policer to a logical interface input.

```
[edit interfaces ge-1/3/1 unit 0]
user@host# set layer2-policerinput-three-color trTCM2-cb
```

Results Confirm the configuration of the logical interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    layer2-policer {
      input-three-color trTCM2-cb;
    }
    family inet {
      address 10.10.10.1/30;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      address 20.20.20.1/30 {
        arp 20.20.20.2 mac 00:00:11:22:33:44;
      }
    }
  }
}
```

```

    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying Traffic Statistics and Policers for the Logical Interface on page 4939](#)
- [Displaying Statistics for the Policer on page 4939](#)

Displaying Traffic Statistics and Policers for the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show interfaces** operational mode command for logical interface **ge-1/3/1.0**, and include the **detail** or **extensive** option. The command output section for **Traffic statistics** lists the number of bytes and packets received and transmitted on the logical interface, and the **Protocol inet** section contains a **Policer** field that would list the policer **trTCM2-cb** as an input or output policer as follows:

- Input: trTCM2-cb-ge-1/3/1.0-log_int-i
- Output: trTCM2-cb-ge-1/3/1.0-log_int-o

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to in the input direction only.

Displaying Statistics for the Policer

Purpose Verify the number of packets evaluated by the policer.

Action Use the **show policer** operational mode command and optionally specify the name of the policer. The command output displays the number of packets evaluated by each configured policer (or the specified policer), in each direction. For the policer **trTCM2-cb**, the input and output policer names are displayed as follows:

- trTCM2-cb-ge-1/3/1.0-log_int-i
- trTCM2-cb-e-1/3/1.0-log_int-o

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to input traffic only.

Two-Color and Three-Color Physical Interface Policers

- [Physical Interface Policer Overview on page 4940](#)
- [Example: Configuring a Physical Interface Policer for Aggregate Traffic at a Physical Interface on page 4941](#)

Physical Interface Policer Overview

A *physical interface policer* is a two-color or three-color policer that defines traffic rate limiting that you can apply to input or output traffic for all the logical interfaces and protocol families configured on a physical interface, even if the logical interfaces belong to different routing instances. This feature is useful when you want to perform aggregate policing for different protocol families and different logical interfaces on the same physical interface.

For example, suppose that a provider edge (PE) router has numerous logical interfaces, each corresponding to a different customer, configured on the same link to a customer edge (CE) device. Now suppose that a customer wants to apply one set of rate limits aggregately for certain types of traffic on a single physical interface. To accomplish this, you could apply a single physical interface policer to the physical interface, which rate-limits all the logical interfaces configured on the interface and all the routing instances to which those interfaces belong.

To configure a single-rate two-color physical interface policer, include the **physical-interface-policer** statement at one of the following hierarchy levels:

- [edit **firewall policer** *policer-name*]
- [edit logical-system *logical-system-name* **firewall policer** *policer-name*]
- [edit routing-instances *routing-instance-name* **firewall policer** *policer-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* **firewall policer** *policer-name*]

To configure a single-rate or two-rate three-color physical interface policer, include the **physical-interface-policer** statement at one of the following hierarchy levels:

- [edit **firewall three-color-policer** *policer-name*]
- [edit logical-system *logical-system-name* **firewall three-color-policer** *policer-name*]
- [edit routing-instances *routing-instance-name* **firewall three-color-policer** *policer-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* **firewall three-color-policer** *policer-name*]

You apply a physical interface policer to Layer 3 traffic by referencing the policer from a stateless firewall filter term and then applying the filter to a logical interface. You cannot apply a physical interface to Layer 3 traffic directly to the interface configuration.

To reference a single-rate two-color policer from a stateless firewall filter term, use the **policer** nonterminating action. To reference a single-rate or two-rate three-color policer from a stateless firewall filter term, use the **three-color-policer** nonterminating action.

The following requirements apply to a stateless firewall filter that references a physical interface policer:

- You must configure the firewall filter for a specific, supported protocol family: **ipv4**, **ipv6**, **mpls**, **vpls**, or circuit cross-connect (**ccc**), but not for **family any**.
- You must configure the firewall filter as a *physical interface filter* by including the **physical-interface-filter** statement at the **[edit firewall family family-name filter filter-name]** hierarchy level.
- A firewall filter that is defined as a physical interface filter can reference a physical interface policer only.
- A firewall filter that is defined as a physical interface filter cannot reference a policer configured with the **interface-specific** statement.
- You cannot configure a firewall filter as both a physical interface filter and as a logical interface filter that also includes the **interface-specific** statement.

Example: Configuring a Physical Interface Policer for Aggregate Traffic at a Physical Interface

This example shows how to configure a single-rate two-color policer as a physical interface policer.

- [Requirements on page 4941](#)
- [Overview on page 4941](#)
- [Configuration on page 4942](#)
- [Verification on page 4946](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

A *physical interface policer* specifies rate-limiting for aggregate traffic, which encompasses all protocol families and logical interfaces configured on a physical interface, even if the interfaces belong to different routing instances.

You can apply a physical interface policer to Layer 3 input or output traffic only by referencing the policer from a stateless firewall filter that is configured for specific a specific protocol family (not for **family any**) and configured as a physical interface filter. You configure the filter terms with match conditions that select the types of packets you want to rate-limit, and you specify the physical interface policer as the action to apply to matched packets.

Topology

The physical interface policer in this example, **shared-policer-A**, rate-limits to 10,000,000 bps and permits a maximum burst of traffic of 500,000 bytes. You configure the policer to discard packets in nonconforming flows, but you could instead configure the policer to re-mark nonconforming traffic with a forwarding class, a packet loss priority (PLP) level, or both.

To be able to use the policer to rate-limit IPv4 traffic, you reference the policer from an IPv4 physical interface filter. For this example, you configure the filter to pass the policer IPv4 packets that meet either of the following match terms:

- Packets received through TCP and with the IP precedence fields **critical-ecp** (0xa0), **immediate** (0x40), or **priority** (0x20)
- Packets received through TCP and with the IP precedence fields **internet-control** (0xc0) or **routine** (0x00)

You could also reference the policer from physical interface filters for other protocol families.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Logical Interfaces on the Physical Interface on page 4943](#)
- [Configuring a Physical Interface Policer on page 4943](#)
- [Configuring an IPv4 Physical Interface Filter on page 4944](#)
- [Applying the IPv4 Physical interface Filter to a Physical Interface on page 4945](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the [edit] hierarchy level.

```
set interfaces so-1/0/0 unit 0 family inet address 192.168.1.1/24
set interfaces so-1/0/0 unit 0 family vpls
set interfaces so-1/0/0 unit 1 family mpls
set firewall policer shared-policer-A physical-interface-policer
set firewall policer shared-policer-A if-exceeding bandwidth-limit 100m burst-size-limit 500k
set firewall policer shared-policer-A then discard
set firewall family inet filter ipv4-filter physical-interface-filter
set firewall family inet filter ipv4-filter term tcp-police-1 from precedence [ critical-ecp immediate priority ]
set firewall family inet filter ipv4-filter term tcp-police-1 from protocol tcp
set firewall family inet filter ipv4-filter term tcp-police-1 then policer shared-policer-A
set firewall family inet filter ipv4-filter term tcp-police-2 from precedence [ internet-control routine ]
set firewall family inet filter ipv4-filter term tcp-police-2 from protocol tcp
set firewall family inet filter ipv4-filter term tcp-police-2 then policer shared-policer-A
```

```
set interfaces so-1/0/0 unit 0 family inet filter input ipv4-filter
```

Configuring the Logical Interfaces on the Physical Interface

Step-by-Step Procedure

To configure the logical interfaces on the physical interface:

1. Enable configuration of logical interfaces.

[edit]
user@host# edit interfaces so-1/0/0
2. Configure protocol families on logical unit 0.

[edit interfaces so-1/0/0]
user@host# set unit 0 family inet address 192.168.1.1/24
user@host# set unit 0 family vpls
3. Configure protocol families on logical unit 1.

[edit interfaces so-1/0/0]
user@host# set unit 1 family mpls

Results

Confirm the configuration of the firewall filter by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
so-1/0/0 {
  unit 0 {
    family inet {
      address 192.168.1.1/24;
    }
    family vpls;
  }
  unit 1 {
    family mpls;
  }
}
```

Configuring a Physical Interface Policer

Step-by-Step Procedure

To configure a physical interface policer:

1. Enable configuration of the two-color policer.

[edit]
user@host# edit firewall policer shared-policer-A
2. Configure the type of two-color policer.

[edit firewall policer shared-policer-A]
user@host# set physical-interface-policer
3. Configure the traffic limits and the action for packets in a nonconforming traffic flow.

[edit firewall policer shared-policer-A]

```
user@host# set if-exceeding bandwidth-limit 100m burst-size-limit 500k
user@host# set then discard
```

For a physical interface filter, the actions you can configure for packets in a nonconforming traffic flow are to discard the packets, assign a forwarding class, assign a PLP value, or assign both a forwarding class and a PLP value.

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
policer shared-policer-A {
  physical-interface-policer;
  if-exceeding {
    bandwidth-limit 100m;
    burst-size-limit 500k;
  }
  then discard;
}
```

Configuring an IPv4 Physical Interface Filter

Step-by-Step Procedure To configure a physical interface policer as the action for terms in an IPv4 physical interface policer:

1. Configure a standard stateless firewall filter under a specific protocol family.

```
[edit]
user@host# edit firewall family inet filter ipv4-filter
```

You cannot configure a physical interface firewall filter for **family any**.

2. Configure the filter as a physical interface filter so that you can apply the physical interface policer as an action.

```
[edit firewall family inet filter ipv4-filter]
user@host# set physical-interface-filter
```

3. Configure the first term to match IPv4 packets received through TCP with the IP precedence fields **critical-ecp**, **immediate**, or **priority** and to apply the physical interface policer as a filter action.

```
[edit firewall family inet filter ipv4-filter]
user@host# set term tcp-police-1 from precedence [ critical-ecp immediate priority ]
user@host# set term tcp-police-1 from protocol tcp
user@host# set term tcp-police-1 then policer shared-policer-A
```

4. Configure the first term to match IPv4 packets received through TCP with the IP precedence fields **internet-control** or **routine** and to apply the physical interface policer as a filter action.

```
[edit firewall family inet filter ipv4-filter]
user@host# set term tcp-police-2 from precedence [ internet-control routine ]
user@host# set term tcp-police-2 from protocol tcp
user@host# set term tcp-police-2 then policer shared-policer-A
```

Results Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter ipv4-filter {
    physical-interface-filter;
    term tcp-police-1 {
      from {
        precedence [ critical-ecp immediate priority ];
        protocol tcp;
      }
      then policer shared-policer-A;
    }
    term tcp-police-2 {
      from {
        precedence [ internet-control routine ];
        protocol tcp;
      }
      then policer shared-policer-A;
    }
  }
}
policer shared-policer-A {
  physical-interface-policer;
  if-exceeding {
    bandwidth-limit 100m;
    burst-size-limit 500k;
  }
  then discard;
}
```

Applying the IPv4 Physical interface Filter to a Physical Interface

Step-by-Step Procedure To apply the physical interface filter to a physical interface:

1. Enable configuration of IPv4 on the logical interface.

```
[edit]
user@host# edit interfaces so-1/0/0 unit 0 family inet
```

2. Apply the IPv4 physical interface filter in the input direction.

```
[edit interfaces so-1/0/0 unit 0 family inet]
user@host# set filter input ipv4-filter
```

Results Confirm the configuration of the firewall filter by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
so-1/0/0 {
  unit 0 {
```

```

family inet {
  filter {
    input ipv4-filter;
  }
  address 192.168.1.1/24;
}
family vpls;
}
unit 1 {
  family mpls;
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying the Firewall Filters Applied to an Interface on page 4946](#)
- [Displaying the Number of Packets Processed by the Policer at the Logical Interface on page 4946](#)

Displaying the Firewall Filters Applied to an Interface

Purpose Verify that the firewall filter **ipv4-filter** is applied to the IPv4 input traffic at logical interface **so-1/0/0.0**.

Action Use the **show interfaces statistics** operational mode command for logical interface **so-1/0/0.0**, and include the **detail** option. In the **Protocol inet** section of the command output, the **Input Filters** field shows that the firewall filter **ipv4-filter** is applied in the input direction.

```

user@host> show interfaces statistics so-1/0/0 detail
Logical interface so-1/0/0.0 (Index 79) (SNMP ifIndex 510) (Generation 149)
Flags: Hardware-Down Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPP
Protocol inet, MTU: 4470, Generation: 173, Route table: 0
Flags: Sendbcast-pkt-to-re, Protocol-Down
Input Filters: ipv4-filter
Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
Destination: 10.39/16, Local: 10.39.1.1, Broadcast: 10.39.255.255,
Generation: 163

```

Displaying the Number of Packets Processed by the Policer at the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show firewall** operational mode command for the filter you applied to the logical interface.

```

user@host> show firewall filter ipv4-filter
Filter: ipv4-filter
Policers:
Name                                     Packets

```

shared-policer-A-tcp-police-1	32863
shared-policer-A-tcp-police-2	3870

The command output displays the name of policer (**shared-policer-A**), the name of the filter term (**police-1**) under which the policer action is specified, and the number of packets that matched the filter term. This is only the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.

Guidelines for Configuring Two-Color Policing of Layer 2 Traffic

The following guidelines apply to two-color policing of Layer 2 traffic:

- You can apply a two-color policer to ingress or egress Layer 2 traffic at a logical interface hosted on a Gigabit Ethernet interface (**ge-**) or a 10-Gigabit Ethernet interface (**xe-**) only.
- A single logical interface supports Layer 2 policing in both directions.

- You can apply a two-color policer to Layer 2 traffic as a logical interface policer only. You cannot apply a two-color policer to Layer 2 traffic as a stateless firewall filter action.
- You can apply a two-color policer to Layer 2 traffic by referencing the policer in the interface configuration at the logical unit level, and not at the protocol level.

For information about configuring three-color policing of Layer 2 traffic, see [“Three-Color Policing at Layer 2 Overview” on page 4949](#).

Statement Hierarchy for Configuring a Two-Color Policer for Layer 2 Traffic

To enable a single-rate two-color policer to rate-limit Layer 2 traffic, include the **logical-interface-policer** statement in the **policer** configuration.

```
firewall {
  policer policer-name {
    logical-interface-policer;
    if-exceeding {
      (bandwidth-limit bps | bandwidth-percent percentage);
      burst-size-limit bytes;
    }
    then {
      discard;
      forwarding-class class-name;
      loss-priority (high | low | medium-high | medium-low);
    }
  }
}
```

You can include the configuration at the following hierarchy levels:

- You can apply a three-color policer to Layer 2 traffic by referencing the policer in the interface configuration at the logical unit level, and not at the protocol level.
- You can apply a color-aware three-color policer to Layer 2 traffic in the egress direction only, but you apply a color-blind three-color policer to Layer 2 traffic in either direction.

For information about configuring two-color policing of Layer 2 traffic, see [“Two-Color Policing at Layer 2 Overview” on page 4947](#).

Statement Hierarchy for Configuring a Three-Color Policer for Layer 2 Traffic

To enable a single-rate or two-rate three-color policer to rate-limit Layer 2 traffic, include the **logical-interface-policer** statement in the **three-color-policer** configuration.

```
firewall {
  three-color-policer policer-name {
    action {
      loss-priority high then discard;
    }
    logical-interface-policer;
    single-rate {
      (color-aware | color-blind);
      committed-burst-size bytes;
      committed-information-rate bps;
      excess-burst-size bytes;
    }
    two-rate {
      (color-aware | color-blind);
      committed-burst-size bytes;
      committed-information-rate bps;
      peak-burst-size bytes;
      peak-information-rate bps;
    }
  }
}
```

```
}
```

You can include the configuration at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

Statement Hierarchy for Applying a Three-Color Policer to Layer 2 Traffic

To apply a logical interface policer to Layer 2 traffic, include the **layer2-policer** statement for a supported logical interface at the logical unit level. Use the **input-three-color *policer-name*** statement or **output-three-color *policer-name*** statement to specify the direction of the traffic to be policed.

```
interfaces {  
  (ge-fpc/pic/port | xe-fpc/pic/port) {  
    unit unit-number {  
      layer2-policer {  
        input-three-color policer-name;  
        output-three-color policer-name;  
      }  
    }  
  }  
}
```

You can include the configuration at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

Example: Configuring a Three-Color Logical Interface (Aggregate) Policer

This example shows how to configure a two-rate three-color color-blind policer as a logical interface (aggregate) policer and apply the policer directly to Layer 2 input traffic at a supported logical interface.

- [Requirements on page 4950](#)
- [Overview on page 4951](#)
- [Configuration on page 4952](#)
- [Verification on page 4955](#)

Requirements

Before you begin, make sure that the logical interface to which you apply the three-color logical interface policer is hosted on a Gigabit Ethernet interface (**ge-**) or a 10-Gigabit Ethernet interface (**xe-**) on an MX Series router and EX Series switch.

Overview

A two-rate three-color policer meters a traffic flow against a bandwidth limit and burst-size limit for guaranteed traffic, plus a second set of bandwidth and burst-size limits for peak traffic. Traffic that conforms to the limits for guaranteed traffic is categorized as green, and nonconforming traffic falls into one of two categories:

- Nonconforming traffic that does not exceed the bandwidth and burst-size limits for peak traffic is categorized as yellow.
- Nonconforming traffic that exceeds the bandwidth and burst-size limits for peak traffic is categorized as red.

A logical interface policer defines traffic rate-limiting rules that you can apply to multiple protocol families on the same logical interface without creating multiple instances of the policer.

NOTE: You apply a logical interface policer directly to a logical interface at the logical unit level, and not by referencing the policer in a stateless firewall filter and then applying the filter to the logical interface at the protocol family level.

Topology

In this example, you configure the two-rate three-color policer **trTCM2-cb** as a color-blind logical interface policer and apply the policer to incoming Layer 2 traffic on logical interface **ge-1/3/1.0**.

NOTE: When using a three-color policer to rate-limit Layer 2 traffic, color-aware policing can be applied to egress traffic only.

The policer defines guaranteed traffic rate limits such that traffic that conforms to the bandwidth limit of 40 Mbps with a 100 KB allowance for traffic bursting (based on the token-bucket formula) is categorized as green. As with any policed traffic, the packets in a green flow are implicitly set to a **low** loss priority and then transmitted.

Nonconforming traffic that falls within the peak traffic limits of a 60 Mbps bandwidth limit and a 200 KB allowance for traffic bursting (based on the token-bucket formula) is categorized as yellow. The packets in a yellow traffic flow are implicitly set to a **medium-high** loss priority and then transmitted.

Nonconforming traffic that exceeds the peak traffic limits are categorized as red. The packets in a red traffic flow are implicitly set to a **high** loss priority. In this example, the optional policer action for red traffic (**loss-priority high then discard**) is configured, so packets in a red traffic flow are discarded instead of transmitted.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#).

To configure this example, perform the following tasks:

- [Configuring the Logical Interfaces on page 4952](#)
- [Configuring the Two-Rate Three-Color Policer as a Logical Interface Policer on page 4953](#)
- [Applying the Three-Color Policer to the Layer 2 Input at the Logical Interface on page 4954](#)

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, and then paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-1/3/1 vlan-tagging
set interfaces ge-1/3/1 unit 0 vlan-id 100
set interfaces ge-1/3/1 unit 0 family inet address 10.10.10.1/30
set interfaces ge-1/3/1 unit 1 vlan-id 101
set interfaces ge-1/3/1 unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac
00:00:11:22:33:44
set firewall three-color-policer trTCM2-cb logical-interface-policer
set firewall three-color-policer trTCM2-cb two-rate color-blind
set firewall three-color-policer trTCM2-cb two-rate committed-information-rate 40m
set firewall three-color-policer trTCM2-cb two-rate committed-burst-size 100k
set firewall three-color-policer trTCM2-cb two-rate peak-information-rate 60m
set firewall three-color-policer trTCM2-cb two-rate peak-burst-size 200k
set firewall three-color-policer trTCM2-cb action loss-priority high then discard
set interfaces ge-1/3/1 unit 0 layer2-policer input-three-color trTCM2-cb
```

Configuring the Logical Interfaces

Step-by-Step Procedure

To configure the logical interfaces:

1. Enable configuration of the interface.

```
[edit]
user@host# edit interfaces ge-1/3/1
```

2. Configure single tagging.

```
[edit interfaces ge-1/3/1]
user@host# set vlan-tagging
```

3. Configure logical interface **ge-1/3/1.0**.

```
[edit interfaces ge-1/3/1]
user@host# set unit 0 vlan-id 100
user@host# set unit 0 family inet address 10.10.10.1/30
```

4. Configure logical interface **ge-1/3/1.0**.

```
[edit interfaces ge-1/3/1]
user@host# set unit 1 vlan-id 101
user@host# set unit 1 family inet address 20.20.20.1/30 arp 20.20.20.2 mac
00:00:11:22:33:44
```

Results Confirm the configuration of the logical interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 10.10.10.1/30;
    }
  }
  unit 1 {
    vlan-id 101;
    family inet {
      address 20.20.20.1/30 {
        arp 20.20.20.2 mac 00:00:11:22:33:44;
      }
    }
  }
}
```

Configuring the Two-Rate Three-Color Policer as a Logical Interface Policer

Step-by-Step Procedure To configure the two-rate three-color policer as a logical interface policer:

1. Enable configuration of a three-color policer.

```
[edit]
user@host# edit firewall three-color-policer trTCM2-cb
```

2. Specify that the policer is a logical interface (aggregate) policer.

```
[edit firewall three-color-policer trTCM2-cb]
user@host# set logical-interface-policer
```

A logical interface policer rate-limits traffic based on a percentage of the media rate of the physical interface underlying the logical interface to which the policer is applied, and the policer is applied directly to the interface rather than referenced by a firewall filter.

3. Specify that the policer is two-rate and color-blind.

```
[edit firewall three-color-policer trTCM2-cb]
user@host# set two-rate color-blind
```

A color-aware three-color policer takes into account any coloring markings that might have been set for a packet by another traffic policer configured at a previous network node, and any preexisting color markings are used in determining the appropriate policing action for the packet.

Because you are applying this three-color policer applied to input at Layer 2, you must configure the policer to be color-blind.

- Specify the policer traffic limits used to classify a green traffic flow.

```
[edit firewall three-color-policer trTCM2-cb]
user@host# set two-rate committed-information-rate 40m
user@host# set two-rate committed-burst-size 100k
```

- Specify the additional policer traffic limits used to classify a yellow or red traffic flow.

```
[edit firewall three-color-policer trTCM2-cb]
user@host# set two-rate peak-information-rate 60m
user@host# set two-rate peak-burst-size 200k
```

- (Optional) Specify the configured policer action for packets in a red traffic flow.

```
[edit firewall three-color-policer trTCM2-cb]
user@host# set action loss-priority high then discard
```

In color-aware mode, the three-color policer configured action can increase the packet loss priority (PLP) level of a packet, but never decrease it. For example, if a color-aware three-color policer meters a packet with a medium PLP marking, it can raise the PLP level to high, but cannot reduce the PLP level to low.

Results Confirm the configuration of the three-color policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
three-color-policer trTCM2-cb {
  logical-interface-policer;
  action {
    loss-priority high then discard;
  }
  two-rate {
    color-blind;
    committed-information-rate 40m;
    committed-burst-size 100k;
    peak-information-rate 60m;
    peak-burst-size 200k;
  }
}
```

Applying the Three-Color Policer to the Layer 2 Input at the Logical Interface

Step-by-Step Procedure

To apply the three-color policer to the Layer 2 input at the logical interface:

- Enable application of Layer 2 logical interface policers.

```
[edit]
user@host# edit interfaces ge-1/3/1 unit 0
```

- Apply the three-color logical interface policer to a logical interface input.

```
[edit interfaces ge-1/3/1 unit 0]
user@host# set layer2-policerinput-three-color trTCM2-cb
```

Results Confirm the configuration of the logical interfaces by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-1/3/1 {
  vlan-tagging;
  unit 0 {
    vlan-id 100;

- [Displaying Statistics for the Policer on page 4956](#)

Displaying Traffic Statistics and Policers for the Logical Interface

Purpose Verify the traffic flow through the logical interface and that the policer is evaluated when packets are received on the logical interface.

Action Use the **show interfaces** operational mode command for logical interface **ge-1/3/1.0**, and include the **detail** or **extensive** option. The command output section for **Traffic statistics** lists the number of bytes and packets received and transmitted on the logical interface, and the **Protocol inet** section contains a **Policer** field that would list the policer **trTCM2-cb** as an input or output policer as follows:

- **Input:** trTCM2-cb-ge-1/3/1.0-log_int-i
- **Output:** trTCM2-cb-ge-1/3/1.0-log_int-o

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to in the input direction only.

Displaying Statistics for the Policer

Purpose Verify the number of packets evaluated by the policer.

Action Use the [show policer](#) operational mode command and optionally specify the name of the policer. The command output displays the number of packets evaluated by each configured policer (or the specified policer), in each direction. For the policer **trTCM2-cb**, the input and output policer names are displayed as follows:

- **trTCM2-cb-ge-1/3/1.0-log_int-i**
- **trTCM2-cb-e-1/3/1.0-log_int-o**

The **log_int-i** suffix denotes a logical interface policer applied to input traffic, while the **log_int-o** suffix denotes a logical interface policer applied to output traffic. In this example, the logical interface policer is applied to input traffic only.

Configuration Statements

- [\[edit firewall\] Hierarchy Level on page 4956](#)

[edit firewall] Hierarchy Level

Several statements in the **[edit firewall]** hierarchy are valid at numerous locations within the hierarchy. To make the complete hierarchy easier to read, the repeated statements are listed in the following sections, which are referenced at the appropriate locations in “Complete [edit firewall] Hierarchy” on page 325.

- [Common Firewall Actions on page 4957](#)
- [Common IP Firewall Actions on page 4957](#)
- [Common IPv4 Firewall Actions on page 4957](#)
- [Common IP Firewall Match Conditions on page 4958](#)
- [Common IPv4 Firewall Match Conditions on page 4959](#)
- [Common Layer 2 Firewall Match Conditions on page 4959](#)
- [Complete \[edit firewall\] Hierarchy on page 4961](#)

Common Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family (any | ccc | ethernet-switching | inet | inet6 | mpls | vpls) filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common firewall actions are as follows:

```
count counter-name;
forwarding-class class-name;
loss-priority (high | low | medium-high | medium-low);
next term;
policer policer-name;
three-color-policer policer-name {
    (single-rate single-rate-policer-name | two-rate two-rate-policer-name);
}
```

Common IP Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet filter *filter-name* term *term-name* then]
- [edit firewall family inet6 filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common IP firewall actions are as follows:

```
log;
logical-system logical-system-name <routing-instance routing-instance-name>
    <topology topology-name>;
port-mirror;
port-mirror-instance instance-name;
routing-instance routing-instance-name <topology topology-name>;
sample;
service-filter-hit;
syslog;
topology topology-name;
```

Common IPv4 Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common IP version 4 (IPv4) firewall actions are as follows:

```
(accept | discard <accounting collector-name> | reject <administratively-prohibited |
bad-host-tos | bad-network-tos | fragmentation-needed | host-prohibited |
host-unknown | host-unreachable | network-prohibited | network-unknown |
network-unreachable | port-unreachable | precedence-cutoff | precedence-violation |
protocol-unreachable | source-host-isolated | source-route-failed | tcp-reset>);
ipsec-sa sa-name;
load-balance sa-name;
next-hop-group group-name;
prefix-action action-name;
```

Common IP Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- **[edit firewall family inet dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in “[Complete \[edit firewall\] Hierarchy](#)” on page 325)
- **[edit firewall family inet filter *filter-name* term *term-name* from]**
- **[edit firewall family inet6 dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in “[Complete \[edit firewall\] Hierarchy](#)” on page 325)
- **[edit firewall family inet6 filter *filter-name* term *term-name* from]**
- **[edit firewall filter *filter-name* term *term-name* from]**

The common IP firewall match conditions are as follows:

```
address {
  ip-prefix </prefix-length> <except>;
}
destination-address {
  ip-prefix </prefix-length> <except>;
}
destination-class [ class-names ] | destination-class-except [ class-names ];
(destination-port [ port-names ] | destination-port-except [ port-names ]);
destination-prefix-list {
  list-name <except>;
}
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);
icmp-code [ codes ] | icmp-code-except [ codes ];
icmp-type [ types ] | icmp-type-except [ types ];
interface interface-name;
(interface-group [ group-names ] | interface-group-except [ group-names ]);
interface-set set-name;
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(packet-length [ values ] | packet-length-except [ values ]);
(port [ port-names ] | port-except [ port-names ]);
prefix-list {
  list-name <except>;
}
service-filter-hit;
source-address {
```

```

    ip-prefix </prefix-length> <except>;
  }
  (source-class [ class-names ] | source-class-except [ class-names ]);
  (source-port [ port-names ] | source-port-except [ port-names ]);
  source-prefix-list {
    list-name <except>;
  }
  tcp-established;
  tcp-flags flag;
  tcp-initial;

```

Common IPv4 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family inet dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- **[edit firewall family inet filter *filter-name* term *term-name* from]**
- **[edit firewall filter *filter-name* term *term-name* from]**

The common IPv4 firewall match conditions are as follows:

```

  (ah-spi [ values ] | ah-spi-except [ values ]);
  (dscp [ code-point-values ] | dscp-except [ code-point-values ]);
  (esp-spi [ values ] | esp-spi-except [ values ]);
  first-fragment;
  fragment-flags flag;
  (fragment-offset [ offsets ] | fragment-offset-except [ offsets ]);
  (ip-options [ option-names ] | ip-options-except [ option-names ]);
  is-fragment;
  (precedence [ precedence-names ] | precedence-except [ precedence-names ]);
  (protocol [ protocol-names ] | protocol-except [ protocol-names ]);
  (ttl [ ttl-values ] | ttl-except [ ttl-values ]);

```

Common Layer 2 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family ethernet-switching filter *filter-name* term *term-name* from]**
- **[edit firewall family vpls filter *filter-name* term *term-name* from]**

The common Layer 2 firewall match conditions are as follows:

```

  destination-mac-address {
    mac-address <except>;
  }
  (destination-port [ port-names ] | destination-port-except [ port-names ]);
  (dscp [ code-point-values ] | dscp-except [ code-point-values ]);
  (ether-type [ protocol-types ] | ether-type-except [ protocol-types ]);
  (forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);

```

```
(icmp-code [ codes ] | icmp-code-except [ codes ]);
icmp-type [ types ] | icmp-type-except [ types ];
(interface-group [ group-names ] | interface-group-except [ group-names ]);
ip-address {
    ip-prefix </prefix-length> <except>;
}
ip-destination-address {
    ip-prefix </prefix-length> <except>;
}
(ip-precedence [ precedence-names ] | ip-precedence-except [ precedence-names ]);
(ip-protocol [ protocol-names ] | ip-protocol-except [ protocol-names ]);
ip-source-address ip-prefix </prefix-length>;
(learn-vlan-lp-priority [ priorities ] | learn-vlan-lp-priority [ priorities ]);
(learn-vlan-id [ vlan-ids ] | learn-vlan-id-except [ vlan-ids ]);
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(port [ port-names ] | port-except [ port-names ]);
source-mac-address {
    mac-address <except>;
}
(source-port [ port-names ] | source-port-except [ port-names ]);
tcp-flags flag;
(traffic-type [ broadcast known-unicast multicast unknown-unicast ] |
    traffic-type-except [ broadcast known-unicast multicast unknown-unicast ]);
(user-vlan-lp-priority [ priorities ] | user-vlan-lp-priority [ priorities ]);
(user-vlan-id [ vlan-ids ] | user-vlan-id-except [ vlan-ids ]);
(vlan-ether-type [ protocol-types ] | vlan-ether-type-except [ protocol-types ]);
```

bandwidth-percent

Syntax	<code>bandwidth-percent <i>percentage</i>;</code>
Hierarchy Level	[edit dynamic-profiles <i>profile-name</i> firewall policer <i>policer-name</i> if-exceeding], [edit firewall policer <i>policer-name</i> if-exceeding], [edit logical-systems <i>logical-system-name</i> policer <i>policer-name</i> if-exceeding]
Release Information	Statement introduced before Junos OS Release 7.4. Support at the [edit dynamic-profiles ... if-exceeding] hierarchy level introduced in Junos OS Release 11.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	For a single-rate two-color policer, configure the bandwidth limit as a percentage value. Single-rate two-color policing uses the <i>single token bucket algorithm</i> to measure traffic-flow conformance to a two-color policer rate limit. Traffic at the interface that conforms to the bandwidth limit is categorized green. Traffic that exceeds the specified rate is also categorized as green provided that sufficient tokens remain in the single token bucket. Packets in a green flow are implicitly marked with low packet loss priority and then passed through the interface. Traffic that exceeds the specified rate when insufficient tokens remain in the single token bucket is categorized red. Depending on the configuration of the two-color policer, packets in a red traffic flow might be implicitly discarded; or the packets might be re-marked with a specified forwarding class, a specified PLP, or both, and then passed through the interface.

NOTE: This statement specifies the bandwidth limit as a percentage of either the physical interface port speed or the configured logical interface shaping rate. Alternatively, you can use the **bandwidth-limit *bps*** statement to specify the bandwidth limit as an absolute number of bits per second.

The function of the bandwidth limit is extended by the burst size (configured using the **burst-size-limit *bytes*** statement) to allow bursts of traffic up to a limit based on the overall traffic load:

- When a single-rate two-color policer is applied to the input or output traffic at an interface, the initial capacity for traffic bursting is equal to the number of bytes specified by this statement.
- During periods of relatively low traffic (traffic that arrives at or departs from the interface at overall rates below the token arrival rate), unused tokens accumulate in the bucket, but only up to the configured token bucket depth.

Single-rate two-color policing allows bursts of traffic for short periods, whereas single-rate and two-rate three-color policing allows more sustained bursts of traffic.

Hierarchical policing is a form of two-color policing that applies different policing actions based on whether the packets are classified for expedited forwarding (EF) or for a lower priority. You apply a hierarchical policer to ingress Layer 2 traffic to allow bursts of EF traffic for short periods and bursts of non-EF traffic for short periods, with EF traffic always taking precedence over non-EF traffic.

Options *percentage*—Traffic rate as a percentage of either the physical interface media rate or the logical interface configured shaping rate. You can configure a shaping rate on a logical interface by using class-of-service statement.

NOTE: You cannot rate-limit based on bandwidth percentage for aggregate, tunnel, and software interfaces. The bandwidth percentage policer cannot be used for forwarding table filters. Bandwidth percentage policers can only be used for interface-specific filters.

Range: 0 through 100

Default: None.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

burst-size-limit (Policer)

Syntax	<code>burst-size-limit bytes;</code>
Hierarchy Level	[edit dynamic-profiles <i>profile-name</i> firewall policer <i>policer-name</i> if-exceeding], [edit firewall policer <i>policer-name</i> if-exceeding], [edit logical-systems <i>logical-system-name</i> policer <i>policer-name</i> if-exceeding]
Release Information	Statement introduced before Junos OS Release 7.4. Support at the [edit dynamic-profiles ... if-exceeding] hierarchy level introduced in Junos OS Release 11.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	<p>For a single-rate two-color policer, configure the burst size as a number of bytes. The burst size allows for short periods of traffic bursting (back-to-back traffic at average rates that exceed the configured bandwidth limit). Single-rate two-color policing uses the <i>single token bucket algorithm</i> to measure traffic-flow conformance to a two-color policer rate limit.</p> <p>Traffic at the interface that conforms to the bandwidth limit is categorized green. Traffic that exceeds the specified rate is also categorized as green provided that sufficient tokens remain in the single token bucket. Packets in a green flow are implicitly marked with low packet loss priority and then passed through the interface.</p> <p>Traffic that exceeds the specified rate when insufficient tokens remain in the single token bucket is categorized red. Depending on the configuration of the two-color policer, packets in a red traffic flow might be implicitly discarded; or the packets might be re-marked with a specified forwarding class, a specified PLP, or both, and then passed through the interface.</p> <p>The burst size extends the function of the bandwidth limit (configured using either the bandwidth-limit <i>bps</i> statement or the bandwidth-percent <i>percentage</i> statement) to allow bursts of traffic up to a limit based on the overall traffic load:</p> <ul style="list-style-type: none"> • When a single-rate two-color policer is applied to the input or output traffic at an interface, the initial capacity for traffic bursting is equal to the number of bytes specified by this statement. • During periods of relatively low traffic (traffic that arrives at or departs from the interface at overall rates below the token arrival rate), unused tokens accumulate in the bucket, but only up to the configured token bucket depth. <p>Single-rate two-color policing allows bursts of traffic for short periods, whereas single-rate and two-rate three-color policing allows more sustained bursts of traffic.</p> <p>Hierarchical policing is a form of two-color policing that applies different policing actions based on whether the packets are classified for expedited forwarding (EF) or for a lower priority. You apply a hierarchical policer to ingress Layer 2 traffic to allow bursts of EF traffic for short period and bursts of non-EF traffic for short periods, with EF traffic always taking precedence over non-EF traffic.</p>

Table 370 on page 4976 summarizes the relationship between the **bandwidth-limit** and the token arrival rate. This information is useful in calculating the minimum **burst-size-limit**.

Table 370: Bandwidth Limits and Token Rates

Bandwidth Limit	Token Rate
0-333 Mbps	low (262 μ s)
334-666 Mbps	high (8.2 μ s)
667-1333 Mbps	low
1334 Mbps and above	high

The burst-size limit enforced is based on the burst-size limit you configure. For a rate-limited logical interface, the Packet Forwarding Engine calculates the optimum burst-size-limit values and then applies the value closest to the burst-size-limit value specified in the policer configuration.

On MX Series routers and EX Series switches, the burst-size limit is not as freely configurable as it is on other platforms. Junos OS does not support an unlimited combination of policer bandwidth and burst-size limits on MX Series routers and EX Series switches. For a single-rate two-color policer on an MX Series router and on an EX Series switch, the minimum supported burst-size limit is equivalent to the amount of traffic allowed by the policer bandwidth limit in a time span of 1 millisecond. For example, for a policer configured with a **bandwidth-limit** value of 1 Gbps, the minimum supported value for **burst-size-limit** on an MX Series router and on an EX Series switch is 125 KB. If you configure a value that is smaller than the minimum, Junos OS overrides the configuration and applies the actual minimum.

Options **bytes**—Burst-size limit in bytes. The minimum recommended value is the maximum transmission unit (MTU) of the IP packets being policed. You can specify the value either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 1500 through 100,000,000,000

Default: None

Required Privilege Level firewall—To view this statement in the configuration.
 firewall-control—To add this statement to the configuration.

committed-burst-size

Syntax	<code>committed-burst-size bytes;</code>
Hierarchy Level	[edit dynamic-profiles <i>profile-name</i> firewall three-color-policer <i>name</i> single-rate], [edit dynamic-profiles <i>profile-name</i> firewall three-color-policer <i>name</i> two-rate], [edit firewall three-color-policer <i>policer-name</i> single-rate], [edit firewall three-color-policer <i>policer-name</i> two-rate]
Release Information	Statement introduced in Junos OS Release 7.4. Support at the [edit dynamic-profiles ... single-rate] and [edit dynamic-profiles ... two-rate] hierarchy levels introduced in Junos OS Release 11.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	For a three-color policer, configure the committed burst size (CBS) as a number of bytes.

NOTE: When you include the **committed-burst-size** statement in the configuration, you must also include the **committed-information-rate** statement at the same hierarchy level.

In three-color policing, a committed information rate (CIR) defines the guaranteed bandwidth for traffic arriving at or departing from the interface under normal line conditions. A flow of traffic at an average rate that conforms to the CIR is categorized green.

During periods of average traffic rates below the CIR, any unused bandwidth capacity accumulates up to a maximum amount defined by the CBS. Short periods of bursting traffic (back-to-back traffic at averages rates that exceed the CIR) are also categorized as green provided that unused bandwidth capacity is available.

Traffic that exceeds both the CIR and the CBS is considered nonconforming.

Single-rate three-color policers use a *dual token bucket algorithm* to measure traffic against a single rate limit. Nonconforming traffic is categorized as yellow or red, based on the **excess-burst-size** statement included in the policer configuration.

Two-rate three-color policers use a *dual-rate dual token bucket algorithm* to measure traffic against two rate limits. Nonconforming traffic is categorized as yellow or red based on the **peak-information-rate** and **peak-burst-rate** statements included in the policer configuration.

Options **bytes**—Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 1500 through 100,000,000,000 bytes

Release Information	Statement introduced in Junos OS Release 7.4. Support at the [edit dynamic-profiles ... single-rate] and [edit dynamic-profiles ... two-rate] hierarchy levels introduced in Junos OS Release 11.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	For a three-color policer, configure the committed information rate as a number of bits per second. The committed information rate (CIR) is the guaranteed bandwidth for traffic arriving at or departing from the interface under normal line conditions.

NOTE: When you include the **committed-information-rate** statement in the configuration, you must also include the **committed-burst-size** statement at the same hierarchy level.

In three-color policing, a CIR defines the guaranteed bandwidth for traffic arriving at or departing from the interface under normal line conditions. A flow of traffic at an average rate that conforms to the CIR is categorized green.

During periods of average traffic rates below the CIR, any unused bandwidth capacity accumulates up to a maximum amount defined by the committed burst size (CBS). Short periods of bursting traffic (back-to-back traffic at averages rates that exceed the CIR) are also categorized as green provided that unused bandwidth capacity is available.

Traffic that exceeds both the CIR and the CBS is considered nonconforming.

Single-rate three-color policers use a *dual token bucket algorithm* to measure traffic against a single rate limit. Nonconforming traffic is categorized as yellow or red, based on the **excess-burst-size** statement included in the policer configuration.

Two-rate three-color policers use a *dual-rate dual token bucket algorithm* to measure traffic against two rate limits. Nonconforming traffic is categorized as yellow or red based on the **peak-information-rate** and **peak-burst-rate** statements included in the policer configuration.

Options ***bps***—Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 1500 through 100,000,000,000 bps

Required Privilege Level	firewall—To view this statement in the configuration. firewall-control—To add this statement to the configuration.

excess-burst-size

Syntax	<code>excess-burst-size bytes;</code>
Hierarchy Level	[edit dynamic-profiles <i>profile-name</i> firewall three-color-policer name single-rate], [edit firewall three-color-policer policer-name single-rate]
Release Information	Statement introduced in Junos OS Release 7.4. Support at the [edit dynamic-profiles ... single-rate] hierarchy level introduced in Junos Release OS 11.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	For a single-rate three-color policer, configure the excess burst size (EBS) as a number of bytes. The EBS allows for moderate periods of bursting traffic that exceeds both the committed information rate (CIR) and the committed burst size (CBS).

NOTE: When you include the **excess-burst-size** statement in the configuration, you must also include the **committed-burst-size** and **committed-information-rate** statements at the same hierarchy level.

Traffic that exceeds both the CIR and the CBS is considered nonconforming.

Single-rate three-color policing uses a *dual token bucket algorithm* to measure traffic against a single rate limit. Nonconforming traffic is categorized as yellow or red based on the **excess-burst-size** statement included in the policer configuration.

During periods of traffic that conforms to the CIR, any unused portion of the guaranteed bandwidth capacity accumulates in the first token bucket, up to the maximum number of bytes defined by the CBS. If any accumulated bandwidth capacity overflows the first bucket, the excess accumulates in a second token bucket, up to the maximum number of bytes defined by the EBS.

A nonconforming traffic flow is categorized yellow if its size conforms to bandwidth capacity accumulated in the first token bucket. Packets in a yellow flow are marked with **medium-high** packet loss priority (PLP) and then passed through the interface.

A nonconforming traffic flow is categorized red if its size exceeds the bandwidth capacity accumulated in the second token bucket. Packets in a red traffic flow are marked with **high** PLP and then either passed through the interface or optionally discarded.

Options	bytes —Number of bytes. You can specify a value in bytes either as a complete decimal number or as a decimal number followed by the abbreviation k (1000), m (1,000,000), or g (1,000,000,000). Range: 1500 through 100,000,000,000 bytes
Required Privilege Level	firewall —To view this statement in the configuration. firewall-control —To add this statement to the configuration.

physical-interface-policer

Syntax	physical-interface-policer;
Hierarchy Level	<p>[edit dynamic-profiles <i>profile-name</i> firewall policer <i>policer-name</i>], [edit firewall policer <i>policer-name</i>], [edit firewall three-color-policer <i>policer-name</i>], [edit logical-system <i>logical-system-name</i> firewall policer <i>policer-name</i>], [edit logical-system <i>logical-system-name</i> three-color-policer <i>policer-name</i>], [edit routing-instances <i>routing-instance-name</i> firewall policer <i>policer-name</i>], [edit routing-instances <i>routing-instance-name</i> firewall three-color-policer <i>policer-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> firewall policer <i>policer-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> firewall three-color-policer <i>policer-name</i>]</p>
Release Information	<p>Statement introduced in Junos OS Release 9.6.</p> <p>Support at the [edit dynamic-profiles ... policer <i>policer-name</i>] hierarchy level introduced in Junos Release OS 11.4.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	<p>Configure an aggregate policer for a physical interface.</p> <p>A physical interface policer can be a two-color or three-color policer. When you apply physical interface policer, to different protocol families on the same logical interface, the protocol families share the same policer instance. This means that rate limiting is performed aggregately for the protocol families for which the policer is applied. This feature enables you to use a single policer instance to perform aggregate policing for different protocol families on the same physical interface. If you want a policer instance to be associated with a protocol family, the corresponding physical interface filter needs to be applied to that protocol family. The policer is not automatically applied to all protocol families configured on the physical interface.</p> <p>In contrast, with logical interface policers there are multiple separate policer instances.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

policer (Configuring)

Syntax	<pre> policer <i>policer-name</i> { filter-specific; if-exceeding { bandwidth-limit <i>bps</i>; bandwidth-percent <i>number</i>; burst-size-limit <i>bytes</i>; } logical-bandwidth-policer; logical-interface-policer; physical-interface-policer; shared-bandwidth-policer; then { <i>policer-action</i>; } } </pre>
Hierarchy Level	<p>[edit dynamic-profiles <i>profile-name</i> firewall], [edit firewall], [edit logical-systems <i>logical-system-name</i> firewall]</p>
Release Information	<p>Statement introduced before Junos OS Release 7.4.</p> <p>The out-of-profile policer action added in Junos OS Release 8.1.</p> <p>The logical-bandwidth-policer statement added in Junos OS Release 8.2.</p> <p>Logical systems support introduced in Junos OS Release 9.3.</p> <p>The physical-interface-policer statement introduced in Junos OS Release 9.6.</p> <p>The shared-bandwidth-policer statement added in Junos OS Release 11.2.</p> <p>Support at the [edit dynamic-profiles ... firewall] hierarchy level introduced in Junos OS Release 11.4.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	<p>Configure policer rate limits and actions. When included at the [edit firewall] hierarchy level, the policer statement creates a template, and you do not have to configure a policer individually for every firewall filter or interface. To activate a policer, you must include the policer-action modifier in the then statement in a firewall filter term or on an interface.</p>
Options	<p><i>policer-action</i>—One or more actions to take:</p> <ul style="list-style-type: none"> • discard—Discard traffic that exceeds the rate limits. • forwarding-class <i>class-name</i>—Specify the particular forwarding class. • loss-priority—Set the packet loss priority (PLP) to low, medium-low, medium-high, or high. • out-of-profile—On J Series routers with strict priority queuing, prevent starvation of other queues by rate limiting the data stream entering the strict priority queue, marking the packets that exceed the rate limit as out-of-profile, and dropping the out-of-profile packets if the physical interface is congested.

policer-name—Name that identifies the policer. The name can contain letters, numbers, and hyphens (-), and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" "). Policer names cannot begin with an underscore in the form `_.*`.

then—Actions to take on matching packets.

The remaining statements are explained separately.

Required Privilege Level firewall—To view this statement in the configuration.
firewall-control—To add this statement to the configuration.

Administration

- [Traffic Policing Standards on page 5013](#)
- [Firewall Filter and Policer Operational Mode Commands on page 5013](#)

Traffic Policing Standards

- [Supported Standards for Policing on page 5013](#)

Supported Standards for Policing

Three-color policers are part of an assured forwarding (AF) per-hop-behavior (PHB) classification system for a Differentiated Services (DiffServ) environment, which is described and defined in the following RFCs:

- RFC 2474, *Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers*
- RFC 2475, *An Architecture for Differentiated Service*
- RFC 2597, *Assured Forwarding PHB Group*
- RFC 2598, *An Expedited Forwarding PHB*
- RFC 2698, *A Two Rate Three Color Marker*

In a DiffServ environment, the most significant 6 bits of the type-of-service (ToS) octet in the IP header contain a value called the *Differentiated Services code point* (DSCP). Within the DSCP field, the most significant 3 bits are interpreted as the *IP precedence* field, which can be used to select different per-hop forwarding treatments for the packet.

Firewall Filter and Policer Operational Mode Commands

clear firewall

Syntax	clear firewall (all counter <i>counter-name</i> filter <i>filter-name</i> log (all <i>logical-system-name</i>) logical-system <i>logical-system-name</i>)
Syntax (EX Series Switches)	clear firewall (all counter <i>counter-name</i> filter <i>filter-name</i> log (all <i>logical-system-name</i>) policer counter (all counter-id <i>counter-index</i>))
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches. logical-system option introduced in Junos OS Release 9.3. log option introduced before Junos OS Release 11.4.
Description	Clear statistics about configured firewall filters. When you clear the counters of a filter, this impacts not only the counters shown by the CLI, but also the ones tracked by SNMP2.

NOTE: The clear firewall command cannot be used to clear the Routing Engine filter counters on a backup Routing Engine that is enabled for graceful Routing Engine switchover (GRES).

If you clear statistics for firewall filters that are applied to Trio-based DPCs and that also use the **prefix-action** action on matched packets, wait at least 5 seconds before you enter the **show firewall prefix-action-stats** command. A 5-second pause between issuing the **clear firewall** and **show firewall prefix-action-stats** commands avoids a possible timeout of the **show firewall prefix-action-stats** command.

- Options**
- all**—Clear the packet and byte counts for all filters. On EX Series switches, this option also clears the packet counts for all policer counters.
 - counter *counter-name***—Clear the packet and byte counts for a filter counter that has been configured with the counter firewall filter action.
 - filter *filter-name***—Clear the packet and byte counts for the specified firewall filter.
 - log (all | *logical-system-name*)**—Clear log entries for IPv4 firewall filters that have **then log** as an action. Use **log all** to clear all log entries or **log *logical-system-name*** to clear log entries for the specified logical system.
 - logical-system *logical-system-name***—Clear the packet and byte counts for the specified logical system.
 - policer counter (all | counter-id *counter-index*)**—(EX8200 switches only) Clear all policer counters using the **policer counter all** command, or clear a specific policer counter using the **policer counter counter-id *counter-index*** command. The value of *counter-index* can be 0, 1, or 2.

Required Privilege Level	clear

- Output Fields** [Table 323 on page 4451](#) lists the output fields for the **show firewall** command. Output fields are listed in the approximate order in which they appear.

Table 371: show firewall Output Fields

Field Name	Field Description
Filter	<p>Name of a filter that has been configured with the filter statement at the [edit firewall] hierarchy level.</p> <p>Except on EX Series switches:</p> <ul style="list-style-type: none"> • When an interface-specific filter is displayed, the name of the filter is followed by the full interface name and by either -i for an input filter or -o for an output filter. • When dynamic filters are displayed, the name of the filter is followed by the full interface name and by either -in for an input filter or -out for an output filter. When a logical system-specific filter is displayed, the name of the filter is prefixed with two underscore (__) characters and the name of the logical system (for example, __ls1/filter1).
Counters	<p>Display filter counter information:</p> <ul style="list-style-type: none"> • Name—Name of a filter counter that has been configured with the counter firewall filter action. • Bytes—Number of bytes that match the filter term under which the counter action is specified. • Packets—Number of packets that matched the filter term under which the counter action is specified. <p>NOTE: On M and T series routers, firewall filters cannot count ip-options packets on a per option type and per interface basis. A limited work around is to use the show pfe statistics ip options command to see ip-options statistics on a per Packet Forwarding Engine (PFE) basis. See <i>show pfe statistics ip</i> for sample output.</p>

Table 371: show firewall Output Fields (*continued*)

Field Name	Field Description
Policers	<p>Display policer information:</p> <ul style="list-style-type: none"> • Name—Name of policer. • Bytes—(For two-color policers on MX Series routers and EX Series switches, and for hierarchical policers on interfaces hosted on MICs and MPCs in MX Series routers) Number of bytes that match the filter term under which the policer action is specified. This is only the number out-of-specification (out-of-spec) byte counts, not all the bytes in all packets policed by the policer. For other platforms, this field is blank. • Packets—Number of packets that matched the filter term under which the policer action is specified. This is only the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.
Policer Counter Index	(EX8200 switch only) Global management counter ID. The counter ID value (<i>counter-index</i>) can be 0, 1, or 2.
Green	(EX8200 switch only) Number of packets within the limits. The number of packets is smaller than the committed information rate (CIR).
Yellow	(EX8200 switch only) Number of packets partially within the limits. The number of packets is greater than the CIR, but the burst size is within the excess burst size (EBS) limit.
Discard	(EX8200 switch only) Number of discarded packets.
Bytes	(EX8200 switch only) Number of green, yellow, red, or discarded packets in bytes.
Packets	(EX8200 switch only) Number of green, yellow, red, or discarded packets.
Filter name	(EX8200 switch only) Name of the filter with a term associated to a policer.
Term name	(EX8200 switch only) Name of the term associated with a policer.
Policer name	(EX8200 switch only) Name of the policer that is associated with a global management counter.

Sample Output

show firewall filter version

Syntax	show firewall filter version <filter-name>
Release Information	Command introduced in Junos OS Release 10.2R2. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Display the version number of the installed firewall filter in the Routing Engine.
Options	none—(Optional) Display the version number of all installed firewall filters. filter-name—(Optional) Name of a configured filter. If you specify the name of a filter, only the version number of that filter is displayed.
Additional Information	The initial version number is 1. This number increments by one when you modify the firewall filter settings or an associated prefix action. The maximum version number is 4,294,967,295. When the version number reaches 4,294,967,295, this number is reset to 1.
Required Privilege Level	view
List of Sample Output	show firewall filter version on page 5023
Output Fields	Table 372 on page 5023 lists the output fields for the show firewall filter version command. Output fields are listed in the approximate order in which they appear.

Table 372: show firewall filter version Output Fields

Field Name	Field Description
Filter	Name of a filter that has been configured with the filter statement at the [edit firewall] hierarchy level.
Version	Display the version number of the firewall filter.

Sample Output

show firewall filter version

```

user@host> show firewall filter version
Filter version information :
Filter                                     Version
test                                     10

```

show firewall log

Syntax	show firewall log <detail> <interface <i>interface-name</i> > <logical-system (<i>logical-system-name</i> all)>
Syntax (EX Series Switches)	show firewall log <detail> <interface <i>interface-name</i> >
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches. logical-system option introduced in Junos OS Release 9.3.
Description	Display log information about firewall filters.
Options	none —Display log information about firewall filters. detail —(Optional) Display detailed information. interface <i>interface-name</i> —(Optional) Display log information about a specific interface. logical-system (<i>logical-system-name</i> all) —(Optional) Perform this operation on all logical systems or on a particular system.
Required Privilege Level	view
List of Sample Output	show firewall log on page 5025 show firewall log detail on page 5025
Output Fields	Table 324 on page 4457 lists the output fields for the show firewall log command. Output fields are listed in the approximate order in which they appear.

Table 373: show firewall log Output Fields

Field Name	Field Description
Time of Log	Time that the event occurred.
Filter	<p>Name of a filter that has been configured with the filter statement at the [edit firewall] hierarchy level.</p> <ul style="list-style-type: none"> A hyphen (-) indicates that the packet was handled by the Packet Forwarding Engine. A space (no hyphen) indicates the packet was handled by the Routing Engine. The notation pfe indicates packets logged by the Packet Forwarding Engine hardware filters.

Table 373: show firewall log Output Fields (*continued*)

Field Name	Field Description
Filter Action	Filter action: <ul style="list-style-type: none"> • A—Accept • D—Discard • R—Reject
Name of Interface	Ingress interface for the packet.
Name of protocol	Packet's protocol name: egp, gre, icmp, ipip, ospf, pim, rsvp, tcp, or udp .
Packet length	Length of the packet.
Source address	Packet's source address.
Destination address	Packet's destination address and port.

Sample Output

show firewall log

```

user@host>show firewall log
Time      Filter  Action Interface    Protocol  Src Addr    Dest Addr
13:10:12  pfe       D      rlsq0.902     ICMP      180.1.177.2 180.1.177.1

show firewall prefix-action-stats

Syntax	show firewall prefix-action-stats filter <i>filter-name</i> prefix-action <i>prefix-action-name</i> <from <i>number</i> to <i>number</i> > <logical-system (<i>logical-system-name</i> all)>
Release Information	Command introduced before Junos OS Release 7.4. logical-system option introduced in Junos OS Release 9.3. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Display prefix action statistics about configured firewall filters. If you clear statistics for firewall filters that are applied to Trio-based DPCs and that also use the prefix-action action on matched packets, wait at least 5 seconds before you enter the show firewall prefix-action-stats command. A 5-second pause between issuing the clear firewall and show firewall prefix-action-stats commands avoids a possible timeout of the show firewall prefix-action-stats command.
Options	filter <i>filter-name</i> —Name of a filter. prefix-action <i>prefix-action-name</i> —Name of a prefix action. from <i>number</i> to <i>number</i> —(Optional) Starting and ending counter or policer. logical-system (<i>logical-system-name</i> all) —(Optional) Perform this operation on all logical systems or on a particular system.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • clear firewall on page 4448
List of Sample Output	show firewall prefix-action-stats on page 5028

Table 374: show firewall prefix-action-stats Output Fields

Field Name	Field Description
Filter	Filter name. Filters configured for logical systems include the name of the filter prefixed with the two underscore characters (__) and the name of the logical system (for example, __ls1/filter1).

Sample Output

show firewall prefix-action-stats

```
user@host> show firewall prefix-action-stats filter test prefix-action act1
Filter: __ls2/test
```

show policer

Syntax	show policer <detail> <policer-name>
Release Information	Command introduced before Junos OS Release 7.4. Option detail introduced in Junos OS Release 12.3. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Display the number of policed packets for a given policer or an aggregate policer. An aggregate policer is an aggregate of different policers on the same logical interface.
Options	none —Display the number of policed packets for all configured policers. detail —(Optional) Display enhanced statistics for policers. policer-name —(Optional) Display the number of policed packets for the specified policer.
Required Privilege Level	view
List of Sample Output	show policer (MX Series Router and EX Series Switch) on page 5029 show policer (non MX Series Router) on page 5030 show policer (Aggregate Policer, non MX Series Router) on page 5030 show policer detail on page 5030
Output Fields	Table 375 on page 5029 lists the output fields for the show policer command. Output fields are listed in the approximate order in which they appear.

Table 375: show policer Output Fields

Field Name	Field Description
Name	Name of the policer.
Bytes	(For two-color policers on MX Series routers and EX Series switches, and for hierarchical policers on interfaces hosted on MICs and MPCs in MX Series routers) Total number of bytes policed by the specified policer. For other platforms, this field is blank.
Packets	Total number of packets policed by the specified policer.

Sample Output

Spanning-Tree Protocols Supported

In a Layer 2 environment, you can configure various spanning-tree protocol versions to create a loop-free topology in Layer 2 networks.

A spanning-tree protocol is a Layer 2 control protocol (L2CP) that calculates the best path through a switched network containing redundant paths. A spanning-tree protocol uses bridge protocol data unit (BPDU) data frames to exchange information with other switches. A spanning-tree protocol uses the information provided by the BPDUs to elect a root bridge, identify root ports for each switch, identify designated ports for each physical LAN segment, and prune specific redundant links to create a loop-free tree topology. The resulting tree topology provides a single active Layer 2 data path between any two end stations.

NOTE: In discussions of spanning-tree protocols, the terms *bridge* and *switch* are often used interchangeably.

The Juniper Networks MX Series 3D Universal Edge Routers and EX Series switches support STP, RSTP, MSTP, and VSTP.

- The original Spanning-Tree Protocol (STP) is defined in the IEEE 802.1D 1998 specification. A newer version called Rapid Spanning-Tree Protocol (RSTP) was originally defined in the IEEE 802.1w draft specification and later incorporated into the IEEE 802.1D-2004 specification. A recent version called Multiple Spanning-Tree Protocol (MSTP) was originally defined in the IEEE 802.1s draft specification and later incorporated into the IEEE 802.1Q-2003 specification. The VLAN Spanning-Tree Protocol (VSTP) is compatible with the Per-VLAN Spanning Tree Plus (PVST+) and Rapid-PVST+ protocols supported on Cisco Systems routers and switches.
- RSTP provides faster reconvergence time than the original STP by identifying certain links as point to point and by using protocol handshake messages rather than fixed timeouts. When a point-to-point link fails, the alternate link can transition to the forwarding state without waiting for any protocol timers to expire.
- MSTP provides the capability to logically divide a Layer 2 network into regions. Every region has a unique identifier and can contain multiple instances of spanning trees. All

regions are bound together using a Common Instance Spanning Tree (CIST), which is responsible for creating a loop-free topology *across* regions, whereas the Multiple Spanning-Tree Instance (MSTI) controls topology *within* regions. MSTP uses RSTP as a converging algorithm and is fully interoperable with earlier versions of STP.

- VSTP maintains a separate spanning-tree instance for each VLAN. Different VLANs can use different spanning-tree paths. When different VLANs use different spanning-tree paths, the CPU processing resources being consumed increase as more VLANs are configured. VSTP BPDU packets are tagged with the corresponding VLAN identifier and are transmitted to the multicast destination media access control (MAC) address **01-00-0c-cc-cc-cd** with a protocol type of **0x010b**. VSTP BPDUs are tunneled by pure IEEE 802.1q bridges.

NOTE: All virtual switch routing instances configured on an MX Series router are supported using only one spanning-tree process. The Layer 2 control protocol process is named l2cpd.

For more information about the various versions of spanning-tree protocols, see the appropriate IEEE specification.

BPDU Overview

In a Layer 2 bridge environment, spanning-tree protocols use data frames called Bridge Protocol Data Units (BPDUs) to exchange information among bridges.

Spanning-tree protocols on peer systems exchange BPDUs, which contain information about port roles, bridge IDs, and root path costs. On each MX Series router or EX Series switch, the spanning-tree protocol uses this information to elect a root bridge, identify root ports for each switch, identify designated ports for each physical LAN segment, and prune specific redundant links to create a loop-free tree topology. The resulting tree topology provides a single active Layer 2 data path between any two end stations.

NOTE: In discussions of spanning-tree protocols, the terms *bridge* and *switch* are often used interchangeably.

The transmission of BPDUs is controlled by the Layer 2 Control Protocol process (l2cpd) on MX Series 3D Universal Edge Routers.

The transmission of periodic packets on behalf of the l2cpd process is carried out by periodic packet management (PPM), which, by default, is configured to run on the Packet Forwarding Engine. The ppm process on the Packet Forwarding Engine ensures that

the BPDUs are transmitted even when the l2cpd process control plane is unavailable, and keeps the remote adjacencies alive during a unified in-service software upgrade (unified ISSU). However, if you want the distributed PPM (ppmd) process to run on the Routing Engine instead of the Packet Forwarding Engine, you can disable the ppm process on the Packet Forwarding Engine. For more information, see the *Junos OS High Availability Configuration Guide*.

On MX Series routers or EX Series switches with redundant Routing Engines (two Routing Engines that are installed in the same router), you can configure nonstop bridging. Nonstop bridging enables the router to switch from a primary Routing Engine to a backup Routing Engine without losing Layer 2 Control Protocol (L2CP) information. Nonstop bridging uses the same infrastructure as graceful Routing Engine switchover (GRES) to preserve interface and kernel information. However, nonstop bridging also saves L2CP information by running the l2cpd process on the backup Routing Engine.

NOTE: To use nonstop bridging, you must first enable GRES.

Nonstop bridging is supported for the following Layer 2 control protocols:

- Spanning-Tree Protocol (STP)
- Rapid Spanning-Tree Protocol (RSTP)
- Multiple Spanning-Tree Protocol (MSTP)

For more information about GRES and nonstop bridging, see the *Junos OS High Availability Configuration Guide*.

Loop Protection for Spanning-Tree Instance Interfaces Overview

Spanning-tree protocol loop protection enhances the normal checks that spanning-tree protocols perform on interfaces. Loop protection performs a specified action when BPDUs are not received on a nondesignated port interface. You can choose to block the interface or issue an alarm when bridge protocol data units (BPDUs) are not received on the port.

The spanning-tree protocol family is responsible for breaking loops in a network of bridges with redundant links. However, hardware failures can create forwarding loops (STP loops) and cause major network outages. Spanning-tree protocols break loops by blocking ports (interfaces). However, errors occur when a blocked port transitions erroneously to a forwarding state.

Ideally, a spanning-tree protocol bridge port remains blocked as long as a superior alternate path to the root bridge exists for a connected LAN segment. This designated port is determined by receiving superior BPDUs from a peer on that port. When other

ports no longer receive BPDUs, the spanning-tree protocol considers the topology to be loop free. However, if a blocked or alternate port moves into a forwarding state, this creates a loop.

By default (that is, without spanning-tree protocol loop protection configured), an interface that stops receiving BPDUs will assume the designated port role and possibly result in a spanning-tree protocol loop.

You can configure spanning-tree protocol loop protection to improve the stability of Layer 2 networks.

You configure spanning-tree protocol loop protection to prevent selected interfaces from interpreting the lack of received BPDUs as a “false positive” condition for making the interface the designated port.

- [Configuring Loop Protection for a Spanning-Tree Instance Interface on page 5082](#)
- [Example: Enabling Loop Protection for Spanning-Tree Protocols on page 5052](#)

Root Protection for Spanning-Tree Instance Interfaces Overview

Root protect helps to enforce the root bridge placement in a Layer 2 switched network. Enable root protect on interfaces that should not receive superior bridge protocol data units (BPDUs) from the root bridge. Typically, these ports are Spanning-Tree-Protocol-designated ports on an administrative boundary. Enabling root protect ensures the port remains a spanning-tree designated port.

If the bridge receives superior BPDUs on a port that has root protect enabled, that port transitions to a root-prevented STP state and the interface is blocked. This prevents a bridge that should not be the root bridge from being elected the root bridge.

After the bridge stops receiving superior BPDUs on the port with root protect enabled and the received BPDUs time out, that port transitions back to the STP-designated port state.

**Related
Documentation**

- [Root Protect for a Spanning-Tree Instance Interface on page 5048](#)
- [Enabling Root Protect for a Spanning-Tree Instance Interface on page 5083](#)

BPDU Protection for Spanning-Tree Instance Interfaces Overview

By default, if a Bridge Protocol Data Unit (BPDU) data frame is received on a blocked interface, the system will disable the interface and stop forwarding frames out the interface until the interface is explicitly cleared.

The Spanning-Tree Protocol (STP) family is designed to break possible loops in a Layer 2 bridged network. Loop prevention avoids damaging broadcast storms that can potentially render the network useless. STP processes on bridges exchange BPDUs to determine the LAN topology, decide the root bridge, stop forwarding on some ports, and so on.

However, a misbehaving user application or device can interfere with the operation of the STP protocols and cause network problems.

On the MX Series routers or EX Series switches only, you can configure BPDU protection to ignore BPDUs received on interfaces where none should be expected (for example, a LAN interface on a network edge with no other bridges present). If a BPDU is received on a blocked interface, the interface is disabled and stops forwarding frames. By default, all BPDUs are accepted and processed on all interfaces.

You can configure BPDU protection on interfaces with the following encapsulation types:

- **ethernet-bridge**
- **ethernet-vpls**
- **extended-vlan-bridge**
- **vlan-vpls**
- **extended-vlan-vpls**

You can configure BPDU protection on individual interfaces or on all the edge ports of the bridge.

- [VPLS Multihomed Layer 2 Ring and MPLS Infrastructure Overview on page 5036](#)

VPLS Multihomed Layer 2 Ring and MPLS Infrastructure Overview

Redundancy is built into many networks through the use of alternate links and paths, which often take the shape of rings.

In the case of multiple hosts attached to customer edge (CE) routers and provider edge (PE) routers to secure virtual private LAN service (VPLS), this practice is often called *multihoming*:

- Multiple hosts attach to CE routers, which are attached to each other as well as to the PE routers that access the VPLS network cloud. Any single link between the edge routers can fail without impacting the hosts' access to the VPLS services.
- This Layer 2 ring connects to the multiprotocol link switching (MPLS) infrastructure through two PE routers. Link breaks on the ring are protected by running a version of the spanning-tree protocol with the root-protect option enabled.

The virtual private network (VPN) protocols at Layer 3, however, are not aware of the blocking state that results from this root protection setup (rings or loops are not permitted at Layer 2 because the Layer 2 protocols will not function properly).

However, to keep the Layer 2 ring functioning in a multihomed environment with link failures, the spanning-tree protocol running on the MX Series routers requires the following additional configuration:

- The VPN protocols have to act on the blocking and unblocking of interfaces by the spanning-tree protocol. Specifically, media access control (MAC) flush messages need to be sent by the blocking PE router to LDP peers in order to flush the MAC addresses learned when other interface ports were blocked.
- Also, if an active PE router with VPLS root protection bridging enabled loses VPLS connectivity, root protection requires that the bridge switch to the other PE router to maintain connectivity. The spanning-tree protocol needs to be aware of the status of the VPLS connectivity on the PE router. If the MAC address cache is not flushed when the topology changes, frames could be sent to the wrong device.

You can control the actions taken by the MX Series router when the topology changes in a multihomed Layer 2 ring VPLS environment using *VPLS root protection*.

- [Example: Configuring VPLS Root Topology Change Actions on page 5053](#)

VPLS Multihomed Layer 2 Ring and MPLS Infrastructure Topology

[Figure 110 on page 5038](#) shows hosts connected to CE routers and to a VPLS network through two PE routers. The CE routers are also connected, forming a kind of ring structure.

Figure 110: VPLS Multihoming Configuration

The two PE routers have their own links to a VPLS network service, but are not directly connected to each other. All four edge routers run some type of spanning-tree protocol with root protection enabled, and only one PE interface will be in the forwarding state, the other being blocked.

Assume this forwarding interface is through PE1. If the link between CE1 and CE2 fails, then the blocking PE2 interface must detect a root protection switch and move to the forwarding state. All of the MAC addresses learned by CE2 that connect to the VPLS network service through PE1 need to be flushed. In the same way, when the link between CE1 and CE2 is restored, PE2 again detects the root protection switch and begins blocking again. Now all of the MAC addresses learned by CE2 that connect through PE2 need to be flushed. All of this is controlled by configuring VPLS root protection topology change actions on the CE routers.

Also, at a global level, each type of spanning-tree protocol will have a priority hold time associated with it. This is the number of seconds in the range from 1 through 255 seconds that the system waits to switch to the primary priority when the first core domain comes up. The default is 2 seconds. This allows the maximum number of core domains to come up, and some might be slower than others.

Layer 2 Protocol Tunneling Through a Network Overview

Layer 2 protocol tunneling allows Layer 2 protocol data units (PDUs) to be tunneled through a network. This is useful to provide a single spanning-tree protocol domain for subscribers across a service provider network. It is also useful for tunneling Cisco Discovery Protocol (CDP) or VLAN Trunk Protocol (VTP) PDUs across a network.

Layer 2 protocol tunneling is supported on MX Series routers with Enhanced (Dense Port Concentrators) DPCs and Enhanced Queuing (DPCs), see [Table 377 on page 5040](#) for a list of the DPCs supported. Layer 2 protocol tunneling is supported on all Modular Port Concentrators (MPCs),

NOTE: Layer 2 protocol tunneling is not supported on Rev-A DPCs on MX Series routers because of microcode space limitations.

When a control packet for STP, CDP, or VTP is received on a service provider edge port configured for Layer 2 protocol tunneling, the multicast destination MAC address is rewritten with the predefined multicast tunnel MAC address of **01:00:0c:cd:cd:d0**. The packet is transported across the provider network transparently to the other end of the tunnel and the original multicast destination MAC address is restored when the packet is transmitted.

If a packet is received on a tunnel interface that already has a destination multicast MAC address of **01:00:0c:cd:cd:d0**, the port enters an error state and is shut down. To clear the error condition, the administrator must enter the **clear error mac-rewrite interface *interface-name*** command.

Layer 2 protocol tunneling and MAC rewrite are supported in VPLS, but only certain hardware configurations are supported.

[Table 376 on page 5039](#) shows the MPCs and Enhanced DPCs supported when configuring Layer 2 protocol tunneling and VPLS.

Table 376: MAC Rewrite and VPLS Configurations

CE-Facing Interface	PE-Core Facing Interface	Layer 2 Protocol Tunneling
MPC	MPC	Yes
MPC	Enhanced DPC	Yes
Enhanced DPC	MPC	Yes
Enhanced DPC	Enhanced DPC	No

[Table 377 on page 5040](#) lists the DPCs that support the Layer 2 tunneling protocol.

Table 377: DPCs Supported for Layer 2 Protocol Tunneling

DPC Name	DPC Model Number
Gigabit Ethernet	
<i>Gigabit Ethernet Enhanced DPC with SFP</i>	DPCE-R-40GE-SFP
<i>Gigabit Ethernet Enhanced Ethernet Services DPC with SFP</i>	DPCE-X-40GE-SFP

Spanning-Tree Protocols in Logical Systems

On MX Series routers and EX Series switches only, you can configure spanning-tree protocols in logical systems for bridge domains and other virtual-switch routing instances.

When configuring spanning-tree protocols in logical systems for bridge domains and other virtual-switch routing instances, the following guidelines apply:

- You can only configure 16 logical systems.
- Logging is performed for the entire device and not per logical system.
- You cannot restart Layer 2 learning for an individual logical system.

Related Documentation

- [Spanning-Tree Protocols Supported on page 5032](#)

Bridge Priority for Election of Root Bridge and Designated Bridge

Use the bridge priority to control which bridge is elected as the root bridge and also to control which bridge is elected the root bridge when the initial root bridge fails.

The root bridge for each spanning-tree protocol instance is determined by the bridge ID. The bridge ID consists of a configurable bridge priority and the MAC address of the bridge. The bridge with the lowest bridge ID is elected as the root bridge. If the bridge priorities are equal or if the bridge priority is not configured, the bridge with the lowest MAC address is elected the root bridge.

The bridge priority can also be used to determine which bridge becomes the designated bridge for a LAN segment. If two bridges have the same path cost to the root bridge, the bridge with the lowest bridge ID becomes the designated bridge.

The bridge priority can be set only in increments of 4096.

Maximum Age for Awaiting Arrival of Hello BPDUs

The maximum age timer specifies the maximum expected arrival time of hello BPDUs. If the maximum age timer expires, the bridge detects that the link to the root bridge has failed and initiates a topology reconvergence. The maximum age timer should be longer than the configured hello timer.

Related Documentation

Forward Delay Before Ports Transition to Forwarding State

The forwarding delay timer specifies the length of time a spanning-tree protocol bridge port remains in the listening and learning states before transitioning to the forwarding state. Setting the interval too short could cause unnecessary spanning-tree reconvergence. Before changing this parameter, you should have a thorough understanding of spanning-tree protocols.

Related Documentation

Spanning-Tree Instance Interface

STP and RSTP are limited to a single instance on any physical interface. Use the **interface** statement to configure which interfaces participate in the STP or RSTP instance.

MSTP supports multiple instances on a single physical interface. Use the **interface** statement to configure which logical interfaces participate in MSTP.

For VSTP, interfaces can be configured at the global level or at the VLAN level. Interfaces configured at the global VSTP level will be enabled for all the configured VLANs. If an interface is configured at both the global and VLAN levels, the configuration at the VLAN level overrides the global configuration.

**Related
Documentation**

- [Configuring Rapid Spanning-Tree Protocol on page 5073](#)
- [Configuring Multiple Spanning-Tree Protocol on page 5067](#)

- [cost on page 5094](#)
- [edge on page 5096](#)
- [interface \(Spanning Tree\) on page 1896](#)
- [mode on page 5103](#)
- [priority on page 5106](#)

Spanning-Tree Instance Interface Priority

The root port is the interface on the nonroot bridge with the lowest path cost to the root bridge. When multiple interfaces have the same path cost to the root bridge, the interface with the lowest interface priority is selected as the root port.

If the interface priority is not configured and multiple interfaces have the same path cost to the root bridge, the interface with the lowest interface identifier is selected as the root port.

If the interface priority is configured under the MSTP protocol, this becomes the default value for all interfaces. If the interface priority is configured under the MSTI interface, the value overrides the default for that interface.

If the interface priority is configured at both the VSTP global and VLAN levels, the configuration at the VLAN level overrides the global configuration.

**Related
Documentation**

- [Configuring Rapid Spanning-Tree Protocol on page 5073](#)
- [Configuring Multiple Spanning-Tree Protocol on page 5067](#)
- [Configuring VLAN Spanning-Tree Protocol on page 5077](#)
- [interface \(Spanning Tree\) on page 1896](#)
- [priority on page 5106](#)

Spanning-Tree Instance Interface Cost

The path cost used to calculate the root path cost from any given LAN segment is determined by the total cost of each link in the path. By default, the link cost is determined by the speed of the link. The interface cost can be configured to override the default cost and control which bridge is the designated bridge and which port is the designated port. In MSTP the CIST external path cost is determined by the link speed and the number of hops.

If the interface cost is not configured, the cost is determined by the speed of the interface. For example, a 100-Mbps link has a default path cost of 19, a 1000-Mbps link has a default path cost of 4, and a 10-Gbps link has a default path cost of 2.

If the interface cost is configured under MSTP, this becomes the default value for all interfaces. If the interface cost is configured under the MSTI interface, the value overrides the default for that interface.

If the interface cost is configured at both the VSTP global and VLAN levels, the configuration at the VLAN level overrides the global configuration.

The interface cost should be set the same for all interfaces connected to the same LAN segment.

- [interface \(Spanning Tree\) on page 1896](#)

Spanning-Tree Instance Interface Point-to-Point Link Mode

The interface mode allows RSTP, MSTP, and VSTP to converge faster than the original STP on point-to-point links. The protocol does not need to wait for timers on point-to-point links. Configure interfaces that have a point-to-point link to another Layer 2 bridge as **p2p**. This parameter is ignored if the STP is configured to run the original spanning-tree version.

If the interface mode is configured at both the VSTP global and VLAN levels, the configuration at the VLAN level overrides the global configuration.

Spanning-Tree Instance Interface Configured as an Edge Port

RSTP, MSTP, and VSTP instance interfaces configured as *edge ports* enable the protocol to converge faster than the original IEEE 802.1D STP version. Edge ports transition directly to the forwarding state, and so the protocol does not need to wait for BPDUs to be received on edge ports.

The Junos OS supports automatic detection of edge ports as described in the RSTP standard. Layer 2 bridges do not expect to receive BPDUs for edge ports. If a BPDU is received for an edge port, the port becomes a non-edge port.

Keep the following guidelines in mind when configuring spanning-tree instance interfaces as edge ports:

- Do not configure a spanning-tree instance interface as an edge port if it is connected to any Layer 2 bridge. An instance interface connected to Layer 2 bridges but configured as an edge port can cause physical loops.
- If the spanning-tree protocol is configured to run the original IEEE 802.1D spanning-tree version, the edge-port option (if configured) is ignored.
- If edge ports are configured at both the VSTP global and VLAN levels, the configuration at the VLAN level overrides the global configuration.

Spanning-Tree Protocol Trace Options

In order to trace spanning-tree protocol operations, you can set spanning-tree protocol-specific trace options in the spanning-tree protocol configuration.

For general information about tracing and global tracing options, see the statement summary for the global **traceoptions** statement in the *Junos OS Routing Protocols Configuration Guide*.

MAC Address Rewriting Enabled for Layer 2 Protocol Tunneling

To configure Layer 2 protocol tunneling, you must enable MAC address rewriting by installing the destination multicast tunnel MAC address of **01:00:0c:cd:cd:d0** in the MAC table.

To enable MAC address rewriting, include the **mac-rewrite** statement at the **[edit protocols layer2-control]** hierarchy level.

When enabling MAC address rewriting for Layer 2 protocol tunneling, the following guidelines apply:

- You can enable Layer 2 protocol tunneling for untagged interfaces.
- You can enable Layer 2 protocol tunneling for single-identifier tagged ports.
- You cannot enable Layer 2 protocol tunneling for double identifier tagged interfaces

Related Documentation

- [Layer 2 Protocol Tunneling Through a Network Overview on page 5039](#)
- [Layer 2 Protocol Tunnel Interface on page 5046](#)
- [Layer 2 Protocol to be Tunneled on page 5047](#)
- [Configuring Layer 2 Protocol Tunneling on page 5086](#)

Layer 2 Protocol Tunnel Interface

To configure the interface where Layer 2 protocol tunneling is enabled, include the **interface ge-fpc/pic/port** statement at the **[edit protocols layer2-control]** hierarchy level.

Keep the following guidelines in mind when configuring Layer 2 protocol tunneling:

- Layer 2 protocol tunneling is supported on MX Series routers with enhanced queuing Dense Port Concentrators (DPCs).
- Layer 2 protocol tunneling must be configured on the interfaces at each end of the tunnel.
- You can enable Layer 2 protocol tunneling for untagged interfaces and single-identifier tagged interfaces only.
- For single-identifier tagged ports, configure a logical interface with the native VLAN identifier. This configuration associates the untagged control packets with a logical interface.
- You cannot enable Layer 2 protocol tunneling for double identifier tagged interfaces.

Related Documentation

- [MAC Address Rewriting Enabled for Layer 2 Protocol Tunneling on page 5046](#)
- [Layer 2 Protocol to be Tunneled on page 5047](#)
- [Configuring Layer 2 Protocol Tunneling on page 5086](#)

Layer 2 Protocol to be Tunneled

To configure Layer 2 protocol tunneling, you must specify the protocol that is to be tunneled using the Layer 2 tunnel:

- **cdp**—Cisco Discovery Protocol.
- **stp**—All versions of the spanning-tree protocol.
- **vtp**—Tunnel the VLAN trunk protocol.

For each protocol specified, a static destination MAC address corresponding to the protocol being tunneled is installed in the MAC table.

To specify the protocol that will be tunneled by the Layer 2 protocol tunneling, you can include the **protocol (cdp | stp | vtp)** statement at the **[edit protocols layer2-control mac-rewrite interface ge-fpc/pic/port]** hierarchy level.

NOTE: When CDP, STP, or VTP is configured for tunneling on a customer-facing port in a provider bridge, the corresponding protocol should not be enabled for operation on that interface.

Loop Protection for a Spanning-Tree Instance Interface

By default, a spanning-tree protocol interface that stops receiving Bridge Protocol Data Unit (BPDU) data frames will transition to the designated port (forwarding) state, creating a potential loop. To prevent a spanning-tree instance interface from interpreting a lack of received BPDUs as a “false positive” condition for assuming the designated port role, you can configure one of the following loop protection options:

- Configure the router to raise an alarm condition if the spanning-tree instance interface has not received BPDUs during the timeout interval.
- Configure the router to block the spanning-tree instance interface if the interface has not received BPDUs during the timeout interval.

NOTE: Spanning-tree instance interface loop protection is enabled for all spanning-tree instances on the interface, but blocks or alarms only those instances that stop receiving BPDUs.

We recommend you configure loop protection only on non-designated interfaces such as the root or alternate interfaces. Otherwise, if you configure loop protection on both sides of a designated link, then certain STP configuration events (such as setting the root bridge priority to an inferior value in a topology with many loops) can cause both interfaces to transition to blocking mode.

Root Protect for a Spanning-Tree Instance Interface

When root protect is enabled on an interface, it is enabled for all spanning-tree protocol instances on that interface. The interface is blocked only for those instances that receive superior BPDUs.

By default, root protect is disabled.

**Related
Documentation**

- [Enabling Root Protect for a Spanning-Tree Instance Interface on page 5083](#)
- [interface \(Spanning Tree\) on page 1896](#)
- [no-root-port on page 5119](#)

BPDU Protection for Individual Spanning-Tree Instance Interfaces

To configure BPDU protection on one or more spanning-tree instance interfaces, include the **bpdublock** statement:

```
bpdublock {  
  interface interface-name;  
  disable-timeout seconds;  
}
```

NOTE: If you also include the optional **disable-timeout *seconds*** statement, *blocked interfaces* are automatically cleared after the specified time interval unless the interval is 0.

**Related
Documentation**

- [Root Protection for Spanning-Tree Instance Interfaces Overview on page 5035](#)
- [BPDU Protection for Spanning-Tree Instance Interfaces Overview on page 5035](#)
- [Configuring BPDU Protection on Individual Interfaces on page 5084](#)

BPDU Protection on All Edge Ports of the Bridge

To configure edge port blocking for a particular STP family member, include the **bpdu-block-on-edge** statement for **mstp**, **rstp**, or **vstp**:

```
bpdu-block-on-edge;
interface interface-name;
```

NOTE: In contrast to BPDU protection configured on individual spanning-tree instance interfaces, BPDU protection configured on all edge ports of an entire spanning-tree protocol *disables designated edge ports* and does not enable them again.

VPLS Multihoming: Priority of the Backup Bridge

When an MX Series router in a VPLS multihomed Layer 2 ring is running a spanning-tree protocol with root protection enabled, you can modify the default actions taken by the MX Series router when the topology changes. To do this, configure the VPLS root protection topology change actions.

The default value of the backup bridge is **32,768**. You can set the backup bridge priority to a value from **0** through **61440**, in increments of 4096.

To change the default value, you can use the following statement:

```
backup-bridge-priority vpls-ring-backup-bridge-priority
```

You can include the statement at the **[edit protocols (mstp | rstp | vstp)]** hierarchy level (to control global spanning-tree protocol behavior) or at the **[edit protocols vstp vlan vlan-id]** hierarchy level (to control a particular VLAN).

NOTE: VPLS root topology change actions are configured independently of VPLS, the spanning-tree protocol, or the spanning-tree protocol root protect option.

Related Documentation

- [VPLS Multihomed Layer 2 Ring and MPLS Infrastructure Overview on page 5036](#)
- [VPLS Multihoming: Hold Time Before Switching to Primary Priority on page 5050](#)
- [Configuring VPLS Root Protection Topology Change Actions to Control Global Spanning Tree Behavior on page 5080](#)
- [Example: Configuring VPLS Root Topology Change Actions on page 5053](#)

VPLS Multihoming: Hold Time Before Switching to Primary Priority

When an MX Series router or an EX Series switch in a VPLS multihomed Layer 2 ring is running a spanning-tree protocol with root protection enabled, you can modify the default actions taken by the router or switch when the topology changes. To do this, configure the VPLS root protection topology change actions.

The default number of seconds to hold before switching to the primary priority when the first core domain comes up is 2 seconds.

To change the default value, you can use the following statement:

priority-hold-time *seconds*

You can include the statement at the **[edit protocols (mstp | rstp | vstp)]** hierarchy level (to control global spanning-tree protocol behavior) or at the **[edit protocols vstp vlan *vlan-id*]** hierarchy level (to control a particular VLAN).

NOTE: VPLS root topology change actions are configured independently of VPLS, the spanning-tree protocol, or the spanning-tree protocol root protect option.

Related Documentation

- [VPLS Multihomed Layer 2 Ring and MPLS Infrastructure Overview on page 5036](#)
- [VPLS Multihoming: Priority of the Backup Bridge on page 5049](#)

VPLS Multihoming: System Identifier for Bridges in the Ring

When an MX Series router or an EX Series switch in a VPLS multihomed Layer 2 ring is running a spanning-tree protocol with root protection enabled, you can modify the default actions taken by the router or switch when the topology changes. To do this, configure the VPLS root protection topology change actions.

The system identifier for bridges in the ring is not configured by default.

To configure a system identifier for bridges in the ring, you can use the following statement:

system-id *system-id-value* *bridge-host-ip-address(es)*

You can include the statement at the **[edit protocols (mstp | rstp | vstp)]** hierarchy level (to control global spanning-tree protocol behavior) or at the **[edit protocols vstp vlan *vlan-id*]** hierarchy level (to control a particular VLAN).

NOTE: VPLS root topology change actions are configured independently of VPLS, the spanning-tree protocol, or the spanning-tree protocol root protect option.

Related Documentation

VPLS Multihoming: Bridge Flush of MAC Cache on Topology Change

When an MX Series router or an EX Series switch in a VPLS multihomed Layer 2 ring is running a spanning-tree protocol with root protection enabled, you can modify the default actions taken by the router or switch when the topology changes. To do this, configure the VPLS root protection topology change actions.

By default, if root protect is enabled and then the topology changes, the bridges do not flush the media access control (MAC) address cache of the MAC addresses learned when other interface ports were blocked.

To change the default behavior, you can use the following statement:

vpls-flush-on-topology-change

You can include the statement at the **[edit protocols (mstp | rstp | vstp)]** hierarchy level (to control global spanning-tree protocol behavior) or at the **[edit protocols vstp vlan *vlan-id*]** hierarchy level (to control a particular VLAN).

Specifically, MAC flush messages are sent from the blocked PE to LDP peers based on the mapping of system identifier to IP addresses as specified using the **system-id** statement.

NOTE: VPLS root topology change actions are configured independently of VPLS, the spanning-tree protocol, or the spanning-tree protocol root protect option.

VSTP on a Trunk Port with Tagged Traffic Overview

In 802.1ad provider bridge networks (stacked VLANs), single-tagged access ports and double-tagged trunk ports can co-exist in a single spanning tree context. In this mode, the VLAN Spanning Tree Protocol (VSTP) can send and receive untagged Rapid Spanning Tree Protocol (RSTP) bridge protocol data units (BPDUs) on gigabit Ethernet (ge), 10 gigabit Ethernet (xe), and aggregated Ethernet (ae) interfaces. The untagged RSTP BPDUs interoperate with tagged VSTP BPDUs sent over the double-tagged trunk ports.

Double-tagging can be useful for Internet service providers, allowing them to use VLANs internally while mixing traffic from clients that are already VLAN-tagged.

Example: Configuring VSTP on a Trunk Port with Tagged Traffic

This example shows how to configure the VSTP to send and receive standard untagged Rapid Spanning Tree Protocol (RSTP) bridge protocol data units (BPDUs) on access trunks that interoperate with tagged VSTP BPDUs sent over the double-tagged trunk ports.

- [Requirements on page 5054](#)
- [Overview on page 5054](#)
- [Configuration on page 5055](#)
- [Verification on page 5063](#)

Requirements

This example uses the following hardware and software components:

- Two CE devices (MX Series routers with DPCE or MPC cards)
- Two PE devices (MX Series routers with DPCE or MPC cards)
- Junos OS Release 12.3 or later running on the PE devices

Overview

This example shows how to configure VSTP on a trunk port with tagged traffic.

Topology

[Figure 111 on page 5055](#) shows a sample topology in which two customer edge (CE) bridges are dual-homed to two provider edge (PE) devices. All of the PE-CE links are single-tagged trunks using C-VLANs 1-100. The core link between Devices PE1 and PE2 is a double-tagged trunk that carries traffic from both CE devices, using S-VLANs 100 and 200 to distinguish the CE traffic.

Two VSTP instances are created on the PE devices, one for each S-VLAN. The CE devices run the standard RSTP. The PE devices run VSTP on the core link while sending standard untagged RSTP BPDUs toward the CE devices.

Figure 111: Topology for VSTP Configured on a Trunk Port with Tagged Traffic

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device PE1

```

set interfaces ge-2/0/1 flexible-vlan-tagging

```

Configuring PE1, PE2, CE1, and CE2

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure Device PE1:

1. Configure the network interfaces.

```
[edit interfaces]
user@PE1# set ge-2/0/1 flexible-vlan-tagging
user@PE1# set ge-2/0/1 encapsulation flexible-ethernet-services
```

```

user@PE1# set ge-2/0/1 unit 1 vlan-id 100
user@PE1# set ge-2/0/1 unit 1 family bridge interface-mode trunk
user@PE1# set ge-2/0/1 unit 1 family bridge inner-vlan-id-list 1-100
user@PE1# set ge-2/0/1 unit 2 vlan-id 200
user@PE1# set ge-2/0/1 unit 2 family bridge interface-mode trunk
user@PE1# set ge-2/0/1 unit 2 family bridge inner-vlan-id-list 1-100

```

```

user@PE1# set ge-2/0/4 encapsulation ethernet-vpls
user@PE1# set ge-2/0/4 unit 0 description to_CE1
user@PE1# set ge-2/0/4 unit 0 family bridge interface-mode trunk
user@PE1# set ge-2/0/4 unit 0 family bridge vlan-id-list 1-100

```

```

user@PE1# set ge-2/1/1 unit 0 description to_CE2
user@PE1# set ge-2/1/1 unit 0 family bridge interface-mode trunk
user@PE1# set ge-2/1/1 unit 0 family bridge vlan-id-list 1-100

```

2. Configure the routing instances.

```

[edit routing-instances]
user@PE1# set vs1 instance-type virtual-switch
user@PE1# set vs1 interface ge-2/0/1.1
user@PE1# set vs1 interface ge-2/0/4.0
user@PE1# set vs1 protocols vstp vlan 100 interface ge-2/0/1
user@PE1# set vs1 protocols vstp vlan 100 interface ge-2/0/4 access-trunk
user@PE1# set vs1 bridge-domains bd vlan-id-list 1-100

```

```

user@PE1# set vs2 instance-type virtual-switch
user@PE1# set vs2 interface ge-2/0/1.2
user@PE1# set vs2 interface ge-2/1/1.0
user@PE1# set vs2 protocols vstp vlan 200 interface ge-2/0/1
user@PE1# set vs2 protocols vstp vlan 200 interface ge-2/1/1 access-trunk
user@PE1# set vs2 bridge-domains bd vlan-id-list 1-100

```

Step-by-Step Procedure

To configure Device PE2:

1. Configure the interfaces.

```

[edit interfaces]
user@PE2# set ge-2/0/1 flexible-vlan-tagging
user@PE2# set ge-2/0/1 encapsulation flexible-ethernet-services
user@PE2# set ge-2/0/1 unit 1 vlan-id 100
user@PE2# set ge-2/0/1 unit 1 family bridge interface-mode trunk
user@PE2# set ge-2/0/1 unit 1 family bridge inner-vlan-id-list 1-100
user@PE2# set ge-2/0/1 unit 2 vlan-id 200
user@PE2# set ge-2/0/1 unit 2 family bridge interface-mode trunk
user@PE2# set ge-2/0/1 unit 2 family bridge inner-vlan-id-list 1-100

```

```

user@PE2# set ge-2/1/3 description to_CE1
user@PE2# set ge-2/1/3 unit 0 family bridge interface-mode trunk
user@PE2# set ge-2/1/3 unit 0 family bridge vlan-id-list 1-100

```

```

user@PE2# set ge-2/0/5 description to_CE2
user@PE2# set ge-2/0/5 unit 0 family bridge interface-mode trunk
user@PE2# set ge-2/0/5 unit 0 family bridge vlan-id-list 1-100

```

2. Configure the routing instances.

```
[edit routing-instances]
user@PE2# set vs1 instance-type virtual-switch
user@PE2# set vs1 interface ge-2/0/1.1
user@PE2# set vs1 interface ge-2/1/3.0
user@PE2# set vs1 protocols vstp vlan 100 interface ge-2/0/1
user@PE2# set vs1 protocols vstp vlan 100 interface ge-2/1/3 access-trunk
user@PE2# set vs1 bridge-domains bd vlan-id-list 1-100

user@PE2# set vs2 instance-type virtual-switch
user@PE2# set vs2 interface ge-2/0/1.2
user@PE2# set vs2 interface ge-2/0/5.0
user@PE2# set vs2 protocols vstp vlan 200 interface ge-2/0/1
user@PE2# set vs2 protocols vstp vlan 200 interface ge-2/0/5 access-trunk
user@PE2# set vs2 bridge-domains bd vlan-id-list 1-100
```

Step-by-Step Procedure To configure CE1:

1. Configure the interfaces.

```
[edit interfaces]
user@CE1# set ge-2/0/7 unit 0 description to_PE1
user@CE1# set ge-2/0/7 unit 0 family bridge interface-mode trunk
user@CE1# set ge-2/0/7 unit 0 family bridge vlan-id-list 1-100

user@CE1# set ge-2/1/4 unit 0 description to_PE2
user@CE1# set ge-2/1/4 unit 0 family bridge interface-mode trunk
user@CE1# set ge-2/1/4 unit 0 family bridge vlan-id-list 1-100
```

2. Configure the protocols.

```
[edit protocols]
user@CE1# set rstp interface ge-2/0/7
user@CE1# set rstp interface ge-2/1/4
```

3. Configure the bridge domain.

```
[edit bridge-domains]
user@CE1# set bd vlan-id-list 1-100
```

Step-by-Step Procedure To configure CE2:

1. Configure the interfaces.

```
[edit interfaces]
user@CE2# set ge-2/0/8 unit 0 description to_PE2
user@CE2# set ge-2/0/8 unit 0 family bridge interface-mode trunk
user@CE2# set ge-2/0/8 unit 0 family bridge vlan-id-list 1-100

user@CE2# set ge-2/1/1 unit 0 description to_PE1
user@CE2# set ge-2/1/1 unit 0 family bridge interface-mode trunk
user@CE2# set ge-2/1/1 unit 0 family bridge vlan-id-list 1-100
```

2. Configure the protocols.

```
[edit protocols]
```

```
user@CE2# set rstp interface ge-2/0/8
user@CE2# set rstp interface ge-2/1/1
```

3. Configure the bridge domain.

```
[edit bridge-domains]
user@CE2# set bd vlan-id-list 1-100
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-instances**, **show protocols**, and **show bridge-domains** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
Device PE1 user@PE1# show interfaces
ge-2/0/1 {
  flexible-vlan-tagging;
  encapsulation flexible-ethernet-services;
  unit 1 {
    vlan-id 100;
    family bridge {
      interface-mode trunk;
      inner-vlan-id-list 1-100;
    }
  }
  unit 2 {

}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying That the Interfaces Are Operational on page 5063](#)
- [Verifying the STP Bridge Parameters of the Routing Instances on page 5063](#)
- [Displaying STP Statistics for the Configured Bridge on page 5064](#)

Verifying That the Interfaces Are Operational

Purpose Verify that the interfaces are operational.

Action From operational mode, enter the **show spanning-tree interface routing-instance** command.

```

user@PE1> show spanning-tree interface routing-instance vs1
Spanning tree interface parameters for VLAN 100

```

Interface	Port ID	Designated port ID	Designated bridge ID	Port Cost	State	Role
ge-2/0/1	128:82	128:82	32868.0021590f37d0	20000	FWD	DESG
ge-2/0/4	128:85	128:85	32868.0021590f37d0	20000	FWD	DESG

Meaning The output shows the status of the interfaces configured for VLAN 100.

Verifying the STP Bridge Parameters of the Routing Instances

Purpose Verify the STP bridge parameters configured for the routing instances.

Action From operational mode, enter the **show spanning-tree bridge routing-instance** command.

```
user@PE1> show spanning-tree bridge routing-instance vs1
STP bridge parameters
Routing instance name      : vs1
Enabled protocol           : RSTP

STP bridge parameters for VLAN 100
Root ID                    : 32868.00:21:59:0f:37:d0
Hello time                  : 2 seconds
Maximum age                 : 20 seconds
Forward delay               : 15 seconds
Message age                 : 0
Number of topology changes  : 2
Time since last topology change : 687 seconds
Local parameters
  Bridge ID                 : 32868.00:21:59:0f:37:d0
  Extended system ID        : 100
```

Meaning The output shows the status of the STP bridge parameters for routing instance vs1.

Displaying STP Statistics for the Configured Bridge

Purpose Display spanning-tree statistics for the configured bridge.

Action From operational mode, enter the **show spanning-tree statistics bridge** command.

```

user@PE1> show spanning-tree statistics bridge
STP Context : default
STP Instance : 0
Number of Root Bridge Changes: 0
Number of Root Port Changes: 0

STP Context : x/default
STP Instance : 0
Number of Root Bridge Changes: 0
Number of Root Port Changes: 0

STP Context : vs1
STP Instance : 0
Number of Root Bridge Changes: 2          Last Changed: Thu Sep 20 15:12:18
2012
Number of Root Port Changes: 1          Last Changed: Thu Sep 20 15:01:13
2012
Recent TC Received: ge-2/0/1.1          Received : Thu Sep 20 15:01:17
2012

STP Context : vs2
STP Instance : 0
Number of Root Bridge Changes: 2          Last Changed: Thu Sep 20 15:10:25
2012
Number of Root Port Changes: 2          Last Changed: Thu Sep 20 15:10:25
2012
Recent TC Received: ge-2/1/1.0          Received : Thu Sep 20 15:10:47
2012

STP Context : CE1/default
STP Instance : 0
Number of Root Bridge Changes: 0
Number of Root Port Changes: 0
Recent TC Received: ge-2/1/4.0          Received : Thu Sep 20 15:12:15
2012

```

Meaning The command output shows spanning-tree statistics for the configured bridge.

Example: Tracing Spanning-Tree Protocol Operations

Trace only unusual or abnormal operations to `/var/log/stp-log`:

```

[edit]
routing-options {
  traceoptions {
    file routing-log size 10m world-readable;
    flag all;
  }
}
protocols {
  rstp {
    traceoptions {
      file rstp-log size 10m world-readable;
      flag all;
    }
  }
}

```

}

Configuring Multiple Spanning-Tree Protocol

You can configure the Multiple Spanning-Tree Protocol (MSTP) under the following hierarchy levels:

- [edit *logical-systems logical-system-name protocols*]
- [edit *logical-systems logical-system-name routing-instances routing-instance-name protocols*]
- [edit *protocols*]
- [edit *routing-instances routing-instance-name protocols*]

The routing instance type can be either **virtual-switch** or **layer2-control**.

To configure the Multiple Spanning-Tree Protocol:

1. Enable RSTP as the version of spanning-tree protocol to be configured:

```
[edit]
user@host@ edit ... protocols (STP Type) mstp
```

2. (Optional) Enable provider bridge participation in the MSTP instance:

```
[edit ... protocols mstp]
user@host# set bpd-destination-mac-address provider-bridge-group
```

3. Configure the interfaces that participate in the MSTP instance.

- a. Enable configuration of the interface:

```
[edit ... protocols mstp]
user@host# edit interface interface-name
```

- b. Configure the interface priority:

```
[edit ... protocols mstp interface interface-name]
user@host# set priority interface-priority
```

- c. (Optional) By default, the interface link cost is determined by the link speed. You can configure the interface link cost to control which bridge is the designated bridge and which port is the designated port:

```
[edit ... protocols mstp interface interface-name]
user@host# set cost interface-link-cost
```

- d. Configure the interface link mode to identify point-to-point links:

```
[edit ... protocols mstp interface interface-name]
user@host# set mode (p2p | shared)
```

Specify **p2p** if the link is point to point. Specify **shared** if the link is a shared media.

- e. (Optional) Configure the interface as an edge port:

```
[edit ... protocols mstp interface interface-name]
user@host# set edge
```

Edge ports do not expect to receive bridge protocol data unit (BPDU) packets. If a BPDU packet is received for an edge port, the port becomes a nonedge port.

You can also enable BPDU root protection for all spanning-tree protocol instances on the interface. BPDU root protect ensures the port is the spanning-tree designated port. If the port receives superior BPDU packets, root protect moves this port to a root-prevented spanning-tree state. For configuration details, see [“Checking the Status of Spanning-Tree Instance Interfaces” on page 5125](#).

4. Configure the bridge priority

```
[edit ... protocols mstp]
user@host# set bridge-priority bridge-priority
```

For more information, see [“Bridge Priority for Election of Root Bridge and Designated Bridge” on page 5041](#).

5. Configure hello BPDU timers.

- a. Configure the maximum expected arrival time of hello BPDUs:

```
[edit ... protocols mstp]
user@host# set max-age seconds
```

- b. Configure the time interval at which the root bridge transmits configuration BPDUs:

```
[edit ... protocols mstp]
user@host# set hello-time seconds
```

6. (Optional) By default, the bridge port remains in the listening and learning states for 15 seconds before transitioning to the forwarding state. You can specify a delay from 4 through 20 seconds instead:

```
[edit ... protocols mstp]
```

```
user@host# set forward-delay seconds
```

7. Configure MSTP-specific options.

a. Configure the MSTP region configuration name:

```
[edit ... protocols mstp]
user@host# set configuration-name configuration-name
```

b. Configure the MSTP revision level:

```
[edit ... protocols mstp]
user@host# set revision-level revision-level
```

c. Configure the maximum number of hops a BPDU can be forwarded in the MSTP region:

```
[edit ... protocols mstp]
user@host# set max-hops hops
```

8. Verify the MSTP configuration:

```
[edit]
... { # Optional logical system and/or routing instance
  protocols (STP Type) {
    mstp {
      bpd-destination-mac-address provider-bridge-group; # Optional
      interface interface-name {
        priority interface-priority;
        cost interface-link-cost; # Optional.
        mode (p2p | shared);
        edge; # Optional.
      }
      bridge-priority bridge-priority;
      max-age seconds;
      hello-time seconds;
      forward-delay seconds; # Optional.
      configuration-name configuration-name; # MST region configuration name.
      revision-level revision-level; # MST revision number.
      max-hops hops; # MST maximum hops.
    }
  }
}
```

**Related
Documentation**

- [Configuring MST Instances on a Physical Interface on page 5070](#)
- [Disabling MSTP on page 5071](#)

Configuring MST Instances on a Physical Interface

You can configure a Multiple Spanning-Tree Instance (MSTI) under the following hierarchy levels:

- [edit *logical-systems logical-system-name protocols mstp*]
- [edit *logical-systems logical-system-name routing-instances routing-instance-name protocols mstp*]
- [edit *protocols mstp*]
- [edit *routing-instances routing-instance-name protocols mstp*]

The routing instance type can be either **virtual-switch** or **layer2-control**.

Before you begin, configure Multiple Spanning-Tree Protocol. For configuration details, see “Configuring MSTP” on page 5067.

1. Enable configuration of a MST instance:

```
[edit]
user@host# edit ... protocols mstp msti msti-id
The msti-id value must be from 1 through 64.
```

2. Configure the interfaces that participate in the MST instance.

- a. Enable configuration of the interface:

```
[edit ... protocols mstp msti msti-id]
user@host# edit interface interface-name
```

- b. Configure the interface priority:

```
[edit ... protocols mstp msti msti-id interface interface-name]
user@host# set priority interface-priority
```

- c. (Optional) By default, the interface link cost is determined by the link speed. You can configure the interface link cost to control which bridge is the designated bridge and which port is the designated port:

```
[edit ... protocols mstp msti msti-id interface interface-name]
user@host# set cost interface-link-cost
```

- d. (Optional) Configure the interface as an edge port:

```
[edit ... protocols mstp msti msti-id interface interface-name]
user@host# set edge
```

Edge ports do not expect to receive bridge protocol data unit (BPDU) packets. If a BPDU packet is received for an edge port, the port becomes a nonedge port

3. Configure the bridge priority

```
[edit ... protocols mstp msti msti-id]
user@host# set bridge-priority bridge-priority
```

For more information, see “Bridge Priority for Election of Root Bridge and Designated Bridge” on page 5041.

4. (Optional) An MSTI can map to a range of VLANs just as a logical port can map to a range of VLANs. The MSTP VLAN specifies the VLAN or VLAN range to which this

MSTI is mapped. The vlan-id is configured under the logical interface. Configure the VLAN or VLAN range of the MSTI instance:

```
[edit]
user@host# set vlan (vlan-id | vlan-id-range)
```

5. Verify the MST interface configuration.

```
[edit]
protocols {
  mstp {
    ...basic-mstp-configuration...
    msti msti-id { # Instance identifier 1 – 64.
      bridge-priority priority;
      vlan vlan-id; # Optional
      interface interface-name {
        cost cost;
        edge;
        priority interface-priority;
      }
    }
  }
}
```

Disabling MSTP

To disable the entire MSTP instance:

- Include the **disable** statement. You can include this statement at the following hierarchy levels:
 - **[edit logical-systems logical-system-name protocols mstp]**
 - **[edit logical-systems logical-system-name routing-instances routing-instance-name protocols mstp]**
 - **[edit protocols mstp]**
 - **[edit routing-instances routing-instance-name protocols mstp]**

Provider Bridge Participation in RSTP or MSTP Instances

A provider network can bridge the customer STP BPDU packets between customer sites by default. At the same time, the provider network can prevent forwarding loops by running a spanning-tree protocol in the provider network. On an MX Series router running Rapid Spanning-Tree Protocol (RSTP) or Multiple Spanning-Tree Protocol (MSTP) in a provider network, you can enable provider bridge participation in the RSTP or MSTP instance.

The IEEE 802.1ad specification reserves the group MAC address value of **01:80:c2:00:00:08** to designate the *provider bridge group*. On an MX Series router for which you have enabled provider bridge participation in the RSTP or MSTP instance, the router exchanges BPDU packets with the provider bridge group as follows:

- Transmitted BPDU packets contain the destination MAC address **01:80:c2:00:00:08**.
- Received BPDU packets with the destination MAC address **01:80:c2:00:00:08** are accepted and passed to the Routing Engine.

RSTP or VSTP Forced to Run as IEEE 802.1D STP

On MX Series routers or EX Series switches in a Layer 2 environment, you can force the configured Rapid Spanning-Tree Protocol (RSTP) or VLAN Spanning-Tree Protocol (VSTP) to run as the original IEEE 802.1D Spanning-Tree Protocol (STP) version. Configure this option for compatibility with older bridges that do not support RSTP or VSTP.

Keep the following limitations in mind when RSTP or VSTP are run as the original STP version:

- If you configure an instance interface as an edge port, the configuration statement is ignored.
- If you configure point-to-point link mode for an instance interface, the configuration statement is ignored.

Configuring Rapid Spanning-Tree Protocol

You can configure Rapid Spanning-Tree Protocol (RSTP) under the following hierarchy levels:

- [edit *logical-systems logical-system-name protocols*]
- [edit *logical-systems logical-system-name routing-instances routing-instance-name protocols*]
- [edit *protocols*]
- [edit *routing-instances routing-instance-name protocols*]

The routing instance type can be either **virtual-switch** or **layer2-control**.

To configure the Rapid Spanning-Tree Protocol:

1. Enable RSTP as the version of spanning-tree protocol to be configured:

```
[edit]
user@host@ edit ... protocols (STP Type) rstp
```

2. (Optional) For compatibility with older bridges that do not support RSTP, you can run force RSTP to run as the original IEEE 802.1D Spanning-Tree Protocol (STP) version:

```
[edit ... protocols rstp]
user@host# set force-version stp
```

NOTE: If RSTP has been forced to run as the original STP version, you can revert back to RSTP by first removing the *force-version* statement from the configuration and then entering the *clear spanning-tree protocol-migration* configuration mode command.

3. (Optional) Enable provider bridge participation in the RSTP instance:

```
[edit ... protocols rstp]
user@host# set bpd-destination-mac-address provider-bridge-group
```

4. (Optional) Specify the extended system identifier used in identifiers bridges that participate in RSTP:

```
[edit ... protocols rstp]
user@host# set extended-system-id identifier
```

5. Configure the interfaces that participate in the RSTP instance.

- a. Enable configuration of the interface:

```
[edit ... protocols rstp]
user@host# edit interface interface-name
```

- b. Configure the interface priority:

```
[edit ... protocols rstp interface interface-name]
user@host# set priority interface-priority
```

- c. (Optional) By default, the interface link cost is determined by the link speed. You can configure the interface link cost to control which bridge is the designated bridge and which port is the designated port:

```
[edit ... protocols rstp interface interface-name]
user@host# set cost interface-link-cost
```

- d. Configure the interface link mode to identify point-to-point links:

```
[edit ... protocols rstp interface interface-name]
user@host# set mode (p2p | shared)
```

Specify **p2p** if the link is point to point. Specify **shared** if the link is a shared media.

- e. (Optional) Configure the interface as an edge port:

```
[edit ... protocols rstp interface interface-name]
user@host# set edge
```

Edge ports do not expect to receive bridge protocol data unit (BPDU) packets. If a BPDU packet is received for an edge port, the port becomes a nonedge port.

You can also enable BPDU root protection for all spanning-tree protocol instances on the interface. BPDU root protect ensures the port is the spanning-tree designated port. If the port receives superior BPDU packets, root protect moves this port to a root-prevented spanning-tree state. For configuration details, see [“Checking the Status of Spanning-Tree Instance Interfaces” on page 5125](#).

6. Configure the bridge priority

```
[edit ... protocols rstp]
user@host# set bridge-priority bridge-priority
```

For more information, see [“Bridge Priority for Election of Root Bridge and Designated Bridge” on page 5041](#).

7. Configure hello BPDU timers.

- a. Configure the maximum expected arrival time of hello BPDUs:

```
[edit ... protocols rstp]
user@host# set max-age seconds
```

- b. Configure the time interval at which the root bridge transmits configuration BPDUs:

```
[edit ... protocols rstp]
user@host# set hello-time seconds
```

8. (Optional) By default, the bridge port remains in the listening and learning states for 15 seconds before transitioning to the forwarding state. You can specify a delay from 4 through 20 seconds instead:

```
[edit ... protocols rstp]
```

```
user@host# set forward-delay seconds
```

9. Verify the RSTP configuration:

```
[edit]
... { # Optional logical system and/or routing instance
  protocols (STP Type) {
    rstp {
      force-version stp; # Optional.
      bpdudestination-mac-address provider-bridge-group; # Optional
      extended-system-id identifier; # Optional.
      interface interface-name {
        priority interface-priority;
        cost interface-link-cost; # Optional.
        mode (p2p | shared);
        edge; # Optional.
      }
      bridge-priority bridge-priority;
      max-age seconds;
      hello-time seconds;
      forward-delay seconds; # Optional.
    }
  }
}
```

Reverting RSTP or VSTP Back From Forced IEEE 802.1D STP

On MX Series routers or EX Series switches on which Rapid Spanning-Tree Protocol (RSTP) or VLAN Spanning-Tree Protocol (VSTP) has been forced to run as the original IEEE 802.1D Spanning-Tree Protocol (STP) version, you can revert back to RSTP or VSTP.

To revert from the forced instance of the original IEEE 802.1D STP version back to the configured RSTP or VSTP version:

1. Remove the **force-version** statement from the RSTP or VSTP configuration:

```
user@host# delete force-version
```

Include this statement under the RSTP or VSTP hierarchy level:

- `[edit protocols rstp]`
- `[edit protocols vstp]`
- `[edit routing-instances routing-instance-name protocols rstp]`
- `[edit routing-instances routing-instance-name protocols vstp]`

2. Revert the forced IEEE 802.1D STP to run as the configured RSTP or VSTP:

```
user@host# clear spanning-tree protocol-migration <interface interface-name>
<routing-instance routing-instance-name>
```

To revert the STP protocol for the specified interface only, specify the **interface *interface-name*** option.

To revert the STP protocol for a particular routing instance only, specify the **routing-instance *routing-instance-name*** option.

Provider Bridge Participation in RSTP or MSTP Instances

A provider network can bridge the customer STP BPDU packets between customer sites by default. At the same time, the provider network can prevent forwarding loops by running a spanning-tree protocol in the provider network. On an MX Series router running Rapid Spanning-Tree Protocol (RSTP) or Multiple Spanning-Tree Protocol (MSTP) in a provider network, you can enable provider bridge participation in the RSTP or MSTP instance.

The IEEE 802.1ad specification reserves the group MAC address value of **01:80:c2:00:00:08** to designate the *provider bridge group*. On an MX Series router for which you have enabled provider bridge participation in the RSTP or MSTP instance, the router exchanges BPDU packets with the provider bridge group as follows:

- Transmitted BPDU packets contain the destination MAC address **01:80:c2:00:00:08**.
- Received BPDU packets with the destination MAC address **01:80:c2:00:00:08** are accepted and passed to the Routing Engine.

Configuring VLAN Spanning-Tree Protocol

You can configure the VLAN Spanning-Tree Protocol (VSTP) under the following hierarchy levels:

- [edit *logical-systems logical-system-name protocols*]
- [edit *logical-systems logical-system-name routing-instances routing-instance-name protocols*]
- [edit *protocols*]
- [edit *routing-instances routing-instance-name protocols*]

The routing instance type can be either **virtual-switch** or **layer2-control**.

To configure the VLAN Spanning-Tree Protocol:

1. Enable VSTP as the version of spanning-tree protocol to be configured:

```
[edit]
user@host@ edit ... protocols (STP Type) vstp
```

2. (Optional) For compatibility with older bridges that do not support VSTP, you can run force VSTP to run as the original IEEE 802.1D Spanning-Tree Protocol (STP) version:

```
[edit ... protocols vstp]
user@host# set force-version stp
```

NOTE: If VSTP has been forced to run as the original STP version, you can revert back to VSTP by first removing the **force-version** statement from the configuration and then entering the **clear spanning-tree protocol-migration** configuration mode command.

3. Configure the interfaces that participate in the VSTP instance.

- a. Enable configuration of the interface:

```
[edit ... protocols vstp]
user@host# edit interface interface-name
```

- b. Configure the interface priority:

```
[edit ... protocols vstp interface interface-name]
user@host# set priority interface-priority
```

- c. (Optional) By default, the interface link cost is determined by the link speed. You can configure the interface link cost to control which bridge is the designated bridge and which port is the designated port:

```
[edit ... protocols vstp interface interface-name]
user@host# set cost interface-link-cost
```

- d. Configure the interface link mode to identify point-to-point links:

```
[edit ... protocols vstp interface interface-name]
user@host# set mode (p2p | shared)
```

Specify **p2p** if the link is point to point. Specify **shared** if the link is a shared media.

- e. (Optional) Configure the interface as an edge port:

```
[edit ... protocols vstp interface interface-name]
user@host# set edge
```

Edge ports do not expect to receive bridge protocol data unit (BPDU) packets. If a BPDU packet is received for an edge port, the port becomes a nonedge port

You can also enable BPDU root protection for all spanning-tree protocol instances on the interface. BPDU root protect ensures the port is the spanning-tree designated port. If the port receives superior BPDU packets, root protect moves this port to a root-prevented spanning-tree state. For configuration details, see [“Checking the Status of Spanning-Tree Instance Interfaces” on page 5125](#).

4. Enable configuration of a VLAN instance:

```
[edit ... protocols vstp]
user@host# edit vlan vlan-id
```

5. Configure the bridge priority

```
[edit ... protocols vstp vlan vlan-id]
user@host# set bridge-priority bridge-priority
```

For more information, see [“Bridge Priority for Election of Root Bridge and Designated Bridge” on page 5041](#).

6. Configure hello BPDU timers.

- a. Configure the maximum expected arrival time of hello BPDUs:

```
[edit ... protocols vstp vlan vlan-id]
user@host# set max-age seconds
```

- b. Configure the time interval at which the root bridge transmits configuration BPDUs:

```
[edit ... protocols vstp vlan vlan-id]
user@host# set hello-time seconds
```

7. (Optional) By default, the bridge port remains in the listening and learning states for 15 seconds before transitioning to the forwarding state. You can specify a delay from 4 through 20 seconds instead:

```
[edit ... protocols vstp vlan vlan-id]
user@host# set forward-delay seconds
```

8. Configure the interfaces that participate in the VSTP instance.

- a. Enable configuration of the interface:

```
[edit ... protocols vstp vlan vlan-id]
user@host# edit interface interface-name
```

- b. Configure the interface priority:

```
[edit ... protocols vstp vlan vlan-id interface interface-name]
user@host# set priority interface-priority
```

- c. (Optional) By default, the interface link cost is determined by the link speed. You can configure the interface link cost to control which bridge is the designated bridge and which port is the designated port:

```
[edit ... protocols vstp vlan vlan-id interface interface-name]
user@host# set cost interface-link-cost
```

- d. Configure the interface link mode to identify point-to-point links:

```
[edit ... protocols vstp vlan vlan-id interface interface-name]
user@host# set mode (p2p | shared)
```

Specify **p2p** if the link is point to point. Specify **shared** if the link is a shared media.

- e. (Optional) Configure the interface as an edge port:

```
[edit ... protocols vstp vlan vlan-id interface interface-name]
user@host# set edge
```

Edge ports do not expect to receive bridge protocol data unit (BPDU) packets. If a BPDU packet is received for an edge port, the port becomes a nonedge port

You can also enable BPDU root protection for all spanning-tree protocol instances on the interface. BPDU root protect ensures the port is the spanning-tree designated port. If the port receives superior BPDU packets, root protect moves this port to a root-prevented spanning-tree state. For configuration details, see [“Checking the Status of Spanning-Tree Instance Interfaces” on page 5125](#).

9. Verify the VSTP configuration:

```
[edit]
... { # Optional logical system and/or routing instance
  protocols (STP Type) {
    vstp {
```

```
force-version stp; # Optional.
interface interface-name {
    priority interface-priority;
    cost interface-link-cost; # Optional.
    mode (p2p | shared);
    edge; # Optional.
}
vlan vlan-id {
    bridge-priority bridge-priority;
    max-age seconds;
    hello-time seconds;
    forward-delay seconds; # Optional.
    interface interface-name {
        priority interface-priority;
        cost interface-link-cost; # Optional.
        mode (p2p | shared);
        edge; # Optional.
    }
}
}
```

Configuring VPLS Root Protection Topology Change Actions to Control Global Spanning Tree Behavior

To configure VPLS root protection topology change actions to control global spanning tree behavior:

1. Enable configuration of the spanning-tree protocol:

```
[edit]
user@host# edit protocols (STP Type) (mstp | rstp | vstp)
```

2. (Optional) Change the priority of the backup bridge in a VPLS multihomed Layer 2 ring with MPLS infrastructure:

```
[edit protocols (rstp | mstp | vstp)]
user@host# set backup-bridge-priority vpls-ring-backup-bridge-priority
```

3. (Optional) Change number of seconds to hold before switching to the primary priority when the first core domain comes up:

```
[edit protocols (rstp | mstp | vstp)]
user@host# set priority-hold-time seconds
```

4. Configure the system identifier for bridges in the ring:

```
[edit protocols (rstp | mstp | vstp)]
user@host# set system-id system-id-value bridge-host-ip-address(es)
```

The **system-id-value** is configured in the format *nnnnnn:nnnnnn*, where *n* = any digit from 0 to 9.

Each **bridge-host-ip-address** is a valid host IP address with a /32 mask.

NOTE: There are no default values for the system identifier or host IP addresses.

5. Configure bridges to flush the MAC address cache (of the MAC addresses learned when other interfaces ports were blocked) when the spanning-tree topology changes:

```
[edit protocols (rstp | mstp | vstp)]
user@host# set vpls-flush-on-topology-change
```

6. Verify the configuration of VPLS root protection topology change actions to control global spanning tree behavior:

```
[edit]
protocols {
  (mstp | rstp | vstp) {
    backup-bridge-priority priority; # Default is 32,768.
    priority-hold-time seconds; # Default is 2 seconds.
    system-id system-id-value {
      ip-address;
    }
    vpls-flush-on-topology-change;
  }
}
```

BPDU Protection for Individual Spanning-Tree Instance Interfaces

To configure BPDU protection on one or more spanning-tree instance interfaces, include the **bpdu-block** statement:

```
bpdu-block {
  interface interface-name;
  disable-timeout seconds;
}
```

NOTE: If you also include the optional **disable-timeout seconds** statement, *blocked interfaces* are automatically cleared after the specified time interval unless the interval is 0.

Related Documentation

- [Configuring BPDU Protection on Individual Interfaces on page 5084](#)

Configuring Loop Protection for a Spanning-Tree Instance Interface

Before you begin, you must fully configure the spanning-tree protocol, including instance interfaces. You can configure RSTP, MSTP, or VSTP at the following hierarchy levels:

- **[edit protocols]**
- **[edit routing-instances *routing-instance-name* protocols]**

To configure enhanced loop protection:

1. Include the **bpdu-timeout-action** statement with either the **block** or **log** option for the spanning-tree protocol interface.

- For the STP or RSTP instance on a physical interface:

```
[edit]
protocols {
  rstp {
    interface interface-name {
      bpdu-timeout-action (log | block);
    }
  }
}
```

- For all MSTP instances on a physical interface:

```
[edit]
protocols {
  mstp {
    interface interface-name {
      bpdu-timeout-action (log | block);
    }
  }
}
```

- For all VSTP instances on a physical interface configured at the global level or at the VLAN level:

```
[edit]
protocols {
  vstp {
    interface interface-name {
      bpdu-timeout-action (log | block);
    }
    vlan vlan-id {
      interface interface-name {
        bpdu-timeout-action (log | block);
      }
    }
  }
}
```

```
}
```

2. To display the spanning-tree protocol loop protection characteristics on an interface, use the **show spanning-tree interface** operational command.

Related Documentation

- [Loop Protection for Spanning-Tree Instance Interfaces Overview on page 5034](#)
- [Loop Protection for a Spanning-Tree Instance Interface on page 5047](#)
- [Example: Enabling Loop Protection for Spanning-Tree Protocols on page 5052](#)

Enabling Root Protect for a Spanning-Tree Instance Interface

To enable root protect for a spanning-tree instance interface:

1. Enable configuration of the spanning-tree protocol:

```
[edit]
user@host# edit protocols (mstp | rstp | vstp <vlan vlan-id>)
```

2. Enable configuration of the spanning-tree instance interface:

```
[edit ... protocols (mstp | rstp | vstp <vlan vlan-id>)]
user@host# edit interface interface-name
```

3. Enable root protection on the interface:

```
[edit ... protocols (mstp | rstp | vstp <vlan vlan-id>) interface interface-name]
user@host# set no-root-port
```

4. Verify the configuration of root protect for the spanning-tree instance interface:

```
[edit ... protocols (mstp | rstp | vstp <vlan vlan-id>) interface interface-name]
user@host# top
user@host# show ... protocols
```

```
...
(mstp | rstp | vstp <vlan vlan-id>) {
  interface interface-name {
    no-root-port;
  }
}
```

NOTE: This is not a complete configuration.

Related Documentation

- [Root Protection for Spanning-Tree Instance Interfaces Overview on page 5035](#)
- [Root Protect for a Spanning-Tree Instance Interface on page 5048](#)

Configuring BPDU Protection on Individual Interfaces

On MX Series routers and EX Series switches, you can configure BPDU protection to ignore BPDU received on interfaces where none should be expected. If a BPDU is received on a blocked interface, the interface is disabled and stops forwarding frames. By default, all BPDUs are accepted and processed on all interfaces.

To configure BPDU protection for individual spanning-tree instance interfaces:

1. Enable BPDU protection on a specific spanning-tree instance interface:

```
[edit]
user@host# edit protocols layer2-control bpd-block
user@host# set interface interface (aex | (ge-fpc/pic/port | xe-fpc/pic/port))
```

If a BPDU is received on the interface, the system will disable the interface and stop forwarding frames out the interface until the bridging process is restarted.

2. (Optional) Configure the amount of time the system waits before *automatically* unblocking this interface after it has received a BPDU.

```
[edit protocols layer2-control] bpd-block interface interface-name]
user@host# set disable-timeout seconds
```

The range of the *seconds* option value is from 10 through 3600 seconds (one hour). A *seconds* option value of 0 is allowed, but this results in the default behavior (the interface is blocked until the interface is cleared).

3. Verify the configuration of BPDU blocking for individual interfaces:

```
[edit]
interfaces {
  ge-fpc/pic/port { # VLAN encapsulation on Gigabit Ethernet.
    encapsulation (ethernet-bridge | extended-vlan-bridge | extended-vlan-vpls |
      vlan-vpls);
  }
  xe-fpc/pic/port { # VLAN encapsulation on 10-Gigabit Ethernet.
    encapsulation (ethernet-bridge | extended-vlan-bridge | extended-vlan-vpls |
      vlan-vpls);
  }
  ae-X { # VLAN encapsulation
    encapsulation (ethernet-vpls vlan-vpls); # on Aggregated Ethernet.
    ...
  }
  ae-X { # Extended VLAN encapsulation
    vlan-tagging; # on Aggregated Ethernet.
    encapsulation extended-vlan-vpls;
    unit logical-unit-number {
      vlan-id number;
      .....
    }
    .....
  }
}
protocols
  layer2-control {
    bpd-block
      interface interface-name;
```

```

        disable-timeout seconds;
    }
}

```

Configuring BPDU Protection on All Edge Ports

On MX Series routers and EX Series switches, you can configure BPDU protection to ignore BPDU received on interfaces where none should be expected. If a BPDU is received on a blocked interface, the interface is disabled and stops forwarding frames. By default, all BPDUs are accepted and processed on all interfaces.

To configure BPDU protection for all edge ports for a particular spanning-tree protocol::

1. Enable edge port blocking for a particular spanning-tree protocol:

```

[edit]
user@host# set protocols (STP Type) (mstp | rstp | vstp) bpdu-block-on-edge

```

2. Verify BPDU protection for edge ports.

```

[edit]
protocols (STP Type) {
  (mstp | rstp | vstp) {
    bpdu-block-on-edge;
  }
}

```

Configuring VPLS Root Protection Topology Change Actions to Control VLAN Spanning Tree Behavior

To configure VPLS root protection topology change actions to control a particular VLAN:

1. Enable configuration of the spanning-tree protocol VLAN:

```

[edit]
user@host# edit protocols (STP Type) vstp vlan vlan-id

```

2. Optional) Change the priority of the backup bridge in a VPLS multihomed Layer 2 ring with MPLS infrastructure:

```

[edit protocols vstp vlan vlan-id]
user@host# set backup-bridge-priority vpls-ring-backup-bridge-priority

```

3. (Optional) Change the hold time before switching to the primary priority when the first core domain comes up:

```

[edit protocols vstp vlan vlan-id]

```

```
user@host# set priority-hold-time seconds
```

4. Configure the system identifier for bridges in the ring:

```
[edit protocols vstp vlan vlan-id]
```

```
user@host# set system-id system-id-value bridge-host-ip-address(es)
```

The *system-id-value* is configured in the format *nnnnnn:nnnnnn*, where *n* = any digit from 0 to 9.

Each *bridge-host-ip-address* is a valid host IP address with a /32 mask.

NOTE: There are no default values for the system identifier or host IP addresses.

5. Configure bridges to flush the MAC address cache (of the MAC addresses learned when other interfaces ports were blocked) when the spanning-tree topology changes:

```
[edit protocols vstp vlan vlan-id]
```

```
user@host# set vpls-flush-on-topology-change
```

6. Verify the configuration of VPLS root protection topology change actions to control a particular VLAN:

```
[edit]
protocols {
  vstp {
    vlan vlan-id {
      backup-bridge-priority priority; # Default is 32,768.
      priority-hold-time seconds; # Default is 2 seconds.
      system-id system-id-value {
        ip-address;
      }
      vpls-flush-on-topology-change;
    }
  }
}
```

Configuring Layer 2 Protocol Tunneling

To configure Layer 2 protocol tunneling:

1. Enable MAC address rewriting for Layer 2 protocol tunneling:

```
[edit]
```

```
user@host# edit protocols layer2-control mac-rewrite
```

2. Configure the Layer 2 protocol tunnel interface:

```
[edit ... protocols layer2-control mac-rewrite]
```

```

user@host# edit interface ge-fpc/pic/port
3. Configure the Layer 2 protocol to be tunneled:

[edit protocols layer2-control mac-rewrite interface ge-fpc/pic/port]
user@host# set protocol (cdp | stp | vtp)
4. Verify the configuration:

user@host# show protocols
layer2-control {
  mac-rewrite {
    interface ge-fpc/pic/port {
      protocol (cdp | stp | vtp);
    }
  }
}

```

protocols (STP Type)

Syntax	<pre>protocols { mstp { ... } rstp { ... } vstp { ... } }</pre>
Hierarchy Level	[edit], [edit logical-systems <i>logical-system-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i>], [edit routing-instances <i>routing-instance-name</i>]
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6.
Description	Configure the Spanning Tree Protocol type as MSTP, RSTP, or VSTP.
Options	mstp —Configure the protocol as Multiple Spanning Tree. rstp —Configure the protocol as Rapid Spanning Tree. vstp —Configure the protocol as VLAN Spanning Tree.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Rapid Spanning-Tree Protocol on page 5073 • Configuring Multiple Spanning-Tree Protocol on page 5067 • Configuring VLAN Spanning-Tree Protocol on page 5077

access-trunk

Syntax	access-trunk;
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols vstp] [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vstp] [edit protocols vstp vlan <i>vlan-identifier</i> interface <i>interface-name</i>] [edit routing-instances <i>routing-instance-name</i> instance-type (layer2-control virtual-switch)]
Description	Enable untagged RTSP BDPUs to be sent and received on the interface.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring VSTP on a Trunk Port with Tagged Traffic on page 5053

bpdu-destination-mac-address (Spanning Tree)

Syntax	<code>bpdu-destination-mac-address provider-bridge-group;</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols (mstp rstp)], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (mstp rstp)], [edit protocols (mstp rstp)], [edit routing-instances <i>routing-instance-name</i> protocols (mstp rstp)]
Release Information	Statement introduced in Junos OS Release 9.2. Support for logical systems added in Junos OS Release 9.6.
Description	Enable MX Series router to participate in the provider Rapid Spanning-Tree Protocol (RSTP) instance or a provider Multiple Spanning-Tree Protocol (MSTP) instance.
Default	If the bpdu-destination-mac-address statement is not configured, the bridge participates in the customer RSTP instance, transmitting and receiving standard RSTP BPDU packets.
Options	provider-bridge-group —The destination MAC address of the BPDU packets transmitted is the provider bridge group address 01:80:c2:00:00:08 . Received BPDU packets with this destination MAC address are accepted and passed to the Routing Engine.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• BPDU Overview on page 5033• Provider Bridge Participation in RSTP or MSTP Instances on page 5072• Configuring Rapid Spanning-Tree Protocol on page 5073• Configuring Multiple Spanning-Tree Protocol on page 5067

configuration-name

Syntax	configuration-name <i>configuration-name</i> ;
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols mstp], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mstp], [edit protocols mstp], [edit routing-instances <i>routing-instance-name</i> protocols mstp]
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6.
Description	The configuration name is the MSTP region name carried in the MSTP BPDUs.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• BPDU Overview on page 5033• Configuring Multiple Spanning-Tree Protocol on page 5067

cost

Syntax	<code>cost cost;</code>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> protocols mstp <i>msti</i> <i>msti-id</i> interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> protocols vstp <i>vlan</i> <i>vlan-id</i> interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mstp <i>msti</i> <i>msti-id</i> interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vstp <i>vlan</i> <i>vlan-id</i> interface <i>interface-name</i>],</p> <p>[edit protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit protocols mstp <i>msti</i> <i>msti-id</i> interface <i>interface-name</i>],</p> <p>[edit protocols vstp <i>vlan</i> <i>vlan-id</i> interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols mstp <i>msti</i> <i>msti-id</i> interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols vstp <i>vlan</i> <i>vlan-id</i> interface <i>interface-name</i>]</p>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p>
Description	Configure link cost to control which bridge is the designated bridge and which port is the designated port. By default, the link cost is determined by the link speed.
Options	<p>cost—(Optional) Link cost associated with the port.</p> <p>Range: 1 through 200,000,000</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

edge

Syntax	edge;
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> protocols mstp msti msti-id interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> protocols vstp vlan vlan-id interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mstp msti msti-id interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vstp vlan vlan-id interface <i>interface-name</i>],</p> <p>[edit protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit protocols mstp msti msti-id interface <i>interface-name</i>],</p> <p>[edit protocols vstp vlan vlan-id interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols (mstp rstp vstp) interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols mstp msti msti-id interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols vstp vlan vlan-id interface <i>interface-name</i>]</p>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p>
Description	Configure interfaces as edge ports. Edge ports do not expect to receive BPDUs. If a BPDU is received, the port becomes a nonedge port.
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Spanning-Tree Instance Interface on page 5042 • Spanning-Tree Instance Interface Configured as an Edge Port on page 5045

extended-system-id

Syntax	<code>extended-system-id <i>identifier</i>;</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols rstp], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols rstp], [edit protocols rstp], [edit routing-instances <i>routing-instance-name</i> protocols rstp]
Release Information	Statement introduced in Junos OS Release 8.3. Support for logical systems added in Junos OS Release 9.6.
Description	The extended system ID is used to specify different bridge identifiers for different RSTP or STP routing instances.
Options	<i>identifier</i> —Specify the system identifier to use for the RSTP or STP instance. Range: 0 through 4095
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • System Identifier for Bridges in STP or RSTP Instances on page 5076 • Configuring Rapid Spanning-Tree Protocol on page 5073

force-version (IEEE 802.1D STP)

Syntax	<code>force-version stp;</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols (rstp vstp)], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (rstp vstp)], [edit protocols (rstp vstp)], [edit routing-instances <i>routing-instance-name</i> protocols (rstp vstp)]
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6.
Description	Force the spanning-tree version to be the original IEEE 803.1D STP.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Spanning-Tree Protocols Supported on page 5032 • RSTP or VSTP Forced to Run as IEEE 802.1D STP on page 5072 • Reverting RSTP or VSTP Back From Forced IEEE 802.1D STP on page 5075

forward-delay

Syntax	<code>forward-delay seconds;</code>
Hierarchy Level	<code>[edit logical-systems <i>logical-system-name</i> protocols (<i>mstp</i> <i>rstp</i>)],</code> <code>[edit logical-systems <i>logical-system-name</i> protocols <i>vstp</i> vlan <i>vlan-id</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols</code> <code> (<i>mstp</i> <i>rstp</i>)],</code> <code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols</code> <code> <i>vstp</i> vlan <i>vlan-id</i>],</code> <code>[edit protocols (<i>mstp</i> <i>rstp</i>)],</code> <code>[edit protocols <i>vstp</i> vlan <i>vlan-id</i>],</code> <code>[edit routing-instances <i>routing-instance-name</i> protocols (<i>mstp</i> <i>rstp</i>)],</code> <code>[edit routing-instances <i>routing-instance-name</i> protocols <i>vstp</i> vlan <i>vlan-id</i>]</code>
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6.
Description	Specify the length of time an STP bridge port remains in the listening and learning states before transitioning to the forwarding state.
Options	seconds —(Optional) Number of seconds the bridge port remains in the listening and learning states. Range: 4 through 30 Default: 15 seconds
Required Privilege Level	routing —To view this statement in the configuration. routing-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Forward Delay Before Ports Transition to Forwarding State on page 5042

hello-time

Syntax	<code>hello-time seconds;</code>
Hierarchy Level	<pre>[edit logical-systems <i>logical-system-name</i> protocols (<i>mstp</i> <i>rstp</i>)], [edit logical-systems <i>logical-system-name</i> protocols <i>vstp</i> <i>vlan</i> <i>vlan-id</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (<i>mstp</i> <i>rstp</i>)], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols <i>vstp</i> <i>vlan</i> <i>vlan-id</i>], [edit protocols (<i>mstp</i> <i>rstp</i>)], [edit protocols <i>vstp</i> <i>vlan</i> <i>vlan-id</i>], [edit routing-instances <i>routing-instance-name</i> protocols (<i>mstp</i> <i>rstp</i>)], [edit routing-instances <i>routing-instance-name</i> protocols <i>vstp</i> <i>vlan</i> <i>vlan-id</i>]</pre>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p>
Description	Specify the number of seconds between transmissions of configuration BPDUs by the root bridge.
Options	<p>seconds—(Optional) Number of seconds between transmissions of configuration BPDUs.</p> <p>Range: 1 through 10</p> <p>Default: 2 seconds</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

traceoptions (Spanning Tree)

Syntax	<pre> traceoptions { file <i>filename</i> <files <i>number</i>> <size <i>size</i>> <world-readable no-world-readable>; flag <i>flag</i> <flag-modifier> <disable>; } </pre>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols (mstp rstp vstp)], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (mstp rstp vstp)], [edit protocols (mstp rstp vstp)], [edit routing-instances <i>routing-instance-name</i> protocols (mstp rstp vstp)]
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6.
Description	Set STP protocol-level tracing options.
Default	The default STP protocol-level trace options are inherited from the global traceoptions statement.
Options	<p>disable—(Optional) Disable the tracing operation. One use of this option is to disable a single operation when you have defined a broad group of tracing operations, such as all.</p> <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. We recommend that you place STP tracing output in the file <code>/var/log/stp-log</code>.</p> <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then, the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also specify a maximum file size with the size option.</p> <p>Range: 2 through 1000 files Default: 1 trace file only</p> <p>flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. The following are the STP-specific tracing options:</p> <ul style="list-style-type: none"> • all—Trace all operations. • all-failures—Trace all failure conditions. • bpdud—Trace BPDU reception and transmission. • bridge-detection-state-machine—Trace the bridge detection state machine. • events—Trace events of the protocol state machine.

- **port-information-state-machine**—Trace the port information state machine.
- **port-migration-state-machine**—Trace the port migration state machine.
- **port-receive-state-machine**—Trace the port receive state machine.
- **port-role-transit-state-machine**—Trace the port role transit state machine.
- **port-role-select-state-machine**—Trace the port role selection state machine.
- **port-state-transit-state-machine**—Trace the port state transit state machine.
- **port-transmit-state-machine**—Trace the port transmit state machine.
- **ppmd**—Trace the state and events for the ppmmd process.
- **state-machine-variables**—Trace when the state machine variables change.
- **timers**—Trace protocol timers.
- **topology-change-state-machine**—Trace the topology change state machine.

The following are the global tracing options:

- **all**—All tracing operations.
- **config-internal**—Trace configuration internals.
- **general**—Trace general events.
- **normal**—All normal events.

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **parse**—Trace configuration parsing.
- **policy**—Trace policy operations and actions.
- **regex-parse**—Trace regular-expression parsing.
- **route**—Trace routing table changes.
- **state**—Trace state transitions.
- **task**—Trace protocol task processing.
- **timer**—Trace protocol task timer processing.

no-world-readable—(Optional) Prevent any user from reading the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB) or megabytes (MB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege	routing—To view this statement in the configuration.
Level	routing-control—To add this statement to the configuration.

layer2-control

Syntax

```
layer2-control {
  bpd-block {
    interface interface-name;
    disable-timeout seconds;
  }
  mac-rewrite {
    interface interface-name {
      protocol (cdp | stp | vtp);
    }
  }
  nonstop-bridging;
}
```

Hierarchy Level [edit protocols]

Release Information Statement introduced in Junos OS Release 8.4.
bpd-block statement added in Junos OS Release 9.4.

Description Configure Layer 2 control protocols to enable features such as Layer 2 protocol tunneling or nonstop bridging.

The remaining statements are described separately.

NOTE: For a detailed description of configuring the nonstop-bridging statement, see the *Junos OS High Availability Configuration Guide*. When this statement is configured on routing platforms with two Routing Engines, a master Routing Engine switches over gracefully to a backup Routing Engine and preserves Layer 2 Control Protocol (L2CP) information.

Required Privilege Level interface—To view this statement in the configuration.
 interface-control—To add this statement to the configuration.

- [Tracing Spanning-Tree Operations on page 5128](#)

Checking the Status of Spanning-Tree Instance Interfaces

On an MX Series router with a spanning-tree protocol enabled, the detection of a possible bridging loop from spanning-tree protocol operation can raise a bridge protocol data unit (BPDU) error condition on the affected spanning-tree instance interface.

To check whether a spanning-tree instance interface is blocked due to a BPDU error condition:

1. To check the status of spanning-tree instance interface, use the **show interfaces** command.

```
user@host> show interfaces interface-name
```

2. You can determine the status of the interface as follows:

- If the **BPDU Error** field is **none**, the interface is enabled.
- If the **BPDU Error** field is **Detected** and the link is **down**, the interface is blocked.

**Related
Documentation**

- [Root Protection for Spanning-Tree Instance Interfaces Overview on page 5035](#)
- [BPDU Protection for Spanning-Tree Instance Interfaces Overview on page 5035](#)

- [BPDU Protection on All Edge Ports of the Bridge on page 5049](#)
- [Clearing the Blocked Status of a Spanning-Tree Instance Interface on page 5126](#)

Clearing the Blocked Status of a Spanning-Tree Instance Interface

To clear the blocked status of a spanning-tree instance interface:

- Use the **clear error bpdu** operational mode command.

```
user@host> clear error bpdu interface interface-name
```

NOTE: When you configure BPDU protection on individual interfaces (as opposed to on all the edge ports of the bridge), you can use the **disable-timeout seconds** option to specify that a blocked interface is automatically cleared after the specified time interval elapses (unless the interval is 0). For configuration details, see “[Configuring BPDU Protection on Individual Interfaces](#)” on page 5084.

Checking for a MAC Rewrite Error Condition Blocking a Spanning-Tree Instance Interface

To check whether a spanning-tree instance interface is blocked due to a MAC rewrite error condition:

1. Use the **show interfaces** operational mode command:

```
user@host> show interfaces interface-name
```

2. You can determine the status of the interface as follows:

- If the value in the **Physical interface** includes **Enabled, Physical link is Up** and the value of the **BPDU Error** field is **None**, the interface is enabled
- If the value in the **Physical interface** field is **Enabled, Physical link is Down** and the value in the **BPDU Error** field is **Detected**, the interface is blocked.

Clearing a MAC Rewrite Error Condition Blocking a Spanning-Tree Instance Interface

To clear the blocked status of a spanning-tree instance interface:

- Use the **clear error bpd** operational mode command.

```
user@host> clear error bpd interface interface-name
```

Related Documentation

Tracing Spanning-Tree Operations

You can enable global routing protocol tracing options at the **[edit routing-options] Hierarchy Level**. For general information about tracing and global tracing options, see the statement summary for the global *traceoptions* statement in the *Junos OS Routing Protocols Configuration Guide*.

In addition, you can enable STP-specific trace options at the following hierarchy levels:

- **[edit logical-systems logical-system-name protocols (mstp | rstp | vstp)]**
- **[edit logical-systems logical-system-name routing-instances routing-instance-name protocols (mstp | rstp | vstp)]**
- **[edit protocols (mstp | rstp | vstp)]**
- **[edit routing-instances routing-instance-name protocols (mstp | rstp | vstp)]**

The routing instance type can be either **virtual-switch** or **layer2-control**.

To enable tracing of spanning-tree protocol operations:

1. Enable configuration of the spanning-tree protocol whose operations are to be traced:

```
[edit]
user@host# edit ... protocols (mstp | rstp | vstp)
```

2. Enable configuration of spanning-tree protocol-specific trace options:

```
[edit ... protocols (mstp | rstp | vstp)]
user@host# edit traceoptions
```

3. Configure the files that contain trace logging information:

```
[edit ... protocols (mstp | rstp | vstp)]
user@host# set file filename <files number> <size bytes>
<world-readable | no-world-readable>
```

4. Configure spanning-tree protocol-specific options.

- a. To enable a spanning-tree protocol-specific option, include the
- flag**
- statement:

```
[edit ... protocols (mstp | rstp | vstp)]
user@host# set flag flag <flag-modifier> <disable>
```

You can specify the following spanning-tree protocol-specific **flag** options:

- **all**—Trace all operations.
- **all-failures**—Trace all failure conditions.
- **bpdu**—Trace BPDU reception and transmission.
- **bridge-detection-state-machine**—Trace the bridge detection state machine.
- **events**—Trace events of the protocol state machine.
- **port-information-state-machine**—Trace the port information state machine.
- **port-migration-state-machine**—Trace the port migration state machine.
- **port-receive-state-machine**—Trace the port receive state machine.
- **port-role-transit-state-machine**—Trace the port role transit state machine.
- **port-role-select-state-machine**—Trace the port role selection state machine.
- **port-transmit-state-machine**—Trace the port transmit state machine.
- **port-state-transit-state-machine**—Trace the port state transit state machine.
- **ppmd**—Trace the state and events for the ppm process.
- **state-machine-variables**—Trace when the state machine variables change.
- **timers**—Trace protocol timers.
- **topology-change-state-machine**—Trace the topology change state machine.

NOTE: Use the trace flag **all** with caution. This flag may cause the CPU to become very busy.

- b. To disable an individual spanning-tree protocol-specific option, include the
- disable**
- option with the
- flag**
- statement.

5. Verify the spanning-tree protocol-specific trace options.

```
[edit]
...
routing-options {
  traceoptions {
    ..global-trace-options-configuration...
  }
}
protocols {
  (mstp | rstp | vstp) {
```

```
traceoptions { # Spanning-tree protocol-specific.  
  file filename <files number> <size bytes> <world-readable | no-world-readable>;  
  flag flag <flag-modifier> <disable>;  
}  
}  
...  
}
```

Operational Commands

show bridge mac-table

Syntax	<pre>show bridge mac-table <brief count detail extensive> <bridge-domain (all <i>bridge-domain-name</i>)> <global-count> <interface <i>interface-name</i>> <mac-address> <vlan-id (all-vlan <i>vlan-id</i>)></pre>
Release Information	Command introduced in Junos OS Release 8.4.
Description	(MX Series routers only) Display Layer 2 MAC address information.
Options	<p>none—Display all learned Layer 2 MAC address information.</p> <p>brief count detail extensive—(Optional) Display the specified level of output.</p> <p>bridge-domain (all <i>bridge-domain-name</i>)—(Optional) Display learned Layer 2 MAC addresses for all bridging domains or for the specified bridging domain.</p> <p>global-count—(Optional) Display the total number of learned Layer 2 MAC addresses on the system.</p> <p>instance <i>instance-name</i>—(Optional) Display learned Layer 2 MAC addresses for the specified routing instance.</p> <p>interface <i>interface-name</i>—(Optional) Display learned Layer 2 MAC addresses for the specified interface.</p> <p>mac-address—(Optional) Display the specified learned Layer 2 MAC address information.</p> <p>vlan-id (all-vlan <i>vlan-id</i>)—(Optional) Display learned Layer 2 MAC addresses for all VLANs or for the specified VLAN.</p>
Additional Information	When Layer 2 protocol tunneling is enabled, the tunneling MAC address 01:00:0c:cd:cd:d0 is installed in the MAC table. When the Cisco Discovery Protocol (CDP), Spanning Tree Protocol (STP), or VLAN Trunk Protocol (VTP) is configured for Layer 2 protocol tunneling on an interface, the corresponding protocol MAC address is installed in the MAC table.
Required Privilege Level	view
List of Sample Output	show bridge mac-table on page 5132 show bridge mac-table brief on page 5133 show brief mac-table count on page 5133 show bridge mac-table detail on page 5133
Output Fields	Table 378 on page 5132 describes the output fields for the show bridge mac-table command. Output fields are listed in the approximate order in which they appear.

Table 378: show bridge mac-table Output fields

Field Name	Field Description
Routing instance	Name of the routing instance.
Bridging domain	Name of the bridging domain.
MAC address	MAC address or addresses learned on a logical interface.
MAC flags	Status of MAC address learning properties for each interface: <ul style="list-style-type: none"> • S—Static MAC address is configured. • D—Dynamic MAC address is configured. • SE—MAC accounting is enabled. • NM—Non-configured MAC.
Logical interface	Name of the logical interface.
MAC count	Number of MAC addresses learned on the specific routing instance or interface.
Learning interface	Name of the logical interface on which the MAC address was learned.
Learning VLAN	VLAN ID of the routing instance or bridge domain in which the MAC address was learned.
Layer 2 flags	Debugging flags signifying that the MAC address is present in various lists.
Epoch	Spanning Tree Protocol epoch number identifying when the MAC address was learned. Used for debugging.
Sequence number	Sequence number assigned to this MAC address. Used for debugging.
Learning mask	Mask of the Packet Forwarding Engines where this MAC address was learned. Used for debugging.
IPC generation	Creation time of the logical interface when this MAC address was learned. Used for debugging.

Sample Output

show bridge mac-table

```

user@host> show bridge mac-table
MAC flags (S -static MAC, D -dynamic MAC,
          SE -Statistics enabled, NM -Non configured MAC)

Routing instance : vs1
Bridging domain : vlan100, VLAN : 100
  Learning MAC          MAC          Logical
  VLAN    address      flags      interface
    00:00:00:19:1c:db   D         ge-11/0/3.0
    00:00:00:59:3a:2f   D         xe-10/2/0.100

```

show bridge mac-table brief

```

user@host> show bridge mac-table brief
MAC flags (S -static MAC, D -dynamic MAC,
          SE -Statistics enabled, NM -Non configured MAC)

Routing instance : vs1
  Bridging domain : vlan100, VLAN : 100
    Learning MAC          MAC          Logical
    VLAN      address      flags      interface
      00:00:00:19:1c:db    D          ge-11/0/3.0
      00:00:00:59:3a:2f    D          xe-10/2/0.100

```

show brief mac-table count

```

user@host> show bridge mac-table count
2 MAC address learned in routing instance vs1 bridge domain vlan100

MAC address count per interface within routing instance:
  Logical interface      MAC count
  ge-11/0/3.0            1
  ge-11/1/4.100          0
  ge-11/1/1.100          0
  ge-11/1/0.100          0
  xe-10/2/0.100          1
  xe-10/0/0.100          0

MAC address count per learn VLAN within routing instance:
  Learn VLAN ID          MAC count
  0                       2

0 MAC address learned in routing instance vs1 bridge domain vlan200

MAC address count per interface within routing instance:
  Logical interface      MAC count
  ge-11/1/0.200          0
  ge-11/1/1.200          0
  ge-11/1/4.200          0
  xe-10/0/0.200          0
  xe-10/2/0.200          0

MAC address count per learn VLAN within routing instance:
  Learn VLAN ID          MAC count
  0                       0

```

show bridge mac-table detail

```

user@host> show bridge mac-table detail
MAC address: 00:00:00:19:1c:db
  Routing instance: vs1
  Bridging domain: vlan100
  Learning interface: ge-11/0/3.0   Learning VLAN: 0
  Layer 2 flags: in_ifd, in_ifl, in_vlan, kernel
  Epoch: 4                          Sequence number: 0
  Learning mask: 0x800              IPC generation: 0

MAC address: 00:00:00:59:3a:2f
  Routing instance: vs1
  Bridging domain: vlan100
  Learning interface: xe-10/2/0.100   Learning VLAN: 0
  Layer 2 flags: in_ifd, in_ifl, in_vlan, kernel

```

Epoch: 7
Learning mask: 0x400

Sequence number: 0
IPC generation: 0

show mac-rewrite interface

Syntax	show mac-rewrite interface <brief detail> <interface-name>
Release Information	Command introduced in Junos OS Release 9.1.
Description	(MX Series routers only) Display Layer 2 protocol tunneling information.
Options	brief detail —(Optional) Display the specified level of output. interface <i>interface-name</i> —(Optional) Display Layer 2 protocol tunneling information for the specified interface.
Required Privilege Level	view
List of Sample Output	show mac-rewrite interface on page 5135
Output Fields	Table 379 on page 5135 lists the output fields for the show mac-rewrite interface command. Output fields are listed in the approximate order in which they appear.

Table 379: show mac-rewrite interface Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the interface that has Layer 2 protocol tunneling configured on it.	brief detail
Protocols	Layer 2 protocols being tunneled on this interface: Cisco Discovery Protocol (CDP), Spanning Tree Protocol (STP), or VLAN Trunk Protocol (VTP)	brief detail

Sample Output

show mac-rewrite interface

```

user@host> show mac-rewrite interface
Interface      Protocols

ge-1/0/1      STP VTP CDP

```

show spanning-tree bridge

Syntax	show spanning-tree bridge <brief detail> <msti <i>msti-id</i> > <routing-instance <i>routing-instance-name</i> > <vlan-id <i>vlan-id</i> >
Syntax (QFX Series)	show spanning-tree bridge <brief detail> <msti <i>msti-id</i> > <vlan-id <i>vlan-id</i> >
Release Information	Command introduced in Junos OS Release 8.4. Command introduced in Junos OS Release 11.1 for the QFX Series.
Description	Display the configured or calculated Spanning Tree Protocol (STP) parameters.
Options	<p>none—(Optional) Display brief STP bridge information for all multiple spanning-tree instances (MSTIs).</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>msti <i>msti-id</i>—(Optional) Display STP bridge information for the specified MSTI.</p> <p>routing-instance <i>routing-instance-name</i>—(Optional) Display STP bridge information for the specified routing instance.</p> <p>vlan-id <i>vlan-id</i>—(Optional) Display STP bridge information for the specified VLAN.</p>
Required Privilege Level	view
List of Sample Output	show spanning-tree bridge routing-instance on page 5137 show spanning-tree bridge msti on page 5138 show spanning-tree bridge vlan-id (MSTP) on page 5139 show spanning-tree bridge (RSTP) on page 5139 show spanning-tree bridge vlan-id (RSTP) on page 5140
Output Fields	Table 380 on page 5136 lists the output fields for the show spanning-tree bridge command. Output fields are listed in the approximate order in which they appear.

Table 380: show spanning-tree bridge Output Fields

Field Name	Field Description
Routing instance name	Name of the routing instance under which the bridge is configured.
Enabled protocol	Spanning Tree Protocol type enabled.
Root ID	Bridge ID of the elected spanning-tree root bridge. The bridge ID consists of a configurable bridge priority and the MAC address of the bridge.

Table 380: show spanning-tree bridge Output Fields (*continued*)

Field Name	Field Description
Root cost	Calculated cost to reach the root bridge from the bridge where the command is entered.
Root port	Interface that is the current elected root port for this bridge.
CIST regional root	Bridge ID of the elected MSTP regional root bridge.
CIST internal root cost	Calculated cost to reach the regional root bridge from the bridge where the command is entered.
Hello time	Configured number of seconds between transmissions of configuration bridge protocol data units (BPDUs).
Maximum age	Configured maximum expected arrival time of hello bridge protocol data units (BPDUs).
Forward delay	How long an STP bridge port remains in the listening and learning states before transitioning to the forwarding state.
Hop count	Configured maximum number of hops a BPDUs can be forwarded in the MSTP region.
Message age	Number of elapsed seconds since the most recent BPDUs was received.
Number of topology changes	Total number of STP topology changes detected since the routing device last booted.
Time since last topology change	Number of elapsed seconds since the most recent topology change.
Bridge ID (Local)	Locally configured bridge ID. The bridge ID consists of a configurable bridge priority and the MAC address of the bridge.
Extended system ID	System identifier.
MSTI regional root	Bridge ID of the elected MSTP regional root bridge.

Sample Output

show spanning-tree interface

Syntax	show spanning-tree interface <brief detail> <msti <i>msti-id</i> > <routing-instance <i>routing-instance-name</i> > <vlan-id <i>vlan-id</i> >
Syntax (EX Series Switches and the QFX Series)	show spanning-tree interface <brief detail> <msti <i>msti-id</i> > <vlan-id <i>vlan-id</i> >
Release Information	Command introduced in Junos OS Release 8.4. Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 11.1 for the QFX Series.
Description	Display the configured or calculated interface-level STP parameters.
Options	<p>none—Display brief STP interface information.</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>msti <i>msti-id</i>—(Optional) Display STP interface information for the specified MST instance.</p> <p>routing-instance <i>routing-instance-name</i>—(Optional) Display STP interface information for the specified routing instance.</p> <p>vlan-id <i>vlan-id</i>—(Optional) Display STP interface information for the specified VLAN.</p>
Required Privilege Level	view
List of Sample Output	show spanning-tree interface on page 5142 show spanning-tree interface (QFX Series) on page 5143 show spanning-tree interface detail on page 5143 show spanning-tree interface msti on page 5145 show spanning-tree interface vlan-id on page 5145 show spanning-tree interface (VSTP) on page 5146 show spanning-tree interface vlan-id (VSTP) on page 5146
Output Fields	Table 381 on page 5141 lists the output fields for the show spanning-tree interface command. Output fields are listed in the approximate order in which they appear.

Table 381: show spanning-tree Interface Output Fields

Field Name	Field Description
Interface name	Interface configured to participate in the STP, RSTP, VSTP, or MSTP instance.

Table 381: show spanning-tree Interface Output Fields (*continued*)

Field Name	Field Description
Port ID	Logical interface identifier configured to participate in the MSTP or VSTP instance.
Designated port ID	Port ID of the designated port for the LAN segment to which this interface is attached.
Designated bridge ID	Bridge ID of the designated bridge for the LAN segment to which this interface is attached.
Port Cost	Configured cost for the interface.
Port State	STP port state: forwarding (FWD), blocking (BLK), listening, learning, or disabled.
Port Role	MSTP, VSTP, or RSTP port role: designated (DESG), backup (BKUP), alternate (ALT), (ROOT), or Root Prevented (Root-Prev).
Link type	MSTP, VSTP, or RSTP link type. Shared or point-to-point (pt-pt) and edge or nonedge.
Alternate	Identifies the interface as an MSTP, VSTP, or RSTP alternate root port (Yes) or nonalternate root port (No).
Boundary Port	Identifies the interface as an MSTP regional boundary port (Yes) or nonboundary port (No).

Sample Output

show spanning-tree interface

```
user@host> show spanning-tree interface routing-instance vs1 detail
Spanning tree interface parameters for instance 0
```

Interface	Port ID	Designated port ID	Designated bridge ID	Port Cost	State	Role
ae1	128:1	128:1	32768.0090690b47d1	1000	FWD	DESG
ge-2/1/2	128:2	128:2	32768.0090690b47d1	20000	FWD	DESG

MBGP Multicast VPN Sites

The main characteristics of MBGP MVPNs are:

- They extend Layer 3 VPN service (RFC 4364) to support IP multicast for Layer 3 VPN service providers.
- They follow the same architecture as specified by RFC 4364 for unicast VPNs. Specifically, BGP is used as the provider edge (PE) router-to-PE router control plane for multicast VPN.

- They eliminate the requirement for the virtual router (VR) model (as specified in Internet draft draft-rosen-vpn-mcast, *Multicast in MPLS/BGP VPNs*) for multicast VPNs and the RFC 4364 model for unicast VPNs.
- They rely on RFC 4364-based unicast with extensions for intra-AS and inter-AS communication.

An MBGP MVPN defines two types of site sets, a sender site set and a receiver site set. These sites have the following properties:

- Hosts within the sender site set can originate multicast traffic for receivers in the receiver site set.
- Receivers outside the receiver site set should not be able to receive this traffic.
- Hosts within the receiver site set can receive multicast traffic originated by any host in the sender site set.
- Hosts within the receiver site set should not be able to receive multicast traffic originated by any host that is not in the sender site set.

A site can be in both the sender site set and the receiver site set, so hosts within such a site can both originate and receive multicast traffic. For example, the sender site set could be the same as the receiver site set, in which case all sites could both originate and receive multicast traffic from one another.

Sites within a given MBGP MVPN might be within the same organization or in different organizations, which means that an MBGP MVPN can be either an intranet or an extranet. A given site can be in more than one MBGP MVPN, so MBGP MVPNs might overlap. Not all sites of a given MBGP MVPN have to be connected to the same service provider, meaning that an MBGP MVPN can span multiple service providers. Feature parity for the MVPN extranet functionality or overlapping MVPNs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

Another way to look at an MBGP MVPN is to say that an MBGP MVPN is defined by a set of administrative policies. These policies determine both the sender site set and the receiver site set. These policies are established by MBGP MVPN customers, but implemented by service providers using the existing BGP and MPLS VPN infrastructure.

PIM Sparse Mode, PIM Dense Mode, Auto-RP, and BSR for MBGP MVPNs

You can configure PIM sparse mode, PIM dense mode, auto-RP, and bootstrap router (BSR) for MBGP MVPN networks:

- PIM sparse mode—Allows a router to use any unicast routing protocol and performs reverse-path forwarding (RPF) checks using the unicast routing table. PIM sparse mode includes an explicit join message, so routers determine where the interested receivers are and send join messages upstream to their neighbors, building trees from the receivers to the rendezvous point (RP).
- PIM dense mode—Allows a router to use any unicast routing protocol and performs reverse-path forwarding (RPF) checks using the unicast routing table. Packets are forwarded to all interfaces except the incoming interface. Unlike PIM sparse mode, where explicit joins are required for packets to be transmitted downstream, packets are flooded to all routers in the routing instance in PIM dense mode.
- Auto-RP—Uses PIM dense mode to propagate control messages and establish RP mapping. You can configure an auto-RP node in one of three different modes: discovery mode, announce mode, and mapping mode.
- BSR—Establishes RPs. A selected router in a network acts as a BSR, which selects a unique RP for different group ranges. BSR messages are flooded using a data tunnel between PE routers.

Understanding Wildcards to Configure Selective Point-to-Multipoint LSPs for an MBGP MVPN

Selective LSPs are also referred to as selective provider tunnels. Selective provider tunnels carry traffic from some multicast groups in a VPN and extend only to the PE routers that have receivers for these groups. You can configure a selective provider tunnel for group prefixes and source prefixes, or you can use wildcards for the group and source, as described in the Internet draft draft-rekhter-mvpn-wildcard-spmsi-01.txt, *Use of Wildcard in S-PMSI Auto-Discovery Routes*.

The following sections describe the scenarios and special considerations when you use wildcards for selective provider tunnels.

About S-PMSI

The provider multicast service interface (PMSI) is a BGP tunnel attribute that contains the tunnel ID used by the PE router for transmitting traffic through the core of the provider network. A selective PMSI (S-PMSI) autodiscovery route advertises binding of a given MVPN customer multicast flow to a particular provider tunnel. The S-PMSI autodiscovery route advertised by the ingress PE router contains /32 IPv4 or /128 IPv6 addresses for the customer source and the customer group derived from the source-tree customer multicast route.

Figure 112 on page 5154 shows a simple MVPN topology. The ingress router, PE1, originates the S-PMSI autodiscovery route. The egress routers, PE2 and PE3, have join state as a result of receiving join messages from CE devices that are not shown in the topology. In response to the S-PMSI autodiscovery route advertisement sent by PE1, PE2, and PE3, elect whether or not to join the tunnel based on the join state. The selective provider tunnel configuration is configured in a VRF instance on PE1.

NOTE: The MVPN mode configuration (RPT-SPT or SPT-only) is configured on all three PE routers for all VRFs that make up the VPN. If you omit the MVPN mode configuration, the default mode is SPT-only.

Figure 112: Simple MVPN Topology

Scenarios for Using Wildcard S-PMSI

A wildcard S-PMSI has the source or the group (or both the source and the group) field set to the wildcard value of 0.0.0.0/0 and advertises binding of multiple customer multicast flows to a single provider tunnel in a single S-PMSI autodiscovery route.

The scenarios under which you might configure a wildcard S-PMSI are as follows:

- When the customer multicast flows are PIM-SM in ASM-mode flows. In this case, a PE router connected to an MVPN customer's site that contains the customer's RP (C-RP) could bind all the customer multicast flows traveling along a customer's RPT tree to a single provider tunnel.
- When a PE router is connected to an MVPN customer's site that contains multiple sources, all sending to the same group.
- When the customer multicast flows are PIM-bidirectional flows. In this case, a PE router could bind to a single provider tunnel all the customer multicast flows for the same group that have been originated within the sites of a given MVPN connected to that PE, and advertise such binding in a single S-PMSI autodiscovery route.
- When the customer multicast flows are PIM-SM in SSM-mode flows. In this case, a PE router could bind to a single provider tunnel all the customer multicast flows coming from a given source located in a site connected to that PE router.
- When you want to carry in the provider tunnel all the customer multicast flows originated within the sites of a given MVPN connected to a given PE router.

Types of Wildcard S-PMSI

The following types of wildcard S-PMSI are supported:

- A (*G) S-PMSI matches all customer multicast routes that have the group address. The customer source address in the customer multicast route can be any address, including 0.0.0.0/0 for shared-tree customer multicast routes. A (*, C-G) S-PMSI autodiscovery route is advertised with the source field set to 0 and the source address length set to 0. The multicast group address for the S-PMSI autodiscovery route is derived from the customer multicast joins.
- A (*,*) S-PMSI matches all customer multicast routes. Any customer source address and any customer group address in a customer multicast route can be bound to the (*,*) S-PMSI. The S-PMSI autodiscovery route is advertised with the source address and length set to 0 and the group address and length set 0. The remaining fields in the S-PMSI autodiscovery route follow the same rule as (C-S, C-G) S-PMSI, as described in section 12.1 of the BGP-MVPN draft (draft-ietf-l3vpn-2547bis-mcast-bgp-00.txt).

Differences Between Wildcard S-PMSI and (S,G) S-PMSI

For dynamic provider tunnels, each customer multicast stream is bound to a separate provider tunnel, and each tunnel is advertised by a separate S-PMSI autodiscovery route. For static LSPs, multiple customer multicast flows are bound to a single provider tunnel by having multiple S-PMSI autodiscovery routes advertise the same provider tunnel.

When you configure a wildcard (*;G) or (*;*) S-PMSI, one or more matching customer multicast routes share a single S-PMSI. All customer multicast routes that have a matching source and group address are bound to the same (*;G) or (*;*) S-PMSI and share the same tunnel. The (*;G) or (*;*) S-PMSI is established when the first matching remote customer multicast join message is received in the ingress PE router, and deleted when the last remote customer multicast join is withdrawn from the ingress PE router. Sharing a single S-PMSI autodiscovery route improves control plane scalability.

Wildcard (*;*) S-PMSI and PIM Dense Mode

For (S,G) and (*;G) S-PMSI autodiscovery routes in PIM dense mode (PIM-DM), all downstream PE routers receive PIM-DM traffic. If a downstream PE router does not have receivers that are interested in the group address, the PE router instantiates prune state and stops receiving traffic from the tunnel.

Now consider what happens for (*;*) S-PMSI autodiscovery routes. If the PIM-DM traffic is not bound by a longer matching (S,G) or (*;G) S-PMSI, it is bound to the (*;*) S-PMSI. As is always true for dense mode, PIM-DM traffic is flooded to downstream PE routers over the provider tunnel regardless of the customer multicast join state. Because there is no group information in the (*;*) S-PMSI autodiscovery route, egress PE routers join a (*;*) S-PMSI tunnel if there is any configuration on the egress PE router indicating interest in PIM-DM traffic.

Interest in PIM-DM traffic is indicated if the egress PE router has one of the following configurations in the VRF instance that corresponds to the instance that imports the S-PMSI autodiscovery route:

- At least one interface is configured in dense mode at the **[edit routing-instances instance-name protocols pim interface]** hierarchy level.
- At least one group is configured as a dense-mode group at the **[edit routing-instances instance-name protocols pim dense-groups group-address]** hierarchy level.

Wildcard (*;*) S-PMSI and PIM-BSR

For (S,G) and (*;G) S-PMSI autodiscovery routes in PIM bootstrap router (PIM-BSR) mode, an ingress PE router floods the PIM bootstrap message (BSM) packets over the provider tunnel to all egress PE routers. An egress PE router does not join the tunnel unless the message has the ALL-PIM-ROUTERS group. If the message has this group, the egress PE router joins the tunnel, regardless of the join state. The group field in the message determines the presence or absence of the ALL-PIM-ROUTERS address.

Now consider what would happen for (*;*) S-PMSI autodiscovery routes used with PIM-BSR mode. If the PIM BSM packets are not bound by a longer matching (S,G) or (*;G) S-PMSI, they are bound to the (*;*) S-PMSI. As is always true for PIM-BSR, BSM packets are flooded to downstream PE routers over the provider tunnel to the ALL-PIM-ROUTERS destination group. Because there is no group information in the (*;*) S-PMSI autodiscovery route, egress PE routers always join a (*;*) S-PMSI tunnel. Unlike PIM-DM, the egress PE routers might have no configuration suggesting use of PIM-BSR as the RP discovery mechanism in the VRF instance. To prevent all egress PE routers from always joining the (*;*) S-PMSI tunnel, the (*;*) wildcard group configuration must be ignored.

This means that if you configure PIM-BSR, a wildcard-group S-PMSI can be configured for all other group addresses. The (*,*) S-PMSI is not used for PIM-BSR traffic. Either a matching (*G) or (S,G) S-PMSI (where the group address is the ALL-PIM-ROUTERS group) or an inclusive provider tunnel is needed to transmit data over the provider core. For PIM-BSR, the longest-match lookup is (S,G), (*G), and the inclusive provider tunnel, in that order. If you do not configure an inclusive tunnel for the routing instance, you must configure a (*G) or (S,G) selective tunnel. Otherwise, the data is dropped. This is because PIM-BSR functions like PIM-DM, in that traffic is flooded to downstream PE routers over the provider tunnel regardless of the customer multicast join state. However, unlike PIM-DM, the egress PE routers might have no configuration to indicate interest or noninterest in PIM-BSR traffic.

Wildcard Source and the 0.0.0.0/0 Source Prefix

You can configure a 0.0.0.0/0 source prefix and a wildcard source under the same group prefix in a selective provider tunnel. For example, the configuration might look as follows:

```
routing-instances {
  vpn {
    provider-tunnel {
      selective {
        group 224.1.1.0/24 {
          source 0.0.0.0/0 {
            rsvp-te {
              label-switched-path-template {
                sptnl3;
              }
            }
          }
        }
        wildcard-source {
          rsvp-te {
            label-switched-path-template {
              sptnl2;
            }
            static-lsp point-to-multipoint-lsp-name;
          }
          threshold-rate kbps;
        }
      }
    }
  }
}
```

The functions of the **source 0.0.0.0/0** and **wildcard-source** configuration statements are different. The 0.0.0.0/0 source prefix only matches (C-S, C-G) customer multicast join messages and triggers (C-S, C-G) S-PMSI autodiscovery routes derived from the customer multicast address. Because all (C-S, C-G) join messages are matched by the 0.0.0.0/0 source prefix in the matching group, the wildcard source S-PMSI is used only for (*C-G) customer multicast join messages. In the absence of a configured 0.0.0.0/0 source prefix, the wildcard source matches (C-S, C-G) and (*C-G) customer multicast join messages. In the example, a join message for (10.0.1.0/24, 224.1.1.0/24) is bound to **sptnl3**. A join message for (*, 224.1.1.0/24) is bound to **sptnl2**.

Multicast VPN Terminology

I

- Inclusive tree** A single multicast distribution tree in the backbone that carries all the multicast traffic from a specified set of one or more multicast VPNs. An inclusive tree that carries the traffic of more than one multicast VPN is an aggregate inclusive tree. An inclusive tree contains as its members all the PE routers that attach to the receiver sites of any of the multicast VPNs using the tree.

S

- Selective tree** A single multicast distribution tree in the backbone that carries traffic belonging only to a specified set of one or more multicast groups, from one or more multicast VPNs. An aggregate selective tree carries traffic for multicast groups that belong to different multicast VPNs. By default, traffic from most multicast groups could be carried by an inclusive tree, whereas traffic from high-bandwidth groups should be carried by a selective tree.

Supported Multicast VPN Standards

Junos OS substantially supports the following Internet drafts, which define standards for multicast virtual private networks (VPNs).

- Internet draft draft-ietf-l3vpn-2547bis-mcast-10.txt, *Multicast in MPLS/BGP IP VPNs*
- Internet draft draft-ietf-l3vpn-2547bis-mcast-bgp-08.txt, *BGP Encodings and Procedures for Multicast in MPLS/BGP IP VPNs*

Layer 3 VPNs

- [Introduction to Configuring Layer 3 VPNs on page 5159](#)
- [Layer 3 VPN Platform Support on page 5161](#)

Introduction to Configuring Layer 3 VPNs

To configure Layer 3 virtual private network (VPN) functionality, you must enable VPN support on the provider edge (PE) router. You must also configure any provider (P) routers that service the VPN, and you must configure the customer edge (CE) routers so that their routes are distributed into the VPN.

To configure Layer 3 VPNs, you include the following statements:

```

description text;
instance-type vrf;
interface interface-name;
protocols {
  bgp {
    group group-name {
      peer-as as-number;
      neighbor ip-address;
    }
    multihop tth-value;
  }
  (ospf | ospf3) {
    area area {
      interface interface-name;
    }
    domain-id domain-id;
    domain-vpn-tag number;
    sham-link {
      local address;
    }
    sham-link-remote address <metric number>;
  }
  rip {
    rip-configuration;
  }
}
route-distinguisher (as-number:id | ip-address:id);
router-id address;
routing-options {
  autonomous-system autonomous-system {
    independent-domain;
    loops number;
  }
  forwarding-table {
    export [ policy-names ];
  }
  interface-routes {
    rib-group group-name;
  }
  martians {
    destination-prefix match-type <allow>;
  }
  maximum-paths {
    path-limit;
    log-interval interval;
    log-only;
  }
}

```

```
        threshold percentage;
    }
    maximum-prefixes {
        prefix-limit;
        log-interval interval;
        log-only;
        threshold percentage;
    }
    multipath {
        vpn-unequal-cost;
    }
    options {
        syslog (level level | upto level);
    }
    rib routing-table-name {
        martians {
            destination-prefix match-type <allow>;
        }
        multipath {
            vpn-unequal-cost;
        }
        static {
            defaults {
                static-options;
            }
            route destination-prefix {
                next-hop [next-hops];
                static-options;
            }
        }
    }
}
static {
    defaults {
        static-options;
    }
    route destination-prefix {
        policy [policy-names ];
        static-options;
    }
}
vrf-advertise-selective {
    family {
        inet-mvpn;
        inet6-mvpn;
    }
}
vrf-export [policy-names ];
vrf-import [policy-names ];
vrf-target (community | export community-name | import community-name);
vrf-table-label;
```

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]

- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

For Layer 3 VPNs, only some of the statements in the **[edit routing-instances]** hierarchy are valid. For the full hierarchy, see the *Junos OS Routing Protocols Configuration Guide*.

In addition to these statements, you must enable a signaling protocol, IBGP sessions between the PE routers, and an interior gateway protocol (IGP) on the PE and P routers.

By default, Layer 3 VPNs are disabled.

Many of the configuration procedures for Layer 3 VPNs are common to all types of VPNs.

Layer 3 VPN Platform Support

Layer 3 VPNs are supported on most combinations of Juniper Networks routing and switching platforms and PICs capable of running the JUNOS Software.

MX Series routers configured to be in Ethernet services mode can support some of the Junos OS Layer 3 VPN features. For Layer 3 VPNs, Ethernet services mode supports configuring a loopback interface for a VPN routing and forwarding (VRF) instance. You can configure up to two VRF instances in Ethernet services mode. Each VRF instance can handle up to 10,000 routes. The **ping mpls l3vpn** operational mode command is also supported.

Configuration

- [Configuration Examples on page 5162](#)
- [Configuration Tasks on page 5221](#)
- [Configuration Statements on page 5250](#)

Configuration Examples

- [Example: Configuring MBGP Multicast VPNs on page 5162](#)
- [Example: Configuring PIM Join Load Balancing on Draft-Rosen Multicast VPN on page 5182](#)
- [Example: Configuring PIM Join Load Balancing On Next-Generation Multicast VPN on page 5190](#)
- [Example: Configuring PIM State Limits on page 5198](#)
- [Example: Configuring Redundant Virtual Tunnel Interfaces in MBGP MVPNs on page 5211](#)

Example: Configuring MBGP Multicast VPNs

This example provides a step-by-step procedure to configure multicast services across a multiprotocol BGP (MBGP) Layer 3 virtual private network.

- [Requirements on page 5162](#)
- [Overview and Topology on page 5163](#)
- [Configuration on page 5163](#)

Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.2 or later
- Five M Series, T Series, TX Series, or MX Series Juniper routers
- One host system capable of sending multicast traffic and supporting the Internet Group Management Protocol (IGMP)
- One host systems capable of receiving multicast traffic and supporting IGMP

Depending on the devices you are using, you might be required to configure static routes to:

- The multicast sender
- The Fast Ethernet interface to which the sender is connected on the multicast receiver
- The multicast receiver
- The Fast Ethernet interface to which the receiver is connected on the multicast sender

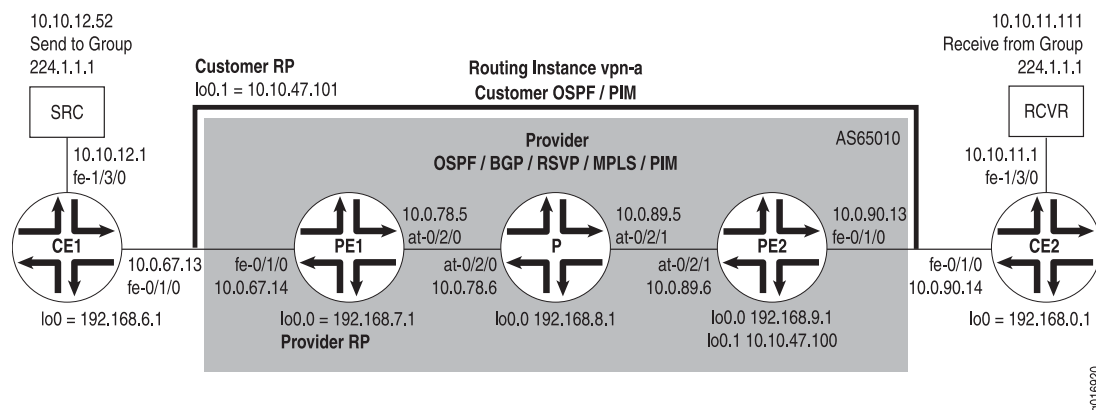

Overview and Topology

This example shows how to configure the following technologies:

- IPv4
- BGP
- OSPF
- RSVP
- MPLS
- PIM sparse mode
- Static RP

The topology of the network is shown in [Figure 113 on page 5163](#).

Figure 113: Multicast Over Layer 3 VPN Example Topology

Configuration

NOTE: In any configuration session, it is a good practice to periodically verify that the configuration can be committed using the `commit check` command.

In this example, the router being configured is identified using the following command prompts:

- **CE1** identifies the customer edge 1 (CE1) router
- **PE1** identifies the provider edge 1 (PE1) router
- **P** identifies the provider core (P) router
- **CE2** identifies the customer edge 2 (CE2) router
- **PE2** identifies the provider edge 2 (PE2) router

To configure MBGP multicast VPNs for the network shown in [Figure 113 on page 5163](#), perform the following steps:

- [Configuring Interfaces on page 5164](#)
- [Configuring OSPF on page 5165](#)
- [Configuring BGP on page 5166](#)
- [Configuring RSVP on page 5167](#)
- [Configuring MPLS on page 5168](#)
- [Configuring the VRF Routing Instance on page 5168](#)
- [Configuring PIM on page 5170](#)
- [Configuring the Provider Tunnel on page 5171](#)
- [Configuring the Rendezvous Point on page 5171](#)
- [Results on page 5172](#)

Configuring Interfaces

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

1. On each router, configure an IP address on the loopback logical interface 0 (**lo0.0**).

```
[edit interfaces]
```

```
user@CE1# set lo0 unit 0 family inet address 192.168.6.1/32 primary
```

```
user@PE1# set lo0 unit 0 family inet address 192.168.7.1/32 primary
```

```
user@P# set lo0 unit 0 family inet address 192.168.8.1/32 primary
```

```
user@PE2# set lo0 unit 0 family inet address 192.168.9.1/32 primary
```

```
user@CE2# set lo0 unit 0 family inet address 192.168.0.1/32 primary
```

Use the **show interfaces terse** command to verify that the IP address is correct on the loopback logical interface.

2. On the PE and CE routers, configure the IP address and protocol family on the Fast Ethernet interfaces. Specify the **inet** protocol family type.

```
[edit interfaces]
```

```
user@CE1# set fe-1/3/0 unit 0 family inet address 10.10.12.1/24
```

```
user@CE1# set fe-0/1/0 unit 0 family inet address 10.0.67.13/30
```

```
[edit interfaces]
```

```
user@PE1# set fe-0/1/0 unit 0 family inet address 10.0.67.14/30
```

```
[edit interfaces]
```

```
user@PE2# set fe-0/1/0 unit 0 family inet address 10.0.90.13/30
```

```
[edit interfaces]
```

```
user@CE2# set fe-0/1/0 unit 0 family inet address 10.0.90.14/30
user@CE2# set fe-1/3/0 unit 0 family inet address 10.10.11.1/24
```

Use the **show interfaces terse** command to verify that the IP address is correct on the Fast Ethernet interfaces.

3. On the PE and P routers, configure the ATM interfaces' VPI and maximum virtual circuits. If the default PIC type is different on directly connected ATM interfaces, configure the PIC type to be the same. Configure the logical interface VCI, protocol family, local IP address, and destination IP address.

```
[edit interfaces]
user@PE1# set at-0/2/0 atm-options pic-type atm1
user@PE1# set at-0/2/0 atm-options vpi 0 maximum-vcs 256
user@PE1# set at-0/2/0 unit 0 vci 0.128
user@PE1# set at-0/2/0 unit 0 family inet address 10.0.78.5/32 destination 10.0.78.6
```

```
[edit interfaces]
user@P# set at-0/2/0 atm-options pic-type atm1
user@P# set at-0/2/0 atm-options vpi 0 maximum-vcs 256
user@P# set at-0/2/0 unit 0 vci 0.128
user@P# set at-0/2/0 unit 0 family inet address 10.0.78.6/32 destination 10.0.78.5
user@P# set at-0/2/1 atm-options pic-type atm1
user@P# set at-0/2/1 atm-options vpi 0 maximum-vcs 256
user@P# set at-0/2/1 unit 0 vci 0.128
user@P# set at-0/2/1 unit 0 family inet address 10.0.89.5/32 destination 10.0.89.6
```

```
[edit interfaces]
user@PE2# set at-0/2/1 atm-options pic-type atm1
user@PE2# set at-0/2/1 atm-options vpi 0 maximum-vcs 256
user@PE2# set at-0/2/1 unit 0 vci 0.128
user@PE2# set at-0/2/1 unit 0 family inet address 10.0.89.6/32 destination 10.0.89.5
```

Use the **show configuration interfaces** command to verify that the ATM interfaces' VPI and maximum VCs are correct and that the logical interface VCI, protocol family, local IP address, and destination IP address are correct.

Configuring OSPF

- Step-by-Step Procedure**
1. On the P and PE routers, configure the provider instance of OSPF. Specify the **lo0.0** and ATM core-facing logical interfaces. The provider instance of OSPF on the PE router forms adjacencies with the OSPF neighbors on the other PE router and Router P.

```
user@PE1# set protocols ospf area 0.0.0.0 interface at-0/2/0.0
user@PE1# set protocols ospf area 0.0.0.0 interface lo0.0
```

```
user@P# set protocols ospf area 0.0.0.0 interface lo0.0
user@P# set protocols ospf area 0.0.0.0 interface all
user@P# set protocols ospf area 0.0.0.0 interface fxp0 disable
```

```
user@PE2# set protocols ospf area 0.0.0.0 interface lo0.0
user@PE2# set protocols ospf area 0.0.0.0 interface at-0/2/1.0
```

Use the **show ospf interfaces** command to verify that the **lo0.0** and ATM core-facing logical interfaces are configured for OSPF.

2. On the CE routers, configure the customer instance of OSPF. Specify the loopback and Fast Ethernet logical interfaces. The customer instance of OSPF on the CE routers form adjacencies with the neighbors within the VPN routing instance of OSPF on the PE routers.

```
user@CE1# set protocols ospf area 0.0.0.0 interface fe-0/1/0.0
user@CE1# set protocols ospf area 0.0.0.0 interface fe-1/3/0.0
user@CE1# set protocols ospf area 0.0.0.0 interface lo0.0
```

```
user@CE2# set protocols ospf area 0.0.0.0 interface fe-0/1/0.0
user@CE2# set protocols ospf area 0.0.0.0 interface fe-1/3/0.0
user@CE2# set protocols ospf area 0.0.0.0 interface lo0.0
```

Use the **show ospf interfaces** command to verify that the correct loopback and Fast Ethernet logical interfaces have been added to the OSPF protocol.

3. On the P and PE routers, configure OSPF traffic engineering support for the provider instance of OSPF.

The **shortcuts** statement enables the master instance of OSPF to use a label-switched path as the next hop.

```
user@PE1# set protocols ospf traffic-engineering shortcuts
```

```
user@P# set protocols ospf traffic-engineering shortcuts
```

```
user@PE2# set protocols ospf traffic-engineering shortcuts
```

Use the **show ospf overview** or **show configuration protocols ospf** command to verify that traffic engineering support is enabled.

Configuring BGP

Step-by-Step Procedure

1. On Router P, configure BGP for the VPN. The local address is the local **lo0.0** address. The neighbor addresses are the PE routers' **lo0.0** addresses.

The **unicast** statement enables the router to use BGP to advertise network layer reachability information (NLRI). The **signaling** statement enables the router to use BGP as the signaling protocol for the VPN.

```
user@P# set protocols bgp group group-mvpn type internal
user@P# set protocols bgp group group-mvpn local-address 192.168.8.1
user@P# set protocols bgp group group-mvpn family inet unicast
user@P# set protocols bgp group group-mvpn family inet-mvpn signaling
user@P# set protocols bgp group group-mvpn neighbor 192.168.9.1
user@P# set protocols bgp group group-mvpn neighbor 192.168.7.1
```

Use the **show configuration protocols bgp** command to verify that the router has been configured to use BGP to advertise NLRI.

2. On the PE and P routers, configure the BGP local autonomous system number.

```
user@PE1# set routing-options autonomous-system 0.65010
```

```
user@P# set routing-options autonomous-system 0.65010
```

```
user@PE2# set routing-options autonomous-system 0.65010
```

Use the **show configuration routing-options** command to verify that the BGP local autonomous system number is correct.

3. On the PE routers, configure BGP for the VPN. Configure the local address as the local **lo0.0** address. The neighbor addresses are the **lo0.0** addresses of Router P and the other PE router, PE2.

```
user@PE1# set protocols bgp group group-mvpn type internal
user@PE1# set protocols bgp group group-mvpn local-address 192.168.7.1
user@PE1# set protocols bgp group group-mvpn family inet-vpn unicast
user@PE1# set protocols bgp group group-mvpn family inet-mvpn signaling
user@PE1# set protocols bgp group group-mvpn neighbor 192.168.9.1
user@PE1# set protocols bgp group group-mvpn neighbor 192.168.8.1
```

```
user@PE2# set protocols bgp group group-mvpn type internal
user@PE2# set protocols bgp group group-mvpn local-address 192.168.9.1
user@PE2# set protocols bgp group group-mvpn family inet-vpn unicast
user@PE2# set protocols bgp group group-mvpn family inet-mvpn signaling
user@PE2# set protocols bgp group group-mvpn neighbor 192.168.7.1
user@PE2# set protocols bgp group group-mvpn neighbor 192.168.8.1
```

Use the **show bgp group** command to verify that the BGP configuration is correct.

4. On the PE routers, configure a policy to export the BGP routes into OSPF.

```
user@PE1# set policy-options policy-statement bgp-to-ospf from protocol bgp
user@PE1# set policy-options policy-statement bgp-to-ospf then accept
```

```
user@PE2# set policy-options policy-statement bgp-to-ospf from protocol bgp
user@PE2# set policy-options policy-statement bgp-to-ospf then accept
```

Use the **show policy bgp-to-ospf** command to verify that the policy is correct.

Configuring RSVP

Step-by-Step Procedure

1. On the PE routers, enable RSVP on the interfaces that participate in the LSP. Configure the Fast Ethernet and ATM logical interfaces.

```
user@PE1# set protocols rsvp interface fe-0/1/0.0
user@PE1# set protocols rsvp interface at-0/2/0.0
```

```
user@PE2# set protocols rsvp interface fe-0/1/0.0
user@PE2# set protocols rsvp interface at-0/2/1.0
```

2. On Router P, enable RSVP on the interfaces that participate in the LSP. Configure the ATM logical interfaces.

```
user@P# set protocols rsvp interface at-0/2/0.0
user@P# set protocols rsvp interface at-0/2/1.0
```

Use the **show configuration protocols rsvp** command to verify that the RSVP configuration is correct.

Configuring MPLS

Step-by-Step Procedure

1. On the PE routers, configure an MPLS LSP to the PE router that is the LSP egress point. Specify the IP address of the **lo0.0** interface on the router at the other end of the LSP. Configure MPLS on the ATM, Fast Ethernet, and **lo0.0** interfaces.

To help identify each LSP when troubleshooting, configure a different LSP name on each PE router. In this example, we use the name **to-pe2** as the name for the LSP configured on PE1 and **to-pe1** as the name for the LSP configured on PE2.

```
user@PE1# set protocols mpls label-switched-path to-pe2 to 192.168.9.1
user@PE1# set protocols mpls interface fe-0/1/0.0
user@PE1# set protocols mpls interface at-0/2/0.0
user@PE1# set protocols mpls interface lo0.0
```

```
user@PE2# set protocols mpls label-switched-path to-pe1 to 192.168.7.1
user@PE2# set protocols mpls interface fe-0/1/0.0
user@PE2# set protocols mpls interface at-0/2/1.0
user@PE2# set protocols mpls interface lo0.0
```

Use the **show configuration protocols mpls** and **show route label-switched-path to-pe1** commands to verify that the MPLS and LSP configuration is correct.

After the configuration is committed, use the **show mpls lsp name to-pe1** and **show mpls lsp name to-pe2** commands to verify that the LSP is operational.

2. On Router P, enable MPLS. Specify the ATM interfaces connected to the PE routers.

```
user@P# set protocols mpls interface at-0/2/0.0
user@P# set protocols mpls interface at-0/2/1.0
```

Use the **show mpls interface** command to verify that MPLS is enabled on the ATM interfaces.

3. On the PE and P routers, configure the protocol family on the ATM interfaces associated with the LSP. Specify the **mpls** protocol family type.

```
user@PE1# set interfaces at-0/2/0 unit 0 family mpls
```

```
user@P# set interfaces at-0/2/0 unit 0 family mpls
user@P# set interfaces at-0/2/1 unit 0 family mpls
```

```
user@PE2# set interfaces at-0/2/1 unit 0 family mpls
```

Use the **show mpls interface** command to verify that the MPLS protocol family is enabled on the ATM interfaces associated with the LSP.

Configuring the VRF Routing Instance

Step-by-Step Procedure

1. On the PE routers, configure a routing instance for the VPN and specify the **vrf** instance type. Add the Fast Ethernet and **lo0.1** customer-facing interfaces. Configure the VPN instance of OSPF and include the BGP-to-OSPF export policy.

```
user@PE1# set routing-instances vpn-a instance-type vrf
user@PE1# set routing-instances vpn-a interface lo0.1
user@PE1# set routing-instances vpn-a interface fe-0/1/0.0
```

```
user@PE1# set routing-instances vpn-a protocols ospf export bgp-to-ospf
user@PE1# set routing-instances vpn-a protocols ospf area 0.0.0.0 interface all
```

```
user@PE2# set routing-instances vpn-a instance-type vrf
user@PE2# set routing-instances vpn-a interface lo0.1
user@PE2# set routing-instances vpn-a interface fe-0/1/0.0
user@PE2# set routing-instances vpn-a protocols ospf export bgp-to-ospf
user@PE2# set routing-instances vpn-a protocols ospf area 0.0.0.0 interface all
```

Use the **show configuration routing-instances vpn-a** command to verify that the routing instance configuration is correct.

2. On the PE routers, configure a route distinguisher for the routing instance. A route distinguisher allows the router to distinguish between two identical IP prefixes used as VPN routes. Configure a different route distinguisher on each PE router. This example uses 65010:1 on PE1 and 65010:2 on PE2.

```
user@PE1# set routing-instances vpn-a route-distinguisher 65010:1
```

```
user@PE2# set routing-instances vpn-a route-distinguisher 65010:2
```

Use the **show configuration routing-instances vpn-a** command to verify that the route distinguisher is correct.

3. On the PE routers, configure default VRF import and export policies. Based on this configuration, BGP automatically generates local routes corresponding to the route target referenced in the VRF import policies. This example uses 2:1 as the route target.

NOTE: You must configure the same route target on each PE router for a given VPN routing instance.

```
user@PE1# set routing-instances vpn-a vrf-target target:2:1
```

```
user@PE2# set routing-instances vpn-a vrf-target target:2:1
```

Use the **show configuration routing-instances vpn-a** command to verify that the route target is correct.

4. On the PE routers, configure the VPN routing instance for multicast support.

```
user@PE1# set routing-instances vpn-a protocols mvpn
```

```
user@PE2# set routing-instances vpn-a protocols mvpn
```

Use the **show configuration routing-instance vpn-a** command to verify that the VPN routing instance has been configured for multicast support.

5. On the PE routers, configure an IP address on loopback logical interface 1 (lo0.1) used in the customer routing instance VPN.

```
user@PE1# set interfaces lo0 unit 1 family inet address 10.10.47.101/32
```

```
user@PE2# set interfaces lo0 unit 1 family inet address 10.10.47.100/32
```

Use the **show interfaces terse** command to verify that the IP address on the loopback interface is correct.

Configuring PIM

Step-by-Step Procedure

1. On the PE and P routers, enable the provider instance of PIM. Add the core-facing ATM interfaces. On the PE routers, also configure the **lo0.0** interface. Specify the mode as **sparse** and the version as **2**.

```
user@PE1# set protocols pim interface at-0/2/0.0 mode sparse
user@PE1# set protocols pim interface at-0/2/0.0 version 2
user@PE1# set protocols pim interface lo0.0 mode sparse
user@PE1# set protocols pim interface lo0.0 version 2
```

```
user@P# set protocols pim interface at-0/2/0.0 mode sparse
user@P# set protocols pim interface at-0/2/0.0 version 2
user@P# set protocols pim interface at-0/2/1.0 mode sparse
user@P# set protocols pim interface at-0/2/1.0 version 2
```

```
user@PE2# set protocols pim interface at-0/2/1.0 mode sparse
user@PE2# set protocols pim interface at-0/2/1.0 version 2
user@PE2# set protocols pim interface lo0.0 mode sparse
user@PE2# set protocols pim interface lo0.0 version 2
```

Use the **show pim interfaces** command to verify that PIM sparse-mode is enabled on the core-facing ATM interfaces.

2. On the PE routers, enable the VPN customer instance of PIM. Configure the **lo0.1** and the customer-facing Fast Ethernet interface. Specify the mode as **sparse** and the version as **2**.

```
user@PE1# set routing-instances vpn-a protocols pim interface lo0.1 mode sparse
user@PE1# set routing-instances vpn-a protocols pim interface lo0.1 version 2
user@PE1# set routing-instances vpn-a protocols pim interface fe-0/1/0.0 mode
sparse
user@PE1# set routing-instances vpn-a protocols pim interface fe-0/1/0.0 version
2
```

```
user@PE2# set routing-instances vpn-a protocols pim interface lo0.1 mode sparse
user@PE2# set routing-instances vpn-a protocols pim interface lo0.1 version 2
user@PE2# set routing-instances vpn-a protocols pim interface fe-0/1/0.0 mode
sparse
user@PE2# set routing-instances vpn-a protocols pim interface fe-0/1/0.0 version
2
```

Use the **show pim interfaces instance vpn-a** command to verify that PIM sparse-mode is enabled on the **lo0.1** interface and the customer-facing Fast Ethernet interface.

3. On the CE routers, enable the customer instance of PIM. In this example, we configure all interfaces. Specify the mode as **sparse** and the version as **2**.

```
user@CE1# set protocols pim interface all
```

```
user@CE2# set protocols pim interface all mode sparse
```

```
user@CE2# set protocols pim interface all version 2
```

Use the **show pim interfaces** command to verify that PIM sparse mode is enabled on all interfaces.

Configuring the Provider Tunnel

Step-by-Step Procedure

1. On Router PE1, configure the provider tunnel. Specify the multicast address to be used.

The **provider-tunnel** statement instructs the router to send multicast traffic across a tunnel. The **pim-asm** statement instructs the router to accept the multicast stream from any source.

```
user@PE1# set routing-instances vpn-a provider-tunnel pim-asm group-address 224.1.1.1
```

Use the **show configuration routing-instance vpn-a** command to verify that the multicast group address is correct on Router PE1.

2. On Router PE2, configure the provider tunnel. Specify the multicast address to be used.

```
user@PE2# set routing-instances vpn-a provider-tunnel pim-asm group-address 224.1.1.1
```

Use the **show configuration routing-instance vpn-a** command to verify that the multicast group address is correct on Router PE2.

Configuring the Rendezvous Point

Step-by-Step Procedure

1. Configure Router PE1 to be the rendezvous point for the provider instance of PIM. Specify the **lo0.0** address of Router PE1.

```
user@PE1# set protocols pim rp local address 192.168.7.1
```

Use the **show pim rps** command to verify that the correct local IP address is configured for the provider instance RP.

2. Configure the static rendezvous point on Router P and the PE2 router for the provider instance of PIM. Specify the **lo0.0** address of Router PE1. Specify the version as 2.

```
user@P# set protocols pim rp static address 192.168.7.1 version 2
```

```
user@PE2# set protocols pim rp static address 192.168.7.1 version 2
```

Use the **show pim rps** command to verify that the correct static IP address is configured for the provider instance RP.

3. Configure Router PE1 to be the rendezvous point for the customer instance of PIM. Specify the **lo0.1** address of Router PE1. Specify the multicast address to be used.

```
user@PE1# set routing-instances vpn-a protocols pim rp local address 10.10.47.101
user@PE1# set routing-instances vpn-a protocols pim rp local group-ranges 224.1.1.1/32
```

Use the **show pim rps instance vpn-a** command to verify that the correct local IP address is configured for the customer instance RP.

4. On Router PE2, configure the static rendezvous point for the customer instance of PIM. Specify the **lo0.1** address of Router PE1.

```
user@PE2# set routing-instances vpn-a protocols pim rp static address 10.10.47.101
```

Use the **show pim rps instance vpn-a** command to verify that the correct static IP address is configured for the customer instance RP.

5. On the CE routers, configure the static rendezvous point for the customer instance of PIM. Specify the **lo0.1** address of Router PE1.

```
user@CE1# set protocols pim rp static address 10.10.47.101 version 2
```

```
user@CE2# set protocols pim rp static address 10.10.47.101 version 2
```

Use the **show pim rps** command to verify that the correct static IP address is configured for the customer instance RP.

6. Use the **commit check** command to verify that the configuration can be successfully committed. If the configuration passes the check, commit the configuration.
7. Start the multicast sender device connected to CE1.
8. Start the multicast receiver device connected to CE2.
9. Verify that the receiver is receiving the multicast stream.
10. Use **show** commands to verify the routing, VPN, and multicast operation.

Results

The configuration and verification parts of this example have been completed. The following section is for your reference.

The relevant sample configuration for Router CE1 follows.

```
Router CE1 interfaces {
  lo0 {
    unit 0 {
      family inet {
        address 192.168.6.1/32 {
          primary;
        }
      }
    }
  }
  fe-0/1/0 {
    unit 0 {
      family inet {
        address 10.0.67.13/30;
      }
    }
  }
  fe-1/3/0 {
    unit 0 {
      family inet {
        address 10.10.12.1/24;
      }
    }
  }
}
```

```

    }
  }
}
protocols {
  ospf {
    area 0.0.0.0 {
      interface fe-0/1/0.0;
      interface lo0.0;
      interface fe-1/3/0.0;
    }
  }
  pim {
    rp {
      static {
        address 10.10.47.101 {
          version 2;
        }
      }
    }
    interface all;
  }
}

```

The relevant sample configuration for Router PE1 follows.

```

Router PE1  interfaces {
              lo0 {
                unit 0 {
                  family inet {
                    address 192.168.7.1/32 {
                      primary;
                    }
                  }
                }
              }
              fe-0/1/0 {
                unit 0 {
                  family inet {
                    address 10.0.67.14/30;
                  }
                }
              }
              at-0/2/0 {
                atm-options {
                  pic-type atm1;
                  vpi 0 {
                    maximum-vcs 256;
                  }
                }
                unit 0 {
                  vci 0.128;
                  family inet {
                    address 10.0.78.5/32 {
                      destination 10.0.78.6;
                    }
                  }
                }
              }
            }

```

```
        family mpls;
      }
    }
    lo0 {
      unit 1 {
        family inet {

                mode sparse;
                version 2;
            }
        }
        mvpn;
    }
}

```

```
}
```

The relevant sample configuration for Router P follows.

```
Router P  interfaces {
            lo0 {
              unit 0 {
                family inet {
                  address 192.168.8.1/32 {
                    primary;
                  }
                }
              }
            }
            at-0/2/0 {
              atm-options {
                pic-type atm1;
              }
              vpi 0 {
                maximum-vcs 256;
              }
            }
            unit 0 {
              vci 0.128;
              family inet {
                address 10.0.78.6/32 {
                  destination 10.0.78.5;
                }
              }
              family mpls;
            }
          }

Example: Configuring PIM Join Load Balancing on Draft-Rosen Multicast VPN

This example shows how to configure multipath routing for external and internal virtual private network (VPN) routes with unequal interior gateway protocol (IGP) metrics, and Protocol Independent Multicast (PIM) join load balancing on provider edge (PE) routers running Draft-Rosen multicast VPN (MVPN). This feature allows customer PIM (C-PIM) join messages to be load-balanced across external and internal BGP (EIBGP) upstream paths when the PE router has both external BGP (EBGP) and internal BGP (IBGP) paths toward the source or rendezvous point (RP).

- [Requirements on page 5182](#)
- [Overview and Topology on page 5183](#)
- [Configuration on page 5186](#)
- [Verification on page 5189](#)

Requirements

This example requires the following hardware and software components:

- Three routers that can be a combination of M Series Multiservice Edge Routers, MX Series 3D Universal Edge Routers, or T Series Core Routers.
- Junos OS Release 12.1 or later running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure the following routing protocols on all PE routers:
 - OSPF
 - MPLS
 - LDP
 - PIM
 - BGP
3. Configure a multicast VPN.

Overview and Topology

Junos OS Release 12.1 and later support multipath configuration along with PIM join load balancing. This allows C-PIM join messages to be load-balanced across unequal EIBGP routes, if a PE router has EBGP and IBGP paths toward the source (or RP). In previous releases, only the active EBGP path was used to send the join messages. This feature is applicable to IPv4 C-PIM join messages.

During load balancing, if a PE router loses one or more EBGP paths toward the source (or RP), the C-PIM join messages that were previously using the EBGP path are moved to a multicast tunnel interface, and the reverse path forwarding (RPF) neighbor on the multicast tunnel interface is selected based on a hash mechanism.

On discovering the first EBGP path toward the source (or RP), only the new join messages get load-balanced across EIBGP paths, whereas the existing join messages on the multicast tunnel interface remain unaffected.

Though the primary goal for multipath PIM join load balancing is to utilize unequal EIBGP paths for multicast traffic, potential join loops can be avoided if a PE router chooses only the EBGP path when there are one or more join messages for different groups from a remote PE router. If the remote PE router's join message arrives after the PE router has already chosen IBGP as the upstream path, then the potential loops can be broken by changing the selected upstream path to EBGP.

NOTE: During a graceful Routing Engine switchover (GRES), the EIBGP path selection for C-PIM join messages can vary, because the upstream interface selection is performed again for the new Routing Engine based on the join messages it receives from the CE and PE neighbors. This can lead to disruption of multicast traffic depending on the number of join messages received and the load on the network at the time of the graceful restart. However, the nonstop active routing feature is not supported and has no impact on the multicast traffic in a Draft-Rosen MVPN scenario.

In this example, PE1 and PE2 are the upstream PE routers for which the multipath PIM join load-balancing feature is configured. Routers PE1 and PE2 have one EBGP path and one IBGP path each toward the source. The Source and Receiver attached to customer edge (CE) routers are Free BSD hosts.

On PE routers that have EIBGP paths toward the source (or RP), such as PE1 and PE2, PIM join load balancing is performed as follows:

1. The existing join-count-based load balancing is performed such that the algorithm first selects the least loaded C-PIM interface. If there is equal or no load on all the C-PIM interfaces, the join messages get distributed equally across the available upstream interfaces.

In [Figure 114 on page 5186](#), if the PE1 router receives PIM join messages from the CE2 router, and if there is equal or no load on both the EBGp and IBGP paths toward the source, the join messages get load-balanced on the EIBGP paths.

2. If the selected least loaded interface is a multicast tunnel interface, then there can be a potential join loop if the downstream list of the customer join (C-join) message already contains the multicast tunnel interface. In such a case, the least loaded interface among EBGp paths is selected as the upstream interface for the C-join message.

Assuming that the IBGP path is the least loaded, the PE1 router sends the join messages to PE2 using the IBGP path. If PIM join messages from the PE3 router arrive on PE1, then the downstream list of the C-join messages for PE3 already contains a multicast tunnel interface, which can lead to a potential join loop, because both the upstream and downstream interfaces are multicast tunnel interfaces. In this case, PE1 uses only the EBGp path to send the join messages.

3. If the selected least loaded interface is a multicast tunnel interface and the multicast tunnel interface is not present in the downstream list of the C-join messages, the loop prevention mechanism is not necessary. If any PE router has already advertised data multicast distribution tree (MDT) type, length, and values (TLVs), that PE router is selected as the upstream neighbor.

When the PE1 router sends the join messages to PE2 using the least loaded IBGP path, and if PE3 sends its join messages to PE2, no join loop is created.

4. If no data MDT TLV corresponds to the C-join message, the least loaded neighbor on a multicast tunnel interface is selected as the upstream interface.

On PE routers that have only IBGP paths toward the source (or RP), such as PE3, PIM join load balancing is performed as follows:

1. The PE router only finds a multicast tunnel interface as the RPF interface, and load balancing is done across the C-PIM neighbors on a multicast tunnel interface.

Router PE3 load-balances PIM join messages received from the CE4 router across the IBGP paths to the PE1 and PE2 routers.

2. If any PE router has already advertised data MDT TLVs corresponding to the C-join messages, that PE router is selected as the RPF neighbor.

For a particular C-multicast flow, at least one of the PE routers having EIBGP paths toward the source (or RP) must use only the EBGp path to avoid or break join loops. As a result of the loop avoidance mechanism, a PE router is constrained to choose among EIBGP paths when a multicast tunnel interface is already present in the downstream list.

In [Figure 114 on page 5186](#), assuming that the CE2 host is interested in receiving traffic from the Source and CE2 initiates multiple PIM join messages for different groups (Group 1 with group address 225.1.1.1, and Group 2 with group address 225.1.1.2), the join messages for both groups arrive on the PE1 router.

Router PE1 then equally distributes the join messages between the EIBGP paths toward the Source. Assuming that Group 1 join messages are sent to the CE1 router directly using the EBGp path, and Group 2 join messages are sent to the PE2 router using the IBGP path, PE1 and PE2 become the RPF neighbors for Group 1 and Group 2 join messages, respectively.

When the CE3 router initiates Group 1 and Group 2 PIM join messages, the join messages for both groups arrive on the PE2 router. Router PE2 then equally distributes the join messages between the EIBGP paths toward the Source. Since PE2 is the RPF neighbor for Group 2 join messages, it sends the Group 2 join messages directly to the CE1 router using the EBGp path. Group 1 join messages are sent to the PE1 router using the IBGP path.

However, if the CE4 router initiates multiple Group 1 and Group 2 PIM join messages, there is no control over how these join messages received on the PE3 router get distributed to reach the Source. The selection of the RPF neighbor by PE3 can affect PIM join load balancing on EIBGP paths.

- If PE3 sends Group 1 join messages to PE1 and Group 2 join messages to PE2, there is no change in RPF neighbor. As a result, no join loops are created.
- If PE3 sends Group 1 join messages to PE2 and Group 2 join messages to PE1, there is a change in the RPF neighbor for the different groups resulting in the creation of join loops. To avoid potential join loops, PE1 and PE2 do not consider IBGP paths to send the join messages received from the PE3 router. Instead, the join messages are sent directly to the CE1 router using only the EBGp path.

The loop avoidance mechanism in a Draft-Rosen MVPN has the following limitations:

- Because the timing of arrival of join messages on remote PE routers determines the distribution of join messages, the distribution could be sub-optimal in terms of join count.
- Because join loops cannot be avoided and can occur due to the timing of join messages, the subsequent RPF interface change leads to loss of multicast traffic. This can be avoided by implementing the PIM make-before-break feature.

The PIM make-before-break feature is an approach to detect and break C-PIM join loops in a Draft-Rosen MVPN. The C-PIM join messages are sent to the new RPF neighbor after establishing the PIM neighbor relationship, but before updating the related multicast forwarding entry. Though the upstream RPF neighbor would have updated its multicast forwarding entry and started sending the multicast traffic downstream, the downstream router does not forward the multicast traffic (because of RPF check failure) until the multicast forwarding entry is updated with the new RPF neighbor. This helps to ensure that the multicast traffic is available on the new path before switching the RPF interface of the multicast forwarding entry.

Figure 114: PIM Join Load Balancing on Draft-Rosen MVPN

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

PE1 set routing-instances vpn1 instance-type vrf
    set routing-instances vpn1 interface ge-5/0/4.0
    set routing-instances vpn1 interface ge-5/2/0.0
    set routing-instances vpn1 interface lo0.1
    set routing-instances vpn1 route-distinguisher 1:1
    set routing-instances vpn1 vrf-target target:1:1
    set routing-instances vpn1 routing-options multipath vpn-unequal-cost

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#). To configure the PE1 router:

NOTE: Repeat this procedure for every Juniper Networks router in the MVPN domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure a VPN routing and forwarding (VRF) instance.

```
[edit routing-instances vpn1]
user@PE1# set instance-type vrf
user@PE1# set interface ge-5/0/4.0
user@PE1# set interface ge-5/2/0.0
user@PE1# set interface lo0.1
user@PE1# set route-distinguisher 1:1
user@PE1# set vrf-target target:1:1
```
2. Enable protocol-independent load balancing for the VRF instance.

```
[edit routing-instances vpn1]
user@PE1# set routing-options multipath vpn-unequal-cost equal-external-internal
```
3. Configure BGP groups and neighbors to enable PE to CE routing.

```
[edit routing-instances vpn1 protocols]
user@PE1# set bgp export direct
user@PE1# set bgp group bgp type external
user@PE1# set bgp group bgp local-address 44.44.44.1
```

```
user@PE1# set bgp group bgp family inet unicast
user@PE1# set bgp group bgp neighbor 44.44.44.2 peer-as 3
user@PE1# set bgp group bgp1 type external
user@PE1# set bgp group bgp1 local-address 11.11.11.1
user@PE1# set bgp group bgp1 family inet unicast
user@PE1# set bgp group bgp1 neighbor 11.11.11.2 peer-as 4
```

4. Configure PIM to enable PE to CE multicast routing.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim vpn-group-address 224.1.1.1
user@PE1# set pim rp static address 10.255.8.168
```

5. Enable PIM on all network interfaces.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim interface all
```

6. Enable PIM join load balancing for the VRF instance.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim join-load-balance
```

Results From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
routing-instances {
  vpn1 {
    instance-type vrf;
    interface ge-5/0/4.0;
    interface ge-5/2/0.0;
    interface lo0.1;
    route-distinguisher 1:1;
    vrf-target target:1:1;
    routing-options {
      multipath {
        vpn-unequal-cost equal-external-internal;
      }
    }
  }
  protocols {
    bgp {
      export direct;
      group bgp {
        type external;
        local-address 44.44.44.1;
        family inet {
          unicast;
        }
        neighbor 44.44.44.2 {
          peer-as 3;
        }
      }
    }
    group bgp1 {
      type external;
      local-address 11.11.11.1;
      family inet {
```

```

        unicast;
    }
    neighbor 11.11.11.2 {
        peer-as 4;
    }
}
pim {
    vpn-group-address 224.1.1.1;
    rp {
        static {
            address 10.255.8.168;
        }
    }
    interface all;
    join-load-balance;
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying PIM Join Load Balancing for Different Groups of Join Messages

Purpose Verify PIM join load balancing for the different groups of join messages received on the PE1 router.

Action From operational mode, run the **show pim join instance extensive** command.

```

user@PE1> show pim join instance extensive
Instance: PIM.vpn1 Family: INET
R = Rendezvous Point Tree, S = Sparse, W = Wildcard

Group: 225.1.1.1
Source: *
RP: 10.255.8.168
Flags: sparse,rptree,wildcard
Upstream interface: ge-5/2/0.1
Upstream neighbor: 10.10.10.2
Upstream state: Join to RP
Downstream neighbors:
Interface: ge-5/0/4.0
10.40.10.2 State: Join Flags: SRW Timeout: 207

Group: 225.1.1.2
Source: *
RP: 10.255.8.168
Flags: sparse,rptree,wildcard
Upstream interface: mt-5/0/10.32768
Upstream neighbor: 19.19.19.19
Upstream state: Join to RP

```

```
Downstream neighbors:
  Interface: ge-5/0/4.0
    10.40.10.2 State: Join Flags: SRW Timeout: 207

Group: 225.1.1.3
  Source: *
  RP: 10.255.8.168
  Flags: sparse,rptree,wildcard
  Upstream interface: ge-5/2/0.1
  Upstream neighbor: 10.10.10.2
  Upstream state: Join to RP
  Downstream neighbors:
    Interface: ge-5/0/4.0
      10.40.10.2 State: Join Flags: SRW Timeout: 207

Group: 225.1.1.4
  Source: *
  RP: 10.255.8.168
  Flags: sparse,rptree,wildcard
  Upstream interface: mt-5/0/10.32768
  Upstream neighbor: 19.19.19.19
  Upstream state: Join to RP
  Downstream neighbors:
    Interface: ge-5/0/4.0
      10.40.10.2 State: Join Flags: SRW Timeout: 207
```

Meaning The output shows how the PE1 router has load-balanced the C-PIM join messages for four different groups.

- For Group 1 (group address: 225.1.1.1) and Group 3 (group address: 225.1.1.3) join messages, the PE1 router has selected the EBGp path toward the CE1 router to send the join messages.
- For Group 2 (group address: 225.1.1.2) and Group 4 (group address: 225.1.1.4) join messages, the PE1 router has selected the IBGP path toward the PE2 router to send the join messages.

Example: Configuring PIM Join Load Balancing On Next-Generation Multicast VPN

This example shows how to configure multipath routing for external and internal virtual private network (VPN) routes with unequal interior gateway protocol (IGP) metrics and Protocol Independent Multicast (PIM) join load balancing on provider edge (PE) routers running next-generation multicast VPN (MVPN). This feature allows customer PIM (C-PIM) join messages to be load-balanced across available internal BGP (IBGP) upstream paths when there is no external BGP (EBGP) path present, and across available EBGp upstream paths when external and internal BGP (EIBGP) paths are present toward the source or rendezvous point (RP).

- [Requirements on page 5191](#)
- [Overview and Topology on page 5191](#)

- [Configuration on page 5194](#)
- [Verification on page 5197](#)

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of M Series, MX Series, or T Series routers.
- Junos OS Release 12.1 running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure the following routing protocols on all PE routers:
 - OSPF
 - MPLS
 - LDP
 - PIM
 - BGP
3. Configure a multicast VPN.

Overview and Topology

Junos OS Release 12.1 and later support multipath configuration along with PIM join load balancing. This allows C-PIM join messages to be load-balanced across all available IBGP paths when there are only IBGP paths present, and across all available upstream EBGP paths when EIBGP paths are present toward the source (or RP). Unlike Draft-Rosen MVPN, next-generation MVPN does not utilize unequal EIBGP paths to send C-PIM join messages. This feature is applicable to IPv4 C-PIM join messages.

By default, only one active IBGP path is used to send the C-PIM join messages for a PE router having only IBGP paths toward the source (or RP). When there are EIBGP upstream paths present, only one active EBGP path is used to send the join messages.

In a next-generation MVPN, C-PIM join messages are translated into (or encoded as) BGP customer multicast (C-multicast) MVPN routes and advertised with the BGP MCAST-VPN address family toward the sender PE routers. A PE router originates a C-multicast MVPN route in response to receiving a C-PIM join message through its PE router to customer edge (CE) router interface. The two types of C-multicast MVPN routes are:

- Shared tree join route (C-*, C-G)
 - Originated by receiver PE routers.
 - Originated when a PE router receives a shared tree C-PIM join message through its PE-CE router interface.
- Source tree join route (C-S, C-G)

- Originated by receiver PE routers.
- Originated when a PE router receives a source tree C-PIM join message (C-S, C-G), or originated by the PE router that already has a shared tree join route and receives a source active autodiscovery route.

The upstream path in a next-generation MVPN is selected using the Bitwise-XOR hash algorithm as specified in Internet draft draft-ietf-l3vpn-2547bis-mcast, *Multicast in MPLS/BGP IP VPNs*. The hash algorithm is performed as follows:

1. The PE routers in the candidate set are numbered from lower to higher IP address, starting from **0**.
2. A bitwise exclusive-or of all the bytes is performed on the C-root (source) and the C-G (group) address.
3. The result is taken modulo n , where n is the number of PE routers in the candidate set. The result is **N**.
4. **N** represents the IP address of the upstream PE router as numbered in Step 1.

During load balancing, if a PE router with one or more upstream IBGP paths toward the source (or RP) discovers a new IBGP path toward the same source (or RP), the C-PIM join messages distributed among previously existing IBGP paths get redistributed due to the change in the candidate PE router set.

In this example, PE1, PE2, and PE3 are the PE routers that have the multipath PIM join load-balancing feature configured. Router PE1 has two EBGp paths and one IBGP upstream path, PE2 has one EBGp path and one IBGP upstream path, and PE3 has two IBGP upstream paths toward the Source. Router CE4 is the customer edge (CE) router attached to PE3. Source and Receiver are the Free BSD hosts.

On PE routers that have EIBGP paths toward the source (or RP), such as PE1 and PE2, PIM join load balancing is performed as follows:

1. The C-PIM join messages are sent using EBGp paths only. IBGP paths are not used to propagate the join messages.

In [Figure 115 on page 5193](#), the PE1 router distributes the join messages between the two EBGp paths to the CE1 router, and PE2 uses the EBGp path to CE1 to send the join messages.

2. If a PE router loses one or more EBGp paths toward the source (or RP), the RPF neighbor on the multicast tunnel interface is selected based on a hash mechanism.

On discovering the first EBGp path, only new join messages get load-balanced across available EBGp paths, whereas the existing join messages on the multicast tunnel interface are not redistributed.

If the EBGp path from the PE2 router to the CE1 router goes down, PE2 sends the join messages to PE1 using the IBGP path. When the EBGp path to CE1 is restored, only new join messages that arrive on PE2 use the restored EBGp path, whereas join messages already sent on the IBGP path are not redistributed.

On PE routers that have only IBGP paths toward the source (or RP), such as the PE3 router, PIM join load balancing is performed as follows:

1. The C-PIM join messages from CE routers get load-balanced only as BGP C-multicast data messages among IBGP paths.

In [Figure 115 on page 5193](#), assuming that the CE4 host is interested in receiving traffic from the Source, and CE4 initiates source join messages for different groups (Group 1 [C-S,C-G1] and Group 2 [C-S,C-G2]), the source join messages arrive on the PE3 router.

Router PE3 then uses the Bitwise-XOR hash algorithm to select the upstream PE router to send the C-multicast data for each group. The algorithm first numbers the upstream PE routers from lower to higher IP address starting from 0.

Assuming that Router PE1 router is numbered 0 and Router PE2 is 1, and the hash result for Group 1 and Group 2 join messages is 0 and 1, respectively, the PE3 router selects PE1 as the upstream PE router to send Group 1 join messages, and PE2 as the upstream PE router to send the Group 2 join messages to the Source.

2. The shared join messages for different groups [C-*,C-G] are also treated in a similar way to reach the destination.

set routing-instances vpn1 protocols pim rp static address 10.255.10.119
set routing-instances vpn1 protocols pim interface all
set routing-instances vpn1 protocols mvpn mvpn-mode rpt-spt
set routing-instances vpn1 protocols mvpn mvpn-join-load-balance bitwise-xor-hash

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#). To configure the PE1 router:

NOTE: Repeat this procedure for every Juniper Networks router in the MVPN domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure a VPN routing forwarding (VRF) routing instance.

```

[edit routing-instances vpn1]
user@PE1# set instance-type vrf
user@PE1# set interface ge-3/0/1.0
user@PE1# set interface ge-3/3/2.0
user@PE1# set interface lo0.1
user@PE1# set route-distinguisher 1:1
user@PE1# set provider-tunnel rsvp-te label-switched-path-template
  default-template
user@PE1# set vrf-target target:1:1
user@PE1# set vrf-table-label

```

2. Enable protocol-independent load balancing for the VRF instance.

```

[edit routing-instances vpn1]
user@PE1# set routing-options multipath vpn-unequal-cost equal-external-internal

```

3. Configure BGP groups and neighbors to enable PE to CE routing.

```

[edit routing-instances vpn1 protocols]
user@PE1# set bgp export direct
user@PE1# set bgp group bgp type external
user@PE1# set bgp group bgp local-address 10.40.10.1
user@PE1# set bgp group bgp family inet unicast
user@PE1# set bgp group bgp neighbor 10.40.10.2 peer-as 3
user@PE1# set bgp group bgp1 type external
user@PE1# set bgp group bgp1 local-address 10.10.10.1

```

```
user@PE1# set bgp group bgp1 family inet unicast
user@PE1# set bgp group bgp1 neighbor 10.10.10.2 peer-as 3
```

4. Configure PIM to enable PE to CE multicast routing.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim rp static address 10.255.10.119
```

5. Enable PIM on all network interfaces.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim interface all
```

6. Enable PIM join load balancing for the VRF instance.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim join-load-balance
```

7. Configure the mode for C-PIM join messages to use rendezvous-point trees, and switch to the shortest-path tree after the source is known.

```
[edit routing-instances vpn1 protocols]
user@PE1# set mvpn mvpn-mode rpt-spt
```

8. Configure the VRF instance to use the Bytewise-XOR hash algorithm.

```
[edit routing-instances vpn1 protocols]
user@PE1# set mvpn mvpn-join-load-balance bytewise-xor-hash
```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show routing-instances
routing-instances {
  vpn1 {
    instance-type vrf;
    interface ge-3/0/1.0;
    interface ge-3/3/2.0;
    interface lo0.1;
    route-distinguisher 1:1;
    provider-tunnel {
      rsvp-te {
        label-switched-path-template {
          default-template;
        }
      }
    }
    vrf-target target:1:1;
    vrf-table-label;
    routing-options {
      multipath {
        vpn-unequal-cost equal-external-internal;
      }
    }
    protocols {
      bgp {
```

```

export direct;
group bgp {
    type external;
    local-address 10.40.10.1;
    family inet {
        unicast;
    }
    neighbor 10.40.10.2 {
        peer-as 3;
    }
}
group bgp1 {
    type external;
    local-address 10.10.10.1;
    family inet {
        unicast;
    }
    neighbor 10.10.10.2 {
        peer-as 3;
    }
}
}
pim {
    rp {
        static {
            address 10.255.10.119;
        }
    }
    interface all;
    join-load-balance;
}
mvpn {
    mvpn-mode {
        rpt-spt;
    }
    mvpn-join-load-balance {
        bitwise-xor-hash;
    }
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying MVPN C-Multicast Route Information for Different Groups of Join Messages on page 5197](#)

Verifying MVPN C-Multicast Route Information for Different Groups of Join Messages

Purpose Verify MVPN C-multicast route information for different groups of join messages received on the PE3 router.

Action From operational mode, run the **show mvpn c-multicast** command.

```

user@PE3> show mvpn c-multicast
MVPN instance:
Legend for provider tunnel
I-P-tnl -- inclusive provider tunnel S-P-tnl -- selective provider tunnel
Legend for c-multicast routes properties (Pr)
DS -- derived from (*, c-g)          RM -- remote VPN route
Family : INET

Instance : vpn1
MVPN Mode : RPT-SPT
C-mcast IPv4 (S:G)          Ptnl          St
0.0.0.0/0:225.1.1.1/32      RSVP-TE P2MP:10.255.10.2, 5834,10.255.10.2
4.4.4.2/32:225.1.1.1/32     RSVP-TE P2MP:10.255.10.2, 5834,10.255.10.2
0.0.0.0/0:225.1.1.2/32     RSVP-TE P2MP:10.255.10.14, 47575,10.255.10.14
4.4.4.2/32:225.1.1.2/32     RSVP-TE P2MP:10.255.10.14, 47575,10.255.10.14

```

Meaning The output shows how the PE3 router has load-balanced the C-multicast data for the different groups.

- For source join messages (S,G):
 - 4.4.4.2/32:225.1.1.1/32 (S,G1) toward the PE1 router (10.255.10.2 is the loopback address of Router PE1).
 - 4.4.4.2/32:225.1.1.2/32 (S,G2) toward the PE2 router (10.255.10.14 is the loopback address of Router PE2).
- For shared join messages (*,G):
 - 0.0.0.0/0:225.1.1.1/32 (*,G1) toward the PE1 router (10.255.10.2 is the loopback address of Router PE1).
 - 0.0.0.0/0:225.1.1.2/32 (*,G2) toward the PE2 router (10.255.10.14 is the loopback address of Router PE2).

Controlling PIM Resources for Multicast VPNs Overview

A service provider network must protect itself from potential attacks from misconfigured or misbehaving customer edge (CE) devices and their associated VPN routing and forwarding (VRF) routing instances. Misbehaving CE devices can potentially advertise a large number of multicast routes toward a provider edge (PE) device, thereby consuming memory on the PE device and using other system resources in the network that are reserved for routes belonging to other VPNs.

To protect against potential misbehaving CE devices and VRF routing instances for specific multicast VPNs (MVPNs), you can control the following Protocol Independent Multicast (PIM) resources:

- Limit the number of accepted PIM join messages for any-source groups (*G) and source-specific groups (S,G).

Note how the device counts the PIM join messages:

- Each (*G) counts as one group toward the limit.
- Each (S,G) counts as one group toward the limit.
- Limit the number of PIM register messages received for a specific VRF routing instance. Use this configuration if the device is configured as a rendezvous point (RP) or has the potential to become an RP. When a source in a multicast network becomes active, the source's designated router (DR) encapsulates multicast data packets into a PIM register message and sends them by means of unicast to the RP router.

Note how the device counts PIM register messages:

- Each unique (S,G) join received by the RP counts as one group toward the configured register messages limit.
- Periodic register messages sent by the DR for existing or already known (S,G) entries do not count toward the configured register messages limit.
- Register messages are accepted until either the PIM register limit or the PIM join limit (if configured) is exceeded. Once either limit is reached, any new requests are dropped.
- Limit the number of group-to-RP mappings allowed in a specific VRF routing instance. Use this configuration if the device is configured as an RP or has the potential to become an RP. This configuration can apply to devices configured for automatic RP announce and discovery (Auto-RP) or as a PIM bootstrap router. Every multicast device within a PIM domain must be able to map a particular multicast group address to the same RP. Both Auto-RP and the bootstrap router functionality are the mechanisms used to learn the set of group-to-RP mappings. Auto-RP is typically used in a PIM dense-mode deployment, and the bootstrap router is typically used in a PIM sparse-mode deployment.

NOTE: The group-to-RP mappings limit does not apply to static RP or embedded RP configurations.

Some important things to note about how the device counts group-to-RP mappings:

- One group prefix mapped to five RPs counts as five group-to-RP mappings.
- Five distinct group prefixes mapped to one RP count as five group-to-RP mappings.

Once the configured limits are reached, no new PIM join messages, PIM register messages, or group-to-RP mappings are accepted unless one of the following occurs:

- You clear the current PIM join states by using the **clear pim join** command. If you use this command on an RP configured for PIM register message limits, the register limit count is also restarted because the PIM join messages are unknown by the RP.

NOTE: On the RP, you can also use the **clear pim register** command to clear all of the PIM registers. This command is useful if the current PIM register count is greater than the newly configured PIM register limit. After you clear the PIM registers, new PIM register messages are received up to the configured limit.

- The traffic responsible for the excess PIM join messages and PIM register messages stops and is no longer present.

CAUTION: Never restart any of the software processes unless instructed to do so by a customer support engineer.

You restart the PIM routing process on the device. This restart clears all of the configured limits but disrupts routing and therefore requires a maintenance window for the change.

System Log Messages for PIM Resources

You can optionally configure a system log warning threshold for each of the PIM resources. With this configuration, you can generate and review system log messages to detect if an excessive number of PIM join messages, PIM register messages, or group-to-RP mappings have been received on the device. The system log warning thresholds are configured per PIM resource and are a percentage of the configured maximum limits of the PIM join messages, PIM register messages, and group-to-RP mappings. You can further specify a log interval for each configured PIM resource, which is the amount of time (in seconds) between the log messages.

The log messages convey when the configured limits have been exceeded, when the configured warning thresholds have been exceeded, and when the configured limits drop below the configured warning threshold. [Table 384 on page 5200](#) describes the different types of PIM system messages that you might see depending on your system log warning and log interval configurations.

Table 384: PIM System Log Messages

System Log Message	Definition
RPD_PIM_SG_THRESHOLD_EXCEED	Records when the (S,G)/(*G) routes exceed the configured warning threshold.
RPD_PIM_REG_THRESH_EXCEED	Records when the PIM registers exceed the configured warning threshold.
RPD_PIM_GRP_RP_MAP_THRES_EXCEED	Records when the group-to-RP mappings exceed the configured warning threshold.

Table 384: PIM System Log Messages (*continued*)

System Log Message	Definition
RPD_PIM_SG_LIMIT_EXCEED	Records when the (S,G)/(*G) routes exceed the configured limit, or when the configured log interval has been met and the routes exceed the configured limit.
RPD_PIM_REGISTER_LIMIT_EXCEED	Records when the PIM registers exceed the configured limit, or when the configured log interval has been met and the registers exceed the configured limit.
RPD_PIM_GRP_RP_MAP_LIMIT_EXCEED	Records when the group-to-RP mappings exceed the configured limit, or when the configured log interval has been met and the mapping exceeds the configured limit.
RPD_PIM_SG_LIMIT_BELOW	Records when the (S,G)/(*G) routes drop below the configured limit and the configured log interval.
RPD_PIM_REGISTER_LIMIT_BELOW	Records when the PIM registers drop below the configured limit and the configured log interval.
RPD_PIM_GRP_RP_MAP_LIMIT_BELOW	Records when the group-to-RP mappings drop below the configured limit and the configured log interval.

Example: Configuring PIM State Limits

This example shows how to set limits on the Protocol Independent Multicast (PIM) state information so that a service provider network can protect itself from potential attacks from misconfigured or misbehaving customer edge (CE) devices and their associated VPN routing and forwarding (VRF) routing instances.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In this example, a multiprotocol BGP-based multicast VPN (next-generation MBGP MVPN) is configured with limits on the PIM state resources.

The **sglimit maximum** statement sets a limit for the number of accepted (*G) and (S,G) PIM join states received for the vpn-l routing instance.

The **rp register-limit maximum** statement configures a limit for the number of PIM register messages received for the vpn-l routing instance. You configure this statement on the rendezvous point (RP) or on all the devices that might become the RP.

The **group-rp-mapping maximum** statement configures a limit for the number of group-to-RP mappings allowed in the vpn-1 routing instance.

For each configured PIM resource, the **threshold** statement sets a percentage of the maximum limit at which to start generating warning messages in the PIM log file.

For each configured PIM resource, the **log-interval** statement is an amount of time (in seconds) between system log message generation.

Figure 116 on page 5202 shows the topology used in this example.

Figure 116: PIM State Limits Topology

“CLI Quick Configuration” on page 5202 shows the configuration for all of the devices in Figure 116 on page 5202. The section “Step-by-Step Procedure” on page 5205 describes the steps on Device PE1.

Configuration

CLI Quick Configuration	To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.
Device CE1	<pre> set interfaces ge-1/2/0 unit 1 family inet address 10.1.1.1/30 set interfaces ge-1/2/0 unit 1 family mpls set interfaces lo0 unit 1 family inet address 1.1.1.1/32 set protocols ospf area 0.0.0.0 interface lo0.1 passive set protocols ospf area 0.0.0.0 interface ge-1/2/0.1 set protocols pim rp static address 100.1.1.2 set protocols pim interface all set routing-options router-id 1.1.1.1 </pre>

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 4704](#) in the *CLI User Guide*.

To configure PIM state limits:

1. Configure the network interfaces.

```

[edit interfaces]
user@PE1# set ge-1/2/0 unit 2 family inet address 10.1.1.2/30
user@PE1# set ge-1/2/0 unit 2 family mpls

user@PE1# set ge-1/2/1 unit 5 family inet address 10.1.1.5/30
user@PE1# set ge-1/2/1 unit 5 family mpls

user@PE1# set vt-1/2/0 unit 2 family inet

```

```
user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32
user@PE1# set lo0 unit 102 family inet address 100.1.1.2/32
```

2. Configure MPLS on the core-facing interface.

```
[edit protocols mpls]
user@PE1# set interface ge-1/2/1.5
```

3. Configure internal BGP (IBGP) on the main router.

The IBGP neighbors are the other PE devices.

```
[edit protocols bgp group ibgp]
user@PE1# set type internal
user@PE1# set local-address 1.1.1.2
user@PE1# set family inet-vpn any
user@PE1# set family inet-mvpn signaling
user@PE1# set neighbor 1.1.1.4
user@PE1# set neighbor 1.1.1.5
```

4. Configure OSPF on the main router.

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface lo0.2 passive
user@PE1# set interface ge-1/2/1.5
```

5. Configure a signaling protocol (RSVP or LDP) on the main router.

```
[edit protocols ldp]
user@PE1# set interface ge-1/2/1.5
user@PE1# set p2mp
```

6. Configure the BGP export policy.

```
[edit policy-options policy-statement parent_vpn_routes]
user@PE1# set from protocol bgp
user@PE1# set then accept
```

7. Configure the routing instance.

The customer-facing interfaces and the BGP export policy are referenced in the routing instance.

```
[edit routing-instances vpn-1]
user@PE1# set instance-type vrf
```

```
user@PE1# set interface ge-1/2/0.2
user@PE1# set interface vt-1/2/0.2
user@PE1# set interface lo0.102
```

```
user@PE1# set route-distinguisher 100:100
user@PE1# set provider-tunnel ldp-p2mp
user@PE1# set vrf-target target:1:1
```

```
user@PE1# set protocols ospf export parent_vpn_routes
user@PE1# set protocols ospf area 0.0.0.0 interface lo0.102 passive
user@PE1# set protocols ospf area 0.0.0.0 interface ge-1/2/0.2
```

```
user@PE1# set protocols pim rp static address 100.1.1.2
```

```
user@PE1# set protocols pim interface ge-1/2/0.2 mode sparse
```

```
user@PE1# set protocols mvpn
```

8. Configure the PIM state limits.

```
[edit routing-instances vpn-1 protocols pim]
user@PE1# set sglimit family inet maximum 100
user@PE1# set sglimit family inet threshold 70
user@PE1# set sglimit family inet log-interval 10
```

```
user@PE1# set rp register-limit family inet maximum 100
user@PE1# set rp register-limit family inet threshold 80
user@PE1# set rp register-limit family inet log-interval 10
```

```
user@PE1# set rp group-rp-mapping family inet maximum 100
user@PE1# set rp group-rp-mapping family inet threshold 80
user@PE1# set rp group-rp-mapping family inet log-interval 10
```

9. Configure the router ID and AS number.

```
[edit routing-options]
user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 1001
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@PE1# show interfaces
ge-1/2/0 {
  unit 2 {
    family inet {
      address 10.1.1.2/30;
    }
    family mpls;
  }
}

        }
      }
      static {
        address 100.1.1.2;
      }
    }
    interface ge-1/2/0.2 {
      mode sparse;
    }
  }
  mvpn;
}

```

```

user@PE1# show routing-options
router-id 1.1.1.2;
autonomous-system 1001;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Monitoring the PIM State Information

Purpose Verify that the counters are set as expected and are not exceeding the configured limits.

Action From operational mode, enter the **show pim statistics** command.

```
user@PE1> show pim statistics instance vpn-1
PIM Message type      Received      Sent  Rx errors
V2 Hello              393          390      0
...
V4 (S,G) Maximum                        100
V4 (S,G) Accepted                       0
V4 (S,G) Threshold                      70
V4 (S,G) Log Interval                   10
V4 (grp-prefix, RP) Maximum             100
V4 (grp-prefix, RP) Accepted             0
V4 (grp-prefix, RP) Threshold            80
V4 (grp-prefix, RP) Log Interval         10
V4 Register Maximum                     100
V4 Register Accepted                     0
V4 Register Threshold                    80
V4 Register Log Interval                 10
```

Meaning The V4 (S,G) Maximum field shows the maximum number of (S,G) IPv4 multicast routes accepted for the VPN routing instance. If this number is met, additional (S,G) entries are not accepted.

The V4 (S,G) Accepted field shows the number of accepted (S,G) IPv4 multicast routes.

The V4 (S,G) Threshold field shows the threshold at which a warning message is logged (percentage of the maximum number of (S,G) IPv4 multicast routes accepted by the device).

The V4 (S,G) Log Interval field shows the time (in seconds) between consecutive log messages.

The V4 (grp-prefix, RP) Maximum field shows the maximum number of group-to-rendezvous point (RP) IPv4 multicast mappings accepted for the VRF routing instance. If this number is met, additional mappings are not accepted.

The V4 (grp-prefix, RP) Accepted field shows the number of accepted group-to-RP IPv4 multicast mappings.

The V4 (grp-prefix, RP) Threshold field shows the threshold at which a warning message is logged (percentage of the maximum number of group-to-RP IPv4 multicast mappings accepted by the device).

The V4 (grp-prefix, RP) Log Interval field shows the time (in seconds) between consecutive log messages.

The V4 Register Maximum field shows the maximum number of IPv4 PIM registers accepted for the VRF routing instance. If this number is met, additional PIM registers are not accepted. You configure the register limits on the RP.

The V4 Register Accepted field shows the number of accepted IPv4 PIM registers.

The V4 Register Threshold field shows the threshold at which a warning message is logged (percentage of the maximum number of IPv4 PIM registers accepted by the device).

The V4 Register Log Interval field shows the time (in seconds) between consecutive log messages.

Understanding Redundant Virtual Tunnel Interfaces in MBGP MVPNs

In multiprotocol BGP (MBGP) multicast VPNs (MVPNs), VT interfaces are needed for multicast traffic on routing devices that function as combined provider edge (PE) and provider core (P) routers to optimize bandwidth usage on core links. VT interfaces prevent traffic replication when a P router also acts as a PE router (an exit point for multicast traffic).

Starting in Junos OS Release 12.3, you can configure up to eight VT interfaces in a routing instance, thus providing Tunnel PIC redundancy inside the same multicast VPN routing instance. When the active VT interface fails, the secondary one takes over, and you can continue managing multicast traffic with no duplication.

Redundant VT interfaces are supported with RSVP point-to-multipoint provider tunnels as well as multicast LDP provider tunnels. This feature also works for extranets.

You can configure one of the VT interfaces to be the primary interface. If a VT interface is configured as the primary, it becomes the next hop that is used for traffic coming in from the core on the label-switched path (LSP) into the routing instance. When a VT interface is configured to be primary and the VT interface is used for both unicast and multicast traffic, only the multicast traffic is affected.

If no VT interface is configured to be the primary or if the primary VT interface is unusable, one of the usable configured VT interfaces is chosen to be the next hop that is used for traffic coming in from the core on the LSP into the routing instance. If the VT interface in use goes down for any reason, another usable configured VT interface in the routing instance is chosen. When the VT interface in use changes, all multicast routes in the instance also switch their reverse-path forwarding (RPF) interface to the new VT interface to allow the traffic to be received.

To realize the full benefit of redundancy, we recommend that when you configure multiple VT interfaces, at least one of the VT interfaces be on a different Tunnel PIC from the other VT interfaces. However, Junos OS does not enforce this.

Example: Configuring Redundant Virtual Tunnel Interfaces in MBGP MVPNs

This example shows how to configure redundant virtual tunnel (VT) interfaces in multiprotocol BGP (MBGP) multicast VPNs (MVPNs). To configure, include multiple VT interfaces in the routing instance and, optionally, apply the **primary** statement to one of the VT interfaces.

Requirements

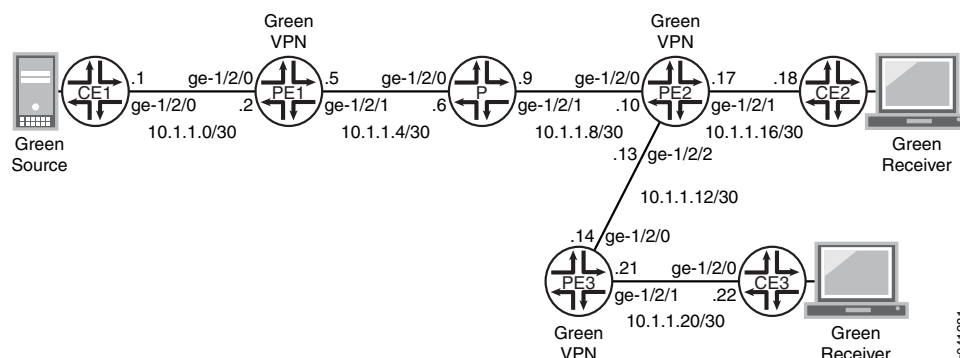

The routing device that has redundant VT interfaces configured must be running Junos OS Release 12.3 or later.

Overview

In this example, Device PE2 has redundant VT interfaces configured in a multicast LDP routing instance, and one of the VT interfaces is assigned to be the primary interface.

[Figure 117 on page 5212](#) shows the topology used in this example.

Figure 117: Multiple VT Interfaces in MBGP MVPN Topology

“CLI Quick Configuration” on page 5212 shows the configuration for the customer edge (CE), provider (P), and provider edge (PE) devices in [Figure 117 on page 5212](#). The section “Step-by-Step Procedure” on page 5215 describes the steps on Device PE2.

Configuration**CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device CE1

```

set routing-options autonomous-system 1001

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode”](#) on page 4704 in the *CLI User Guide*.

To configure redundant VT interfaces in an MBGP MVPN:

1. Configure the physical interfaces and loopback interfaces.

```

[edit interfaces]
user@PE2# set ge-1/2/0 unit 0 family inet address 10.1.1.10/30
user@PE2# set ge-1/2/0 unit 0 family mpls

user@PE2# set ge-1/2/2 unit 0 family inet address 10.1.1.13/30
user@PE2# set ge-1/2/2 unit 0 family mpls

```

```
user@PE2# set ge-1/2/1 unit 0 family inet address 10.1.1.17/30
user@PE2# set ge-1/2/1 unit 0 family mpls
```

```
user@PE2# set lo0 unit 0 family inet address 1.1.1.4/32
user@PE2# set lo0 unit 1 family inet address 100.1.1.4/32
```

2. Configure the VT interfaces.

Each VT interface is configurable under one routing instance.

```
[edit interfaces]
user@PE2# set vt-1/1/0 unit 0 family inet
user@PE2# set vt-1/2/1 unit 0 family inet
```

3. Configure MPLS on the physical interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-1/2/0.0
user@PE2# set interface ge-1/2/2.0
```

4. Configure BGP.

```
[edit protocols bgp group ibgp]
user@PE2# set type internal
user@PE2# set local-address 1.1.1.4
user@PE2# set family inet-vpn any
user@PE2# set family inet-mvpn signaling
user@PE2# set neighbor 1.1.1.2
user@PE2# set neighbor 1.1.1.5
```

5. Configure an interior gateway protocol.

```
[edit protocols ospf area 0.0.0.0]
user@PE2# set interface lo0.0 passive
user@PE2# set interface ge-1/2/0.0
user@PE2# set interface ge-1/2/2.0
```

6. Configure LDP.

```
[edit protocols ldp]
user@PE2# set interface ge-1/2/0.0
user@PE2# set interface ge-1/2/2.0
user@PE2# set p2mp
```

7. Configure the routing policy.

```
[edit policy-options policy-statement parent_vpn_routes]
user@PE2# set from protocol bgp
user@PE2# set then accept
```

8. Configure the routing instance.

```
[edit routing-instances vpn-1]
user@PE2# set instance-type vrf
user@PE2# set interface ge-1/2/1.0
user@PE2# set interface lo0.1
user@PE2# set route-distinguisher 100:100
user@PE2# set vrf-target target:1:1
user@PE2# set protocols ospf export parent_vpn_routes
user@PE2# set protocols ospf area 0.0.0.0 interface lo0.1 passive
user@PE2# set protocols ospf area 0.0.0.0 interface ge-1/2/1.0
```

```

user@PE2# set protocols pim rp static address 100.1.1.2
user@PE2# set protocols pim interface ge-1/2/1.0 mode sparse
user@PE2# set protocols mvpn

```

9. Configure redundant VT interfaces in the routing instance.

Make vt-1/1/0.0 the primary interface.

```

[edit routing-instances vpn-1]
user@PE2# set interface vt-1/1/0.0 multicast primary
user@PE2# set interface vt-1/2/1.0 multicast

```

10. Configure the router ID and autonomous system (AS) number.

```

[edit routing-options]
user@PE2# set router-id 1.1.1.4
user@PE2# set autonomous-system 1001

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@PE2# show interfaces
ge-1/2/0 {
  unit 0 {
    family inet {
      address 10.1.1.10/30;
    }
    family mpls;
  }
}
ge-1/2/2 {
  unit 0 {
    family inet {
      address 10.1.1.13/30;
    }
    family mpls;
  }
}
ge-1/2/1 {
  unit 0 {
    family inet {
      address 10.1.1.17/30;
    }
    family mpls;
  }
}
vt-1/1/0 {
  unit 0 {
    family inet;
  }
}
vt-1/2/1 {
  unit 0 {
    family inet;
  }
}

```

```
}
lo0 {
  unit 0 {
    family inet {
      address 1.1.1.4/32;
    }
  }
  unit 1 {
    family inet {
      address 100.1.1.4/32;
    }
  }
}

user@PE2# show protocols
mpls {
  interface ge-1/2/0.0;
  interface ge-1/2/2.0;
}
bgp {
  group ibgp {
    type internal;
    local-address 1.1.1.4;
    family inet-vpn {
      any;
    }
    family inet-mvpn {
      signaling;
    }
    neighbor 1.1.1.2;
    neighbor 1.1.1.5;
  }
}
ospf {
  area 0.0.0.0 {
    interface lo0.0 {
      passive;
    }
    interface ge-1/2/0.0;
    interface ge-1/2/2.0;
  }
}
ldp {
  interface ge-1/2/0.0;
  interface ge-1/2/2.0;
  p2mp;
}

user@PE2# show policy-options
policy-statement parent_vpn_routes {
  from protocol bgp;
  then accept;
}

user@PE2# show routing-instances
vpn-1 {
  instance-type vrf;
```

```

interface vt-1/1/0.0 {
    multicast;
    primary;
}
interface vt-1/2/1.0 {
    multicast;
}
interface ge-1/2/1.0;
interface lo0.1;
route-distinguisher 100:100;
vrf-target target:1:1;
protocols {
    ospf {
        export parent_vpn_routes;
        area 0.0.0.0 {
            interface lo0.1 {
                passive;
            }
            interface ge-1/2/1.0;
        }
    }
    pim {
        rp {
            static {
                address 100.1.1.2;
            }
        }
        interface ge-1/2/1.0 {
            mode sparse;
        }
    }
}
mvpn;
}

user@PE2# show routing-options
router-id 1.1.1.4;
autonomous-system 1001;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

NOTE: The `show multicast route extensive instance instance-name` command also displays the VT interface in the multicast forwarding table when multicast traffic is transmitted across the VPN.

Checking the LSP Route

Purpose Verify that the expected LT interface is assigned to the LDP-learned route.

Action 1. From operational mode, enter the `show route table mpls` command.

```

user@PE2> show route table mpls
mpls.0: 13 destinations, 13 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

```

0          *[MPLS/0] 02:09:36, metric 1
            Receive
1          *[MPLS/0] 02:09:36, metric 1
            Receive
2          *[MPLS/0] 02:09:36, metric 1
            Receive
13         *[MPLS/0] 02:09:36, metric 1
            Receive
299776     *[LDP/9] 02:09:14, metric 1
            > via ge-1/2/0.0, Pop
299776(S=0) *[LDP/9] 02:09:14, metric 1
            > via ge-1/2/0.0, Pop
299792     *[LDP/9] 02:09:09, metric 1
            > via ge-1/2/2.0, Pop
299792(S=0) *[LDP/9] 02:09:09, metric 1
            > via ge-1/2/2.0, Pop
299808     *[LDP/9] 02:09:04, metric 1
            > via ge-1/2/0.0, Swap 299808
299824     *[VPN/170] 02:08:56
            > via ge-1/2/1.0, Pop
299840     *[VPN/170] 02:08:56
            > via ge-1/2/1.0, Pop
299856     *[VPN/170] 02:08:56
            receive table vpn-1.inet.0, Pop
299872     *[LDP/9] 02:08:54, metric 1
            > via vt-1/1/0.0, Pop
            > via ge-1/2/2.0, Swap 299872

```

- From configuration mode, change the primary VT interface by removing the **primary** statement from the vt-1/1/0.0 interface and adding it to the vt-1/2/1.0 interface.

```

[edit routing-instances vpn-1]
user@PE2# delete interface vt-1/1/0.0 primary
user@PE2# set interface vt-1/2/1.0 primary
user@PE2# commit

```

- From operational mode, enter the **show route table mpls** command.

```

user@PE2> show route table mpls
mpls.0: 13 destinations, 13 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

```

0          *[MPLS/0] 02:09:36, metric 1
            Receive
1          *[MPLS/0] 02:09:36, metric 1
            Receive
2          *[MPLS/0] 02:09:36, metric 1
            Receive
13         *[MPLS/0] 02:09:36, metric 1
            Receive
299776     *[LDP/9] 02:09:14, metric 1
            > via ge-1/2/0.0, Pop
299776(S=0) *[LDP/9] 02:09:14, metric 1
            > via ge-1/2/0.0, Pop
299792     *[LDP/9] 02:09:09, metric 1
            > via ge-1/2/2.0, Pop
299792(S=0) *[LDP/9] 02:09:09, metric 1
            > via ge-1/2/2.0, Pop

```

```

299808      *[LDP/9] 02:09:04, metric 1
              >   via ge-1/2/0.0, Swap 299808
299824      *[VPN/170] 02:08:56
              >   via ge-1/2/1.0, Pop
299840      *[VPN/170] 02:08:56
              >   via ge-1/2/1.0, Pop
299856      *[VPN/170] 02:08:56
              receive table vpn-1.inet.0, Pop
299872      *[LDP/9] 02:08:54, metric 1
              >   via vt-1/2/1.0, Pop
              via ge-1/2/2.0, Swap 299872

```

Meaning With the original configuration, the output shows the vt-1/1/0.0 interface. If you change the primary interface to vt-1/2/1.0, the output shows the vt-1/2/1.0 interface.

Introduction to Configuring MBGP MVPNs

You configure multiprotocol BGP-based (MBGP) multicast VPNs (MVPNs) at a number of different hierarchy levels within the Junos OS. However, a majority of MBGP MVPN statements are configured within a routing instance as follows:

```

description text;
instance-type vrf;
interface interface-name;
route-distinguisher (as-number:number | ip-address:number);
vrf-export [policy-names];
vrf-import [policy-names];
vrf-target (community | export community-name | import community-name);

```

```
protocols {
  mvpn {
    mvpn-mode (rpt-spt | spt-only);
    receiver-site;
    sender-site;
    route-target {
      export-target {
        target target-community;
        unicast;
      }
      import-target {
        target {
          target-value;
          receiver target-value;
          sender target-value;
        }
        unicast {
          receiver;
          sender;
        }
      }
    }
  }
}
provider-tunnel {
  ldp-p2mp;
  pim-ssm {
    group-address address;
  }
  rsvp-te {

Configuring Routing Instances for an MBGP MVPN

To configure MBGP MVPNs, include the **mvpn** statement:

```
mvpn {
  mvpn-mode (rpt-spt | spt-only);
  receiver-site;
  route-target {
    export-target {
      target target-community;
      unicast;
    }
    import-target {
      target {
        target-value;
        receiver target-value;
        sender target-value;
      }
      unicast {
        receiver;
        sender;
      }
    }
  }
  sender-site;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]

By default an MBGP MVPN routing instance is associated with both the multicast sender and the receiver sites. If you configure the **receiver-site** option, the routing instance is associated with only multicast receiver sites. Configuring the **sender-site** option associates the routing instance with only multicast sender sites.

NOTE: When you configure the routing instance for the MBGP MVPN, you must configure MPLS LSPs (either RSVP-signaled or LDP-signaled) between the PE routers of the routing instance to ensure VPN unicast connectivity. Point-to-multipoint LSPs are used for multicast data forwarding only.

Configuring SPT-Only Mode for Multiprotocol BGP-Based Multicast VPNs

For MBGP MVPNs (also referred to as next-generation Layer 3 multicast VPNs), the default mode of operation is shortest path tree only (SPT-only) mode. In SPT-only mode, the active multicast sources are learned through multicast VPN source-active routes. This mode of operation is described in section 14 of the BGP-MVPN draft (draft-ietf-l3vpn-2547bis-mcast-bgp-00.txt).

In contrast to SPT-only mode, rendezvous point tree (RPT)-SPT mode (also known as shared-tree data distribution) supports the native PIM model of transmitting (*G) messages from the receiver to the RP for intersite shared-tree join messages.

In SPT-only mode, when a PE router receives a (*, C-G) join message, the router looks for an active source transmitting data to the customer group. If the PE router has a source-active route for the customer group, the router creates a source tree customer multicast route and sends the route to the PE router connected to the VPN site with the source. The source is determined by MVPN's single-forwarder election. When a receiver sends a (*G) join message in a VPN site, the (*G) join message only travels as far as the PE router. After the join message is converted to a type 6 multicast route, which is equivalent to a (S,G) join message, the route is installed with the no-advertise community setting.

NOTE: The MVPN single-forwarder election follows the rule documented in section 9.1.1 of the BGP-MVPN draft (draft-ietf-l3vpn-2547bis-mcast-bgp-00.txt). The single-forwarder election winner is based on the following rules:

- If the active unicast route to the source is through the interface, then this route is used to determine the upstream multicast hop (UMH).
- If the active unicast route to the source is a VPN route, MVPN selects the UMH based on the highest IP address in the route import community for the VPN routes, and the local master loopback address for local VRF routes.

Single-forwarder election guarantees selection of a unique forwarder for a given customer source (C-S). The upstream PE router might differ for the source tree and the shared tree because the election is based on the customer source and C-RP, respectively. Although the single-forwarder election is sufficient for SPT-only mode, the alternative RPT-SPT mode involves procedures to prevent duplicate traffic from being sent on the shared tree and the source tree. These procedures might require administrator-configured parameters to reduce duplicate traffic and reduce blackholes during RPT to SPT switch and the reverse.

In SPT-only mode, when a source is active, PIM creates a register state for the source both on the DR and on the C-RP (or on a PE router that is running Multicast Source Discovery Protocol [MSDP] between itself and the C-RP). After the register states are created, MVPN creates a source-active route. These type 5 source-active routes are installed on all PE routers. When the egress PE router with the (*G) join message receives the source-active route, it has two routes that it can combine to produce the (S,G)

multicast route. The type 6 route informs the PE router that a receiver is interested in group G. The source active route informs the PE router that a source S is transmitting data to group G. MVPN combines this information to produce a multicast join message and advertises this to the ingress PE router, as determined by the single-forwarder election.

NOTE: If you are using a Trio FPC, the MVPN sender PE router can not have a local receiver.

For some service providers, the SPT-only implementation is not ideal because it creates a restriction on C-RP configuration. For a PE router to create customer multicast routes from (* C-G) join messages, the router must learn about active sources through MVPN type 5 source-active routes. These source-active routes can be originated only by a PE router. This means that a PE router in the MVPN must learn about all PIM register messages sent to the RP, which is possible only in the following cases:

- The C-RP is colocated on one of the PEs in the MVPN.
- MSDP is run between the C-RP and the VRF instance on one of the PE routers in the MVPN.

If this restriction is not acceptable, providers can use RPT-SPT mode instead of the default SPT-only mode. However, because SPT-only mode does not transmit (*G) routes between VPN sites, SPT-only mode has the following advantages over RPT-SPT mode:

- Simplified operations by exchanging and processing only source-tree customer multicast routes among PE routers
- Simplified operations by eliminating the need for the service provider to suppress MVPN transient duplicates during the switch from RPT to SPT
- Less control plane overhead in the service provider space by limiting the type of customer multicast routes exchanged, which results in more scalable deployments
- More stable traffic patterns in the backbone without the traffic shifts involved in the RPT-SPT mode
- Easier maintenance in the service provider space due to less state information

To configure SPT-only mode:

1. Explicitly configure SPT-only mode:

```
[edit routing-instances routing-instance-name protocols mvpn mvpn-mode]  
user@router# set spt-only
```

2. Include the **spt-only** statement for all VRFs that make up the VPN.

Related Documentation

- [Configuring Shared-Tree Data Distribution Across Provider Cores for Providers of MBGP MVPNs on page 5227](#)
- [Understanding Wildcards to Configure Selective Point-to-Multipoint LSPs for an MBGP MVPN on page 5153](#)

Configuring Shared-Tree Data Distribution Across Provider Cores for Providers of MBGP MVPNs

For MBGP MVPNs (also referred to as next-generation Layer 3 multicast VPNs), the default mode of operation supports only intersite shortest-path trees (SPTs) for customer PIM (C-PIM) join messages. It does not support rendezvous-point trees (RPTs) for C-PIM join messages. The default mode of operation provides advantages, but it requires either that the customer rendezvous point (C-RP) be located on a PE router or that the Multicast Source Discovery Protocol (MSDP) be used between the C-RP and a PE router so that the PE router can learn about active sources advertised by other PE routers.

If the default mode is not suitable for your environment, you can configure RPT-SPT mode (also known as *shared-tree data distribution*), as documented in section 13 of the BGP-MVPN draft (draft-ietf-l3vpn-2547bis-mcast-bgp-00.txt). RPT-SPT mode supports the native PIM model of transmitting (*G) messages from the receiver to the RP for intersite shared-tree join messages. This means that the type 6 (*G) routes get transmitted from one PE router to another. In RPT-SPT mode, the shared-tree multicast routes are advertised from an egress PE router to the upstream router connected to the VPN site with the C-RP. The single-forwarder election is performed for the C-RP rather than for the source. The egress PE router takes the upstream hop to advertise the (*G) and sends the type 6 route toward the upstream PE router. To send the data on the RPT, either inclusive or selective provider tunnels can be used. After the data starts flowing on the RPT, the last-hop router switches to SPT mode, unless you include the **spt-threshold infinity** statements in the configuration.

NOTE: The MVPN single-forwarder election follows the rule documented in section 9.1.1 of the BGP-MVPN draft (draft-ietf-l3vpn-2547bis-mcast-bgp-00.txt). The single-forwarder election winner is based on the following rules:

- If the active unicast route to the source is through the interface, then this route is used to determine the upstream multicast hop (UMH).
- If the active unicast route to the source is a VPN route, MVPN selects the UMH based on the highest IP address in the route import community for the VPN routes, and the local master loopback address for local VRF routes.

The switch to SPT mode is performed by PIM and not by MVPN type 5 and type 6 routes. After the last-hop router switches to SPT mode, the SPT (S,G) join messages follow the same rules as the SPT-only default mode.

The advantage of RPT-SPT mode is that it provides a method for PE routers to discover sources in the multicast VPN when the C-RP is located on the customer site instead of on a PE router. Because the shared C-tree is established between VPN sites, there is no need to run MSDP between the C-RP and the PE routers. RPT-SPT mode also enables egress PE routers to switch to receiving data from the PE connected to the source after the source information is learned, instead of receiving data from the RP.

CAUTION: When you configure RPT-SPT mode, receivers or sources directly attached to the PE router are not supported. As a workaround, place a CE router between any receiver or source and the PE router.

To configure RPT-SPT mode:

1. Enable shared-tree data distribution:

```
[edit routing-instances routing-instance-name protocols mvpn mvpn-mode]
user@router# set rpt-spt
```

2. Include the **rpt-spt** statement for all VRFs that make up the VPN.

Limiting Routes to Be Advertised by an MVPN VRF Instance

If a hub-and-spoke deployment uses one VPN routing and forwarding (VRF) routing instance for unicast routing and a separate VRF for MVPN routing, you need to limit the PE routers at the hub site to advertise only IPv4 MVPN routes, only IPv6 MVPN routes, or both. This is necessary to prevent the multicast VRF instance from advertising unicast VPN routes to other PE routers.

NOTE: This configuration does not prevent the exportation of VPN routes to other VRF instances on the same router if the **auto-export** statement is included in the **[edit routing-options]** hierarchy.

To configure a VRF routing instance with the name **green** to advertise MVPN routes from both the **inet** and **inet6** address families, perform the following steps:

1. Configure the VRF routing instance to advertise IPv4 routes.

```
user@host# set routing-instances green vrf-advertise-selective family inet-mvpn
```

2. Configure the VRF routing instance to advertise IPv6 routes.

```
user@host# set routing-instances green vrf-advertise-selective family inet6-mvpn
```

After the configuration is committed, only the MVPN routes for the specified address families are advertised from the VRF instance to remote PE routers. To remove the restriction on routes being advertised, delete the **vrf-advertise-selective** statement.

NOTE: You cannot include the `vrf-advertise-selective` statement and the `no-vrf-advertise` statement in the same VRF configuration. However, if you configure the `vrf-advertise-selective` statement without any of its options, the router has the same behavior as if you configured the `no-vrf-advertise` statement. VPN routes are prevented from being advertised from a VRF routing instance to the remote PE routers.

Configuring VRF Route Targets for Routing Instances for an MBGP MVPN

By default, the VPN routing and forwarding (VRF) import and export route targets (configured either using VRF import and export policies or using the **vrf-target** statement) are used for importing and exporting routes with the MBGP MVPN network layer reachability information (NLRI).

You can use the **export-target** and **import-target** statements to override the default VRF import and export route targets. Export and import targets can also be specified specifically for sender sites or receiver sites, or can be borrowed from a configured unicast route target. Note that a sender site export route target is always advertised when security association routes are exported.

NOTE: When you configure an MBGP MVPN routing instance, you should not configure a target value for an MBGP MVPN specific route target that is identical to a target value for a unicast route target configured in another routing instance.

Specifying route targets in the MBGP MVPN NLRI for sender and receiver sites is useful when there is a mix of sender only, receiver only, and sender and receiver sites. A sender site route target is used for exporting automatic discovery routes by a sender site and for importing automatic discovery routes by a receiver site. A receiver site route target is used for exporting routes by a receiver site and importing routes by a sender site. A sender and receiver site exports and imports routes with both route targets.

A provider edge (PE) router with sites in a specific MBGP MVPN must determine whether a received automatic discovery route is from a sender site or receiver site based on the following:

- If the PE router is configured to be only in a sender site, route targets are imported only from receiver sites. Imported automatic discovery routes must be from a receiver site.

- If the PE router is configured to be only in a receiver site, route targets are imported only from sender sites. Imported automatic discovery routes must be from a sender site.
- If a PE router is configured to be in both sender sites and receiver sites, these guidelines apply:
 - Along with an import route target, you can optionally configure whether the route target is from a receiver or a sender site.
 - If a configuration is not provided, an imported automatic discovery route is treated as belonging to both the sender site set and the receiver site set.

To configure a route target for the MBGP MVPN routing instance, include the **route-target** statement:

```
route-target {  
  export-target {  
    target target-community;  
    unicast;  
  }  
  import-target {  
    target {  
      target-value;  
      receiver target-value;  
      sender target-value;  
    }  
    unicast {  
      receiver;  
      sender;  
    }  
  }  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols mvpn]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols mvpn]

The following sections describes how to configure the export target and the import target for an MBGP MVPN:

- [Configuring the Export Target for an MBGP MVPN on page 5230](#)
- [Configuring the Import Target for an MBGP MVPN on page 5231](#)

Configuring the Export Target for an MBGP MVPN

To configure an export target, include the **export-target** statement:

```
export-target {  
  target target-community;  
  unicast;  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols mvpn route-target]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols mvpn route target]

Configure the **target** option to specify the export target community. Configure the **unicast** option to use the same target community that has been specified for unicast.

Configuring the Import Target for an MBGP MVPN

To configure an import target, include the **import-target** statement:

```
import-target {
  target target-value {
    receiver;
    sender;
  }
  unicast {
    receiver;
    sender;
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols mvpn route-target]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols mvpn route-target]

The following sections describe how to configure the import target and unicast parameters:

- [Configuring the Import Target Receiver and Sender for an MBGP MVPN on page 5231](#)
- [Configuring the Import Target Unicast Parameters for an MBGP MVPN on page 5232](#)

Configuring the Import Target Receiver and Sender for an MBGP MVPN

To configure the import target community, include the **target** statement and specify the target community. The target community must be in the format **target:x:y**. The x value is either an IP address or an AS number followed by an optional L to indicate a 4 byte AS number, and y is a number (for example, **target:123456L:100**)

```
target target-value {
  receiver;
  sender;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols mvpn route-target import-target]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols mvpn route-target import-target]

You can specify the target community used when importing either receiver site sets or sender site sets by including one of the following statements:

- **receiver**—Specify the target community used when importing receiver site sets.
- **sender**—Specify the target community used when importing sender site sets.

Configuring the Import Target Unicast Parameters for an MBGP MVPN

To configure a unicast target community as the import target, include the **unicast** statement:

```
unicast {  
    receiver;  
    sender;  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols mvpn route-target import-target]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols mvpn route-target import-target]

You can specify the unicast target community used when importing either receiver site sets or sender site sets by including one of the following statements:

- **receiver**—Specify the unicast target community used when importing receiver site sets.
- **sender**—Specify the unicast target community used when importing sender site sets.

Configuring NLRI Parameters for an MBGP MVPN

To enable VPN signaling where multiprotocol BGP carries multicast VPN NLRI for the IPv4 address family, include the **family inet-mvpn** statement:

```
inet-mvpn {  
    signaling {  
        accepted-prefix-limit {  
            maximum number;  
            teardown percentage {  
                idle-timeout (forever | minutes);  
            }  
        }  
        loops number;  
        prefix-limit {  
            maximum number;  
            teardown percentage {  
                idle-timeout (forever | minutes);  
            }  
        }  
    }  
}
```

To enable VPN signaling where multiprotocol BGP carries multicast VPN NLRI for the IPv6 address family, include the **family inet6-mvpn** statement:

```

inet6-mvpn {
  signaling {
    accepted-prefix-limit {
      maximum number;
      teardown percentage {
        idle-timeout (forever | minutes);
      }
    }
  }
  loops number
  prefix-limit {
    maximum number;
    teardown percentage {
      idle-timeout (forever | minutes);
    }
  }
}

```

Configuring PIM Provider Tunnels for an MBGP MVPN

To configure a Protocol Independent Multicast (PIM) sparse mode provider tunnel for a multicast VPN, include the **pim-asm** statement:

```

pim-asm {
  group-address address;
}

```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel]

To complete the PIM sparse mode provider tunnel configuration, you also need to specify the group address using the **group-address** option. The source address for a PIM sparse mode provider tunnel is configured to be the loopback address of the loopback interface in the **inet.0** routing table.

Configuring PIM-SSM GRE Selective Provider Tunnels

This topic describes how to configure a PIM-SSM GRE selective provider tunnel for an MBGP MVPN. A selective provider tunnel uses a point-to-multipoint LSP.

Creating a selective provider tunnel enables you to move high-rate traffic off the inclusive tunnel and deliver the multicast traffic only to receivers that request it. This improves bandwidth utilization.

To configure a PIM-SSM GRE selective provider tunnel for the 224.1.1.1/32 customer multicast group address, the 10.2.2.2/32 customer source address, and a virtual routing instance named **green**:

1. Configure the multicast group address range to be used for creating selective tunnels. The address prefix can be any valid nonreserved IPv4 multicast address range. Whether you configure a range of addresses or a single address, make sure that you configure enough group addresses for all the selective tunnels needed.

```
user@host# set routing-instances green provider-tunnel selective group 224.1.1.1/32
source 10.2.2.2/32 pim-ssm group-range 232.1.1.0/24
```

2. Configure the threshold rate in kilobits per second (Kbps) for triggering the creation of the selective tunnel. If you set the threshold rate to zero Kbps, the selective tunnel is created immediately, and the multicast traffic does not use an inclusive tunnel at all. Optionally, you can leave the threshold rate unconfigured and the result is the same as setting the threshold to zero.

```
user@host# set routing-instances green provider-tunnel selective group 224.1.1.1/32
source 10.2.2.2/32 threshold-rate 0
```

3. Configure the autonomous system number in the global routing options. This is required in MBGP MVPNs.

```
user@host# set routing-options autonomous-system 100
```

When configuring PIM-SSM GRE selective provider tunnels, keep the following in mind:

- Aggregation of multiple customer multicast routes to a single PIM S-PMSI is not supported.
- Provider tunnel multicast group addresses must be IPv4 addresses, even in configurations in which the customer multicast group and source are IPv6 addresses.

**Related
Documentation**

Configuring Point-to-Multipoint LSPs for an MBGP MVPN

The Junos OS supports point-to-multipoint label-switched paths (LSPs) for MBGP MVPNs. Point-to-multipoint LSPs for multicast VPNs are supported for intra-autonomous system (AS) environments (within an AS), but are not supported for inter-AS environments (between autonomous systems). A point-to-multipoint LSP is an RSVP-signaled LSP with a single source and multiple destinations.

You can configure point-to-multipoint LSPs for MBGP MVPNs as follows:

- Static point-to-multipoint LSPs—Configure static point-to-multipoint LSPs using the standard MPLS LSP statements specified at the **[edit protocols mpls]** hierarchy level. You manually configure each of the leaf nodes for the point-to-multipoint LSP.
- Dynamic point-to-multipoint LSPs using the default template—Configuring dynamic point-to-multipoint LSPs using the **default-template** option causes the leaf nodes to be discovered automatically. The leaf nodes are discovered through BGP intra-AS automatic discovery. The **default-template** option allows you to minimize the amount of configuration needed. However, it does not allow you to configure any of the standard MPLS options.
- Dynamic point-to-multipoint LSPs using a user-configured template—Configuring dynamic point-to-multipoint LSPs using a user-configured template also causes the

leaf nodes to be discovered automatically. By creating your own template for the point-to-multipoint LSPs, all of the standard MPLS features (such as bandwidth allocation and traffic engineering) can be configured.

Be aware of the following properties for the egress PE router in a point-to-multipoint LSP configured for a multicast VPN:

- Penultimate hop-popping is not used by point-to-multipoint LSPs for multicast VPNs. Only ultimate hop-popping is used.
- You must configure either the **vrf-table-label** statement or a virtual loopback tunnel interface on the egress PE router.
- If you configure the **vrf-table-label** statement on the egress PE router, and the egress PE router is also a transit router for the point-to-multipoint LSP, the penultimate hop router sends two copies of each packet over the link to the egress PE router.
- If you configure the **vrf-table-label** statement on the egress PE router, and the egress PE router is not a transit router for the point-to-multipoint LSP, the penultimate hop router can send just one copy of each packet over the link to the egress PE router.
- If you configure a virtual loopback tunnel interface on the egress PE router, and the egress PE router is also a transit router for the point-to-multipoint LSP, the penultimate hop router sends just one copy of each packet over the link to the egress PE router. A virtual loopback tunnel interface can perform two lookups on an incoming packet, one for the multicast MPLS lookup and one for the IP lookup.

NOTE: Junos OS Release 11.2 and earlier do not support point-to-multipoint LSPs with next-generation multicast VPNs on MX80 routers.

The following sections describe how to configure point-to-multipoint LSPs for MBGP MVPNs:

- [Configuring RSVP-Signaled Inclusive Point-to-Multipoint LSPs for an MBGP MVPN on page 5235](#)
- [Configuring Selective Provider Tunnels for an MBGP MVPN on page 5236](#)

Configuring RSVP-Signaled Inclusive Point-to-Multipoint LSPs for an MBGP MVPN

You can configure LDP-signaled or RSVP-signaled inclusive point-to-multipoint LSPs for MBGP MVPNs. Aggregation is not supported, so you need to configure an inclusive point-to-multipoint LSP for each sender PE router in each multicast VPN routing instance. The sender PE router is in the sender site set of the MBGP MVPN.

To configure a static RSVP-signaled inclusive point-to-multipoint LSP, include the **static-lsp** statement:

```
static-lsp lsp-name;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* provider-tunnel rsvp-te]**

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel rsvp-te]

To configure dynamic inclusive point-to-multipoint LSPs, include the **label-switched-path-template** statement:

```
label-switched-path-template {  
  (default-template | lsp-template-name);  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel rsvp-te]

You can configure either the **default-template** option or manually configure a point-to-multipoint LSP template and specify the template name.

Configuring Selective Provider Tunnels for an MBGP MVPN

You can configure LDP-signaled or RSVP-signaled selective point-to-multipoint LSPs (also referred to as selective provider tunnels) for MBGP MVPNs. Selective point-to-multipoint LSPs send traffic only to the receivers configured for the multicast VPNs, helping to minimize flooding in the service provider's network.

As with inclusive point-to-multipoint LSPs, you can configure both dynamic and static selective tunnels for the multicast VPN.

To configure selective point-to-multipoint provider tunnels, include the **selective** statement:

```
selective {  
  group multicast--prefix/prefix-length {  
    source ip--prefix/prefix-length {  
      ldp-p2mp;  
      pim-ssm {  
        group-range multicast-prefix;  
      }  
      rsvp-te {  
        label-switched-path-template {  
          (default-template | lsp-template-name);  
        }  
        static-lsp point-to-multipoint-lsp-name;  
      }  
      threshold-rate kbits;  
    }  
  }  
  wildcard-source {  
    ldp-p2mp;  
    pim-ssm {  
      group-range multicast-prefix;  
    }  
    rsvp-te {  
      label-switched-path-template {  
        (default-template | lsp-template-name);  
      }  
    }  
  }  
}
```

```

        }
        static-lsp point-to-multipoint-lsp-name;
    }
    threshold-rate kbits;
}
}
tunnel-limit number;
wildcard-group-inet {
    wildcard-source {
        ldp-p2mp;
        pim-ssm {
            group-range multicast-prefix;
        }
        rsvp-te {
            label-switched-path-template {
                (default-template | lsp-template-name);
            }
            static-lsp lsp-name;
        }
        threshold-rate number;
    }
}
wildcard-group-inet6 {
    wildcard-source {
        ldp-p2mp;
        pim-ssm {
            group-range multicast-prefix;
        }
        rsvp-te {
            label-switched-path-template {
                (default-template | lsp-template-name);
            }
            static-lsp lsp-name;
        }
        threshold-rate number;
    }
}
}

```

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel]

The following sections describe how to configure selective point-to-multipoint LSPs for MBGP MVPNs:

- [Configuring the Multicast Group Address for an MBGP MVPN on page 5238](#)
- [Configuring the Multicast Source Address for an MBGP MVPN on page 5238](#)
- [Configuring Static Selective Point-to-Multipoint LSPs for an MBGP MVPN on page 5238](#)
- [Configuring Dynamic Selective Point-to-Multipoint LSPs for an MBGP MVPN on page 5239](#)

- [Configuring the Threshold for Dynamic Selective Point-to-Multipoint LSPs for an MBGP MVPN on page 5239](#)
- [Configuring the Tunnel Limit for Dynamic Selective Point-to-Multipoint LSPs for an MBGP MVPN on page 5240](#)

Configuring the Multicast Group Address for an MBGP MVPN

To configure a point-to-multipoint LSP for an MBGP MVPN, you need to specify a multicast group address by including the **group** statement:

```
group address { ... }
```

You can include this statements at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* provider-tunnel selective]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel selective]**

The address must be a valid multicast group address. Multicast uses the Class D IP address range (224.0.0.0 through 239.255.255.255).

Configuring the Multicast Source Address for an MBGP MVPN

To configure a point-to-multipoint LSP for an MBGP MVPN, specify a multicast source address by including the **source** statement:

```
source address { ... }
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* provider-tunnel selective group address]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel selective group address]**

Configuring Static Selective Point-to-Multipoint LSPs for an MBGP MVPN

You can configure a static selective point-to-multipoint LSP for an MBGP MVPN. You need to configure a static LSP using the standard MPLS LSP statements at the **[edit protocols mpls]** hierarchy level. You then include the static LSP in your selective point-to-multipoint LSP configuration by using the **static-lsp** statement. Once this functionality is enabled on the source PE router, the static point-to-multipoint LSP is created based on your configuration.

To configure a static selective point-to-multipoint LSP, include the **rsvp-te** and the **static-lsp** statements:

```
rsvp-te static-lsp lsp-name;
```

You can include these statements at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* provider-tunnel selective group address source *source-address*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel selective group address source *source-address*]**

Configuring Dynamic Selective Point-to-Multipoint LSPs for an MBGP MVPN

You can configure a dynamic selective point-to-multipoint LSP for an MBGP MVPN. The leaf nodes for a dynamic point-to-multipoint LSP can be automatically discovered using leaf automatic discovery routes. Selective provider multicast service interface (S-PMSI) automatic discovery routes are also supported.

To configure a dynamic selective point-to-multipoint provider tunnel, include the **rsvp-te** and **label-switched-path-template** statements:

```
rsvp-te label-switched-path-template {
  (default-template | lsp-template-name);
}
```

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel selective group address source *source-address*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel selective group address source *source-address*]

The **label-switched-path-template** statement includes the following options:

- **default-template**—Specify that point-to-multipoint LSPs are generated dynamically based on the default template. No user configuration is required for the LSPs. However, the automatically generated LSPs include none of the common LSP features, such as bandwidth allocation and traffic engineering.
- ***lsp-template-name***—Specify the name of an LSP template to be used for the point-to-multipoint LSP. You need to configure the LSP template to be used as a basis for the point-to-multipoint LSPs. You can configure any of the common LSP features for this template.

Configuring the Threshold for Dynamic Selective Point-to-Multipoint LSPs for an MBGP MVPN

To configure a selective point-to-multipoint LSP dynamically, you need to specify the data threshold (in kilobits per second) required before a new tunnel is created using the **threshold-rate** statement:

```
threshold-rate number;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel selective group address source *source-address*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel selective group address source *source-address*]

Configuring the Tunnel Limit for Dynamic Selective Point-to-Multipoint LSPs for an MBGP MVPN

To configure a limit on the number of tunnels that can be generated for a dynamic point-to-multipoint LSP, include the **tunnel-limit** statement:

```
tunnel-limit number;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel selective]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel selective]

Configuring a Selective Provider Tunnel Using Wildcards

When you configure a selective provider tunnel for MBGP MVPNs (also referred to as next-generation Layer 3 multicast VPNs), you can use wildcards for the multicast group and source address prefixes. Using wildcards enables a PE router to use a single route to advertise the binding of multiple multicast streams of a given MVPN customer to a single provider's tunnel, as described in

<http://tools.ietf.org/html/draft-rekhter-mvpn-wildcard-spmsi-00>.

Sharing a single route improves control plane scalability because it reduces the number of S-PMSI autodiscovery routes.

To configure a selective provider tunnel using wildcards:

1. Configure a wildcard group matching any group IPv4 address and a wildcard source for (*,*) join messages.

```
[edit routing-instances vpn provider-tunnel selective]
user@router# set wildcard-group-inet wildcard-source
```

2. Configure a wildcard group matching any group IPv6 address and a wildcard source for (*,*) join messages.

```
[edit routing-instances vpn provider-tunnel selective]
user@router# set wildcard-group-inet6 wildcard-source
```

3. Configure an IP prefix of a multicast group and a wildcard source for (*,G) join messages.

```
[edit routing-instances vpn provider-tunnel selective]
user@router# set group 224.0.0/24 wildcard-source
```

4. Map the IPv4 join messages to a selective provider tunnel.

```
[edit routing-instances vpn provider-tunnel selective wildcard-group-inet
wildcard-source]
user@router# set rsvp-te (Routing Instances Provider Tunnel Selective)
label-switched-path-template provider-tunnel
```

5. Map the IPv6 join messages to a selective provider tunnel.

```
[edit routing-instances vpna provider-tunnel selective wildcard-group-inet6
wildcard-source]
user@router# set rsvp-te (Routing Instances Provider Tunnel Selective)
label-switched-path-template provider-tunnel2
```

6. Map the (*,224.0.0/24) join messages to a selective provider tunnel.

```
[edit routing-instances vpna provider-tunnel selective group 224.0.0/24
wildcard-source]
user@router# set rsvp-te (Routing Instances Provider Tunnel Selective)
label-switched-path-template provider-tunnel3
```

Example: Configuring Selective Provider Tunnels Using Wildcards

With the (*,G) and (*,*) S-PMSI, a customer multicast join message can match more than one S-PMSI. In this case, a customer multicast join message is bound to the longest matching S-PMSI. The longest match is a (S,G) S-PMSI, followed by a (*,G) S-PMSI and a (*,*) S-PMSI, in that order.

Consider the following configuration:

```
routing-instances {
  vpna {
    provider-tunnel {
      selective {
        wildcard-group-inet {
          wildcard-source {
            rsvp-te {
              label-switched-path-template {
                sptnl1;
              }
            }
          }
        }
      }
    }
    group 224.1.1.0/24 {
      wildcard-source {
        rsvp-te {
          label-switched-path-template {
            sptnl2;
          }
        }
      }
    }
    source 10.1.1/24 {
      rsvp-te {
```

```
label-switched-path-template {  
    sptnl3;  
}  
}  
}  
}  
}  
}  
}
```

For this configuration, the longest-match rule works as follows:

- A customer multicast (10.1.1.1, 224.1.1.1) join message is bound to the sptnl3 S-PMSI autodiscovery route.
- A customer multicast (10.2.1.1, 224.1.1.1) join message is bound to the sptnl2 S-PMSI autodiscovery route.
- A customer multicast (10.1.1.1, 224.2.1.1) join message is bound to the sptnl1 S-PMSI autodiscovery route.

When more than one customer multicast route is bound to the same wildcard S-PMSI, only one S-PMSI autodiscovery route is created. An egress PE router always uses the same matching rules as the ingress PE router that advertises the S-PMSI autodiscovery route. This ensures consistent customer multicast mapping on the ingress and the egress PE routers.

Configuring Internet Multicast Using Ingress Replication Provider Tunnels

The routing instance type `mpls-internet-multicast` uses ingress replication provider tunnels to carry IP multicast data between routers through an MPLS cloud, enabling a faster path for multicast traffic between sender and receiver routers in large-scale implementations.

The `mpls-internet-multicast` routing instance is a non-forwarding instance used only for control plane procedures; it does not support any interface configurations. Only one `mpls-internet-multicast` routing instance can be defined for a logical system. All multicast and unicast routes used for Internet multicast are associated only with the master instance (`inet.0`), not with the routing instance.

Each router participating in Internet multicast must be configured with BGP MPLS-based Internet multicast for control plane procedures and with ingress replication for the data plane provider tunnel, which forms a full mesh of MPLS point-to-point LSPs. The ingress replication tunnel can be selective or inclusive, matching the configuration of the provider tunnel in the routing instance.

The topology consists of routers on the edge of the IP multicast domain that have a set of IP interfaces and a set of MPLS core-facing interfaces, see [Figure 118 on page 5244](#). Internet multicast traffic is carried between the IP routers, through the MPLS cloud, using ingress replication tunnels for the data plane and a full-mesh IGBP session for the control plane.

Figure 118: Internet Multicast Topology

The `mpls-internet-multicast` routing instance type is configured for the default master instance on each router to support Internet multicast over MPLS. When using PIM as the multicast protocol, the `mpls-internet-multicast` configuration statement is also included at the `[edit protocols pim]` hierarchy level in the master instance. This creates a pseudo-interface that associates PIM with the `mpls-internet-multicast` routing instance.

When a new destination needs to be added to the ingress replication provider tunnel, the resulting behavior differs depending on how the ingress replication provider tunnel is configured:

- `create-new-ucast-tunnel`—When this statement is configured, a new unicast tunnel to the destination is created, and is deleted when the destination is no longer needed. Use this mode for RSVP LSPs using ingress replication.
- `label-switched-path-template`—When this statement is configured, an LSP template is used for the point-to-multipoint LSP for ingress replication.

Example: Configure Internet Multicast Using Ingress Replication Tunnels

This example configures VPN-B with the instance type **mpls-internet-multicast**. This example also uses PIM for the multicast protocol.

1. Configure the routing instance type for VPN-B as **mpls-internet-multicast**:

```
user@host# set routing-instances VPN-B instance-type mpls-internet-multicast
```

2. Configure the ingress replication provider tunnel to create a new unicast tunnel each time an application requests to add a destination:

```
user@host# set routing-instances VPN-B provider-tunnel ingress-replication
create-new-ucast-tunnel
```

3. Configure the point-to-point LSP to use the default template settings.

```
user@host# set routing-instances VPN-B provider-tunnel ingress-replication
label-switched-path label-switched-path-template default-template
```

4. Configure the ingress replication provider tunnel to be selective:

```
user@host# set routing-instances VPN-B provider-tunnel selective group
232.1.1.1/32 source 192.168.195.145/32 ingress-replication label-switched-path
```

5. Configure MVPN protocol in the routing instance:

```
user@host# set routing-instances VPN-B protocols mvpn
```

6. Commit the configuration:

```
user@host# commit
```

7. Use show command to verify the instance has been created:

```
user@host# run show mvpn instance VPN-B
MVPN instance:
Legend for provider tunnel I-P-tnl -- inclusive provider tunnel S-P-tnl --
selective provider tunnel
Legend for c-multicast routes properties (Pr)
DS -- derived from (*, c-g)          RM -- remote VPN route
Instance : VPN-B
MVPN Mode : SPT-ONLY
Provider tunnel: I-P-tnl:INGRESS-REPLICATION:MPLS Label 18:10.255.245.6
Neighbor          I-P-tnl
10.255.245.2       INGRESS-REPLICATION:MPLS Label 22:10.255.245.2
10.255.245.7       INGRESS-REPLICATION:MPLS Label 19:10.255.245.7
C-mcast IPv4 (S:G) Ptnl          St
192.168.195.145/32:232.1.1.1/32 INGRESS-REPLICATION:MPLS Label
18:10.255.245.6          RM
```

8. Add the **mpls-internet-multicast** configuration statement under the **[edit protocols pim]** hierarchy level in the master instance:

```
user@host# set protocols pim mpls-internet-multicast
```

9. Commit the configuration:

```
user@host# commit
```

10. Use **show ingress-replication mvpn** command to verify configuration settings:

```
user@host# run show ingress-replication mvpn
Ingress Tunnel: mvpn:11
Application: MVPN
Unicast tunnels
Leaf Address      Tunnel-type      Mode      State
10.255.245.2      P2P LSP         New       Up
10.255.245.4      P2P LSP         New       Up
Ingress Tunnel: mvpn:2
```

Application: MVPN

Unicast tunnels

Leaf Address	Tunnel-type	Mode	State
10.255.245.2	P2P LSP	Existing	Up

11. Use this if you want to configure the ingress replication provider tunnel to be inclusive:

```
user@host# set routing-instances VPN-B provider-tunnel ingress-replication
create-new-ucast-tunnel
user@host# set routing-instances VPN-B provider-tunnel ingress-replication
label-switched-path label-switched-path-template default-template
```

12. Use show mvpn instance command to verify tunnel is inclusive:

```
user@host# run show mvpn instance VPN-B
MVPN instance:
Legend for provider tunnel
I-P-tnl -- inclusive provider tunnel S-P-tnl -- selective provider tunnel

Configuring GRE Tunnels for Layer 3 VPNs

Junos OS allows you to configure a generic routing encapsulation (GRE) tunnel between the PE and CE routers for a Layer 3 VPN. The GRE tunnel can have one or more hops. You can configure the tunnel from the PE router to a local CE router (as shown in [Figure 119 on page 5246](#)) or to a remote CE router (as shown in [Figure 120 on page 5247](#)).

Figure 119: GRE Tunnel Configured Between the Local CE Router and the PE Router

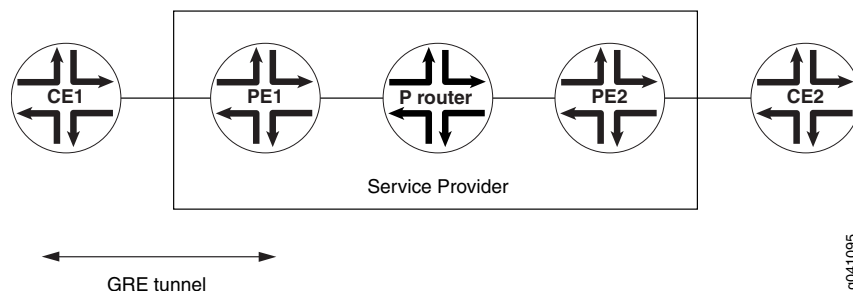

Figure 120: GRE Tunnel Configured Between the Remote CE Router and the PE Router

For more information about how to configure tunnel interfaces, see the *Junos Services Interfaces Configuration Release 11.2*.

You can configure the GRE tunnels manually or configure the Junos OS to instantiate GRE tunnels dynamically.

The following sections describe how to configure GRE tunnels manually and dynamically:

- [Configuring GRE Tunnels Manually Between PE and CE Routers on page 5247](#)
- [Configuring GRE Tunnels Dynamically on page 5248](#)

Configuring GRE Tunnels Manually Between PE and CE Routers

You can manually configure a GRE tunnel between a PE router and either a local CE router or a remote CE router for a Layer 3 VPN as explained in the following sections:

- [Configuring the GRE Tunnel Interface on the PE Router on page 5247](#)
- [Configuring the GRE Tunnel Interface on the CE Router on page 5248](#)

Configuring the GRE Tunnel Interface on the PE Router

You configure the GRE tunnel as a logical interface on the PE router. To configure the GRE tunnel interface, include the **unit** statement:

```
unit logical-unit-number {
  tunnel {
    source source-address;
    destination destination-address;
    routing-instance {
      destination routing-instance-name;
    }
  }
  family inet {
    address address;
  }
}
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name*]**

As part of the GRE tunnel interface configuration, you need to include the following statements:

- **source *source-address***—Specify the source or origin of the GRE tunnel, typically the PE router.
- **destination *destination-address***—Specify the destination or end point of the GRE tunnel. The destination can be a Provider router, the local CE router, or the remote CE router.

By default, the tunnel destination address is assumed to be in the default Internet routing table, **inet.0**. If the tunnel destination address is not in **inet.0**, you need to specify which routing table to search for the tunnel destination address by configuring the **routing-instance** statement. This is the case if the tunnel encapsulating interface is also configured under the routing instance.

- **destination *routing-instance-name***—Specify the name of the routing instance when configuring the GRE tunnel interface on the PE router.

To complete the GRE tunnel interface configuration, include the **interface** statement for the GRE interface under the appropriate routing instance:

```
interface interface-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

Configuring the GRE Tunnel Interface on the CE Router

You can configure either the local or the remote CE router to act as the endpoint for the GRE tunnel.

To configure the GRE tunnel interface on the CE router, include the **unit** statement:

```
unit logical-unit-number {  
  tunnel {  
    source address;  
    destination address;  
  }  
  family inet {  
    address address;  
  }  
}
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

Configuring GRE Tunnels Dynamically

When the router receives a VPN route to a BGP next hop address, but no MPLS path is available, a GRE tunnel can be dynamically generated to carry the VPN traffic across the

BGP network. The GRE tunnel is generated and then its routing information is copied into the inet.3 routing table. IPv4 routes are the only type of routes supported for dynamic GRE tunnels. Also, the routing platform must have a tunnel PIC.

NOTE: When configuring a dynamic GRE tunnel to a remote CE router, do not configure OSPF over the tunnel interface. It creates a routing loop forcing the router to take the GRE tunnel down. The router attempts to reestablish the GRE tunnel, but will be forced to take it down again when OSPF becomes active on the tunnel interface and discovers a route to the tunnel endpoint. This is not an issue when configuring static GRE tunnels to a remote CE router.

To generate GRE tunnels dynamically, include the **dynamic-tunnels** statement:

```
dynamic-tunnels tunnel-name {
  destination-networks prefix;
  source-address address;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

Specify the IPv4 prefix range (for example, 10/8 or 11.1/16) for the destination network by including the **destination-networks** statement. Only tunnels within the specified IPv4 prefix range are allowed to be initiated.

```
destination-networks prefix;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options dynamic-tunnels *tunnel-name*]
- [edit logical-systems *logical-system-name* routing-options dynamic-tunnels *tunnel-name*]

Specify the source address for the GRE tunnels by including the **source-address** statement. The source address specifies the address used as the source for the local tunnel endpoint. This could be any local address on the router (typically the router ID or the loopback address).

```
source-address address;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options dynamic-tunnels *tunnel-name*]
- [edit logical-systems *logical-system-name* routing-options dynamic-tunnels *tunnel-name*]

[edit protocols bgp] Hierarchy Level

Several statements in the **[edit protocols mpls]** hierarchy are valid at numerous locations within it. To make the complete hierarchy easier to read, the repeated statements are listed in “[Common BGP Family Options](#)” on page 369 and that section is referenced at the appropriate locations in “[Complete \[edit protocols bgp\] Hierarchy](#)” on page 369.

Common BGP Family Options

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit protocols bgp\] Hierarchy](#)” on page 369 instead of the statements being repeated.

- **[edit protocols bgp family inet (any | flow | labeled-unicast | multicast | unicast)]**
- **[edit protocols bgp family inet6 (any | labeled-unicast | multicast | unicast)]**
- **[edit protocols bgp family (inet-mdt | inet-mvpn | inet6-mvpn | l2vpn) signaling]**
- **[edit protocols bgp family inet-vpn (any | flow | multicast | unicast)]**
- **[edit protocols bgp family inet6-vpn (any | multicast | unicast)]**
- **[edit protocols bgp family iso-vpn unicast]**

The common BGP family options are as follows:

```
accepted-prefix-limit {
    maximum number;
    teardown <percentage> <idle-timeout (forever | minutes)>;
}
damping;
loops number;
prefix-limit {
    maximum number;
    teardown <percentage> <idle-timeout (forever | minutes)>;
}
rib-group group-name;
topology name {
    community {
        target identifier;
    }
}
```

Complete [edit protocols bgp] Hierarchy

The statement hierarchy listed in this section can also be included at the **[edit logical-systems *logical-system-name*]** hierarchy level.

Layer 2 Routing Instances Configuration Hierarchy

Use the **vpls** routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN.

To configure routing instances for Layer 2 networks, include the following statements:

```
routing-instances {
  routing-instance-name {
    access {
      address-assignment {
        ... same statements as in the address-assignment subhierarchy in [edit access]
        Hierarchy Level ...
      }
      address-protection;
      description text;
      egress-protection {
        context-identifier context-id;
      }
      forwarding-options {
        ...forwarding-options...
      }
      instance-role role;
      instance-type type;
      interface interface-name;
      l2-domain-id-for-l3 id;
      l2vpn-id community;
      layer3-domain-identifier identifier;
      multicast-snooping-options {
        ... same statements as in [edit multicast-snooping-options] Hierarchy Level EXCEPT
        FOR ...
        traceoptions {...} # NOT valid at this level
      }
      no-irb-layer-2-copy;
      no-local-switching;
      no-vrf-advertise;
      no-vrf-propagate-ttl;
      pbb-options {
        default-bvlan bvlan;
        peer-instance instance;
        vlan-id vlan-id isid-list [ isid-numbers ]
      }
      protocols {
        ... the protocols subhierarchy appears after the main [edit routing-instances

        vlan-tags outer number inner number;
        bridge-options {
            interface-mac-limit limit {
                packet-action drop;
            }
            interface interface-name {
                interface-mac-limit limit {
                    packet-action drop;
                }
            }
        }
        mac-statistics;
    }
}

```

```
        mac-table-size limit {  
            packet-action drop;  
        }  
        no-mac-learning;  
        static-mac mac-address;  
    }  
}  
}
```

With the exception of the **instance-type virtual-switch** statement (which configures a virtual-switch routing instance), you can include the statements at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

The **instance-type virtual-switch** statement is not supported at the **[edit logical-systems *logical-system-name*]** hierarchy level.

advertise-from-main-vpn-tables

Syntax	advertise-from-main-vpn-tables;
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols bgp], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols bgp], [edit protocols bgp], [edit routing-instances <i>routing-instance-name</i> protocols bgp],
Release Information	Statement introduced in Junos OS Release 12.3.
Description	<p>Advertise VPN routes from the main VPN tables in the master routing instance (for example, <i>bgp.l3vpn.0</i>, <i>bgp.mvpn.0</i>) instead of advertising VPN routes from the tables in the VPN routing instances (for example, <i>instance-name.inet.0</i>, <i>instance-name.mvpn.0</i>).</p> <p>When this statement is enabled, before advertising a route for a VPN prefix, the path selection algorithm is run on all routes (local and received) that have the same route distinguisher (RD).</p> <div style="margin-top: 20px;">  <p>NOTE: Adding or removing this statement causes all BGP sessions that have VPN address families to be removed and then added again. On the other hand, having this statement in the configuration prevents BGP sessions from going down when route reflector (RR) or autonomous system border router (ASBR) functionality is enabled or disabled on a routing device that has VPN address families configured.</p> </div>
Default	If you do not include this statement, VPN routes are advertised from the tables in the VPN routing instances.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • <i>Understanding Junos OS Routing Tables</i> • <i>Types of VPNs</i>

create-new-ucast-tunnel

Syntax	create-new-ucast-tunnel;
Hierarchy Level	[edit routing-instances <i>routing-instance-name</i> provider-tunnel ingress-replication], [edit routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>address</i> source <i>source-address</i> ingress-replication]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	One of two modes for building unicast tunnels when ingress replication is configured for the provider tunnel. When this statement is configured, each time a new destination is added to the multicast distribution tree, a new unicast tunnel to the destination is created in the ingress replication tunnel. The new tunnel is deleted if the destination is no longer needed. Use this mode for RSVP LSPs using ingress replication.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Example: Configuring Ingress Replication for IP Multicast Using MBGP MVPNs</i>• Configuring Routing Instances for an MBGP MVPN on page 5223• mpls-internet-multicast on page 5272• ingress-replication on page 5269

export-target

Syntax	<code>export-target { target <i>target-community</i>; unicast; }</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvpn route-target], [edit routing-instances <i>routing-instance-name</i> protocols mvpn route-target]
Release Information	Statement introduced in Junos OS Release 8.4.
Description	Enable you to override the Layer 3 VPN import and export route targets used for importing and exporting routes for the MBGP MVPN network layer reachability information (NLRI).
Options	target <i>target-community</i> —Specify the export target community. unicast —Use the same target community as specified for unicast.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring the Export Target for an MBGP MVPN on page 5230

family (VRF Advertisement)

Syntax	<code>family { inet-mvpn; inet6-mvpn; }</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> vrf-advertise-selective], [edit routing-instances <i>routing-instance-name</i> vrf-advertise-selective],
Release Information	Statement introduced in Junos OS Release 10.1.
Description	Explicitly enable IPv4 or IPv6 MVPN routes to be advertised from the VRF instance while preventing all other route types from being advertised. The options are explained separately.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

group (Routing Instances)

Syntax	<pre>group address { source source-address { pim-ssm { group-range multicast-prefix; } ldp-p2mp; rsvp-te { label-switched-path-template { (default-template lsp-template-name); } static-lsp lsp-name; } threshold-rate number; } }</pre>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel selective], [edit routing-instances <i>routing-instance-name</i> provider-tunnel selective]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the IP address for the multicast group configured for point-to-multipoint label-switched paths (LSPs) and PIM-SSM GRE selective provider tunnels.
Options	address —Specify the IP address for the multicast group. This address must be a valid multicast group address. The remaining statements are explained separately.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring the Multicast Group Address for an MBGP MVPN on page 5238• Configuring PIM-SSM GRE Selective Provider Tunnels on page 5233

group-range (MBGP MVPN Tunnel)

Syntax	<code>group-range <i>multicast-prefix</i>;</code>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>group-address</i> source <i>source-address</i> pim-ssm],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>group-address</i> wildcard-source pim-ssm],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel selective wildcard-group-inet wildcard-source pim-ssm],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel selective wildcard-group-inet6 wildcard-source pim-ssm],</p> <p>[edit routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>group-address</i> source <i>source-address</i> pim-ssm],</p> <p>[edit routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>group-address</i> wildcard-source pim-ssm],</p> <p>[edit routing-instances <i>routing-instance-name</i> provider-tunnel selective wildcard-group-inet wildcard-source pim-ssm],</p> <p>[edit routing-instances <i>routing-instance-name</i> provider-tunnel selective wildcard-group-inet6 wildcard-source pim-ssm]</p>
Release Information	Statement introduced in Junos OS Release 10.1.
Description	Establish the multicast group address range to use for creating MBGP MVPN source-specific multicast selective PMSI tunnels.
Options	<p><i>multicast-prefix</i>—Multicast group address range to be used to create MBGP MVPN source-specific multicast selective PMSI tunnels.</p> <p>Range: Any valid, nonreserved IPv4 multicast address range</p> <p>Default: None</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring PIM-SSM GRE Selective Provider Tunnels on page 5233

group-rp-mapping

Syntax	<pre>group-rp-mapping { family (inet inet6) { log-interval seconds; maximum limit; threshold value; } log-interval seconds; maximum limit; threshold value; }</pre>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> protocols pim rp],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols pim rp],</p> <p>[edit protocols pim rp],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols pim rp]</p>
Release Information	Statement introduced in Junos OS Release 12.2.
Description	Configure a limit for the number of incoming group-to-RP mappings.
	<div>  <p>NOTE: The maximum limit settings that you configure with the <code>maximum</code> and the <code>family (inet inet6) maximum</code> statements are mutually exclusive. For example, if you configure a global maximum group-to-RP mapping limit, you cannot configure a limit at the family level for IPv4 or IPv6. If you attempt to configure a limit at both the global level and the family level, the device will not accept the configuration.</p> </div>
Options	<p>family (inet inet6)—(Optional) Specify either IPv4 or IPv6 messages to be counted towards the configured group-to-RP mapping limit.</p> <p>Default: Both IPv4 and IPv6 messages are counted towards the configured group-to-RP limit.</p> <p>The remaining statements are described separately.</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

ingress-replication

Syntax	<pre>ingress-replication { create-new-ucast-tunnel; label-switched-path { label-switched-path-template { (template-name default-template); } } }</pre>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel],</p> <p>[edit routing-instances <i>routing-instance-name</i> provider-tunnel],</p> <p>[edit routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>address</i> source <i>source-address</i>]</p>
Release Information	Statement introduced in Junos OS Release 10.4.
Description	<p>A provider tunnel type used for passing multicast traffic between routers through the MPLS cloud, or between PE routers when using MVPN. The ingress replication provider tunnel uses MPLS point-to-point LSPs to create the multicast distribution tree.</p> <p>Optionally, you can specify a label-switched path template. If you configure ingress-replication label-switched-path and do not include label-switched-path-template, ingress replication works with existing LDP or RSVP tunnels. If you include label-switched-path-template, the tunnels must be RSVP.</p>
Options	<p>create-new-ucast-tunnel—A new unicast tunnel to the destination that is created and used for ingress replication. The unicast tunnel is deleted later if the destination is no longer included in the multicast distribution tree. A template must be specified when and only when create-new-ucast-tunnel is included in the configuration..</p> <p>template-name—Name of the point-to-point LSP used for the new unicast tunnel.</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

interface (Virtual Tunnel in Routing Instances)

Syntax	<pre>interface vt-<i>fpc/pic/port.unit-number</i> { multicast; primary; unicast; }</pre>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i>], [edit routing-instances <i>routing-instance-name</i>]
Release Information	Statement introduced in Junos OS Release 9.4.
Description	<p>In a multiprotocol BGP (MBGP) multicast VPN (MVPN), configure a virtual tunnel (VT) interface.</p> <p>VT interfaces are needed for multicast traffic on routing devices that function as combined provider edge (PE) and provider core (P) routers to optimize bandwidth usage on core links. VT interfaces prevent traffic replication when a P router also acts as a PE router (an exit point for multicast traffic).</p> <p>In an MBGP MVPN extranet, if there is more than one VRF routing instance on a PE router that has receivers interested in receiving multicast traffic from the same source, VT interfaces must be configured on all instances.</p> <p>Starting in Junos OS Release 12.3, you can configure multiple VT interfaces in each routing instance. This provides redundancy. A VT interface can be used in only one routing instance.</p>
Options	<p><i>vt-fpc/pic/port.unit-number</i>—Name of the VT interface.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Example: Configuring Redundant Virtual Tunnel Interfaces in MBGP MVPNs on page 5212• Example: Configuring MBGP MVPN Extranets

label-switched-path-template

Syntax	label-switched-path-template { (default-template <i>lsp-template-name</i>); }
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel rsvp-te], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel ingress-replication label-switched-path], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>address</i> source <i>source-address</i> rsvp-te], [edit logical-systems <i>logical-system-name</i> routing-options dynamic-tunnels <i>tunnel-name</i> rsvp-te <i>entry-name</i>], [edit routing-instances <i>routing-instance-name</i> provider-tunnel ingress-replication label-switched-path], [edit routing-instances <i>routing-instance-name</i> provider-tunnel rsvp-te], [edit routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>address</i> source <i>source-address</i> rsvp-te], [edit routing-options dynamic-tunnels <i>tunnel-name</i> rsvp-te <i>entry-name</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs. This feature can be used for a number of applications, including point-to-multipoint LSPs, flooding VPLS traffic, configuring ingress replication for IP multicast using MBGP MVPNs, and to enable RSVP automatic mesh. There is no default setting for the label-switched-path-template statement, so you must configure either the default-template using the default-template option, or you must specify the name of your preconfigured LSP template.
Options	default-template —Specify that the default LSP template be used for the dynamically generated LSPs. lsp-template-name —Specify the name of an LSP to be used as a template for the dynamically generated LSPs.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

primary (Virtual Tunnel in Routing Instances)

Syntax	<code>primary;</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> interface <i>vt-fpc/pic/port.unit-number</i>], [edit routing-instances <i>routing-instance-name</i> interface <i>vt-fpc/pic/port.unit-number</i>]
Release Information	Statement introduced in Junos OS Release 12.3.
Description	<p>In a multiprotocol BGP (MBGP) multicast VPN (MVPN), configure the virtual tunnel (VT) interface to be used as the primary interface for multicast traffic.</p> <p>Junos OS supports up to eight VT interfaces configured for multicast in a routing instance to provide redundancy for MBGP (next-generation) MVPNs. This support is for RSVP point-to-multipoint provider tunnels as well as multicast Label Distribution Protocol (MLDP) provider tunnels. This feature works for extranets as well.</p> <p>This statement allows you to configure one of the VT interfaces to be the primary interface, which is always used if it is operational. If a VT interface is configured as the primary, it becomes the nexthop that is used for traffic coming in from the core on the label-switched path (LSP) into the routing instance. When a VT interface is configured to be primary and the VT interface is used for both unicast and multicast traffic, only the multicast traffic is affected.</p> <p>If no VT interface is configured to be the primary or if the primary VT interface is unusable, one of the usable configured VT interfaces is chosen to be the nexthop that is used for traffic coming in from the core on the LSP into the routing instance. If the VT interface in use goes down for any reason, another usable configured VT interface in the routing instance is chosen. When the VT interface in use changes, all multicast routes in the instance also switch their reverse-path forwarding (RPF) interface to the new VT interface to allow the traffic to be received.</p> <p>To realize the full benefit of redundancy, we recommend that when you configure multiple VT interfaces, at least one of the VT interfaces be on a different Tunnel PIC from the other VT interfaces. However, Junos OS does not enforce this.</p>
Default	If you omit this statement, Junos OS chooses a VT interface to be the active interface for multicast traffic.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel], [edit routing-instances <i>routing-instance-name</i> provider-tunnel]
Release Information	Statement introduced in Junos OS Release 8.5. The ingress-replication statement and substatements added in Junos OS Release 10.4.
Description	Configure selective point-to-multipoint LSPs for an MBGP MVPN. Selective point-to-multipoint LSPs send traffic only to the receivers configured for the MBGP MVPNs, helping to minimize flooding in the service provider's network. The remaining statements are explained separately.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Selective Provider Tunnels for an MBGP MVPN on page 5236 • Configuring PIM-SSM GRE Selective Provider Tunnels on page 5233

sglimit

Syntax	<pre>sglimit { family (inet inet6) { log-interval seconds; maximum limit; threshold value; } log-interval seconds; maximum limit; threshold value; }</pre>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> protocols pim],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols pim],</p> <p>[edit protocols pim],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols pim]</p>
Release Information	Statement introduced in Junos OS Release 12.2.
Description	Configure a limit for the number of accepted (*G) and (S,G) PIM join states.
	<div>  <p>NOTE: The maximum limit settings that you configure with the <code>maximum</code> and the <code>family (inet inet6) maximum</code> statements are mutually exclusive. For example, if you configure a global maximum PIM join state limit, you cannot configure a limit at the family level for IPv4 or IPv6 joins. If you attempt to configure a limit at both the global level and the family level, the device will not accept the configuration.</p> </div>
Options	<p>family (inet inet6)—(Optional) Specify either IPv4 or IPv6 join states to be counted towards the configured join state limit.</p> <p>Default: Both IPv4 and IPv6 join states are counted towards the configured join state limit.</p> <p>The remaining statements are described separately.</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

traceoptions (Protocols MVPN)

Syntax	<pre>traceoptions { file <i>filename</i> <files <i>number</i>> <size <i>size</i>> <world-readable no-world-readable>; flag <i>flag</i> <<i>flag-modifier</i>> <disable>; }</pre>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvpn],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols mvpn]</p>
Release Information	Statement introduced in Junos OS Release 8.4.
Description	Trace traffic flowing through an MBGP MVPN.
Options	<p>disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as all.</p> <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks (" ").</p> <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file named <i>trace-file</i> reaches this size, it is renamed <i>trace-file.0</i>. When <i>trace-file</i> again reaches its maximum size, <i>trace-file.0</i> is renamed <i>trace-file.1</i> and <i>trace-file</i> is renamed <i>trace-file.0</i>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option.</p> <p>Range: 2 through 1000 files</p> <p>Default: 2 files</p> <p>flag <i>flag</i>—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can specify any of the following flags:</p> <ul style="list-style-type: none"> • all—All multicast VPN tracing options • error—Error conditions • general—General events • nlri—Multicast VPN advertisements received or sent by means of the BGP • normal—Normal events • policy—Policy processing • route—Routing information • state—State transitions • task—Routing protocol task processing • timer—Routing protocol timer processing

- **topology**—Multicast VPN topology changes caused by reconfiguration or advertisements received from other provider edge (PE) routers using BGP

flag-modifier—(Optional) Modifier for the tracing flag. You can specify the following modifiers:

- **detail**—Provide detailed trace information
- **disable**—Disable the tracing flag
- **receive**—Trace received packets
- **send**—Trace sent packets

no-world-readable—Do not allow any user to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option.

Syntax: *xk* to specify kilobytes, *xm* to specify megabytes, or *xg* to specify gigabytes

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—Allow any user to read the log file.

Required Privilege Level	routing—To view this statement in the configuration.
	routing-control—To add this statement to the configuration.

Troubleshooting Multicast VPNs

- [Tracing MBGP MVPN Traffic and Operations on page 5299](#)

Tracing MBGP MVPN Traffic and Operations

To trace MBGP MVPN traffic, you can specify options with the **traceoptions** statement:

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

You can include this statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols mvpn]
- [edit routing-instances *routing-instance-name* protocols mvpn]

The following trace flags display the operations associated with multicast VPNs:

- **all**—All multicast VPN tracing options
- **error**—Error conditions
- **general**—General events
- **nlri**—Multicast VPN advertisements received or sent by means of BGP
- **normal**—Normal events
- **policy**—Policy processing
- **route**—Routing information
- **state**—State transitions
- **task**—Routing protocol task processing
- **timer**—Routing protocol timer processing
- **topology**—Multicast VPN topology changes caused by reconfiguration or advertisements received from other PE routers using BGP

Introduction to VPLS

VPLS is an Ethernet-based point-to-multipoint Layer 2 VPN. It allows you to connect geographically dispersed Ethernet local area networks (LAN) sites to each other across an MPLS backbone. For customers who implement VPLS, all sites appear to be in the same Ethernet LAN even though traffic travels across the service provider's network.

VPLS, in its implementation and configuration, has much in common with a Layer 2 VPN. In VPLS, a packet originating within a service provider customer's network is sent first to a customer edge (CE) device (for example, a router or Ethernet switch). It is then sent to a provider edge (PE) router within the service provider's network. The packet traverses the service provider's network over a MPLS label-switched path (LSP). It arrives at the egress PE router, which then forwards the traffic to the CE device at the destination customer site.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The difference is that for VPLS, packets can traverse the service provider's network in point-to-multipoint fashion, meaning that a packet originating from a CE device can be broadcast to all the PE routers participating in a VPLS routing instance. In contrast, a Layer 2 VPN forwards packets in point-to-point fashion only.

The paths carrying VPLS traffic between each PE router participating in a routing instance are called pseudowires. The pseudowires are signaled using either BGP or LDP.

VPLS Routing and Virtual Ports

Because VPLS carries Ethernet traffic across a service provider network, it must mimic an Ethernet network in some ways. When a PE router configured with a VPLS routing instance receives a packet from a CE device, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, it forwards the packet to the appropriate PE router or CE device. If it does not, it broadcasts the packet to all other PE routers and CE devices that are members of that VPLS routing instance. In both cases, the CE device receiving the packet must be different from the one sending the packet.

NOTE: In the VPLS documentation, the term *router* is used to refer to any device that provides routing functions.

When a PE router receives a packet from another PE router, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, the PE router either forwards the packet or drops it depending on whether the destination is a local or remote CE device:

- If the destination is a local CE device, the PE router forwards the packet to it.
- If the destination is a remote CE device (connected to another PE router), the PE router discards the packet.

If the PE router cannot determine the destination of the VPLS packet, it floods the packet to all attached CE devices.

This process is illustrated in [Figure 121 on page 5301](#).

Figure 121: Flooding a Packet with an Unknown Destination to All PE Routers in the VPLS Instance

VPLS can be directly connected to an Ethernet switch. Layer 2 information gathered by an Ethernet switch (for example, media access control [MAC] addresses and interface ports) is included in the VPLS routing instance table. However, instead of all VPLS

interfaces being physical switch ports, the router allows remote traffic for a VPLS instance to be delivered across an MPLS LSP and arrive on a virtual port. The virtual port emulates a local, physical port. Traffic can be learned, forwarded, or flooded to the virtual port in almost the same way as traffic is sent to a local port.

The VPLS routing table learns MAC address and interface information for both physical and virtual ports. The main difference between a physical port and a virtual port is that the router captures additional information from the virtual port, an outgoing MPLS label used to reach the remote site and an incoming MPLS label for VPLS traffic received from the remote site. The virtual port is generated dynamically on a Tunnel Services Physical Interface Card (PIC) when you configure VPLS on the router.

You can also configure VPLS without a Tunnel Services PIC. To do so, you use a label-switched interface (LSI) to provide VPLS functionality. An LSI MPLS label is used as the inner label for VPLS. This label maps to a VPLS routing instance. On the PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.

One restriction on flooding behavior in VPLS is that traffic received from remote PE routers is never forwarded to other PE routers. This restriction helps prevent loops in the core network. However, if a CE Ethernet switch has two or more connections to the same PE router, you must enable the Spanning Tree Protocol (STP) on the CE switch to prevent loops. STP is supported on MX Series routers and EX Series switches only.

The Junos OS allows standard Bridge Protocol Data Unit (BPDU) frames to pass through emulated Layer 2 connections, such as those configured with Layer 2 VPNs, Layer 2 circuits, and VPLS routing instances. However, CE Ethernet switches that generate proprietary BPDU frames might not be able to run STP across Juniper Networks routing platforms configured for these emulated Layer 2 connections.

NOTE: Under certain circumstances, VPLS provider routers might duplicate an Internet Control Message Protocol (ICMP) reply from a CE router when a PE router has to flood an ICMP request because the destination MAC address has not yet been learned. The duplicate ICMP reply can be triggered when a CE router with promiscuous mode enabled is connected to a PE router. The PE router automatically floods the promiscuous mode-enabled CE router, which then returns the ICMP request to the VPLS provider routers. The VPLS provider routers consider the ICMP request to be new and flood the request again, creating a duplicate ping reply.

VPLS and Aggregated Ethernet Interfaces

You can configure aggregated Ethernet interfaces between CE devices and PE routers for VPLS routing instances. Traffic is load-balanced across all of the links in the aggregated interface. If one or more links in the aggregated interface fails, the traffic is switched to the remaining links.

Forwarding is based on a lookup of the DA MAC address. For the remote site, if a packet needs to be forwarded over an LSP, the packet is encapsulated and forwarded through

the LSP. If the packet destination is a local site, it is forwarded over appropriate local site interface. For an aggregated Ethernet interface on the local site, packets are sent out of the load-balanced child interface. The Packet Forwarding Engine acquires the child link to transmit the data.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

When a received packet does not have a match to a MAC address in the forwarding database, the packet is forwarded over a set of interfaces determined from a lookup in the flooding database based on the incoming interface. This is denoted by a flood next hop. The flood next hop can include the aggregated Ethernet interface as the set of interfaces to flood the packet.

Each VPLS routing instance configured on a PE router has its own forwarding database entries that associate all of the MAC addresses the VPLS routing instance acquires with each corresponding port. A route is added to the kernel with a MAC address as the prefix and the next hop used to reach the destination. The route is an interface if the destination is local. For a remote destination, the route is a next hop for the remote site.

For local aggregated Ethernet interfaces on M Series and T Series routers, learning is based on the parent aggregated Ethernet logical interface. To age out MAC addresses for aggregated Ethernet interfaces, each Packet Forwarding Engine is queried to determine where the individual child interfaces are located. MAC addresses are aged out based on the age of the original interface.

For MX Series routers and EX Series switches, when a Dense Port Concentrator (DPC) learns a MAC address it causes the Routing Engine to age out the entry. This behavior applies to all logical interfaces. For an aggregated Ethernet logical interface, once all the member DPCs have aged out the entry, the entry is deleted from the Routing Engine.

BGP Signaling for VPLS PE Routers Overview

BGP can autonomously signal pseudowires between the PE routers participating in the same virtual private LAN service (VPLS) network. As PE routers are added to and removed from the VPLS network, BGP can signal pseudowires to new PE routers and tear down old pseudowires to old PE routers. Each PE router only needs to be configured with the identity of the VPLS routing instance. Each PE router does not need to be configured with the identities of all of the PE routers that are or might become a part of the VPLS network.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

When you configure BGP for signaling in a VPLS network, customer sites can be either single-homed to a single PE router or multihomed to two or more PE routers. Multihoming provides redundancy for the connection between the customer site and the service provider's network.

You can either configure all of the PE routers in the VPLS network as a full mesh or you can use BGP route reflectors. For full mesh configurations, each PE router needs to be able to create a bidirectional pseudowire to each of the other PE routers participating in the VPLS network.

BGP Route Reflectors for VPLS

In large networks, it might be necessary to configure BGP route reflectors to reduce the control plane workload for the routers participating in the VPLS network. BGP route reflectors can help to reduce the workload of the network control plane in the following ways.

- Making it unnecessary to configure all of the VPLS PE routers in a full mesh.
- Limiting the total volume of BGP VPLS messages exchanged within the network by transmitting messages to interested routers only (instead of all of the BGP routers in the network)
- Reducing the network signaling load whenever another BGP router is added to or removed from the network

The basic solution to these problems is to deploy a small group of BGP route reflectors that are in a full mesh with one another. Each of the VPLS PE routers is configured to have a BGP session with one or more of the route reflectors, making it unnecessary to maintain a full mesh of BGP sessions between all of the PE routers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

This type of configuration only affects the control plane of the VPLS network (how routers signal and tear down pseudowires to one another in the network). The actual data plane state and forwarding paths for the VPLS traffic are not modified by the route reflectors. Effectively, the VPLS pseudowires should take the same paths across the network whether or not you have configured route reflectors. For a description of how VPLS selects the best path to a PE router, see [“VPLS Path Selection Process for PE Routers” on page 5309](#).

The MAC addresses themselves are not exchanged or processed in any way by BGP. Each VPLS PE router performs all MAC address learning and aging individually. BGP's only function relative to VPLS is to exchange messages related to automatic discovery of PE routers being added to and removed from the VPLS network and the MPLS label exchange needed to signal a pseudowire from one PE router to another.

VPLS Multihoming Overview

Virtual private LAN service (VPLS) multihoming enables you to connect a customer site to two or more PE routers to provide redundant connectivity. A redundant PE router can provide network service to the customer site as soon as a failure is detected. VPLS multihoming helps to maintain VPLS service and traffic forwarding to and from the multihomed site in the event of the following types of network failures:

- PE router to CE device link failure
- PE router failure
- MPLS-reachability failure between the local PE router and a remote PE router

Figure 122: CE Device Multihomed to Two PE Routers

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Figure 122 on page 5305 illustrates how a CE device could be multihomed to two PE routers. Device CE1 is multihomed to Routers PE1 and PE2. Device CE2 has two potential paths to reach Device CE1, but only one path is active at any one time. If Router PE1 were the designated VPLS edge (VE) device (also called a designated forwarder), BGP would signal a pseudowire from Router PE3 to Router PE1. If a failure occurred over this path, Router PE2 would be made the designated VE device, and BGP would re-signal the pseudowire from Router PE3 to Router PE2.

Multihomed PE routers advertise network layer reachability information (NLRI) for the multihomed site to the other PE routers in the VPLS network. The NLRI includes the site ID for the multihomed PE routers. For all of the PE routers multihomed to the same CE device, you need to configure the same site ID. The remote VPLS PE routers use the site ID to determine where to forward traffic addressed to the customer site. To avoid route collisions, the site ID shared by the multihomed PE routers must be different than the site IDs configured on the remote PE routers in the VPLS network.

Although you configure the same site ID for each of the PE routers multihomed to the same CE device, you can configure unique values for other parameters, such as the route distinguisher. These values help to determine which multihomed PE router is selected as the designated VE device to be used to reach the customer site.

BEST PRACTICE: We recommend that you configure unique route distinguishers for each multihomed PE router. Configuring unique route distinguishers helps with faster convergence when the connection to a primary multihomed PE router goes down. If you configure unique route distinguishers, the other PE routers in the VPLS network must maintain additional state for the multihomed PE routers.

Remote PE routers in the VPLS network need to determine which of the multihomed PE routers should forward traffic to reach the CE device. To make this determination, remote PE routers use the VPLS path-selection process to select one of the multihomed PE routers based on its NLRI advertisement. Because remote PE routers pick only one of the NLRI advertisements, it establishes a pseudowire to only one of the multihomed PE routers, the PE router that originated the winning advertisement. This prevents multiple paths from being created between sites in the network, preventing the formation of Layer 2 loops. If the selected PE router fails, all PE routers in the network automatically switch to the backup PE router and establish new pseudowires to it.

BEST PRACTICE: To prevent the formation of Layer 2 loops between the CE devices and the multihomed PE routers, we recommend that you employ the Spanning Tree Protocol (STP) on your CE devices. Layer 2 loops can form due to incorrect configuration. Temporary Layer 2 loops can also form during convergence after a change in the network topology.

The PE routers run the BGP path selection procedure on locally originated and received Layer 2 route advertisements to establish that the routes are suitable for advertisement to other peers, such as BGP route reflectors. If a PE router in a VPLS network is also a

route reflector, the path selection process for the multihomed site has no effect on the path selection process performed by this PE router for the purpose of reflecting Layer 2 routes. Layer 2 prefixes that have different route distinguishers are considered to have different NLRIs for route reflection. The VPLS path selection process enables the route reflector to reflect all routes that have different route distinguishers to the route reflector clients, even though only one of these routes is used to create the VPLS pseudowire to the multihomed site.

Enabling BGP Path Selection for Layer 2 VPNs and VPLS

Layer 2 VPNs and VPLS share the same path selection process for determining the optimal path to reach all of the destinations shared within a single routing instance. For Layer 2 VPN and VPLS topologies that do not include multihomed PE routers, the path selection process is straightforward since there is just a single path from each PE router to each CE device. However, if multihoming is configured for one or more of the CE devices, the path selection process becomes more complex, since there can be two or more valid paths to reach each multihomed CE device.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The Layer 2 VPN and VPLS path selection process uses the following path selection algorithms:

- On the Provider routers within the service providers network, the standard BGP path selection algorithm is used. Using the standard BGP path selection for Layer 2 VPN and VPLS routes allows service providers to leverage their existing Layer 3 VPN network infrastructure to also support Layer 2 VPNs and VPLS. The BGP path selection algorithm also helps to ensure that the service provider's network behaves predictably with regard to Layer 2 VPN and VPLS path selection. This is particularly important in networks employing route reflectors and multihoming.

When a Provider router receives multiple paths for the same destination prefix (for example, a multihomed CE device), one path is selected based on the BGP path selection algorithm and placed in the `bgp.l2vpn.0` routing table and the appropriate `instance.l2vpn.0` routing table. However, all of the available paths (including the backup paths for multihomed CE devices) are advertised to the intermediate BGP routers and the PE routers in the Layer 2 VPN or VPLS routing instances.

For more information about the BGP path selection process, see *Understanding BGP Path Selection*.

- Once a PE router receives all of the available paths to each CE device, it runs the designated forwarder path selection algorithm to select the preferred path to reach each CE device, independently of the results of the earlier BGP path selection algorithm run on the Provider router. The VPLS designated forwarder algorithm uses the D-bit, preference, and PE router identifier to determine which of the valid paths to each CE device to use. The PE router might select a path to reach a CE device which is different from the path selected by the BGP-based Provider routers. In this scenario, the following is the expected behavior for traffic sent to the multihomed CE device:
 1. If the path selected by the remote PE router is available, traffic will traverse the network to the multihomed CE device using the remote PE router's preferred path (again, ignoring the path selected by the BGP-based Provider routers).
 2. If the path selected by the remote PE router fails, the Provider routers switch the traffic destined for the multihomed CE device to the alternate path as soon as failure is detected. They then notify the remote PE router of the path failure. The remote PE router updates its routing table accordingly.

For more information about the VPLS designated forwarder path selection algorithm, see [“VPLS Path Selection Process for PE Routers” on page 5309](#). This algorithm is also described in the Internet draft [draft-ietf-l2vpn-vpls-multihoming-03.txt](#), *BGP based Multi-homing in Virtual Private LAN Service*.

- [VPLS Path Selection Process for PE Routers on page 5309](#)

VPLS Path Selection Process for PE Routers

The VPLS path selection process is used to select the best path between a remote PE router and a local PE router in a VPLS network. This path selection process is applied to routes received from both single-homed and multi-homed PE routers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

When the VPLS path selection process is complete, a PE router is made the designated VPLS edge (VE) device. The designated VE device effectively acts as the endpoint for the VPLS pseudowire that is signaled from the remote PE router. Once a PE router is made the designated VE device, a pseudowire can be signaled between the remote PE router and the local PE router and then VPLS packets can begin to flow between the PE routers.

Routes from multihomed PE routers connected to the same customer site share the same site ID, but can have different route distinguishers and block offsets. You can alter the configurations of the route distinguishers and block offsets to make a router more likely or less likely to be selected as the designated VE device.

On each PE router in the VPLS network, the best path to the CE device is determined by completing the following VPLS path selection process on each route advertisement received:

1. If the advertisement has the down bit set to 0, the advertisement is discarded.
2. Select the path with a higher preference. The preference attribute is obtained from the site-preference configured using the **site-preference** statement at the **[edit routing-instances routing-instance-name protocols vpls site site-name]** hierarchy level. If the site preference is 0, the preference attribute is obtained from the local preference.
3. If the preference values are the same, select the path with the lower router ID.
4. If the router IDs are the same, the routes are from the same PE router and the advertisement is considered to be an update. The router ID corresponds to the value of the originator ID for the BGP attribute (if present). Otherwise, the IP address for the remote BGP peer is used.
5. If the block offset values are the same, the advertisement is considered to be an update.

Once the VPLS path selection process has been completed and the designated VE device has been selected, a pseudowire is signaled between the remote PE router and the local PE router.

NOTE: The VPLS path selection process works the same whether or not the route has been received from another PE router, a route reflector, or an autonomous system border router (ASBR).

When the remote PE router establishes or refreshes a pseudowire to the local PE router, it verifies that the prefix is in the range required for the site ID based on the block offset and label range advertised by the designated VE device. If the prefix is out of range, the pseudowire status is set to out of range.

The following cases outline the potential decisions that could be made when a PE router completes the VPLS path selection process for a Layer 2 advertisement in the VPLS network:

- The PE router originated one of the advertisements and selected its own advertisement as the best path.

This PE router has been selected as the designated VE device. Selection as the designated VE device triggers the creation of pseudowires to and from the other PE routers in the VPLS network. If the remote customer site is multihomed, the designated VE device triggers the creation of pseudowires to and from only the designated VE device for the remote site.

- The PE router originated one of the advertisements but did not select its own advertisement as the best path.

This PE router is a redundant PE router for a multihomed site, but it was not selected as the designated VE device. However, if this PE router has just transitioned from being the designated VE device (meaning it was receiving traffic from the remote PE routers addressed to the multihomed customer site), the PE router tears down all the pseudowires that it had to and from the other PE routers in the VPLS network.

- The PE router received the route advertisements and selected a best path. It did not originate any of these advertisements because it was not connected to the customer site.

If the best path to the customer site (the designated VE device) has not changed, nothing happens. If the best path has changed, this PE router brings up pseudowires to and from the newly designated VE device and tears down the pseudowires to and from the previously designated VE device.

If this PE router does not select a best path after running the VPLS path selection process, then the local PE router does not consider the remote site to exist.

When a VE device receives an advertisement for a Layer 2 NLRI that matches its own site ID but the site is not multihomed, the pseudowire between the VE device and the transmitting PE router transitions to a site collision state and is not considered to be up.

**Related
Documentation**

- [BGP Route Reflectors for VPLS on page 5304](#)

BGP and VPLS Path Selection for Multihomed PE Routers

The BGP and VPLS path selection procedures are used to select the best path between the remote PE router and one of the multihomed PE routers. As part of these path selection procedures, one of the multihomed PE routers is made the designated VE device. The designated VE device effectively acts as the endpoint for the VPLS pseudowire from the remote PE router. Once a multihomed PE router is made the designated VE device, a pseudowire can be created between the remote PE router and the multihomed PE router.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Routes from multihomed PE routers connected to the same customer site share the same site ID, but can have different route distinguishers and block offsets. On each PE router in the VPLS network, the best path to the multihomed PE router is determined by completing the following VE device-selection procedures on each route advertisement received from a multihomed PE router:

1. BGP designated VE device-selection procedure—Runs before the VPLS designated VE device-selection procedure. However, the BGP designated VE device-selection procedure is used only when the route distinguishers for the multihomed PE routers are identical. If the route distinguishers are unique, only the VPLS designated VE device-selection procedure is run.
2. VPLS designated VE device-selection procedure—Runs after the BGP designated VE device-selection procedure. However, if the route distinguishers for each multihomed PE router are unique, the advertisements are not considered relevant to the BGP designated VE device-selection procedure. As a consequence, only the VPLS designated VE device-selection procedure is used.

The BGP designated VE device-selection procedure is as follows:

1. If the advertisement has the down bit set to 0, the advertisement is discarded.
2. Select the path with a higher preference. The preference attribute is obtained from the site-preference configured using the **site-preference** statement at the [edit routing-instances *routing-instance-name* protocols vpls site *site-name*] hierarchy level. If the site-preference is 0, the preference attribute is obtained from the local-preference.
3. If the preference values are the same, select the path with the lower router-id.
4. If the router-ids are the same, the routes are from the same PE router and the advertisement is considered to be an update.

Once the BGP designated VE device-selection procedure is complete, the VPLS designated VE device-selection procedure begins. This procedure is carried out regardless of the outcome of the BGP designated VE device-selection procedure:

1. If the advertisement has the down bit set to 0, the advertisement is discarded.
2. Select the path with a higher preference. The preference attribute is obtained from the site-preference configured using the **site-preference** statement at the [edit routing-instances *routing-instance-name* protocols vpls site *site-name*] hierarchy level. If the site-preference is 0, the preference attribute is obtained from the local-preference.
3. If the preference values are the same, select the path with the lower router-id.
4. If the router-ids are the same, select the path with a lower route distinguisher.
5. If the route distinguishers are the same, select the path with the lower block offset value.
6. If the block offset values are the same, the advertisement is considered to be an update.

Once the BGP and VPLS path selection procedures have been completed and the designated VE devices have been selected, a pseudowire can be created between the remote PE router and the multihomed PE router.

When the remote PE router establishes or refreshes a pseudowire to the local PE router, it verifies that the prefix is in the range required for the site ID based on the block offset and label range advertised by the designated VE device. If the prefix is out of range, the pseudowire status is set to out of range.

The following cases outline the potential decisions that could be made when a PE router completes the BGP and VPLS path selection procedures for a Layer 2 advertisement in the VPLS network:

- The PE router originated one of the multihomed advertisements and selected its own advertisement as the best path.

This PE router has been selected as the designated VE device. Selection as the designated VE device triggers the creation of pseudowires to and from the other PE routers in the VPLS network. When the remote customer site is also multihomed, the designated VE device triggers the creation of pseudowires to and from only the designated VE device for the remote site.

- The PE router originated one of the multihomed advertisements but did not select its own advertisement as the best path.

This PE router is one of the redundant PE routers for the multihomed site; it was not selected as the designated VE device. However, if this PE router has just transitioned from being the designated VE device (meaning it was receiving traffic from the remote PE routers addressed to the multihomed customer site), the PE router tears down all the pseudowires that it had to and from the other PE routers in the VPLS network.

- The PE router receives the multihomed advertisements and selects a best path; it does not originate any of these advertisements because it is not connected to the multihomed customer site.

If the preferred path to the customer site (the designated VE device) has not changed, nothing happens. If the preferred path has changed, this PE router brings up pseudowires to and from the newly designated VE device and tears down the pseudowires to and from the previously designated VE device.

If this PE router does not select a best path after running the BGP and VPLS path selection process, the local PE router does not consider the remote site to exist.

When a VE device receives an advertisement for a Layer 2 NLRI which matches its own site ID but the site is not multihomed, the pseudowire between it and the transmitting PE router transitions to a site collision state and is not considered to be up.

VPLS Multihoming Reactions to Network Failures

VPLS multihoming is designed to protect customer sites from a loss of network connectivity in the event of the following types of network failures:

- Link failure between the CE device and the PE router—BGP on the PE router is notified when the link goes down. BGP sets the circuit status vector bit in the MP_REACH_NLRI to indicate that the circuit is down.

If all of the VPLS local attachment circuits are down, then BGP modifies the down bit in the VPLS advertisement Layer2-Extended-Community to indicate that the customer site is down. When the bit is modified, BGP advertises the route to all of the remote PE routers to notify them that the circuit (and site) is down. Each of the remote PE routers run the BGP and VPLS path selection procedures again and reroute the VPLS pseudowires as needed.

- MPLS connectivity failure to the remote PE router—On the multihomed PE router, BGP discovers that MPLS cannot connect to the BGP next hop in the service provider's network. BGP modifies the circuit status vector bit in the MP_REACH_NLRI to indicate that the LSP is down. Once the bit is modified, BGP readvertises the route to all of the remote PE routers to notify them that connectivity from the local site to the remote site is down.

The remote PE routers each run the BGP and VPLS path selection procedures again. With the LSP to the original multihomed PE router down, the remote PE routers designate the backup multihomed PE router as the VE device for the multihomed customer site. The pseudowires to and from the remote PE routers are then rerouted to the backup multihomed PE router.

- PE router failure—When either the multihomed PE router or the BGP process running on it fails, the remote PE routers detect the expiration of the holdtimer, bring down their peering sessions, and delete the Layer 2 advertisements from that multihomed PE router. The remote PE routers each run the BGP and VPLS path selection procedures again and reroute their pseudowires to the backup multihomed PE router.

Alternatively, the remote PE routers could discover that the BGP next hop, represented by the failed multihomed PE router, is unreachable. For this case, the remote PE routers mark the Layer 2 routes advertised by the multihomed PE router as unreachable. The

remote PE routers each run the BGP and VPLS path selection procedures again and reroute their pseudowires to the backup multihomed PE router.

The remote PE routers behave in the same manner if you reconfigure the local preference attribute of the primary multihomed PE router (effectively performing an administrative failover to the backup multihomed PE router). On the primary multihomed PE router, BGP advertises a Layer 2 update with the new local preference attribute to all of the remote PE routers. The remote PE routers each run the BGP and VPLS path selection procedures again and reroute their pseudowires to the backup multihomed PE router.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Interoperability between BGP Signaling and LDP Signaling in VPLS

You can configure a VPLS routing instance where some of the PE routers use BGP for signaling and some use LDP for signaling.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following concepts form the basis of the configuration needed to include both BGP-signaled and LDP-signaled PE routers in a VPLS routing instance:

- **PE router mesh group**—Consists of a set of routers participating in a VPLS routing instance that share the same signaling protocol, either BGP or LDP, and are also fully meshed. Each VPLS routing instance can have just one BGP mesh group. However, you can configure multiple LDP mesh groups for each routing instance.
- **Border router**—A PE router that must be reachable by all of the other PE routers participating in a VPLS routing instance, whether they are LDP-signaled or BGP-signaled. Bidirectional pseudowires are created between the border router and all of these PE routers. The border router is aware of the composition of each PE mesh group configured as a part of the VPLS routing instance. It can also have direct connections to local CE routers, allowing it to act as a typical PE router in a VPLS routing instance.

The following sections describe how the LDP-signaled and BGP-signaled PE routers function when configured to interoperate within a VPLS routing instance:

- [LDP-Signaled and BGP-Signaled PE Router Topology on page 5314](#)
- [Flooding Unknown Packets Across Mesh Groups on page 5316](#)
- [Unicast Packet Forwarding on page 5316](#)

LDP-Signaled and BGP-Signaled PE Router Topology

[Figure 123 on page 5315](#) illustrates a topology for a VPLS routing instance configured to support both BGP and LDP signaling. Router B is the border router. Routers PE1 and PE2 are in the LDP-signaled mesh group LDP-1. Routers PE3, PE4, and PE5 are in the

LDP-signaled mesh group LDP-2. Routers PE6, PE7, PE8, and router B (the border router) are in the BGP-signaled mesh group. The border router also acts as a standard VPLS router (having local connections to CE routers). All of the PE routers shown are within the same VPLS routing instance.

Figure 123: BGP and LDP Signaling for a VPLS Routing Instance

Two-way pseudowires are established between the PE routers in each mesh group and between each PE router in the VPLS routing instance and the border router. In [Figure 123 on page 5315](#), two-way pseudowires are established between routers PE1 and PE2 in mesh group LDP-1, routers PE3, PE4, and PE5 in mesh group LDP-2, and routers PE6, PE7, and PE8 in the BGP mesh group. Routers PE1 through PE8 also all have two-way pseudowires to the Border router. Based on this topology, the LDP-signaled routers are able to interoperate with the BGP-signaled routers. Both the LDP-signaled and BGP-signaled PE routers can logically function within a single VPLS routing instance.

NOTE: The following features are not supported for VPLS routing instances configured with both BGP and LDP signaling:

- Point-to-multipoint LSPs
- Integrated routing and bridging
- IGMP snooping

Flooding Unknown Packets Across Mesh Groups

Broadcast, multicast, and unicast packets of unknown origin received from a PE router are flooded to all local CE routers. They are also flooded to all of the PE routers in the VPLS routing instance except the PE routers that are a part of the originating PE router mesh group.

For example, if a multicast packet is received by the border router in [Figure 123 on page 5315](#), it is flooded to the two local CE routers. It is also flooded to routers PE1 and PE2 in the LDP-1 mesh group and to routers PE3, PE4, and PE5 in the LDP-2 mesh group. However, the packet is not flooded to routers PE6, PE7, and PE8 in the BGP mesh group.

Unicast Packet Forwarding

The PE border router is made aware of the composition of each PE router mesh group. From the data plane, each PE router mesh group is viewed as a virtual pseudowire LAN. The border router is configured to interconnect all of the PE router mesh groups belonging to a single VPLS routing instance. To interconnect the mesh groups, a common MAC table is created on the border router.

Unicast packets originating within a mesh group are dropped if the destination is another PE router within the same mesh group. However, if the destination MAC address of the unicast packet is a PE router located in a different mesh group, the packet is forwarded to that PE router.

VPLS Label Blocks Operation

A virtual private LAN service (VPLS) is a Layer 2 (L2) service that emulates a local area network (LAN) across a wide area network (WAN). VPLS labels are defined and exchanged in the Border Gateway Protocol (BGP) control plane. In the Junos OS implementation, label blocks are allocated and used in the VPLS control plane for two primary functions: autodiscovery and signaling.

- Autodiscovery—A method for automatically recognizing each provider edge (PE) router in a particular VPLS domain, using BGP update messages.
- Signaling—Each pair of PE routers in a VPLS domain sends and withdraws VPN labels to each other. The labels are used to establish and dismantle pseudowires between the routers. Signaling is also used to transmit certain characteristics of a pseudowire.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The PE router uses BGP extended communities to identify the members of its VPLS. Once the PE router discovers its members, it is able to establish and tear down pseudowires between members by exchanging and withdrawing labels and transmitting certain characteristics of the pseudowires.

The PE router sends common update messages to all remote PE routers, using a distinct BGP update message, thereby reducing the control plane load. This is achieved by using VPLS label blocks.

Elements of Network Layer Reachability Information

VPLS BGP network layer reachability information (NLRI) is used to exchange VPLS membership and parameters. The elements of a VPLS BGP NLRI are defined in [Table 385 on page 5317](#).

Table 385: NLRI Elements

Element	Acronym	Description	Default Size (Octets)
Length		Total length of the NLRI size represented in bytes.	2
Route Distinguisher	RD	Unique identifier for each routing instance configured on a PE.	8
VPLS Edge ID	VE ID	Unique number to identify the edge site.	2
VE Block Offset	VBO	Value used to identify a label block from which a label value is selected to set up pseudowires for a remote site.	2
VE Block Size	VBS	Indicates the number of pseudowires that peers can have in a single block.	2
Label Base	LB	Starting value of the label in the advertised label block.	3

Requirements for NLRI Elements

Junos OS requires a unique route distinguisher (RD) for each routing instance configured on a PE router. A PE router might use the same RD across a VPLS (or VPN) domain or it might use different RDs. Using different RDs helps identify the originator of the VPLS NLRI.

The VPLS edge (VE) ID can be a unique VE ID, site ID, or customer edge (CE) ID. The VE ID is used by a VPLS PE router to index into label blocks used to derive the transmit and receive VPN labels needed for transport of VPLS traffic. The VE ID identifies a particular site, so it needs to be unique within the VPLS domain, except for some scenarios such as multihoming.

All PE routers have full mesh connectivity with each other to exchange labels and set up pseudowires. The VE block size (VBS) is a configurable value that represents the number of label blocks required to cover all the pseudowires for the remote peer.

A single label block contains 8 labels (1 octet) by default. The default VBS in Junos OS is 2 blocks (2 octets) for a total of 16 labels.

How Labels are Used in Label Blocks

Each PE router creates a mapping of the labels in the label block to the sites in a VPLS domain. A PE router advertising a label block with a block offset indicates which sites can use the labels to reach it. When a PE router is ready to advertise its membership to

a VPLS domain, it allocates a label block and advertises the VPLS NLRI. In this way, other PE routers in the same VPLS domain can learn of the existence of the VPLS and set up pseudowires to it if needed. The VPLS NLRI advertised for this purpose is referred to as the *default VPLS NLRI*. The label block in the default VPLS NLRI is referred to as the *default label block*.

Label Block Composition

A label block (set of labels) is used to reach a given site ID. A single label block contains 8 labels (1 octet) by default. The VBS is 2 octets by default in Junos OS.

The label block advertised is defined as a label base (LB) and a VE block size (VBS). It is a contiguous set of labels (LB, LB+1,...,LB+VBS-1). For example, when Router PE-A sends a VPLS update, it sends the same label block information to all other PE routers. Each PE router that receives the LB advertisement infers the label intended for Router PE-A by adding its own site ID to the label base.

In this manner, each receiving PE gets a unique label for PE-A for that VPLS. This simple method is enhanced by using a VE block offset (VBO).

A label block is defined as: <Label Base (LB), VE block offset (VBO), VE block size (VBS)> is the set {LB+VBO, LB+VBO+1,...,LB+VBO+VBS-1}.

Label Blocks in Junos OS

Instead of a single large label block to cover all VE IDs in a VPLS, the Junos OS implementation contains several label blocks, each with a different label base. This makes label block management easier, and also allows Router PE-A to seamlessly integrate a PE router joining a VPLS with a site ID not covered by the set of label blocks that Router PE-A has already advertised.

VPLS Label Block Structure

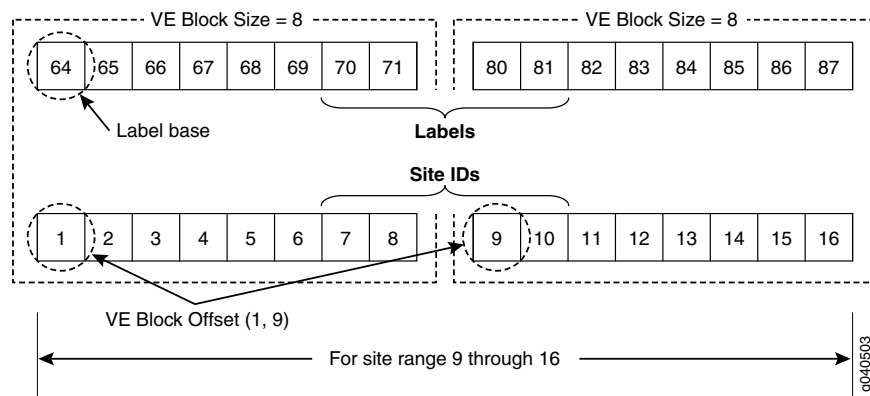

This section illustrates how a label block is uniquely identified.

A VPLS BGP NLRI with site ID V, VE block offset VBO, VE block size VBS, and label base LB communicates the following to its peers:

- Label block for V: Labels from LB to (LB + VBS -1).
- Remote VE set for V: from VBO to (VBO + VBS -1).

The label block advertised is a set of labels used to reach a given site ID. If there are several label blocks, the remote VE set helps to identify which label block to use. The example in [Figure 124 on page 5319](#) illustrates label blocks. There are two blocks and each block has eight labels. In this example, the label values are 64 to 71 and 80 to 87.

Figure 124: VPLS Label Block Structure

To create a one-to-one mapping of these 16 labels to 16 sites, assume the site IDs are the numbers 1 to 16, as shown in the illustration. The site block indicates which site ID can use which label in the label block. So, in the first block, site ID 1 uses 64, site ID 2 uses 65, and so forth. Finally, site ID 8 uses 71. The 9th site ID will use the second block instead of the first block.

The labels are calculated by comparing the values of $VBO \leq \text{Local site ID} < (VBO + VBS)$. Consequently, site ID 9 uses 80, site ID 10 uses 81, and so on.

To further illustrate the one-to-one mapping of labels to sites, assume a label block with site offset of 1 and a label base of 10. The combination of label base and block offset contained in the VPLS NLRI provides the mapping of labels to site IDs. The block offset is the starting site ID that can use the label block as advertised in the VPLS NLRI.

To advertise the default VPLS NLRI, a PE router picks a starting block offset that fits its own site ID and is such that the end block offset is a multiple of a single label block. In Junos OS a single label block is eight labels by default.

The end block offset is the last site ID that maps to the last label in the label block. The end offset for the first block is 8 which maps to label 17 and the second block is 16. For example, a site with ID 3 picks a block offset of 1 and advertises a label block of size 8 to cover sites with IDs 1 to 8. A site with ID 10 picks a block offset of 9 to cover sites with IDs 9 to 16.

The VPLS NLRI shown in [Figure 125 on page 5320](#) is for site ID 18. The label base contains value 262145. The block offset contains value 17. The illustration shows which site IDs correspond to which labels.

Figure 125: Label Mapping Example

VPLS NLRI for Site ID 18

Length
RD
VE ID - 18
VE Block Offset - 17
VE Block Size - 8
Label Base - 262145

Label Mapping for Site ID 18

Label Base = 262145

Label Block

Label	262145	262146	262147	262148	262149	262150	262151	262152
Site ID	17	18	19	20	21	22	23	24

Site Offset = 17

Site IDs

g040504

If a PE router configured with site ID 17 is in the same VPLS domain as a PE router configured with site ID 18, it receives the VPLS NLRI as shown in Figure 3. So it uses label 262145 to send traffic to site 18. Similarly, a PE router configured with site ID 19 uses label 262147 to send traffic to a PE router configured with site ID 18. However, only PE routers configured with site IDs 17 to 24 can use the label block shown to set up pseudowires.

PE Router Mesh Groups for VPLS Routing Instances

A PE router mesh group consists of a set of routers participating in a VPLS routing instance that share the same signaling protocol, either BGP or LDP. Each VPLS routing instance can have just one BGP mesh group. However, you can configure multiple LDP mesh groups for each routing instance.

The Junos OS can support up to 16 mesh groups on MX Series routers and up to 128 on M Series and T Series routers. However, two mesh groups are created by default, one for the CE routers and one for the PE routers. Therefore, the maximum number of user-defined mesh groups is 14 for MX Series routers and 126 for M Series and T Series routers. PE router mesh groups are not supported on J Series routers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The Junos OS supports both forwarding equivalency class (FEC) 128 and FEC 129. FEC 129 uses VPLS autodiscovery to convey endpoint information. FEC 128 requires manually configured pseudowires.

The following describes the behavior of mesh groups in regards to BGP-signaled PE routers and LDP-signaled PE routers:

- BGP-signaled PE routers—Automatically discovered PE routers that use BGP for signaling are associated with the default VE mesh group. You cannot configure the Junos OS to associate these routers with a user-defined VE mesh group.

- LDP-signaled PE routers (FEC 128)—PE routers statically configured using FEC-128 LDP signaling are placed in a default mesh group. However, you can configure a VE mesh group and associate each LDP FEC-128 neighbor with it. Each configured VE mesh group contains a set of VEs that are in the same interior gateway protocol (IGP) routing instance and are fully meshed with each other in the control and data planes.
- LDP-signaled PE routers (FEC 129)—Configuration for a mesh group for FEC 129 is very similar to the configuration for FEC 128.

Note the following differences for FEC 129:

- Each user-defined mesh group must have a unique route distinguisher. Do not use the route distinguisher that is defined for the default mesh group at the **[edit routing-instances]** hierarchy level.
- Each user-defined mesh group must have its own import and export route target.
- Each user-defined mesh group can have a unique Layer 2 VPN ID. By default, all the mesh groups that are configured for the a VPLS routing-instance use the same Layer 2 VPN ID, the one that you configure at the **[edit routing-instances]** hierarchy level.

Understanding PIM Snooping for VPLS

There are two ways to direct PIM control packets:

- By the use of PIM snooping
- By the use of PIM proxying

PIM snooping configures a device to examine and operate only on PIM hello and join/prune packets. A PIM snooping device snoops PIM hello and join/prune packets on each interface to find interested multicast receivers and populates the multicast forwarding tree with this information. PIM snooping differs from PIM proxying in that both PIM hello and join/prune packets are transparently flooded in the VPLS as opposed to the flooding of only hello packets in the case of PIM proxying. PIM snooping is configured on PE routers connected through pseudowires. PIM snooping ensures that no new PIM packets are generated in the VPLS, with the exception of PIM messages sent through LDP on pseudowires.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

A device that supports PIM snooping snoops hello packets received on attachment circuits. It does not introduce latency in the VPLS core when it forwards PIM join/prune packets.

To configure PIM snooping on a PE router, use the **pim-snooping** statement at the **[edit routing-instances instance-name protocols]** hierarchy level:

```
routing-instances {
  customer {
    instance-type vpls;
    ...
    protocols {
      pim-snooping {
        traceoptions {
          file pim.log size 10m;
          flag all;
          flag timer disable;
        }
      }
    }
  }
}
```

“[Example: Configuring PIM Snooping for VPLS](#)” on [page 3746](#) explains the PIM snooping method. The use of the PIM proxying method is not discussed here and is outside the scope of this document. For more information about PIM proxying, see [PIM Snooping over VPLS](#).

Configuring an Ethernet Switch as the CE Device

For VPLS configurations, the CE device does not necessarily need to be a router. You can link the PE routers directly to Ethernet switches. However, there are a few configuration issues to be aware of:

- When you configure VPLS routing instances and establish two or more connections between a CE Ethernet switch and a PE router, you must enable the Spanning Tree Protocol (STP) on the switch to prevent loops.
- The Junos OS allows standard Bridge Protocol Data Unit (BPDU) frames to pass through emulated Layer 2 connections, such as those configured with Layer 2 VPNs, Layer 2 circuits, and VPLS instances. However, CE Ethernet switches that generate proprietary BPDU frames might not be able to run STP across Juniper Networks routing platforms configured for these emulated Layer 2 connections.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Introduction to Configuring VPLS

Virtual private LAN service (VPLS) allows you to provide a point-to-multipoint LAN between a set of sites in a virtual private network (VPN).

To configure VPLS functionality, you must enable VPLS support on the provider edge (PE) router. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the customer edge (CE) routers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Each VPLS is configured under a routing instance of type **vpls**. A **vpls** routing instance can transparently carry Ethernet traffic across the service provider's network. As with other routing instances, all logical interfaces belonging to a VPLS routing instance are listed under that instance.

In addition to VPLS routing instance configuration, you must configure MPLS label-switched paths (LSPs) between the PE routers, IBGP sessions between the PE routers, and an interior gateway protocol (IGP) on the PE and provider (P) routers.

By default, VPLS is disabled.

Many configuration procedures for VPLS are identical to the procedures for Layer 2 VPNs and Layer 3 VPNs.

Configuring VPLS Routing Instances

To configure a VPLS routing instance, include the **vpls** statement:

```
vpls {  
  active-interface {  
    any;  
    primary interface-name;  
  }  
  connectivity-type (ce | irb | permanent);  
  encapsulation-type encapsulation-type;  
  interface-mac-limit limit;  
  label-block-size size;  
  mac-table-aging-time time;  
  mac-table-size size;  
  neighbor neighbor-id;  
  no-tunnel-services;  
  site site-name {  
    active-interface {  
      any;  
      primary interface-name;  
    }  
    interface interface-name {  
      interface-mac-limit limit;  
    }  
    mesh-group mesh-group-name;  
    multi-homing;  
    site-identifier identifier;  
    site-preference preference-value;  
  }  
  site-range number;  
  traceoptions {  
    file filename <files number> <size size> <world-readable | no-world-readable>;  
    flag flag <flag-modifier> <disable>;  
  }  
  tunnel-services {  
    devices device-names;  
    primary primary-device-name;  
  }  
  vpls-id vpls-id;  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]

NOTE: You cannot configure a routing protocol (OSPF, RIP, IS-IS or BGP) inside a VPLS routing instance (`instance-type vpls`). The Junos CLI disallows this configuration.

The configuration for the VPLS routing instance statements is explained in the following sections:

- [Configuring BGP Signaling for VPLS on page 5325](#)
- [Configuring LDP Signaling for VPLS on page 5330](#)
- [Configuring VPLS Routing Instance and VPLS Interface Connectivity on page 5332](#)
- [Configuring the VPLS Encapsulation Type on page 5332](#)
- [Configuring the VPLS MAC Table Timeout Interval on page 5333](#)
- [Configuring the Size of the VPLS MAC Address Table on page 5333](#)
- [Limiting the Number of MAC Addresses Learned from an Interface on page 5334](#)
- [Removing Addresses from the MAC Address Database on page 5335](#)

Configuring BGP Signaling for VPLS

You can configure BGP signaling for the VPLS routing instance. BGP is used to signal the pseudowires linking each of the PE routers participating in the VPLS routing instance. The pseudowires carry VPLS traffic across the service provider's network between the VPLS sites.

NOTE: You cannot configure both BGP signaling and LDP signaling for the same VPLS routing instance. If you attempt to configure the statements that enable BGP signaling for the VPLS routing instance (the `site`, `site-identifier`, and `site-range` statements) and the statements that enable LDP signaling for the same instance (the `neighbor` and `vpls-id` statements), the commit operation fails.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Configure BGP signaling for the VPLS routing instance by completing the steps in the following sections:

- [Configuring the VPLS Site Name and Site Identifier on page 5326](#)
- [Configuring Automatic Site Identifiers for VPLS on page 5326](#)
- [Configuring the Site Range on page 5327](#)
- [Configuring the VPLS Site Interfaces on page 5329](#)
- [Configuring the VPLS Site Preference on page 5329](#)

Configuring the VPLS Site Name and Site Identifier

When you configure BGP signaling for the VPLS routing instance, on each PE router you must configure each VPLS site that has a connection to the PE router. All the Layer 2 circuits provisioned for a VPLS site are listed as the set of logical interfaces (using the **interface** statement) within the **site** statement.

You must configure a site name and site identifier for each VPLS site.

To configure the site name and the site identifier, include the **site** and the **site-identifier** statements:

```
site site-name {  
  interface interface-name {  
    interface-mac-limit limit;  
  }  
  site-identifier identifier;  
}
```

The numerical identifier can be any number from 1 through 65,534 that uniquely identifies the local VPLS site.

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

Configuring Automatic Site Identifiers for VPLS

When you enable automatic site identifiers, the Junos OS automatically assigns site identifiers to VPLS sites. To configure automatic site identifiers for a VPLS routing instance, include the **automatic-site-id** statement:

```
automatic-site-id {  
  collision-detect-time seconds;  
  new-site-wait-time seconds;  
  reclaim-wait-time minimum seconds maximum seconds;  
  startup-wait-time seconds;  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name*]

The **automatic-site-id** statement includes a number of options that control different delays in network layer reachability information (NLRI) advertisements. All of these options are configured with default values. See the statement summary for the **automatic-site-id** statement for more information.

The **automatic-site-id** statement includes the following options:

- **collision-detect-time**—The time in seconds to wait after a claim advertisement is sent to the other routers in a VPLS instance before a PE router can begin using a site identifier. If the PE router receives a competing claim advertisement for the same site identifier during this time period, it initiates the collision resolution procedure for site identifiers.
- **new-site-wait-time**—The time in seconds to wait to receive VPLS information for a newly configured routing instance or a new site. This time interval is also applied whenever the automatic site identifier feature is activated on a VPLS routing instance other than at startup. Effectively, this timer indicates how long to wait before an attempt is made to allocate a site identifier. This timer is also triggered whenever a VPLS routing instance is enabled.
- **reclaim-wait-time**—The time to wait before attempting to claim a site identifier after a collision. A collision occurs whenever an attempt is made to claim a site identifier by two separate VPLS sites.
- **startup-wait-time**—The time in seconds to wait at startup to receive all the VPLS information for the route targets configured on the other PE routers included in the VPLS routing instance.

Configuring the Site Range

When you enable BGP signaling for each VPLS routing instance, you can optionally configure the site range. The site range specifies an upper limit on the maximum site identifier that can be accepted to allow a pseudowire to be brought up. You must specify a value from 1 through 65,534. The default value is **65,534**. We recommend using the default. Pseudowires cannot be established to sites with site identifiers greater than the configured site range. If you issue the **show vpls connections** command, such sites are displayed as OR (out of range).

To configure the site range, include the **site-range** statement:

```
site-range number;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

There are networks that require that the site range be configured using a value smaller than the local site identifier, for example, a hub-and-spoke VPLS with multihomed sites. For this type of network, you need to allow pseudowires to be established between the spoke routers and the hub router. However, you also need to prevent pseudowires from being established between spoke routers directly. Due to the multihoming requirement of spoke sites, Layer 2 VPN NRIs need to be accepted from other spoke routers (at least

from spokes with the same site identifier as the locally configured sites) to determine the status of local spoke routers (active or not active) based on the local preference included in the NRLIs received from the other spoke routers.

This type of VPLS network can be implemented by, for example, numbering hub sites with identifiers 1 through 8 and spoke sites with identifiers 9 and larger. You can then configure a site range of 8 on each of the spoke sites. Although the spoke sites accept NRLIs and install them in the Layer 2 VPN routing tables (allowing the multihomed sites to determine the status of the local site), the spoke sites cannot establish pseudowires directly to the other spoke sites due to the configured site range.

The following configurations illustrate this concept. The configurations are for the VPLS routing instances on three routers, two spoke routers and one hub router:

Router 1—spoke:

```
routing-instance hub-and-spoke {
  no-local-switching;
  protocols {
    vpls {
      site-range 8;
      no-tunnel-services;
      site spoke-9 {
        site-identifier 9 {
          multi-homing;
          site-preference primary;
        }
      }
      site spoke-10 {
        site-identifier 10 {
          multi-homing;
          site-preference backup;
        }
      }
    }
  }
}
```

Router 2—spoke:

```
routing-instance hub-and-spoke {
  no-local-switching;
  protocols {
    vpls {
      site-range 8;
      no-tunnel-services;
      site spoke-9 {
        site-identifier 9 {
          multi-homing;
          site-preference backup;
        }
      }
      site spoke-10 {
        site-identifier 10 {
          multi-homing;
        }
      }
    }
  }
}
```

```

        site-preference primary;
    }
}
}
}

```

Hub—router 3:

```

routing-instance hub-and-spoke {
    no-local-switching;
    protocols {
        vpls {
            no-tunnel-services;
            site hub {
                site-identifier 1;
            }
        }
    }
}

```

Configuring the VPLS Site Interfaces

You must configure an interface for each of the pseudowires you specify for the VPLS site.

To configure an interface for the VPLS site, include the **interface** statement:

```

interface interface-name {
    interface-mac-limit limit;
}

```

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

You can also configure a limit on the number of MAC addresses that can be learned from the specified interface. For more information, see [“Limiting the Number of MAC Addresses Learned from an Interface” on page 5334](#).

Configuring the VPLS Site Preference

You can specify the local preference value advertised for a particular VPLS site. The site preference value is specified using the **site-preference** statement configured at the [edit routing-instances *routing-instance-name* protocols vpls site *site-name*] hierarchy level. By configuring the **site-preference** statement, a value configured for the **local-preference** statement at the [edit protocols bgp] hierarchy level is ignored by the VPLS routing instance. However, you can change the site preference value for VPLS routes exported to other routers by configuring an export policy. When a PE router receives multiple advertisements with the same VPLS edge (VE) device identifier, the advertisement with the highest local preference value is preferred.

To configure the VPLS site preference, include the **site-preference** statement:

```
site-preference preference-value {  
    backup;  
    primary;  
}
```

You can also specify either the **backup** option or the **primary** option for the **site-preference** statement. The **backup** option specifies the preference value as 1, the lowest possible value, ensuring that the VPLS site is the least likely to be selected. The **primary** option specifies the preference value as 65,535, the highest possible value, ensuring that the VPLS site is the most likely to be selected.

For a list of hierarchy levels at which you can include the **site-preference** statement, see the statement summary section for this statement.

Configuring LDP Signaling for VPLS

You can configure LDP as the signaling protocol for a VPLS routing instance. This functionality is described in RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*.

The Junos OS does not support all of RFC 4762. When enabling LDP signaling for a VPLS routing instance, network engineers should be aware that only the following values are supported:

- FEC—128 or 129
- Control bit—0
- Ethernet pseudowire type—0x0005
- Ethernet tagged mode pseudowire type—0x0004

To enable LDP signaling for the set of PE routers participating in the same VPLS routing instance, you need to use the **vpls-id** statement configured at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level to configure the same VPLS identifier on each of the PE routers. The VPLS identifier must be globally unique. When each VPLS routing instance (domain) has a unique VPLS identifier, it is possible to configure multiple VPLS routing instances between a given pair of PE routers.

LDP signaling requires that you configure a full-mesh LDP session between the PE routers in the same VPLS routing instance. Neighboring PE routers are statically configured. Tunnels are created between the neighboring PE routers to aggregate traffic from one PE router to another. Pseudowires are then signaled to demultiplex traffic between VPLS routing instances. These PE routers exchange the pseudowire label, the MPLS label that acts as the VPLS pseudowire demultiplexer field, by using LDP forwarding equivalence classes (FECs). Tunnels based on both MPLS and generic routing encapsulation (GRE) are supported.

NOTE: You cannot configure both BGP signaling and LDP signaling for the same VPLS routing instance. If you attempt to configure the statements that enable BGP signaling for the VPLS routing instance (the `site`, `site-identifier`, and `site-range` statements), and the statements that enable LDP signaling for the same instance, `neighbor` and `vpls-id`, the commit operation fails.

To enable LDP signaling for the VPLS routing instance, complete the steps in the following sections:

- [Configuring LDP Signaling for the VPLS Routing Instance on page 5331](#)
- [Configuring LDP Signaling on the Router on page 5331](#)

Configuring LDP Signaling for the VPLS Routing Instance

To configure the VPLS routing instance to use LDP signaling, you must configure the same VPLS identifier on each PE router participating in the instance. Specify the VPLS identifier with the `vpls-id` statement:

```
vpls-id vpls-id;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

To configure the VPLS routing instance to use LDP signaling, you also must include the `neighbor` statement to specify each of the neighboring PE routers that are a part of this VPLS domain:

```
neighbor neighbor-id;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

Configuring LDP Signaling on the Router

To enable LDP signaling, you need to configure LDP on each PE router participating in the VPLS routing instance. A minimal configuration is to enable LDP on the loopback interface, which includes the router identifier (`router-id`), on the PE router using the `interface` statement:

```
interface interface-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols ldp]
- [edit logical-systems *logical-system-name* protocols ldp]

You can enable LDP on all the interfaces on the router using the **all** option for the **interfaces** statement. For more information about how to configure LDP, see the *Junos OS MPLS Applications Configuration Guide*.

Configuring VPLS Routing Instance and VPLS Interface Connectivity

You can configure the VPLS routing instance to take down or maintain its VPLS connections depending on the status of the interfaces configured for the VPLS routing instance. By default, the VPLS connection is taken down whenever a customer-facing interface configured for the VPLS routing instance fails. This behavior can be explicitly configured by specifying the **ce** option for the **connectivity-type** statement:

```
connectivity-type ce;
```

You can alternatively specify that the VPLS connection remain up so long as an Integrated Routing and Bridging (IRB) interface is configured for the VPLS routing instance by specifying the **irb** option for the **connectivity-type** statement:

```
connectivity-type irb;
```

To ensure that the VPLS connection remain up until explicitly taken down, specify the **permanent** option for the **connectivity-type** statement:

```
connectivity-type permanent;
```

This option is reserved for use in configuring Layer 2 Wholesale subscriber networks. See the *Broadband Subscriber Management Solutions Guide* for details about configuring a Layer 2 Wholesale network.

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

Configuring the VPLS Encapsulation Type

You can specify a VPLS encapsulation type for the pseudowires established between VPLS neighbors. The encapsulation type is carried in the LDP-signaling messages exchanged between VPLS neighbors when pseudowires are created. You might need to alter the encapsulation type depending on what other vendors' equipment is deployed within your network.

VPLS effectively provides a bridge between Ethernet networks. As a consequence, only two encapsulation types are available:

- **ethernet**—Ethernet
- **ethernet-vlan**—Ethernet virtual LAN (VLAN)

If you do not specify an encapsulation type for the VPLS routing instance or the VPLS neighbor, **ethernet** is used.

To specify an encapsulation type for the VPLS routing instance, include the **encapsulation-type** statement:

encapsulation-type (ethernet | ethernet-vlan);

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

You can also specify an encapsulation type for a specific VPLS neighbor by including the **encapsulation-type** statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls neighbor *address*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls neighbor *address*]

Configuring the VPLS MAC Table Timeout Interval

You can modify the timeout interval for the VPLS table. We recommend you that configure longer values for small, stable VPLS networks and shorter values for large, dynamic VPLS networks. If the VPLS table does not receive any updates during the timeout interval, the router waits one additional interval before automatically clearing the MAC address entries from the VPLS table.

To modify the timeout interval for the VPLS table, include the **mac-table-aging-time** statement:

mac-table-aging-time *seconds*;

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

NOTE: The **mac-table-aging-time** statement is not available on MX Series routers.

Configuring the Size of the VPLS MAC Address Table

You can modify the size of the VPLS media access control (MAC) address table. The default table size is 512 MAC addresses, the minimum is 16 addresses, and the maximum is 65,536 addresses.

NOTE: T4000 routers with Type 5 FPCs support up to 262,143 MAC addresses per VPLS routing instance. To enable the improved VPLS MAC address learning limit (that is, 262,143 MAC addresses), you must include the **enhanced-mode** statement at the [edit chassis network-services] hierarchy level, reboot the router, and then modify the size of the VPLS MAC address table.

If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

To change the VPLS MAC table size for each VPLS or VPN routing instance, include the **mac-table-size** statement:

```
mac-table-size size;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

When you include the **mac-table-size** statement, the affected interfaces include all interfaces within the VPLS routing instance, including the local interfaces, the LSI interfaces, and the VT interfaces.

Limiting the Number of MAC Addresses Learned from an Interface

You can configure a limit on the number of MAC addresses learned by a VPLS routing instance using the **mac-table-size** statement. If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

Because this limit applies to each VPLS routing instance, the MAC addresses of a single interface can consume all the available space in the table, preventing the routing instance from acquiring addresses from other interfaces.

You can limit the number of MAC addresses learned from each interface configured for a VPLS routing instance. To do so, include the **interface-mac-limit** statement:

```
interface-mac-limit limit;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

The **interface-mac-limit** statement affects the local interfaces only (the interfaces facing CE devices).

Configuring the **interface-mac-limit** statement at the [edit routing-instances *routing-instance-name* protocols vpls] hierarchy level causes the same limit to be applied to all of the interfaces configured for that specific routing instance.

You can also limit the number of MAC addresses learned by a specific interface configured for a VPLS routing instance. This gives you the ability to limit particular interfaces that you expect might generate a lot of MAC addresses.

To limit the number of MAC addresses learned by a specific interface, include the **interface-mac-limit** statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name* interfaces *interface-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name* interfaces *interface-name*]

The MAC limit configured for an individual interface at this hierarchy level overrides any value configured at the [edit routing-instances *routing-instance-name* protocols vpls] hierarchy level. Also, the MAC limit configured using the **mac-table-size** statement can override the limit configured using the **interface-mac-limit** statement.

The MAC address limit applies to customer-facing interfaces only.

Removing Addresses from the MAC Address Database

You can enable MAC flush processing for the VPLS routing instance or for the mesh group under a VPLS routing instance. MAC flush processing removes MAC addresses from the MAC address database that have been learned dynamically. With the dynamically learned MAC addresses removed, MAC address convergence requires less time to complete.

You can clear dynamically learned MAC addresses from the MAC address database by including the **mac-flush** statement:

mac-flush [*explicit-mac-flush-message-options*];

To clear dynamically learned MAC addresses globally across all devices participating in the routing instance, you can include the statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]
- [edit routing-instances *routing-instance-name* protocols vpls]

To clear the MAC addresses on the routers in a specific mesh group, you can include the statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]
- [edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]

For certain cases where MAC flush processing is not initiated by default, you can also specify **explicit-mac-flush-message-options** to additionally configure the router to send explicit MAC flush messages under specific conditions. For a list of the explicit MAC flush message options you can include with this statement, see the summary section for this statement.

- [enhanced-mode](#)

Configuring Interfaces for VPLS Routing

On each PE router and for each VPLS routing instance, specify which interfaces are intended for the VPLS traffic traveling between PE and CE routers. To specify the interface for VPLS traffic, include the **interface** statement in the routing instance configuration:

```
interface interface-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

You must also define each interface by including the following statements:

```
vlan-tagging;  
encapsulation encapsulation-type;  
unit logical-unit-number {  
    family vpls;  
    vlan-id vlan-id-number;  
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following sections provide enough information to enable you to configure interfaces for VPLS routing. For detailed information about configuring interfaces and the statements at the [edit interfaces] hierarchy level, see the *Junos® OS Network Interfaces*.

- [Configuring the VPLS Interface Name on page 5336](#)
- [Configuring VPLS Interface Encapsulation on page 5337](#)
- [Enabling VLAN Tagging on page 5339](#)
- [Configuring VLAN IDs for Logical Interfaces on page 5340](#)
- [Enabling VLANs for Hub and Spoke VPLS Networks on page 5340](#)
- [Configuring Aggregated Ethernet Interfaces for VPLS on page 5341](#)

Configuring the VPLS Interface Name

Specify both the physical and logical portions of the interface name, in the following format:

physical.logical

For example, in **ge-1/2/1.2**, **ge-1/2/1** is the physical portion of the interface name and **2** is the logical portion. If you do not specify the logical portion of the interface name, **0** is set by default.

A logical interface can be associated with only one routing instance.

If you enable a routing protocol on all instances by specifying **interfaces all** when configuring the master instance of the protocol at the **[edit protocols]** hierarchy level, and you configure a specific interface for VPLS routing at the **[edit routing-instances routing-instance-name]** hierarchy level, the latter interface statement takes precedence and the interface is used exclusively for VPLS.

If you explicitly configure the same interface name at both the **[edit protocols]** and **[edit routing-instances routing-instance-name]** hierarchy levels and then attempt to commit the configuration, the commit operation fails.

Configuring VPLS Interface Encapsulation

You need to specify an encapsulation type for each PE-router-to-CE-router interface configured for VPLS. This section describes the **encapsulation** statement configuration options available for VPLS. For a complete description of all of the options available for this statement, see the *Junos® OS Network Interfaces*.

To configure the encapsulation type on the physical interface, include the **encapsulation** statement:

encapsulation (ethernet-vpls | ether-vpls-over-atm-llc | extended-vlan-vpls | vlan-vpls);

You can include the **encapsulation** statement for physical interfaces at the following hierarchy levels:

- **[edit interfaces interface-name]**
- **[edit logical-systems logical-system-name interfaces interface-name]**

You can configure the following physical interface encapsulations for VPLS routing instances:

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled. The PE router expects to receive Ethernet frames with VLAN tags that are not service-delimiting. The Ethernet frames are not meaningful to the PE router and cannot be used by the service provider to separate customer traffic.

On M Series routers (except the M320 router), the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

- **ether-vpls-over-atm-llc**—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from

the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

- **extended-vlan-vpls**—Use extended virtual LAN (VLAN) VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers (except the M320 router), the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN 802.1Q tagging and VPLS enabled. The PE router expects to receive Ethernet frames with VLAN tags that are service-delimiting. These VLAN tags can be used by the service provider to separate customer traffic. For example, LAN traffic from different customers can flow through the same service provider switch, which can then apply VLAN tags to distinguish one customer's traffic from the others. The traffic can then be forwarded to the PE router.

Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers (except the M320 router), the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

To configure the encapsulation type for logical interfaces, include the **encapsulation** statement:

```
encapsulation (ether-vpls-over-atm-llc | vlan-vpls);
```

You can include the **encapsulation** statement for logical interfaces at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *number*]**

You can configure the following logical interface encapsulations for VPLS routing instances:

- **ether-vpls-over-atm-llc**—Use Ethernet VPLS over Asynchronous Transfer Mode (ATM) logical link control (LLC) encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3-encapsulated Ethernet frames with the frame check sequence (FCS) field removed. This encapsulation type is supported on ATM intelligent queuing (IQ) interfaces only.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN 802.1Q tagging and VPLS enabled. The PE router expects to receive Ethernet frames with VLAN tags that are service-delimiting. These VLAN tags can be used by the service provider to separate customer traffic. For example, LAN traffic from different customers

can flow through the same service provider switch, which can then apply VLAN tags to distinguish one customer's traffic from the others. The traffic can then be forwarded to the PE router.

Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers (except the M320 router), the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.

When you configure the physical interface encapsulation as **vlan-vpls**, you also need to configure the same interface encapsulation for the logical interface. You need to configure the **vlan-vpls** encapsulation on the logical interface because the **vlan-vpls** encapsulation allows you to configure a mixed mode, where some of the logical interfaces use regular Ethernet encapsulation (the default for logical interfaces) and some use **vlan-vpls**. For more information, see the *Junos® OS Network Interfaces*.

Enabling VLAN Tagging

Junos OS supports receiving and forwarding routed Ethernet frames with 802.1Q virtual local area network (VLAN) tags and running the Virtual Router Redundancy Protocol (VRRP) over 802.1Q-tagged interfaces. For VPLS to function properly, configure the router to receive and forward frames with 802.1Q VLAN tags by including the **vlan-tagging** statement at the **[edit interfaces interface-name]** hierarchy level:

```
[edit interfaces interface-name]
vlan-tagging;
```

Gigabit Ethernet interfaces can be partitioned. You can assign up to 4095 different logical interfaces, one for each VLAN, but you are limited to a maximum of 1024 VLANs on any single Gigabit Ethernet or 10-Gigabit Ethernet port. Fast Ethernet interfaces can also be partitioned, with a maximum of:

- 1024 logical interfaces for the 4-port FE PIC
- 1024 logical interfaces for the 2-port Fixed Interface Card (FIC) on an M7i router
- 16 logical interfaces for the M40e router

Table 386 on page 5339 lists VLAN ID ranges by interface type.

Table 386: VLAN ID Range by Interface Type

Interface Type	VLAN ID Range
Fast Ethernet	512 through 1023
Gigabit Ethernet	512 through 4094

Configuring VLAN IDs for Logical Interfaces

You can bind a VLAN identifier to a logical interface by including the **vlan-id** statement:

```
vlan-id number;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can also configure a logical interface to forward packets and learn MAC addresses within each VPLS routing instance configured with a VLAN ID that matches a VLAN ID specified in a list using the **vlan-id-list** statement. VLAN IDs can be entered individually using a space to separate each ID, entered as an inclusive list separating the starting VLAN ID and ending VLAN ID with a hyphen, or a combination of both.

For example, to configure the VLAN IDs 20 and 45 and the range of VLAN IDs between 30 and 40, issue the following command from the CLI:

```
set interfaces ge-1/0/1 unit 1 vlan-id-list [20 30-40 45];
```

To configure a list of VLAN IDs for a logical interface, include the **vlan-id-list** statement:

```
vlan-id-list list-of-vlan-ids;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

For more information about how to configure VLANs, see the *Junos® OS Network Interfaces*. For detailed information about how VLAN identifiers in a VPLS routing instance are processed and translated, see the *MX Series Layer 2 Configuration Guide*.

Enabling VLANs for Hub and Spoke VPLS Networks

For hub and spoke VPLS networks, you need to configure the **swap** option for the **output-vlan-map** statement on the hub facing interface of each spoke PE router. The **output-vlan-map** statement ensures that the vlan ID of the spoke PE router matches the VLAN ID of the hub PE router in the VPLS network. The following configuration example illustrates an interface configuration with the output-vlan-map statement included:

```
[edit interfaces xe-4/0/0]
vlan-tagging;
encapsulation flexible-ethernet-services;
unit 610 {
  encapsulation vlan-ccc;
  vlan-id 610;
  output-vlan-map swap;
}
```

Configuring Aggregated Ethernet Interfaces for VPLS

You can configure aggregated Ethernet interfaces between CE devices and PE routers for VPLS routing instances. Traffic is load-balanced across all of the links in the aggregated interface. If one or more links in the aggregated interface fails, the traffic is switched to the remaining links.

For more information about how aggregated Ethernet interfaces function in the context of VPLS, see [“VPLS and Aggregated Ethernet Interfaces” on page 5302](#).

To configure aggregated Ethernet interfaces for VPLS, configure the interface for the VPLS routing instance as follows:

```
interfaces aex {
  vlan-tagging;
  encapsulation encapsulation-type;
  unit logical-unit-number {
    vlan-id number;
  }
}
```

You can configure the following physical link-layer encapsulation types for the VPLS aggregated Ethernet interface:

- **ethernet-vpls**
- **extended-vlan-vpls**
- **flexible-ethernet-services**
- **vlan-vpls**

For the **interface** configuration statement, in **aex**, the **x** represents the interface instance number to complete the link association; **x** can be from 0 through 127, for a total of 128 aggregated interfaces.

For more information about how to configure aggregated Ethernet interfaces, see the *Junos® OS Network Interfaces*.

The aggregated Ethernet interface must also be configured for the VPLS routing instance as shown in the following example:

```
[edit]
routing-instances {
  green {
    instance-type vpls;
    interface ae0.0;
    route-distinguisher 10.255.234.34:1;
    vrf-target target:1111:1;
    protocols {
      vpls {
        site-range 10;
        site green3 {
          site-identifier 3;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

Interface **ae0.0** represents the aggregated Ethernet interface in the routing instance configuration. The VPLS routing instance configuration is otherwise standard.

Configuring Static Pseudowires for VPLS

You can configure a VPLS domain using static pseudowires. A VPLS domain consists of a set of PE routers that act as a single virtual Ethernet bridge for the customer sites connected to these routers. By configuring static pseudowires for the VPLS domain, you do not need to configure the LDP or BGP protocols that would normally be used for signaling. However, if you configure static pseudowires, any changes to the VPLS network topology have to be managed manually.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Static pseudowires require that you configure a set of in and out labels for each pseudowire configured for the VPLS domain. You still need to configure a VPLS identifier and neighbor identifiers for a static VPLS domain. You can configure both static and dynamic neighbors within the same VPLS routing instance.

To configure a static pseudowire for a VPLS neighbor, include the **static** statement:

```

static (Protocols VPLS) {
    incoming-label label;
    outgoing-label label;
}

```

You must configure an incoming and outgoing label for the static pseudowire using the **incoming-label** and **outgoing-label** statements. These statements identify the static pseudowire's incoming traffic and destination.

To configure a static pseudowire for a VPLS neighbor, include the **static** statement at the **[edit routing-instances routing-instance-name protocols vpls neighbor address]** hierarchy level.

You can also configure the **static** statement for a backup neighbor (if you configure the neighbor as static the backup must also be static) by including it at the **[edit routing-instances routing-instance-name protocols vpls neighbor address backup-neighbor address]** hierarchy level and for a mesh group by including it at the **[edit routing-instances routing-instance-name protocols vpls mesh-group mesh-group-name neighbor address]** hierarchy level.

For a list of hierarchy levels at which you can include the **static** statement, see the statement summary section for this statement.

To enable static VPLS on a router, you need to either configure a virtual tunnel interface (requires the router to have a tunnel services PIC) or you can configure a label switching interface (LSI). To configure an LSI, include the **no-tunnel-services** statement at the **[edit**

`protocols vpls static-vpls]` hierarchy level. For more information, see [“Configuring VPLS Without a Tunnel Services PIC” on page 5351](#).

NOTE: Static pseudowires for VPLS using an LSI is supported on MX series routers and EX Series switches only. For M series and T series routers, a tunnel services PIC is required.

If you issue a **show vpls connections** command, static neighbors are displayed with **"SN"** next to their addresses in the command output.

Related Documentation

- [Configuring VPLS Without a Tunnel Services PIC on page 5351](#)

Configuring VPLS Multihoming (FEC 128)

VPLS multihoming allows you to connect a customer site to multiple PE routers to provide redundant connectivity while preventing the formation of Layer 2 loops in the service provider's network. A VPLS site multihomed to two or more PE routers provides redundant connectivity in the event of a PE router-to-CE device link failure or the failure of a PE router. For more information about VPLS multihoming, see [“VPLS Multihoming Overview” on page 5305](#).

NOTE: If you want to enable multihoming for a VPLS routing instance, you cannot also enable LDP signaling. You can only enable BGP signaling.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following sections describe how to configure VPLS multihoming. Some information is also provided on single-homed site configuration versus multihomed site configuration.

- [VPLS Multihomed Site Configuration on page 5343](#)
- [VPLS Single-Homed Site Configuration on page 5345](#)

VPLS Multihomed Site Configuration

The following describes the requirements for a VPLS multihomed site configuration:

- Assign the same site ID on all PE routers connected to the same CE devices.
- Assign the same route distinguisher on all PE routers connected to the same CE devices.
- Reference all interfaces assigned to the multihomed VPLS site on each PE router. Only one of these interfaces is used to send and receive traffic for this site at a time.
- Either designate a primary interface or allow the router to select the interface to be used as the primary interface.

If the router selects the interface, the interface used to connect the PE router to the site depends on the order in which interfaces are listed in the PE router's configuration. The first operational interface in the set of configured interfaces is chosen to be the designated interface. If this interface fails, the next interface in the list is selected to send and receive traffic for the site.

- Configure multihoming for the site.

The following configuration shows the statements you need to configure to enable VPLS multihoming:

```
[edit routing-instances routing-instance-name]  
instance-type vpls;  
interface interface-name;  
interface interface-name;  
protocols vpls {  
  site site-name {  
    active-interface {  
      any;  
      primary interface-name;  
    }  
    interface interface-name;  
    interface interface-name;  
    multi-homing;

  }  
}  
route-distinguisher (as-number:id | ip-address:id);
```

NOTE: If you add a direct connection between CE devices that are multihomed to the same VPLS site on different PE routers, the traffic can loop and a loss of connectivity might occur. We do not recommend this topology.

Most of these statements are explained in more detail in the rest of this chapter. The following sections explain how to configure the statements that are specific to VPLS multihoming:

- [Specifying an Interface as the Active Interface on page 5344](#)
- [Configuring Multihoming on the PE Router on page 5345](#)

Specifying an Interface as the Active Interface

You need to specify one of the interfaces for the multihomed site as the primary interface. If there are multiple interfaces, the remaining interfaces are activated only when the primary interface goes down. If no active interfaces are configured at the site level, all traffic for a VPLS site travels through a single, non-multihomed PE router.

You must configure one of the following options for the **active-interface** statement:

- **any**—One configured interface is randomly designated as the active interface for the VPLS site.

- **primary**—Specify the name of the multihomed interface to be used as the primary interface by the VPLS site.

To specify a multihomed interface as the primary interface for the VPLS site, include the **active-interface** statement:

```
active-interface {
    any;
    primary interface-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name*]

Configuring Multihoming on the PE Router

When a CE device is connected to the same VPLS site on more than one PE router, include the **multi-homing** statement on all associated PE routers. Configuration of this statement tracks BGP peers. If no BGP peer is available, VPLS deactivates all active interfaces for a site. To specify that the PE router is part of a multihomed VPLS site, include the **multi-homing** statement:

```
multi-homing;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name*]

Include the **multi-homing** statement on all PE routers associated with a particular VPLS site.

VPLS Single-Homed Site Configuration

All VPLS single-homed sites are connected to the same default VE device. All interfaces in a VPLS routing instance that are not configured as part of a multihomed site are assumed to be single-homed to the default VE device.

Enabling BGP Path Selection for Layer 2 VPNs and VPLS

Layer 2 VPNs and VPLS share the same path selection process for determining the optimal path to reach all of the destinations shared within a single routing instance. For Layer 2 VPN and VPLS topologies, the path selection process is straightforward if there is just a single path from each PE router to each CE device. However, the path selection process becomes more complex if the PE routers receive two or more valid paths to reach a specific CE device.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following network scenarios provide examples of what might cause a PE router to receive more than one valid path to reach a specific CE device:

- Multihoming—One or more CE devices within a routing instance are multihomed to two or more PE routers. Each multihomed CE device has at least two valid paths.
- Route reflectors—There are multiple route reflectors deployed within the same network and they are supporting PE routers within the same routing instance. Due to time delays in large complex networks, the route reflectors can separately receive a different valid path to reach a CE device at different times. When they readvertise these valid paths, a PE router could receive two or more separate but apparently valid paths to the same CE device.

By default, Juniper Networks routers use just the designated forwarder path selection algorithm to select the best path to reach each Layer 2 VPN or VPLS routing instance destination (for more information, see [“VPLS Path Selection Process for PE Routers” on page 5309](#)). However, you can also configure the routers in your network to use both the BGP path selection algorithm and the designated forwarder path selection algorithm as follows:

- On the Provider routers within the service providers network, the standard BGP path selection algorithm is used (for more information, see *Understanding BGP Path Selection*). Using the standard BGP path selection for Layer 2 VPN and VPLS routes allows a service provider to leverage the existing Layer 3 VPN network infrastructure to also support Layer 2 VPNs and VPLS. The BGP path selection algorithm also helps to ensure that the service provider’s network behaves predictably with regard to Layer 2 VPN and VPLS path selection. This is particularly important in networks employing route reflectors and multihoming.

When a Provider router receives multiple paths for the same destination prefix (for example, a multihomed CE device), one path is selected based on the BGP path selection algorithm and placed in the `bgp.l2vpn.0` routing table and the appropriate `instance.l2vpn.0` routing table.

- When a PE router receives all of the available paths to each CE device, it runs the designated forwarder path selection algorithm to select the preferred path to reach each CE device, independently of the results of the earlier BGP path selection algorithm run on the Provider router. The VPLS designated forwarder algorithm uses the D-bit, preference, and PE router identifier to determine which of the valid paths to each CE device to use. The PE router might select a path to reach a CE device which is different from the path selected by the BGP-based Provider routers. In this scenario, the following is the expected behavior for traffic sent to the multihomed CE device:
 - If the path selected by the remote PE router is available, traffic will traverse the network to the multihomed CE device using the remote PE router's preferred path (again, ignoring the path selected by the BGP-based Provider routers).
 - If the path selected by the remote PE router fails:
 1. The Provider routers switch the traffic destined for the multihomed CE device to the alternate path as soon as failure is detected.
 2. The Provider routers notify the remote PE routers of the path failure.
 3. The remote PE routers update their routing tables accordingly.

For more information about the VPLS designated forwarder path selection algorithm, see [“VPLS Path Selection Process for PE Routers” on page 5309](#). This algorithm is also described in the Internet draft [draft-kompella-l2vpn-vpls-multihoming-03.txt](#), *Multi-homing in BGP-based Virtual Private LAN Service*.

To enable the BGP path selection algorithm for Layer 2 VPN and VPLS routing instances, complete the following steps:

1. Run Junos OS Release 12.3 or later on all of the PE and Provider routers participating in Layer 2 VPN or VPLS routing instances.

Attempting to enable this functionality on a network with a mix of routers that both do and do not support this feature can result in anomalous behavior.

2. Specify a unique route distinguisher on each PE router participating in a Layer 2 VPN or VPLS routing instance.
3. Configure the **l2vpn-use-bgp-rules** statement on all of the PE and Provider routers participating in Layer 2 VPN or VPLS routing instances.

You can configure this statement at the **[edit protocols bgp path-selection]** hierarchy level to apply this behavior to all of the routing instances on the router or at the **[edit routing-instances routing-instance-name protocols bgp path-selection]** hierarchy level to apply this behavior to a specific routing instance.

Configuring EXP-Based Traffic Classification for VPLS

You can enable EXP classification on traffic entering core facing VPLS LSI interfaces on a VPLS routing instance by configuring either a logical tunnel interface (**lt-**) or the **no-tunnel-services** statement. By configuring either of these, a default EXP classifier is enabled on every core facing interface that includes **family mpls** in its configuration. This feature works on MX Series routers and EX Series switches only. You can configure an EXP classifier explicitly at the **[edit class-of-service]** hierarchy level. For more information about EXP classifiers, see the *Junos OS Class of Service Configuration Guide*.

To enable EXP classification on traffic entering core facing VPLS LSI interfaces on a VPLS routing instance, include the **no-tunnel-services** statement:

```
no-tunnel-services;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* protocols vpls]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]**

Configuring VPLS Load Balancing

By default, when there are multiple equal-cost paths to the same destination for the active route, the Junos OS uses a hash algorithm to select one of the next-hop addresses to install in the forwarding table. Whenever the set of next hops for a destination changes, the next-hop address is reselected using the hash algorithm.

You can configure the Junos OS so that, for the active route, all next-hop addresses for a destination are installed in the forwarding table. This feature is called per-packet load balancing. You can use load balancing to spread traffic across multiple paths between routers. You can also configure per-packet load balancing to optimize VPLS traffic flows across multiple paths.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

You can load-balance VPLS traffic based on Layer 2 media access control (MAC) information, IP information and MPLS labels, or MPLS labels only.

NOTE: For platform support information, see **family multiservice**.

To optimize VPLS traffic flows across multiple paths, include the **family multiservice** statement at the **[edit forwarding-options hash-key]** hierarchy level:

```
family multiservice {  
    destination-mac;  
    label-1;  
    label-2;  
}
```

```

payload {
  ip {
    layer-3 {
      (destination-ip-only | source-ip-only);
    }
    layer-3-only;
    layer-4;
  }
}
source-mac;
symetric-hash {
  complement;
}
}

```

You can configure one or more of the following options to load-balance using the specified packet information:

- **destination-mac**—Include the destination-address MAC information in the hash key for Layer 2 load balancing.
- **source-mac**—Include the source-address MAC information in the hash key.
- **label-1**—Include the first MPLS label in the hash key. Used for including a one-label packet for per-flow load balancing of IPv4 VPLS traffic based on IP information and MPLS labels.
- **label-2**—Include the second MPLS label in the hash key. If both **label-1** and **label-2** are specified, the entire first label and the first 16 bits of the second label are hashed.
- **payload**—Include the packet's IP payload in the hash key.
- **ip**—Include the IP address of the IPv4 or IPv6 payload in the hash key.
- **layer-3-only**—Include only the Layer 3 information from the packet's IP payload in the hash key.
- **layer-3**—Include Layer 3 information from the packet's IP payload in the hash key.
- **destination-address-only**—Include only the destination IP address in the payload in the hash key.

NOTE: You can include either the **source-address-only** or the **destination-address-only** statement, not both. They are mutually exclusive.

- **source-address-only**—Include only the source IP address in the payload in the hash key.

NOTE: You can include either the **source-address-only** or the **destination-address-only** statement, not both. They are mutually exclusive.

- **layer-4**—Include Layer 4 information from the packet's IP payload in the hash key.

- **symmetric-hash**—Configure the symmetric hash or symmetric hash complement for configuring symmetrical load balancing on an 802.3ad Link Aggregation Group.
- **complement**—Include the complement of the symmetric hash in the hash key.

For more information about how to configure per-packet load balancing, see the *Routing Policy Configuration Guide*.

Configuring VPLS Fast Reroute Priority

When a path is rerouted after a link failure by using the MPLS fast reroute feature, the affected next hops are repaired by switching them from the active label switched path (LSP) to the standby LSP. To specify the order in which the next hops are repaired and traffic convergence is restored for VPLS routing instances after a fast reroute event, you can use the **fast-reroute-priority** statement to configure **high**, **medium**, or **low** fast reroute priority for a VPLS routing instance. By default, the fast reroute priority for a VPLS routing instance is **low**.

Next hops are repaired and known unicast, unknown unicast, broadcast, and multicast traffic for VPLS routing instances are restored in the following order, based on the fast reroute priority configuration:

1. Next hops for high-priority VPLS routing instances are repaired.
2. Next hops for medium-priority VPLS routing instances are repaired.
3. Next hops for low-priority VPLS routing instances are repaired.

Because next hops for VPLS routing instances configured with **high** fast reroute priority are repaired first, the traffic traversing high-priority VPLS instances is restored faster than the traffic for VPLS instances configured with **medium** or **low** fast reroute priority. The ability to prioritize specific VPLS routing instances for faster convergence and traffic restoration enables service providers to offer differentiated service levels to their customers.

Within a particular fast reroute priority level (**high**, **medium**, or **low**), no particular order for traffic restoration of VPLS routing instances is followed.

NOTE: VPLS fast reroute priority is not supported on J Series routers.

To configure **high**, **medium**, or **low** fast reroute priority for a VPLS routing instance, include the **fast-reroute-priority** statement:

fast-reroute-priority (high | medium | low);

You can include this statement at the following hierarchy levels:

- **[edit forwarding-options]**

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* forwarding-options]
- [edit routing-instances *routing-instance-name* forwarding-options]

You can configure fast reroute priority only for routing instances with the **instance-type** set to **vpls**. If you attempt to configure fast reroute priority for a routing instance with an **instance-type** other than **vpls**, the router displays a warning message and the configuration fails.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following example snippet shows configuration of **high** fast reroute priority for a VPLS routing instance named **test-vpls**:

```
test-vpls {
  instance-type vpls;
  forwarding-options {
    fast-reroute-priority high;
  }
}
```

To display the fast reroute priority setting configured for a VPLS routing instance, use the **show route instance detail** operational command. For information about using this command, see the *Junos OS Operational Mode Commands*.

Configuring VPLS Without a Tunnel Services PIC

VPLS normally uses a dynamic virtual tunnel logical interface on a Tunnel Services PIC to model traffic from a remote site (a site on a remote PE router that is in a VPLS domain). All traffic coming from a remote site is treated as coming in over the virtual port representing this remote site, for the purposes of Ethernet flooding, forwarding, and learning. An MPLS lookup based on the inner VPN label is done on a PE router. The label is stripped and the Layer 2 Ethernet frame contained within is forwarded to a Tunnel Services PIC. The PIC loops back the packet and then a lookup based on Ethernet MAC addresses is completed. This approach requires that the router have a Tunnel Services PIC and that the PE router complete two protocol lookups.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

You can configure VPLS without a Tunnel Services PIC by configuring the **no-tunnel-services** statement. This statement creates a label-switched interface (LSI) to provide VPLS functionality. An LSI MPLS label is used as the inner label for VPLS. This label maps to a VPLS routing instance. On the PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.

By default, VPLS requires a Tunnel Services PIC. To configure VPLS on a router without a Tunnel Services PIC and create an LSI, include the **no-tunnel-services** statement:

no-tunnel-services;

For a list of the hierarchy levels at which you can include this statement, see the summary section for this statement.

To configure a VPLS routing instance on a router without a tunnel services PIC, include the **no-tunnel-services** statement at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level. To configure static VPLS on a router without a tunnel services PIC, include the **no-tunnel-services** statement at the **[edit protocols vpls static-vpls]** hierarchy level.

When you configure VPLS without a Tunnel Services PIC by including the **no-tunnel-services** statement, the following limitations apply:

- An Enhanced FPC is required.
- ATM1 interfaces are not supported.
- Aggregated SONET/SDH interfaces are not supported as core-facing interfaces.
- Channelized interfaces are not supported as core-facing interfaces.
- GRE-encapsulated interfaces are not supported as core-facing interfaces.

**Related
Documentation**

- [Configuring Static Pseudowires for VPLS on page 5342](#)

Mapping VPLS Traffic to Specific LSPs

You can map VPLS traffic to specific LSPs by configuring forwarding table policies. This procedure is optional but can be useful. The following example illustrates how you can map lower priority VPLS routing instances to slower LSPs while mapping other higher priority VPLS routing instances to faster LSPs. In this example configuration, **a-to-b1** and **a-to-c1** are high-priority LSPs between the PE routers, while **a-to-b2** and **a-to-c2** are low-priority LSPs between the PE routers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

To map VPLS traffic, include the **policy-statement vpls-priority** statement:

```
policy-statement vpls-priority {
  term a {
    from {
      rib mpls.0;
      community company-1;
    }
    then {
      install-nexthop lsp [ a-to-b1 a-to-c1 ];
      accept;
    }
  }
}
```

```

}
term b {
  from {
    rib mpls.0;
    community company-2;
  }
  then {
    install-nexthop lsp-regex [ "^a-to-b2$" "^a-to-c2$" ];
    accept;
  }
}
}
community company-1 members target:11111:1;
community company-2 members target:11111:2;

```

You can include the **policy-statement vpls-priority** statement at the following hierarchy levels:

- [edit policy-options]
- [edit logical-systems *logical-system-name* policy-options]

Include the **export** statement to apply the **vpls-priority** policy to the forwarding table:

```
export vpls-priority;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options forwarding-table]
- [edit logical-systems *logical-system-name* routing-options forwarding-table]

For more information about how to configure routing policies, see the *Routing Policy Configuration Guide*.

Configuring Firewall Filters and Policers for VPLS

You can configure both firewall filters and policers for VPLS. Firewall filters allow you to filter packets based on their components and to perform an action on packets that match the filter. Policers allow you to limit the amount of traffic that passes into or out of an interface.

VPLS filters and policers act on a Layer 2 frame that includes the media access control (MAC) header (after any VLAN rewrite or other rules are applied), but does not include the cyclical redundancy check (CRC) field.

You can apply VPLS filters and policers on the PE router to customer-facing interfaces only.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following sections explain how to configure filters and policers for VPLS:

- [Configuring a VPLS Filter on page 5354](#)
- [Configuring a VPLS Policer on page 5357](#)

Configuring a VPLS Filter

To configure a filter for VPLS, include the **filter** statement at the **[edit firewall family vpls]** hierarchy level:

```
[edit firewall family vpls]
filter filter-name {
  interface-specific;
  term term-name {
    from {
      match-conditions;
    }
    then {
      actions;
    }
  }
}
```

For more information about how to configure firewall filters, see the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*. For information on how to configure a VPLS filter match condition, see “[Standard Firewall Filter Match Conditions for VPLS Traffic](#)” on page 4727.

To configure a filter for VPLS traffic, complete the following tasks:

- [Configuring an Interface-Specific Counter for VPLS on page 5354](#)
- [Configuring an Action for the VPLS Filter on page 5355](#)
- [Configuring VPLS FTFs on page 5355](#)
- [Changing Precedence for Spanning-Tree BPDU Packets on page 5355](#)
- [Applying a VPLS Filter to an Interface on page 5355](#)
- [Applying a VPLS Filter to a VPLS Routing Instance on page 5356](#)
- [Configuring a Filter for Flooded Traffic on page 5356](#)

Configuring an Interface-Specific Counter for VPLS

When you configure a firewall filter for VPLS and apply it to multiple interfaces, you can specify individual counters specific to each interface. This allows you to collect separate statistics on the traffic transiting each interface.

To generate an interface-specific counter for VPLS, you configure the **interface-specific** statement. A separate instantiation of the filter is generated. This filter instance has a different name (based on the interface name) and collects statistics on the interface specified only.

To configure interface-specific counters, include the **interface-specific** statement at the **[edit firewall family vpls filter filter-name]** hierarchy level:

```
[edit firewall family vpls filter filter-name]
```

interface-specific;

NOTE: The counter name is restricted to 24 bytes. If the renamed counter exceeds this maximum length, it might be rejected.

For more information about the **interface-specific** statement and an example of how to configure it, see the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

Configuring an Action for the VPLS Filter

You can configure the following actions for a VPLS filter at the [edit firewall family vpls filter *filter-name* term *term-name* then] hierarchy level: **accept**, **count**, **discard**, **forwarding-class**, **loss-priority**, **next**, **policer**.

Configuring VPLS FTFs

Forwarding table filters (FTFs) are filters configured for forwarding tables. For VPLS, they are attached to the destination MAC (DMAC) forwarding table of the VPLS routing instance. You define VPLS FTFs in the same manner as any other type of FTF. You can only apply a VPLS FTF as an input filter.

To specify a VPLS FTF, include the **filter input** statement at the [edit routing-instance *routing-instance-name* forwarding-options family vpls] hierarchy level:

```
[edit routing-instance routing-instance-name forwarding-options family vpls]
filter input filter-name;
```

For the statement summaries of these statements, see the *Routing Policy Configuration Guide*.

Changing Precedence for Spanning-Tree BPDU Packets

Spanning tree BPDU packets are automatically set to a high precedence. The queue number on these packets is set to 3. On M Series routers (except the M320 router) by default, a queue value of 3 indicates high precedence. To enable this higher precedence on BPDU packets, an instance-specific BPDU precedence filter named **default_bpdu_filter** is automatically attached to the VPLS DMAC table. This filter places a high precedence on all packets sent to **01:80:c2:00:00:00/24**.

You can overwrite this filter by configuring a VPLS FTF filter and applying it to the VPLS routing instance. For more information, see [“Configuring VPLS FTFs” on page 5355](#) and [“Applying a VPLS Filter to a VPLS Routing Instance” on page 5356](#).

Applying a VPLS Filter to an Interface

To apply a VPLS filter to an interface, include the **filter** statement:

```
filter {
  input input-filter-name;
  output output-filter-name;
  group index;
}
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *number* family vpls]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *number* family vpls]

In the **input** statement, list the name of the VPLS filter to be evaluated when packets are received on the interface. In the **output** statement, list the name of the VPLS filter to be evaluated when packets are transmitted on the interface.

NOTE: For output interface filters, MAC addresses are learned after the filter action is completed. When an output interface filter's action is **discard**, the packet is dropped before the MAC address is learned. However, an input interface filter learns the MAC address before discarding the packet.

For the statement summaries for these statements, see the *Junos® OS Network Interfaces*.

Applying a VPLS Filter to a VPLS Routing Instance

You can apply a VPLS filter to a VPLS routing instance. The filter checks traffic passing through the specified routing instance.

Input routing instance filters learn the MAC address before the filter action is completed, so if the filter action is **discard**, the MAC address is learned before the packet is dropped.

To apply a VPLS filter to packets arriving at a VPLS routing instance and specify the filter, include the **filter input** statement at the [edit routing-instances *routing-instance-name* forwarding-options family vpls] hierarchy level:

```
[edit routing-instances routing-instance-name forwarding-options family vpls]
  filter input input-filter-name;
```

Configuring a Filter for Flooded Traffic

You can configure a VPLS filter to filter flooded packets. CE routers typically flood the following types of packets to PE routers in VPLS routing instances:

- Layer 2 broadcast packets
- Layer 2 multicast packets
- Layer 2 unicast packets with an unknown destination MAC address
- Layer 2 packets with a MAC entry in the DMAC routing table

You can configure filters to manage how these flooded packets are distributed to the other PE routers in the VPLS routing instance.

To apply a flooding filter to packets arriving at the PE router in the VPLS routing instance, and specify the filter, include the **flood input** statement:

```
flood input filter-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* forwarding-options family vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* forwarding-options family vpls]

Configuring a VPLS Policer

You can configure a policer for VPLS traffic. The VPLS policer configuration is similar to the configuration of any other type of policer.

VPLS policers have the following characteristics:

- You cannot police the default VPLS routes stored in the flood table from PE router-sourced flood traffic.
- When specifying policing bandwidth, the VPLS policer considers all Layer 2 bytes in a packet to determine the packet length.

To configure a VPLS policer, include the **policer** statement at the [edit firewall] hierarchy level:

```
[edit firewall]
policer policer-name {
  bandwidth-limit limit;
  burst-size-limit limit;
  then action;
}
```

For the statement summaries of these statements and more information about how to configure policers, see the *Junos OS Firewall Filters and Traffic Policers Configuration Guide*.

To apply a VPLS policer to an interface, include the **policer** statement:

```
policer {
  input input-policer-name;
  output output-policer-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *number* family vpls]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *number* family vpls]

In the **input** statement, list the name of the VPLS policer to be evaluated when packets are received on the interface. In the **output** statement, list the name of the VPLS policer to be evaluated when packets are transmitted on the interface. This type of VPLS policer can only apply to unicast packets. For information about how to filter flood packets, see [“Configuring a Filter for Flooded Traffic” on page 5356](#).

For the statement summaries for these statements, see the *Junos® OS Network Interfaces*.

Standard Firewall Filter Match Conditions for VPLS Traffic

In the **from** statement in the VPLS filter term, you specify conditions that the packet must match for the action in the **then** statement to be taken. All conditions in the **from** statement must match for the action to be taken. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify no match conditions in a term, that term matches all packets.

An individual condition in a **from** statement can contain a list of values. For example, you can specify numeric ranges. You can also specify multiple source addresses or destination addresses. When a condition defines a list of values, a match occurs if one of the values in the list matches the packet.

Individual conditions in a **from** statement can be negated. When you negate a condition, you are defining an explicit mismatch. For example, the negated match condition for **forwarding-class** is **forwarding-class-except**. If a packet matches a negated condition, it is immediately considered not to match the **from** statement, and the next term in the filter is evaluated, if there is one. If there are no more terms, the packet is discarded.

You can configure a standard firewall filter with match conditions for Virtual Private LAN Service (VPLS) traffic (**family vpls**). [Table 346 on page 4728](#) describes the *match-conditions* you can configure at the `[edit firewall family vpls filter filter-name term term-name from]` hierarchy level.

NOTE: Not all match conditions for VPLS traffic are supported on all routing platforms or switching platforms. A number of match conditions for VPLS traffic are supported only on MX Series 3D Universal Edge Routers.

In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Table 387: Standard Firewall Filter Match Conditions for VPLS Traffic

Match Condition	Description
destination-mac-address <i>address</i>	Match the destination media access control (MAC) address of a VPLS packet.

Table 387: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
destination-port <i>number</i>	<p>(MX Series routers and EX Series switches only) Match the UDP or TCP destination port field.</p> <p>You cannot specify both the port and destination-port match conditions in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), ldp (646), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs (49), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xmcp (177).</p>
destination-port-except <i>number</i>	<p>(MX Series routers and EX Series switches only) Do not match on the TCP or UDP destination port field. You cannot specify both the port and destination-port match conditions in the same term.</p>
destination-prefix-list <i>name</i>	<p>(MX Series routers and EX Series switches only) Match destination prefixes in the specified list. Specify the name of a prefix list defined at the [edit policy-options prefix-list <i>prefix-list-name</i>] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>
destination-prefix-list <i>name</i> except	<p>(MX Series routers and EX Series switches only) Do not match destination prefixes in the specified list. For more information, see the destination-prefix-list match condition.</p>
dscp <i>number</i>	<p>(MX Series routers and EX Series switches only) Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see the <i>Junos OS Class of Service Configuration Guide</i>.</p> <p>You can specify a numeric value from 0 through 63. To specify the value in hexadecimal form, include 0x as a prefix. To specify the value in binary form, include b as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: ef (46). RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points: <p>af11 (10), af12 (12), af13 (14),</p> <p>af21 (18), af22 (20), af23 (22),</p> <p>af31 (26), af32 (28), af33 (30),</p> <p>af41 (34), af42 (36), af43 (38)</p>
dscp-except <i>number</i>	<p>(MX Series routers and EX Series switches only) Do not match on the DSCP. For details, see the dscp match condition.</p>

Table 387: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
ether-type values	<p>Match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>You can specify decimal or hexadecimal values from 0 through 65535 (0xFFFF). A value from 0 through 1500 (0x05DC) specifies the length of an Ethernet Version 1 frame. A value from 1536 (0x0600) through 65535 specifies the EtherType (nature of the MAC client protocol) of an Ethernet Version 2 frame.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): aarp (0x80F3), appletalk (0x809B), arp (0x0806), ipv4 (0x0800), ipv6 (0x86DD), mpls-multicast (0x8848), mpls-unicast (0x8847), oam (0x8902), ppp (0x880B), pppoe-discovery (0x8863), pppoe-session (0x8864), or sna (0x80D5).</p>
ether-type-except values	<p>Do not match the 2-octet Length/EtherType field to the specified value or list of values.</p> <p>For details about specifying the values, see the ether-type match condition.</p>
forwarding-class class	Match the forwarding class. Specify assured-forwarding , best-effort , expedited-forwarding , or network-control .
forwarding-class-except class	Do not match the forwarding class. For details, see the forwarding-class match condition.
icmp-code message-code	<p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the next-header icmp or next-header icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type message-type match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except message-code	Do not match the ICMP message code field. For details, see the icmp-code match condition.

Table 387: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
icmp-code <i>number</i>	<p>(MX Series routers and EX Series switches only) Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp or ip-protocol icmp6 match condition in the same term.</p> <p>If you configure this match condition, you must also configure the icmp-type <i>message-type</i> match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> parameter-problem: ip6-header-bad (0), unrecognized-next-header (1), unrecognized-option (2) time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0) destination-unreachable: address-unreachable (3), administratively-prohibited (1), no-route-to-destination (0), port-unreachable (4)
icmp-code-except <i>number</i>	<p>(MX Series routers and EX Series switches only) Do not match on the ICMP code field. For details, see the icmp-code match condition.</p>
icmp-type <i>number</i>	<p>(MX Series routers and EX Series switches only) Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the ip-protocol icmp, ip-protocol icmp6, or ip-protocol icmpv6 match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): destination-unreachable (1), echo-reply (129), echo-request (128), membership-query (130), membership-report (131), membership-termination (132), neighbor-advertisement (136), neighbor-solicit (135), node-information-reply (140), node-information-request (139), packet-too-big (2), parameter-problem (4), redirect (137), router-advertisement (134), router-renumbering (138), router-solicit (133), or time-exceeded (3).</p>
icmp-type-except <i>number</i>	<p>(MX Series routers and EX Series switches only) Do not match the ICMP message type field. For details, see the icmp-type match condition.</p>
interface <i>interface-name</i>	<p>Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received.</p> <p>NOTE: If you configure this match condition with an interface that does not exist, the term does not match any packet.</p>
interface-group <i>group-number</i>	<p>Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For group-number, specify a single value or a range of values from 0 through 255.</p> <p>To assign a logical interface to an interface group group-number, specify the group-number at the [interfaces <i>interface-name</i> unit <i>number</i> family <i>family</i> filter group] hierarchy level.</p> <p>For more information, see “Filtering Packets Received on a Set of Interface Groups Overview” on page 4514.</p> <p>NOTE: This match condition is not supported on T4000 Type 5 FPCs.</p>

Table 387: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
interface-group-except <i>group-name</i>	Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the interface-group match condition. NOTE: This match condition is not supported on T4000 Type 5 FPCs.
interface-set <i>interface-set-name</i>	Match the interface on which the packet was received to the specified interface set. To define an interface set, include the interface-set statement at the [edit firewall] hierarchy level. For more information, see “Filtering Packets Received on an Interface Set Overview” on page 4515 .
ip-address <i>address</i>	(MX Series routers and EX Series switches only) 32-bit address that supports the standard syntax for IPv4 addresses.
ip-destination-address <i>address</i>	(MX Series routers and EX Series switches only) 32-bit address that is the final destination node address for the packet.
ip-precedence <i>ip-precedence-field</i>	(MX Series routers and EX Series switches only) IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): critical-ecp (0xa0), flash (0x60), flash-override (0x80), immediate (0x40), internet-control (0xc0), net-control (0xe0), priority (0x20), or routine (0x00).
ip-precedence-except <i>ip-precedence-field</i>	(MX Series routers and EX Series switches only) Do not match on the IP precedence field.
ip-protocol <i>number</i>	(MX Series routers and EX Series switches only) IP protocol field.
ip-protocol-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the IP protocol field.
ip-source-address <i>address</i>	(MX Series routers and EX Series switches only) IP address of the source node sending the packet.
learn-vlan-1p-priority <i>number</i>	(MX Series routers and EX Series switches only) Match on the IEEE 802.1p learned VLAN priority bits in the provider VLAN tag (the only tag in a single-tag frame with 802.1Q VLAN tags or the outer tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7. Compare with the user-vlan-1p-priority match condition.
learn-vlan-1p-priority-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p learned VLAN priority bits. For details, see the learn-vlan-1p-priority match condition.
learn-vlan-dei	(MX Series routers and EX Series switches only) Match the user VLAN ID drop eligibility indicator (DEI) bit.
learn-vlan-dei-except	(MX Series routers and EX Series switches only) Do not match the user VLAN ID DEI bit.
learn-vlan-id <i>number</i>	(MX Series routers and EX Series switches only) VLAN identifier used for MAC learning.
learn-vlan-id-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the VLAN identifier used for MAC learning.

Table 387: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
loss-priority <i>level</i>	<p>Packet loss priority (PLP) level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and EX Series switches, you must include the tri-color statement at the [edit class-of-service] hierarchy level to commit a PLP configuration with any of the four levels specified. If the tri-color statement is not enabled, you can only configure the high and low levels. This applies to all protocol families.</p> <p>For information about the tri-color statement and about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
loss-priority-except <i>level</i>	<p>Do not match on the packet loss priority level. Specify a single level or multiple levels: low, medium-low, medium-high, or high.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see the <i>Junos OS Class of Service Configuration Guide</i>.</p>
port <i>number</i>	(MX Series routers and EX Series switches only) TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.
port-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the TCP or UDP source or destination port. You cannot specify both the port match condition and either the destination-port or source-port match condition in the same term.
prefix-list <i>name</i>	<p>(MX Series routers and EX Series switches only) Match the destination or source prefixes in the specified list. Specify the name of a prefix list defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>
prefix-list <i>name</i> except	(MX Series routers and EX Series switches only) Do not match the destination or source prefixes in the specified list. For more information, see the destination-prefix-list match condition.
source-mac-address <i>address</i>	Source MAC address of a VPLS packet.
source-port <i>number</i>	(MX Series routers and EX Series switches only) TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.
source-port-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the TCP or UDP source port field. You cannot specify the port and source-port match conditions in the same term.
source-prefix-list <i>name</i>	<p>(MX Series routers and EX Series switches only) Match the source prefixes in the specified prefix list. Specify a prefix list name defined at the [edit policy-options prefix-list prefix-list-name] hierarchy level.</p> <p>NOTE: VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>

Table 387: Standard Firewall Filter Match Conditions for VPLS Traffic (*continued*)

Match Condition	Description
source-prefix-list <i>name</i> except	(MX Series routers and EX Series switches only) Do not match the source prefixes in the specified prefix list. For more information, see the source-prefix-list match condition.
tcp-flags <i>flags</i>	<p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> • fin (0x01) • syn (0x02) • rst (0x04) • push (0x08) • ack (0x10) • urgent (0x20) <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>If you configure this match condition for IPv6 traffic, we recommend that you also configure the next-header tcp match condition in the same term to specify that the TCP protocol is being used on the port.</p>
traffic-type <i>type-name</i>	(MX Series routers and EX Series switches only) Traffic type. Specify broadcast , multicast , unknown-unicast , or known-unicast .
traffic-type-except <i>type-name</i>	(MX Series routers and EX Series switches only) Do not match on the traffic type. Specify broadcast , multicast , unknown-unicast , or known-unicast .
user-vlan-1p-priority <i>number</i>	<p>(MX Series routers and EX Series switches only) Match on the IEEE 802.1p user priority bits in the customer VLAN tag (the inner tag in a dual-tag frame with 802.1Q VLAN tags). Specify a single value or multiple values from 0 through 7.</p> <p>Compare with the learn-vlan-1p-priority match condition.</p>
user-vlan-1p-priority-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the IEEE 802.1p user priority bits. For details, see the user-vlan-1p-priority match condition.
user-vlan-id <i>number</i>	(MX Series routers and EX Series switches only) Match the first VLAN identifier that is part of the payload.
user-vlan-id-except <i>number</i>	(MX Series routers and EX Series switches only) Do not match on the first VLAN identifier that is part of the payload.
vlan-ether-type <i>value</i>	VLAN Ethernet type field of a VPLS packet.
vlan-ether-type-except <i>value</i>	Do not match on the VLAN Ethernet type field of a VPLS packet.

Specifying the VT Interfaces Used by VPLS Routing Instances

By default, the Junos OS automatically selects one of the virtual tunnel (VT) interfaces available to the router for de-encapsulating traffic from a remote site. The Junos OS cycles through the currently available VT interfaces, regularly updating the list of available VT interfaces as new remote sites are discovered and new connections are brought up. However, you can also explicitly configure which VT interfaces will receive the VPLS traffic.

By including the **tunnel-services** statement at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level, you can specify that traffic for particular VPLS routing instances be forwarded to specific VT interfaces. Doing so allows you to load-balance VPLS traffic among all the available VT interfaces on the router.

The **tunnel-services** statement includes the following options:

- **devices**—Specifies the VT interfaces acceptable for use by the VPLS routing instance. If you do not configure this option, all VT interfaces available to the router can be used for de-encapsulating traffic for this instance.
- **primary**—Specifies the primary VT interface to be used by the VPLS routing instance. The VT interface specified is used to de-encapsulate all VPLS traffic from the MPLS core network for this routing instance. If the VT interface specified is unavailable, then one of the other acceptable VT interfaces (specified in the **devices** option) is used for handling the VPLS traffic. If you do not configure this option, any acceptable VT interface can be used to de-encapsulate VPLS traffic from the core.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

To specify that traffic for a particular VPLS routing instance be forwarded to specific VT interfaces, include the **tunnel-services** statement:

```
tunnel-services {
  devices device-names;
  primary primary-device-name;
}
```

These statements can be configured at the following hierarchy levels:

- **[edit routing-instances routing-instance-name protocols vpls]**
- **[edit logical-systems logical-system-name routing-instances routing-instance-name protocols vpls]**

Flooding Unknown Traffic Using Point-to-Multipoint LSPs

For a VPLS routing instance, you can flood unknown unicast, broadcast, and multicast traffic using point-to-multipoint (also called *P2MP*) LSPs. By default, VPLS relies upon

ingress replication to flood unknown traffic to the members of a VPLS routing instance. This can cause replication of data at routing nodes shared by multiple VPLS members, as shown in [Figure 126 on page 5366](#). The flood data is tripled between PE router PE1 and provider router P1 and doubled between provider routers P1 and P2. By configuring point-to-multipoint LSPs to handle flood traffic, the VPLS routing instance can avoid this type of traffic replication in the network, as shown in [Figure 127 on page 5366](#).

Figure 126: Flooding Unknown VPLS Traffic Using Ingress Replication

Figure 127: Flooding Unknown VPLS Traffic Using a Point-to-Multipoint LSP

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The point-to-multipoint LSP used for VPLS flooding can be either static or dynamic. In either case, for each VPLS routing instance, the PE router creates a dedicated point-to-multipoint LSP. All of the neighbors of the VPLS routing instance are added to the point-to-multipoint LSP when the feature is enabled. If there are n PE routers in the VPLS routing instance, n point-to-multipoint LSPs are created in the network where each PE router is the root of the point-to-multipoint tree and includes the rest of the $n - 1$ PE routers as leaf nodes. If you configured static point-to-multipoint LSPs for flooding, any additional VPLS neighbors added to the routing instance later are not automatically added to the point-to-multipoint LSP. You will need to manually add the new VPLS neighbors to the static point-to-multipoint flooding LSP. If you configure dynamic point-to-multipoint LSPs, whenever VPLS discovers a new neighbor through BGP, a sub-LSP for this neighbor is added to the point-to-multipoint LSP for the routing instance.

This feature can be enabled incrementally on any PE router that is part of a specific VPLS routing instance. The PE routers can then use point-to-multipoint LSPs to flood traffic, whereas other PE routers in the same VPLS routing instance can still use ingress replication

to flood traffic. However, when this feature is enabled on any PE router, you must ensure that all PE routers in the VPLS routing instance that participate in the flooding of traffic over point-to-multipoint LSPs are upgraded to Junos OS Release 8.3 or later to support this feature.

To flood unknown unicast, broadcast, and multicast traffic using point-to-multipoint LSPs, configure the **rsvp-te** statement as follows:

```
rsvp-te {
  label-switched-path-template {
    (default-template | lsp-template-name);
  }
  static-lsp lsp-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instance *routing-instance-name* provider-tunnel]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel]

You can configure either a static point-to-multipoint LSP for VPLS flooding or a dynamic point-to-multipoint LSP.

NOTE: You cannot specify both the **static** and **label-switched-path-template** statements at the same time.

The following sections describe how to configure static and dynamic point-to-multipoint LSPs for flooding unknown traffic in a VPLS routing instance:

- [Configuring Static Point-to-Multipoint Flooding LSPs on page 5367](#)
- [Configuring Dynamic Point-to-Multipoint Flooding LSPs on page 5368](#)

Configuring Static Point-to-Multipoint Flooding LSPs

The **static-lsp** option creates a static flooding point-to-multipoint LSP that includes all of the neighbors in the VPLS routing instance. Flood traffic is sent to all of the VPLS neighbors using the generated point-to-multipoint LSP. VPLS neighbors added to the routing instance later are not automatically added to the point-to-multipoint LSP. You will need to manually add the new VPLS neighbors to the static point-to-multipoint flooding LSP. By configuring static point-to-multipoint LSPs for flooding, you have more control over which path each sub-LSP follows.

To configure a static flooding point-to-multipoint LSP, specify the name of the static flooding point-to-multipoint LSP by including the **static-lsp** statement:

```
static-lsp lsp-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te]

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel rsvp-te]

Configuring Dynamic Point-to-Multipoint Flooding LSPs

To configure a dynamic point-to-multipoint flooding LSP, include the **label-switched-path-template** statement option at the [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te] hierarchy level:

```
[edit routing-instances routing-instance-name provider-tunnel rsvp-te]
label-switched-path-template {
  (default-template | lsp-template-name);
}
```

You can automatically generate the point-to-multipoint LSP to be used for flooding unknown traffic or you can manually configure the point-to-multipoint LSP:

- [Configuring Dynamic Point-to-Multipoint Flooding LSPs with the Default Template on page 5368](#)
- [Configuring Dynamic Point-to-Multipoint Flooding LSPs with a Preconfigured Template on page 5368](#)

Configuring Dynamic Point-to-Multipoint Flooding LSPs with the Default Template

The **default-template** option, specified at the [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te label-switched-path-template] hierarchy level, causes the point-to-multipoint LSPs to be created with default parameters. The default parameters are for a minimally configured point-to-multipoint LSP. The name of this point-to-multipoint LSP is also generated automatically and is based on the following model:

id:vppls:router-id:routing-instance-name

The following **show** command output for **show mpls lsp p2mp ingress** illustrates how a point-to-multipoint flood LSP name could appear if you configure the **label-switched-path-template** statement with the **default-template** option:

```
user@host> show mpls lsp p2mp ingress
Ingress LSP: 2 sessions P2MP name: static, P2MP branch count: 3
To          From          State Rt ActivePath      P      LSPname
10.255.14.181 10.255.14.172 Up    0
10.255.14.177 10.255.14.172 Up    0 path2          *      vpn02-vpn11
10.255.14.174 10.255.14.172 Up    0 path3          *      vpn02-vpn07
10.255.14.174 10.255.14.172 Up    0 path3          *      vpn02-vpn04
P2MP name: 9:vppls:10.255.14.172:green, P2MP branch count: 2
To          From          State Rt ActivePath      P      LSPname
10.255.14.177 10.255.14.172 Up    0
11:vppls:10.255.14.172:green
10.255.14.174 10.255.14.172 Up    0
10:vppls:10.255.14.172:green
Total 5 displayed, Up 5, Down 0
```

The dynamically generated point-to-multipoint LSP name is **9:vppls:10.255.14.172:green**.

Configuring Dynamic Point-to-Multipoint Flooding LSPs with a Preconfigured Template

You can configure a point-to-multipoint flooding LSP template for the VPLS routing instance. The template allows you to specify the properties of the dynamic

point-to-multipoint LSPs that are used to flood traffic for the VPLS routing instance. You can specify all of the standard options available for a point-to-multipoint LSP within this template. These properties are inherited by the dynamic point-to-multipoint flood LSPs.

To configure a point-to-multipoint LSP template for flooding VPLS traffic, specify all of the properties you want to include in a point-to-multipoint LSP configuration. To specify this LSP as a point-to-multipoint flooding template, include the **p2mp** and **template** statements:

```
p2mp;  
template;
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls label-switched-path *p2mp-lsp-template-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *p2mp-lsp-template-name*]

For more information about how to configure the **p2mp** statement and point-to-multipoint LSPs, see the *Junos OS MPLS Applications Configuration Guide*.

Once you have configured the point-to-multipoint LSP template, specify the name of the point-to-multipoint LSP template with the **label-switched-path-template** statement:

```
label-switched-path-template p2mp-lsp-template-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel rsvp-te]

Configuring Interoperability Between BGP Signaling and LDP Signaling in VPLS

A single VPLS routing instance can encompass one set of PE routers that use BGP for signaling and another set of PE routers that use LDP for signaling. Within each set, all of the PE routers are fully meshed in both the control and data planes and have a bidirectional pseudowire to each of the other routers in the set. However, the BGP-signaled routers cannot be directly connected to the LDP-signaled routers. To be able to manage the two separate sets of PE routers in a single VPLS routing instance, a border PE router must be configured to interconnect the two sets of routers.

The VPLS RFCs and Internet drafts require that all of the PE routers participating in a single VPLS routing instance must be fully meshed in the data plane. In the control plane, each fully meshed set of PE routers in a VPLS routing instance is called a PE router mesh group. The border PE router must be reachable by and have bidirectional pseudowires to all of the PE routers that are a part of the VPLS routing instance, both the LDP-signaled and BGP-signaled routers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

For LDP BGP interworking to function, LDP-signaled routers can be configured with forwarding equivalence class (FEC) 128 or FEC 129.

The following sections describe how to configure BGP LDP interworking for VPLS:

- [LDP BGP Interworking Platform Support on page 5370](#)
- [Configuring FEC 128 VPLS Mesh Groups for LDP BGP Interworking on page 5370](#)
- [Configuring FEC 129 VPLS Mesh Groups for LDP BGP Interworking on page 5371](#)
- [Configuring Switching Between Pseudowires Using VPLS Mesh Groups on page 5371](#)
- [Configuring Integrated Routing and Bridging Support for LDP BGP Interworking with VPLS on page 5372](#)
- [Configuring Inter-AS VPLS with MAC Processing at the ASBR on page 5372](#)

LDP BGP Interworking Platform Support

LDP BGP interworking is supported on the following Juniper Networks routers and routing platforms:

- M7i
- M10i
- M40e
- M120
- M320
- MX Series routers
- T Series routers
- TX Matrix routers
- EX Series switches

Configuring FEC 128 VPLS Mesh Groups for LDP BGP Interworking

To configure FEC 128 LDP BGP interworking for VPLS, include the **mesh-group** statement in the VPLS routing instance configuration of the PE border router:

```
mesh-group mesh-group-name {  
  local-switching;  
  mac-flush [ explicit-mac-flush-message-options ];  
  neighbor address;  
  peer-as all;  
  vpls-id number;  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

Using the **neighbor** statement, configure each PE router that is a part of the mesh group. You must separate the LDP-signaled routers and the BGP-signaled routers into their own respective mesh groups. The LDP-signaled routers can be divided into multiple mesh groups. The BGP-signaled routers must be configured within a single mesh group for each routing instance.

Configuring FEC 129 VPLS Mesh Groups for LDP BGP Interworking

Configuration for a mesh group for FEC 129 is very similar to the configuration for FEC 128.

Note the following differences for FEC 129:

- Each user-defined mesh group must have a unique route distinguisher. Do not use the route distinguisher that is defined for the default mesh group at the **[edit routing-instances]** hierarchy level.
- Each user-defined mesh group must have its own import and export route target.
- Each user-defined mesh group can have a unique Layer 2 VPN ID. By default, all the mesh groups that are configured for the a VPLS routing-instance use the same Layer 2 VPN ID, the one that you configure at the **[edit routing-instances]** hierarchy level.

Configuring Switching Between Pseudowires Using VPLS Mesh Groups

To configure switching between Layer 2 circuit pseudowires using VPLS mesh groups, you can do either of the following:

- Configure a mesh group for each Layer 2 circuit pseudowire terminating at a VPLS routing instance. The Junos OS can support up to 16 mesh groups on MX Series routers and up to 128 on M Series and T Series routers. However, two mesh groups are created by default, one for the CE routers and one for the PE routers. Therefore, the maximum number of user-defined mesh groups is 14 for MX Series routers and 126 for M Series and T Series routers. PE router mesh groups are not supported on J Series routers.
- Configure a single mesh group, terminate all the Layer 2 circuit pseudowires into it, and enable local switching between the pseudowires by including the **local-switching** statement at the **[edit routing-instances routing-instance-name protocols vpls mesh-group mesh-group-name]** hierarchy level. By default, you cannot configure local switching for mesh groups (except for the CE mesh group) because all of the VPLS PE routers must be configured in a full mesh. However, local switching is useful if you are terminating Layer 2 circuit pseudowires in a mesh group configured for an LDP signaled VPLS routing instance.

NOTE: Do not include the **local-switching** statement on PE routers configured in a full mesh VPLS network.

To terminate multiple pseudowires at a single VPLS mesh group, include the **local-switching** statement:

local-switching;

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]

Configuring Integrated Routing and Bridging Support for LDP BGP Interworking with VPLS

Beginning with Junos OS Release 9.4, you can configure an integrated routing and bridging (IRB) interface on a router that functions as an autonomous system border router (ASBR) in an inter-AS VPLS environment between BGP-signaled VPLS and LDP-signaled VPLS. Previously, IRB interfaces were supported only on Provider Edge (PE) routers.

To configure a IRB support for LDP BGP Interworking with VPLS, include the **routing-interface *interface-name*** statement.

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-routers *logical-router-name* routing-instances *routing-instance-name*]

Configuring Inter-AS VPLS with MAC Processing at the ASBR

Inter-AS VPLS with MAC processing at the ASBR enables you to interconnect customer sites that are located in different ASs. In addition, you can configure the ASs with different signaling protocols. You can configure one of the ASs with BGP-signaled VPLS and the other with LDP-signaled VPLS. For more information about how to configure LDP-signaled and BGP signaled VPLS, see [“Configuring Interoperability Between BGP Signaling and LDP Signaling in VPLS” on page 5369](#).

For inter-AS VPLS to function properly, you need to configure IBGP peering between the PE routers, including the ASBRs in each AS, just as you do for a typical VPLS configuration. You also need to configure EBGP peering between the ASBRs in the separate ASs. The EBGP peering is needed between the ASBRs only. The link between the ASBR routers does not have to be Ethernet. You can also connect a CE router directly to one of the ASBRs, meaning you do not have to have a PE router between the ASBR and the CE router.

The configuration for the connection between the ASBRs makes inter-AS VPLS with MAC operations unique. The other elements of the configuration are described in other sections of this manual. An extensive configuration example for inter-AS VPLS with MAC operations is provided in the *Junos OS Feature Guides*.

The following sections describe how to configure inter-AS VPLS with MAC operations:

- [Inter-AS VPLS with MAC Operations Configuration Summary on page 5373](#)
- [Configuring the ASBRs for Inter-AS VPLS on page 5373](#)

Inter-AS VPLS with MAC Operations Configuration Summary

This section provides a summary of all of the elements which must be configured to enable inter-AS VPLS with MAC operations. These procedures are described in detail later in this chapter and in other parts of the *Junos OS VPNs Configuration Guide*.

The following lists all of major elements of an inter-AS VPLS with MAC operations configuration:

- Configure IBGP between all of the routers within each AS, including the ASBRs.
- Configure EBGP between the ASBRs in the separated ASs. The EBGP configuration includes the configuration that interconnects the ASs.
- Configure a full mesh of LSPs between the ASBRs.
- Configure a VPLS routing instance encompassing the ASBR routers. The ASBRs are VPLS peers and are linked by a single pseudowire. Multihoming between ASs is not supported. A full mesh of pseudowires is needed between the ASBR routers in all of the interconnected ASs.
- Configure the VPLS routing instances using either BGP signaling or LDP signaling. LDP BGP interworking is supported for inter-AS VPLS with MAC operations, so it is possible to interconnect the BGP-signaled VPLS routing instances with the LDP-signaled VPLS routing instances.
- Configure a single VPLS mesh group for all of the ASBRs interconnected using inter-AS VPLS.

Configuring the ASBRs for Inter-AS VPLS

This section describes the configuration on the ASBRs needed to enable inter-AS VPLS with MAC operations.

On each ASBR, you need to configure a VPLS mesh group within the VPLS routing instance which needs to include all of the PE routers within the AS, in addition to the ASBR. You need to configure the same mesh group for each of the ASs you want to interconnect using inter-AS VPLS. The mesh group name should be identical on each AS. You also must include the **peer-as all** statement. This statement enables the router to establish a single pseudowire to each of the other ASBRs.

To configure the mesh group on each ASBR, include the **mesh-group** and **peer-as all** statements:

```
mesh-group mesh-group-name {
  peer-as all;
}
```

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

- Related Documentation**
- *Example: Configuring BGP Autodiscovery for LDP VPLS*
 - *Example: Configuring BGP Autodiscovery for LDP VPLS with User-Defined Mesh Groups*

Tracing VPLS Traffic and Operations

To trace VPLS traffic, include the **traceoptions** statement:

```
traceoptions {  
    file filename <files number> <size size> <world-readable | no-world-readable>;  
    flag flag <flag-modifier> <disable>;  
}
```

You can include this statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]
- [edit routing-instances *routing-instance-name* protocols vpls]

The following trace flags display the operations associated with VPLS:

- **all**—All VPLS tracing options
- **connections**—VPLS connections (events and state changes)
- **error**—Error conditions
- **nlri**—VPLS advertisements received or sent using BGP
- **route**—Trace-routing information
- **topology**—VPLS topology changes caused by reconsideration or advertisements received from other PE routers using BGP

Configuring the Label Block Size

VPLS MPLS packets have a two-label stack. The outer label is used for normal MPLS forwarding in the service provider's network. If BGP is used to establish VPLS, the inner label is allocated by a PE router as part of a label block. One inner label is needed for each remote VPLS site. Four sizes are supported. We recommend using the default size of 8, unless the network design requires a different size for optimal label usage, to allow the router to support a larger number of VPLS instances.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

If you allocate a large number of small label blocks to increase efficiency, you also increase the number of routes in the VPLS domain. This has an impact on the control plane overhead.

Changing the configured label block size causes all existing pseudowires to be deleted. For example, if you configure the label block size to be 4 and then change the size to 8, all existing label blocks of size 4 are deleted, which means that all existing pseudowires are deleted. The new label block of size 8 is created, and new pseudowires are established.

Four label block sizes are supported: 2, 4, 8, and 16. Consider the following scenarios:

- 2—Allocate the label blocks in increments of 2. For a VPLS domain that has only two sites with no future expansion plans.
- 4—Allocate the label blocks in increments of 4.
- 8 (default)—Allocate the label blocks in increments of 8.
- 16—Allocate the label blocks in increments of 16. A label block size of 16 enables you to minimize the number of routes in the VPLS domain. Use this setting only if the number of routes is the most important concern.

Configure the label block size:

```
[edit routing-instances instance-name protocols vpls]
user@router# set label-block-size 2
```

Configuration Statements

active-interface (VPLS Multihoming)

Syntax	<pre>active-interface { any; primary interface-name; }</pre>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols vpls multi-homing],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols vpls multi-homing site <i>site-name</i>],</p> <p>[edit routing-instances <i>instance-name</i> protocols vpls multi-homing],</p> <p>[edit routing-instances <i>instance-name</i> protocols vpls multi-homing site <i>site-name</i>]</p>
Release Information	Statement introduced in Junos OS Release 7.5.
Description	Specify a multihomed interface as the primary interface for the VPLS site. If there are multiple interfaces, the remaining interfaces are activated only when the primary interface goes down. If no active interfaces are configured at the site level, it is assumed that all traffic for a VPLS site travels through a single, nonmultihomed PE router.
	<div>  <p>NOTE: In the VPLS documentation, the word <i>router</i> in terms such as <i>PE router</i> is used to refer to any device that provides routing functions.</p> </div>
	The remaining statements are explained separately.
	For FEC 128, use the [edit routing-instances <i>instance-name</i> protocols vpls multi-homing] hierarchy level.
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

automatic-site-id

Syntax	<pre>automatic-site-id { collision-detect-time <i>seconds</i>; new-site-wait-time <i>seconds</i>; reclaim-wait-time minimum <i>seconds</i> maximum <i>seconds</i>; startup-wait-time <i>seconds</i>; }</pre>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls site <i>site-name</i>], [edit routing-instances <i>routing-instance-name</i> protocols vpls site <i>site-name</i>]
Release Information	Statement introduced in Junos OS Release 9.1.
Description	Enable automatic site identifiers for VPLS routing instances.

When you configure **automatic-site-id** for the first time, you must deactivate and then activate **protocol vpls**. However, if you already have **automatic-site-id** configured, you do not need to deactivate and then activate **protocol vpls**.

Options **collision-detect-time**—The time in seconds to wait after a claim advertisement is sent to the other routers in a VPLS instance before a PE router can begin using a site identifier. If the PE router receives a competing claim advertisement for the same site identifier during this time period, it initiates the collision resolution procedure for site identifiers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

new-site-wait-time—The time in seconds to wait to receive VPLS information for a newly configured routing instance or a new site. This time interval is also applied whenever the automatic site identifier feature is activated on a VPLS routing instance other than at startup. Effectively, this timer indicates how long to wait before an attempt is made to allocate a site identifier. This timer is also triggered whenever a VPLS routing instance is enabled.

reclaim-wait-time—The time in seconds to wait to receive VPLS information for a newly configured routing instance or a new site. This time interval is also applied whenever the automatic site identifier feature is activated on a VPLS routing instance other than at startup. Effectively, this timer indicates how long to wait before an attempt is made to allocate a site identifier. This timer is also triggered whenever a VPLS routing instance is enabled. You can configure two values for this option: the **minimum** wait time and the **maximum** wait time.

startup-wait-time—The time in seconds to wait at startup to receive all the VPLS information for the route targets configured on the other PE routers included in the VPLS routing instance.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

bfd-liveness-detection (VPLS)

Syntax	<pre> bfd-liveness-detection { detection-time { threshold <i>milliseconds</i>; } minimum-interval <i>milliseconds</i>; minimum-receive-interval <i>milliseconds</i>; multiplier <i>number</i>; no-adaptation; transmit-interval { threshold <i>milliseconds</i>; minimum-interval <i>milliseconds</i>; } version (1 automatic); } </pre>
Hierarchy Level	<p>[edit logical-system <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls neighbor <i>neighbor-id</i> oam],</p> <p>[edit logical-system <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls mesh-group <i>mesh-group-name</i> neighbor <i>neighbor-id</i> oam],</p> <p>[edit logical-system <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls oam],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols vpls neighbor <i>neighbor-id</i> oam],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols vpls mesh-group <i>mesh-group-name</i> neighbor <i>neighbor-id</i> oam],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols vpls oam],</p>
Release Information	Statement introduced in Junos OS Release 10.0.
Description	<p>Configure bidirectional failure detection timers.</p> <p>The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the clear bfd adaptation command to return BFD interval timers to their configured values. The clear bfd adaptation command is hitless, meaning that the command does not affect traffic flow on the routing device.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

encapsulation (Physical Interface)

Syntax	encapsulation (atm-ccc-cell-relay atm-pvc cisco-hdlc cisco-hdlc-ccc cisco-hdlc-tcc ethernet-bridge ethernet-ccc ethernet-over-atm ethernet-tcc ethernet-vpls ethernet-vpls-fr ether-vpls-over-atm-llc ethernet-vpls-ppp extended-frame-relay-ccc extended-frame-relay-ether-type-tcc extended-frame-relay-tcc extended-vlan-bridge extended-vlan-ccc extended-vlan-tcc extended-vlan-vpls flexible-ethernet-services flexible-frame-relay frame-relay frame-relay-ccc frame-relay-ether-type frame-relay-ether-type-tcc frame-relay-port-ccc frame-relay-tcc generic-services multilink-frame-relay-uni-nni ppp ppp-ccc ppp-tcc vlan-ccc vlan-vci-ccc vlan-vpls);
Hierarchy Level	[edit interfaces <i>interface-name</i>], [edit interfaces rlsq <i>number:number</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 11.1 for EX Series switches. Statement introduced in Junos OS Release 12.1 for PTX Series Packet Transport Switches (flexible-ethernet-services , ethernet-ccc , and ethernet-tcc options only).
Description	Specify the physical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.
Default	ppp —Use serial PPP encapsulation.
Options	<p>atm-ccc-cell-relay—Use ATM cell-relay encapsulation.</p> <p>atm-pvc—Use ATM PVC encapsulation.</p> <p>cisco-hdlc—Use Cisco-compatible High-Level Data Link Control (HDLC) framing.</p> <p>cisco-hdlc-ccc—Use Cisco-compatible HDLC framing on CCC circuits.</p> <p>cisco-hdlc-tcc—Use Cisco-compatible HDLC framing on TCC circuits for connecting different media.</p> <p>ethernet-bridge—Use Ethernet bridge encapsulation on Ethernet interfaces that have bridging enabled and that must accept all packets.</p> <p>ethernet-ccc—Use Ethernet CCC encapsulation on Ethernet interfaces that must accept packets carrying standard Tag Protocol ID (TPID) values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, CCC is not supported.</p> <p>ethernet-over-atm—For interfaces that carry IPv4 traffic, use Ethernet over ATM encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces. As defined in RFC 2684, <i>Multiprotocol Encapsulation over ATM Adaptation Layer 5</i>, this encapsulation type allows ATM interfaces to connect to devices that support only bridge protocol data units (BPDUs). Junos OS does not completely support bridging, but accepts BPDU packets as a default gateway. If you use the router as an edge device, then the router acts as a default gateway. It accepts Ethernet LLC/SNAP frames with IP or ARP in the payload, and drops the rest. For packets destined to the Ethernet LAN, a route lookup is done using the destination</p>

IP address. If the route lookup yields a full address match, the packet is encapsulated with an LLC/SNAP and MAC header, and the packet is forwarded to the ATM interface.

ethernet-tcc—For interfaces that carry IPv4 traffic, use Ethernet TCC encapsulation on interfaces that must accept packets carrying standard TPID values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC is not supported.

ethernet-vpls—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard TPID values. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

ethernet-vpls-fr—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

ethernet-vpls-ppp—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer layer 2 PPP connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use it to forward the packet into a given VPLS instance.

ether-vpls-over-atm-llc—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

extended-frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to CCC.

extended-frame-relay-ether-type-tcc—Use extended Frame Relay ether type TCC for Cisco-compatible Frame Relay for DLCIs 1 through 1022. This encapsulation type is used for circuits with different media on either side of the connection.

extended-frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits to connect different media. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to TCC.

extended-vlan-bridge—Use extended VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

extended-vlan-ccc—Use extended VLAN encapsulation on CCC circuits with Gigabit Ethernet and 4-port Fast Ethernet interfaces that must accept packets carrying 802.1Q values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, extended VLAN CCC is not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC is not supported.

extended-vlan-tcc—For interfaces that carry IPv4 traffic, use extended VLAN encapsulation on TCC circuits with Gigabit Ethernet interfaces on which you want to use 802.1Q tagging. For 4-port Gigabit Ethernet PICs, extended VLAN TCC is not supported.

extended-vlan-vpls—Use extended VLAN VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

flexible-ethernet-services—For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. Aggregated Ethernet bundles can use this encapsulation type. This encapsulation type allows you to configure any combination of route, TCC, CCC, Layer 2 virtual private networks (VPNs), and VPLS encapsulations on a single physical port. If you configure flexible Ethernet services encapsulation on the physical interface, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.

flexible-frame-relay—For IQ interfaces only, use flexible Frame Relay encapsulation when you want to configure multiple per-unit Frame Relay encapsulations. This encapsulation type allows you to configure any combination of TCC, CCC, and standard Frame Relay encapsulations on a single physical port. Also, each logical interface can have any DLCI value from 1 through 1022.

frame-relay—Use Frame Relay encapsulation.

frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits.

frame-relay-ether-type—Use Frame Relay ether type encapsulation for compatibility with the Cisco Frame Relay.

frame-relay-ether-type-tcc—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media.

frame-relay-port-ccc—Use Frame Relay port CCC encapsulation to transparently carry all the DLCIs between two customer edge (CE) routers without explicitly configuring each DLCI on the two provider edge (PE) routers with Frame Relay transport. When you use this encapsulation type, you can configure the **ccc** family only.

frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits to connect different media.

generic-services—Use generic services encapsulation for services with a hierarchical scheduler.

multilink-frame-relay-uni-nni—Use MLFR UNI NNI encapsulation. This encapsulation is used on link services, voice services interfaces functioning as FRF.16 bundles, and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

ppp—Use serial PPP encapsulation.

ppp-ccc—Use serial PPP encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

ppp-tcc—Use serial PPP encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

vlan-ccc—Use Ethernet VLAN encapsulation on CCC circuits.

vlan-vci-ccc—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only. All logical interfaces configured on the Ethernet interface must also have the encapsulation type set to **vlan-vci-ccc**.

vlan-vpls—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.

Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

family multiservice

```
Syntax  family multiservice {
        destination-mac;
        label-1;
        label-2;
        payload {
            ip {
                layer-3 {
                    (source-ip-only | destination-ip-only);
                }
                layer-3-only;
                layer-4;
            }
        }
        source-mac;
        symmetric-hash {
            complement;
        }
    }
```

Hierarchy Level [edit [forwarding-options](#) hash-key]

Release Information Statement introduced in Junos OS Release 8.0.
ip, **label-1**, **label-2**, **layer-3-only**, and **payload** options introduced in Junos OS Release 9.4.
layer-3, **layer-4**, **source-ip-only**, and **destination-ip-only** options introduced in Junos OS Release 9.5.
symmetric-hash and **complement** options introduced in Junos OS Release 9.6.

Description Configure load balancing based on Layer 2 media access control information. On MX Series routers, configure VPLS load balancing. On M120 and M320 routers only, configure VPLS load balancing based on MPLS labels and IP information. For IPv4 traffic, only the IP source and destination addresses are included in the hash key. For MPLS and IPv4 traffic, one or two MPLS labels and IPv4 source and destination addresses are included. For MPLS Ethernet pseudowires, only one or two MPLS labels are included in the hash key.

Options You can configure one or more options to load-balance using the packet information that you specify.

destination-mac—Include the destination-address MAC information in the hash key for Layer 2 load balancing.

label-1 (M120 and M320 routers only)—Include the first MPLS label in the hash key. Used for including a one-label packet for per-flow load balancing of IPv4 VPLS traffic based on IP information and MPLS labels.

label-2 (M120 and M320 routers only)—Include the second MPLS label in the hash key. If both **label-1** and **label-2** are specified, the entire first label and the first 16 bits of the second label are hashed.

payload (MX Series, M120, and M320 routers only)—Include the packet's IP payload in the hash key.

- **ip** (MX Series, M120, and M320 routers only)—Include the IP address of the IPv4 or IPv6 payload in the hash key.
- **layer-3** (MX Series routers only)—Use this to include Layer 3 information from the packet's IP payload in the hash key.
 - **destination-ip-only** (MX Series routers only)—Use this to include only the destination IP address in the payload in the hash key.
 - **source-ip-only** (MX Series routers only)—Use this to include only the source IP address in the payload in the hash key.

NOTE: You can include either the **source-ip-only** or the **destination-ip-only** statement, not both. They are mutually exclusive.

- **layer-3-only** (M120, and M320 routers only)—Include only the Layer 3 information from the packet's IP payload in the hash key.
- **layer-4** (MX Series routers only)—Include Layer 4 information from the packet's IP payload in the hash key.

NOTE: On MX Series routers only, you can configure either Layer 3 or Layer 4 load balancing, or both at the same time.

NOTE: On I chip platforms, an unknown Layer 4 header is excluded from load-balance hashing to avoid undesired packet reordering.

source-mac—Include the source-address MAC information in the hash key.

symmetric-hash (MX Series routers only)—Configure the symmetric hash or symmetric hash complement for configuring symmetrical load balancing on an 802.3ad Link Aggregation Group.

- **complement** —Include the complement of the symmetric hash in the hash key.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

fast-reroute-priority

Syntax	fast-reroute-priority (high low medium);
Hierarchy Level	[edit forwarding-options] [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> forwarding-options], [edit routing-instances <i>routing-instance-name</i> forwarding-options]
Release Information	Statement introduced in Junos OS Release 9.5. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Specify the fast reroute priority for a VPLS routing instance. You can configure high , medium , or low fast reroute priority to prioritize specific VPLS routing instances for faster convergence and traffic restoration. Because the router repairs next hops for high-priority VPLS routing instances first, the traffic traversing a VPLS routing instance configured with high fast reroute priority is restored faster than the traffic for VPLS routing instances configured with medium or low fast reroute priority.
	<div> NOTE: In the VPLS documentation, the word <i>router</i> in terms such as <i>PE router</i> is used to refer to any device that provides routing functions.</div>
Default	low
Options	high —Set the fast reroute priority for a VPLS routing instance to high. During a fast reroute event, the router repairs next hops for high-priority VPLS routing instances first. low —Set the fast reroute priority for a VPLS routing instance to low, which is the default. During a fast reroute event, the router repairs next hops for low-priority VPLS routing instances last. medium —Set the fast reroute priority for a VPLS routing instance to medium. During a fast reroute event, the router repairs next hops for medium-priority VPLS instances after high-priority VPLS routing instances but before low-priority VPLS routing instances.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

identifier (VPLS Multihoming for FEC 129)

Syntax	<code>identifier <i>identifier</i>;</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols vpls multi-homing site <i>site-name</i>], [edit routing-instances <i>instance-name</i> protocols vpls multi-homing site <i>site-name</i>]
Release Information	Statement introduced in Junos OS Release 12.3.
Description	Configure a Layer 2 VPN or VPLS multihoming identifier (MHID). An identifier needs to be configured for each multihomed site. Multihoming site identifiers are specific to a VPLS domain. They need not be unique on a provider edge (PE) router when multiple VPLS instances are present. The network layer reachability information (NLRI) advertisements sent to a CE device are identified as candidates for designated forwarder selection because the advertisements have the same multihoming identifier. Thus, you should assign the same identifier on all VPLS PE routers that are multihomed to the same customer site.
	<div>  <p>NOTE: The route distinguisher must be unique among PE routers participating in a multihomed site, so that the RD:MHID combination is unique across multiple VPLS domains. For example, one PE router might have a route distinguisher of 1.1.1.4:1, and another PE router in the same site might have a route distinguisher of 1.1.1.2:1. The first number can be, for example, the loopback interface address that identifies the PE router. The second number is the multihoming identifier.</p> </div>
	<div>  <p>NOTE: In the VPLS documentation, the word <i>router</i> in terms such as <i>PE router</i> is used to refer to any device that provides routing functions.</p> </div>
Options	<i>identifier</i> —Number that identifies the multihomed site. Range: 1 through 65535

label-block-size

Syntax	label-block-size <i>size</i> ;
Hierarchy Level	[edit logical-systems <i>profile-name</i> routing-instances <i>instance-name</i> protocols vpls], [edit routing-instances <i>instance-name</i> protocols vpls]
Release Information	Statement introduced in Junos OS Release 10.0.
Description	Configure the label block size for VPLS labels.
Default	8
Options	<ul style="list-style-type: none">• 2—Allocate the label blocks in increments of 2. For a VPLS domain that has only two sites with no future expansion plans.• 4—Allocate the label blocks in increments of 4.• 8 (default)—Allocate the label blocks in increments of 8.• 16—Allocate the label blocks in increments of 16. A label block size of 16 enables you to minimize the number of routes in the VPLS domain. Use this setting only if the number of routes is the most important concern.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring the Label Block Size on page 5375

label-switched-path-template

Syntax	label-switched-path-template { (default-template <i>lsp-template-name</i>); }
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel rsvp-te], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel ingress-replication label-switched-path], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>address</i> source <i>source-address</i> rsvp-te], [edit logical-systems <i>logical-system-name</i> routing-options dynamic-tunnels <i>tunnel-name</i> rsvp-te <i>entry-name</i>], [edit routing-instances <i>routing-instance-name</i> provider-tunnel ingress-replication label-switched-path], [edit routing-instances <i>routing-instance-name</i> provider-tunnel rsvp-te], [edit routing-instances <i>routing-instance-name</i> provider-tunnel selective group <i>address</i> source <i>source-address</i> rsvp-te], [edit routing-options dynamic-tunnels <i>tunnel-name</i> rsvp-te <i>entry-name</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs. This feature can be used for a number of applications, including point-to-multipoint LSPs, flooding VPLS traffic, configuring ingress replication for IP multicast using MBGP MVPNs, and to enable RSVP automatic mesh. There is no default setting for the label-switched-path-template statement, so you must configure either the default-template using the default-template option, or you must specify the name of your preconfigured LSP template.
Options	default-template —Specify that the default LSP template be used for the dynamically generated LSPs. lsp-template-name —Specify the name of an LSP to be used as a template for the dynamically generated LSPs.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Ingress Replication for IP Multicast Using MBGP MVPNs • Configuring RSVP-Signaled Inclusive Point-to-Multipoint LSPs for an MBGP MVPN on page 5235 • Configuring Dynamic Point-to-Multipoint Flooding LSPs on page 5368 • Configuring RSVP Automatic Mesh

local-switching (VPLS)

Release Information	Statement introduced in Junos OS Release 9.3.
Description	Allows you to terminate multiple Layer 2 circuit pseudowires at a single VPLS mesh group.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Switching Between Pseudowires Using VPLS Mesh Groups on page 5371

mac-flush

Syntax	<code>mac-flush [<i>explicit-mac-flush-message-options</i>];</code>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls mesh-group <i>mesh-group-name</i>], [edit routing-instances <i>routing-instance-name</i> protocols vpls], [edit routing-instances <i>routing-instance-name</i> protocols vpls mesh-group <i>mesh-group-name</i>]
Release Information	Statement introduced in Junos OS Release 10.0.
Description	Enable media access control (MAC) flush processing for the virtual private LAN service (VPLS) routing instance or for the mesh group under a VPLS routing instance. MAC flush processing removes MAC addresses from the MAC address database that have been learned dynamically. With the dynamically learned MAC addresses removed, MAC address convergence requires less time to complete.

For certain cases where MAC flush processing is not initiated by default, you can also specify *explicit-mac-flush-message-options* that additionally configure the router to send explicit MAC flush messages. To configure the router to send explicit MAC flush messages under specific conditions, include *explicit-mac-flush-message-options* with the statement.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

In certain cases, BGP updates sent by the provider edge (PE) device are delayed for 1 to 5 seconds.

This happens when all of the following conditions are true:

- BGP-based VPLS multihoming sites are configured.
- The **mac-flush** statement is included in the configuration.
- a non-minimum designated-forwarder site (site-x, for example) transitions to non-designated-forwarder status

The BGP update being delayed corresponds to the explicit-MAC flush notification message sent by site-x's PE device (PE2, for example). This BGP update message is not deferred if the designated-forwarder status is lost due to a locally-triggered event (for example, a local attachment-circuit interface going down). In other words, BGP update messages are deferred (in Device PE2) only when the designated-forwarder state is lost due to external events taking place in remote PE devices that also hold site-x (for example, in PE1). Suppose, for example, that Device PE1 is the default designated-forwarder with site-x's local interface in the DOWN state. Device PE2 defers BGP update message after Device PE1's local interface comes back to the UP state.

Options *explicit-mac-flush-message-options*—(Optional) You can specify one or more of the following explicit MAC flush message options:

- **any-interface**—(Optional) Send a MAC flush message when any customer-facing attachment circuit interface goes down.
- **any-spoke**—(Optional) Send a MAC FLUSH-FROM-ME flush message to all provider edge (PE) routers in the core when one of the spoke pseudowires between the multitenant unit switch and the other network-facing provider edge (NPE) router goes down, causing the multitenant unit switch to switch to this NPE router.

.....

NOTE: This option has a similar effect in a VPLS multihoming environment with multiple multitenant unit switches connected to NPE routers, where both multitenant unit switches have pseudowires that terminate in a mesh group with local-switching configured. If the **any-spoke** option is enabled, then both PE routers send MAC FLUSH-FROM-ME flush messages to all PEs in the core.

.....

- **propagate**—(Optional) Propagate MAC flush to the core.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

no-tunnel-services

Syntax	no-tunnel-services;
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols vpls static-vpls], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls], [edit protocols vpls static-vpls], [edit routing-instances <i>routing-instance-name</i> protocols vpls]
Release Information	Statement introduced in Junos OS Release 7.6. Support for static VPLS added in Junos OS Release 10.2.
Description	<p>Configure VPLS on a router without a Tunnel Services PIC. Configuring the no-tunnel-services statement creates a label-switched interface (LSI) to provide VPLS functionality. An LSI MPLS label is used as the inner label for VPLS. This label maps to a VPLS routing instance. On the PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.</p> <p>Label-switched interfaces configured with the no-tunnel-services statement are not supported with GRE tunnels.</p>
	<div><p>NOTE: In the VPLS documentation, the word <i>router</i> in terms such as <i>PE router</i> is used to refer to any device that provides routing functions.</p></div>

peer-active (VPLS Multihoming for FEC 129)

Syntax	<code>peer-active;</code>
Hierarchy Level	<pre>[edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols vpls multi-homing], [edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols vpls multi-homing site <i>site-name</i>], [edit routing-instances <i>instance-name</i> protocols vpls multi-homing], [edit routing-instances <i>instance-name</i> protocols vpls multi-homing site <i>site-name</i>]</pre>
Release Information	Statement introduced in Junos OS Release 12.3.
Description	Keep customer edge (CE) interfaces in the up state when all BGP peers go down.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Consider a scenario in which two provider edge (PE) routers are sharing two multihomed sites under one routing instance, with two CE devices, CE1 and CE2.

If the BGP peering session drops between Router PE1 and Router PE2, each one would consider itself to be the designated forwarder (DF) for Device CE1 and Device CE2. This creates a loop through the two CE devices, in which traffic loops from one CE device to the other then back to the first.

Junos OS overcomes this scenario by dropping all multihomed CE interface traffic on all multihoming PE routers when the BGP session drops between the PE routers. This functionality is enabled by default for all sites in a routing instance.

The **peer-active** statement disables the default functionality, so that PE routers keep their multihomed CE interfaces in the up state, even though the BGP peering session is down.

If you configure this statement in the **multi-homing** hierarchy, the default functionality is disabled for all sites. If you configure this statement for a site, the default functionality is disabled only for that particular site.

Default	If you omit this statement, Junos OS drops all multihomed CE interface traffic on all multihoming PE routers when the BGP session drops between the PE routers.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls], [edit routing-instances <i>routing-instance-name</i> protocols vpls]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Trace traffic flowing through a VPLS routing instance.
Options	<p>disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as all.</p> <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks (" ").</p> <p>files <i>number</i>—(Optional) Maximum number of trace files. When a trace file named <i>trace-file</i> reaches this size, it is renamed <i>trace-file.0</i>. When <i>trace-file</i> again reaches its maximum size, <i>trace-file.0</i> is renamed <i>trace-file.1</i> and <i>trace-file</i> is renamed <i>trace-file.0</i>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option.</p> <p>Range: 2 through 1000 files</p> <p>Default: 2 files</p> <p>flag <i>flag</i>—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can specify the following tracing flags:</p> <ul style="list-style-type: none"> • all—All VPLS tracing options • connections—VPLS connections (events and state changes) • error—Error conditions • nlri—VPLS advertisements received or sent by means of the BGP • route—Routing information • topology—VPLS topology changes caused by reconfiguration or advertisements received from other provider edge (PE) routers using BGP <p>flag-modifier—(Optional) Modifier for the tracing flag. You can specify the following modifiers:</p> <ul style="list-style-type: none"> • detail—Provide detailed trace information.

- **disable**—Disable the tracing flag.
- **receive**—Trace received packets.
- **send**—Trace sent packets.

no-world-readable—Do not allow any user to read the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option.

Syntax: **xk** to specify kilobytes, **xm** to specify megabytes, or **xg** to specify gigabytes

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—Allow any user to read the log file.

Required Privilege Level	routing—To view this statement in the configuration.
	routing-control—To add this statement to the configuration.

tunnel-services (Routing Instances VPLS)

Syntax	<pre>tunnel-services { devices <i>device-names</i>; primary <i>primary-device-name</i>; }</pre>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls], [edit routing-instances <i>routing-instance-name</i> protocols vpls]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify that traffic for particular VPLS routing instances be forwarded to specific virtual tunnel (VT) interfaces, allowing you to load-balance VPLS traffic among all the available VT interfaces on the router.
<div>  <p>NOTE: In the VPLS documentation, the word <i>router</i> in terms such as <i>PE router</i> is used to refer to any device that provides routing functions.</p> </div>	
Options	<p>devices <i>device-names</i>—Specify the VT interfaces acceptable for use by the VPLS routing instance. If you do not configure this option, all VT interfaces available to the router can be used for de-encapsulating traffic for this instance.</p> <p>primary <i>primary-device-name</i>—Specify the primary VT interface to be used by the VPLS routing instance. The VT interface specified is used to de-encapsulate all VPLS traffic from the MPLS core network for this routing instance. If the VT interface specified is unavailable, then one of the other acceptable VT interfaces is used for handling the VPLS traffic. If you do not configure this option, any acceptable VT interface can be used to de-encapsulate VPLS traffic from the core.</p>
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

vlan-id

Syntax	<code>vlan-id <i>number</i>;</code>
Hierarchy Level	<code>[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i>]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For Fast Ethernet and Gigabit Ethernet interfaces only, bind an 802.1Q VLAN tag ID to a logical interface.
Options	<i>number</i> —A valid VLAN identifier. Range: For 4-port Fast Ethernet PICs configured to handle VPLS traffic, 512 through 1023. For 1-port and 10-port Gigabit Ethernet PICs configured to handle VPLS traffic, 512 through 4094.
Required Privilege Level	<code>interface</code> —To view this statement in the configuration. <code>interface-control</code> —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Interfaces for VPLS Routing on page 5336

vlan-id-list (Interface in VPLS)

Syntax	<code>vlan-id-list [<i>numbers number-number</i>];</code>
Hierarchy Level	<code>[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i>]</code>
Release Information	Statement introduced for VPLS in Junos OS Release 10.2.
Description	Configure a logical interface to forward packets and learn MAC addresses within each VPLS routing instance configured with a VLAN ID that matches a VLAN ID specified in the list. VLAN IDs can be entered individually using a space to separate each ID, entered as an inclusive list separating the starting VLAN ID and ending VLAN ID with a hyphen, or a combination of both.
Options	<i>number number</i> —Individual VLAN IDs separated by a space. <i>number-number</i> —Starting VLAN ID and ending VLAN ID in an inclusive range. Range: 1 through 4095
Required Privilege Level	<code>interface</code> —To view this statement in the configuration. <code>interface-control</code> —To add this statement to the configuration.

vlan-tagging

Syntax	vlan-tagging;
Hierarchy Level	[edit interfaces <i>interface-name</i>], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 12.2 for ACX Series Universal Access Routers.
Description	For Fast Ethernet and Gigabit Ethernet interfaces and aggregated Ethernet interfaces configured for VPLS, enable the reception and transmission of 802.1Q VLAN-tagged frames on the interface.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • <i>Example: Configuring Layer 3 Subinterfaces for a Distribution Switch and an Access Switch</i> • <i>Example: Configuring BGP Autodiscovery for LDP VPLS</i> • <i>Configuring a Layer 3 Subinterface (CLI Procedure)</i> • Configuring Tagged Aggregated Ethernet Interfaces on page 2302 • Configuring Interfaces for VPLS Routing on page 5336 • Enabling VLAN Tagging on page 5339 • <i>802.1Q VLANs Overview</i> • <i>vlan-id</i>

vpls (Interfaces)

Syntax	vpls;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify the VPLS protocol family information for the logical interface.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Interfaces for VPLS Routing on page 5336

vpls-id

Syntax	vpls-id <i>vpls-id</i> ;
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols l2vpn], [edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols l2vpn mesh-group <i>mesh-group-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols vpls], [edit logical-systems <i>logical-system-name</i> routing-instances <i>instance-name</i> protocols vpls mesh-group <i>mesh-group-name</i>], [edit routing-instances <i>instance-name</i> protocols l2vpn], [edit routing-instances <i>instance-name</i> protocols l2vpn mesh-group <i>mesh-group-name</i>], [edit routing-instances <i>instance-name</i> protocols vpls], [edit routing-instances <i>instance-name</i> protocols vpls mesh-group <i>mesh-group-name</i>]
Release Information	Statement introduced in Junos OS Release 8.4.
Description	Identify the virtual circuit identifier used for the VPLS routing instance or mesh group. This statement is a part of the configuration to enable LDP signaling for VPLS.
Options	<i>vpls-id</i> —Specify a valid identifier for the VPLS routing instance.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

Supported VPLS Standards

Junos OS substantially supports the following Internet RFCs and draft, which define standards for virtual private LAN service (VPLS).

- RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*
- RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*
FEC 128, FEC 129, control bit 0, the Ethernet pseudowire type 0x0005, and the Ethernet tagged mode pseudowire type 0x0004 are supported.
- Internet draft draft-kompella-l2vpn-vpls-multihoming, *Multi-homing in BGP-based Virtual Private LAN Service*
