Release Information	<p>Statement introduced in Junos OS Release 9.2.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Set the maximum number of DHCP subscribers or DHCP clients per interface allowed for a specific group or for all groups. A group specification takes precedence over a global specification for the members of that group.
Default	No limit
Options	<i>number</i> —Maximum number of clients allowed.

Range: 1 through 500,000

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

interface-delete (Subscriber Management or DHCP Client Management)

Syntax interface-delete;

Hierarchy Level [edit system services subscriber-management maintain-subscriber]

Release Information Statement introduced in Junos OS Release 11.1.
Statement introduced in Junos OS Release 12.3R2 for EX Series switches.

Description On router—Configure the router to maintain, rather than log out, subscribers when the subscriber interface is deleted. By default, the router logs out subscribers when the subscriber interface is deleted.

On switch—Configure the switch to maintain rather than log out DHCP clients when the client interface is deleted. By default, the switch logs out DHCP clients when the client interface is deleted.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

ip-address-first

Syntax	ip-address-first;
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server pool-match-order],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server pool-match-order],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server pool-match-order],</p> <p>[edit system services dhcp-local-server pool-match-order]</p>
Release Information	<p>Statement introduced in Junos OS Release 9.0.</p> <p>Statement introduced in Junos OS Release 12.1 for EX Series switches.</p>
Description	<p>Configure the extended DHCP local server to use the IP address method to determine which address-assignment pool to use. The local server uses the IP address in the gateway IP address if one is present in the DHCP client PDU. If no gateway IP address is present, the local server uses the IP address of the receiving interface to find the address-assignment pool. The DHCP local server uses this method by default when no method is explicitly specified.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

option-82 (DHCP Local Server Pool Matching)

Syntax	option-82;
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server pool-match-order],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server pool-match-order],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server pool-match-order],</p> <p>[edit system services dhcp-local-server pool-match-order]</p>
Release Information	<p>Statement introduced in Junos OS Release 9.0.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	<p>Configure the extended DHCP local server to use the option 82 value in the DHCP client DHCP PDU together with the ip-address-first method to determine which address-assignment pool to use. You must configure the ip-address-first statement before configuring the option-82 statement. The DHCP local server first determines which address-assignment pool to use based on the ip-address-first method. Then, the local server matches the option 82 value in the client PDU with the option 82 configuration in the address-assignment pool. This statement is supported for IPv4 address-assignment pools only.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

Release Information	<p>Statement introduced in Junos OS Release 9.2.</p> <p>Statement introduced in Junos OS Release 12.1 for EX Series switches.</p>
Description	<p>Override the default configuration settings for the extended DHCP local server. Specifying the overrides statement with no subordinate statements removes all DHCP local server overrides at that hierarchy level.</p> <ul style="list-style-type: none"> To override global DHCP local server configuration options, include the overrides statement and its subordinate statements at the [edit system services dhcp-local-server] hierarchy level. To override configuration options for a named group of interfaces, include the statements at the [edit system services dhcp-local-server group <i>group-name</i>] hierarchy level. To override configuration options for a specific interface within a named group of interfaces, include the statements at the [edit system services dhcp-local-server group <i>group-name</i> interface <i>interface-name</i>] hierarchy level. Use the [edit system services dhcp-local-server dhcpv6] hierarchy level to override DHCPv6 configuration options. <p>The remaining statements are explained separately.</p> <p>The interface-client-limit and no-arp statements are not supported in the [edit system services dhcp-local-server dhcpv6] hierarchy level.</p> <p>The delegated-pool and the rapid-commit statements are supported in the [edit system services dhcp-local-server dhcpv6 ...] hierarchy level only.</p>

Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

Release Information Statement introduced in Junos OS Release 11.4.
 Statement introduced in Junos OS Release 12.3R2 for EX Series switches.

Description	Configure DHCP or DHCPv6 local server to reply to DHCP information request messages (DHCPINFORM for DHCPv4 and INFORMATION-REQUEST for DHCPv6) with information taken from the specified pool without interacting with AAA.
Options	pool-name —Name of the address pool, which must be configured within family inet for DHCP local server and within family inet6 for DHCPv6 local server.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Enabling Processing of Client Information Requests on page 933• Overriding Default DHCP Local Server Configuration Settings on page 928

pool-match-order

Syntax	<pre>pool-match-order { external-authority; ip-address-first; option-82; }</pre>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server], [edit logical-systems <i>logical-system-name</i> system services dhcp-local-server], [edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server], [edit system services dhcp-local-server]
Release Information	Statement introduced in Junos OS Release 9.0. Statement introduced in Junos OS Release 12.1.
Description	Configure the order in which the DHCP local server uses information in the DHCP client PDU to determine how to obtain an address for the client. The remaining statements are explained separately.
Default	DHCP local server uses the ip-address-first method to determine which address pool to use.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring How the Extended DHCP Local Server Determines Which Address-Assignment Pool to Use on page 949• Extended DHCP Local Server Overview on page 876• Configuring a DHCP Server on Switches (CLI Procedure)

process-inform

Syntax	<pre>process-inform { pool pool-name; }</pre>

Release Information	<p>Statement introduced in Junos OS Release 11.4.</p> <p>Statement introduced in Junos OS Release 12.1 for EX Series switches.</p>
Description	<p>Enable the processing of DHCP information request messages (DHCPINFORM for DHCPv4 and INFORMATION-REQUEST for DHCPv6) sent from the client to request DHCP options. For DHCP local servers, the messages are also passed to the configured server list.</p>

The remaining statement is explained separately.

Default Information request messages are not processed.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

radius-disconnect (DHCP Local Server)

Syntax	radius-disconnect;
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server reconfigure trigger],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure trigger],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure trigger],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure trigger],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server reconfigure trigger],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 reconfigure trigger],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure trigger],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure trigger],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server reconfigure trigger],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure trigger],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure trigger],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure trigger],</p> <p>[edit system services dhcp-local-server reconfigure trigger],</p> <p>[edit system services dhcp-local-server dhcpv6 reconfigure trigger],</p> <p>[edit system services dhcp-local-server group <i>group-name</i> reconfigure trigger],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure trigger]</p>
Release Information	<p>Statement introduced in Junos OS Release 10.0.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p> <p>Support at the [edit ... dhcpv6 ...] hierarchy levels introduced in Junos OS Release 10.4.</p>
Description	Configure all DHCP clients or only the DHCP clients serviced by the specified group of interfaces to be reconfigured when a RADIUS-initiated disconnect is received by the DHCP client or group of clients. A group configuration takes precedence over a DHCP local server configuration.
Default	The client is deleted when a RADIUS-initiated disconnect is received.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

rapid-commit (DHCPv6 Local Server)

Syntax	rapid-commit;
Hierarchy Level	[edit system services dhcp-local-server dhcpv6 overrides], [edit system services dhcp-local-server dhcpv6 group group-name overrides], [edit system services dhcp-local-server dhcpv6 group group-name interface interface-name overrides], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 ...], [edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 ...], [edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 ...]
Release Information	Statement introduced in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure DHCPv6 local server to recognize the Rapid Commit option (DHCPv6 option 14) in DHCPv6 solicit messages sent from the DHCPv6 client. When rapid commit is enabled for both DHCPv6 local server and the DHCPv6 client, a two-message handshake is used instead of the standard four-message handshake. You can enable rapid commit support on DHCPv6 local server globally, for a named group, or for a specific interface.
Default	Rapid commit support is not enabled.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Enabling DHCPv6 Rapid Commit Support on page 935• Overriding Default DHCP Local Server Configuration Settings on page 928

reconfigure (DHCP Local Server)

Syntax	<pre> reconfigure { attempts <i>attempt-count</i>; clear-on-abort; strict; timeout <i>timeout-value</i>; token <i>token-value</i>; trigger { radius-disconnect; } } </pre>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server group <i>group-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i>],</p> <p>[edit system services dhcp-local-server],</p> <p>[edit system services dhcp-local-server dhcpv6],</p> <p>[edit system services dhcp-local-server group <i>group-name</i>],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i>]</p>
Release Information	<p>Statement introduced in Junos OS Release 10.0.</p> <p>Support at the [edit ... dhcpv6 ...] hierarchy levels introduced in Junos OS Release 10.4.</p> <p>Statement introduced in Junos OS Release 12.1 for EX Series switches.</p>
Description	<p>Enable dynamic reconfiguration triggered by the DHCP local server of all DHCP clients or only the DHCP clients serviced by the specified group of interfaces. A group configuration takes precedence over a DHCP local server configuration. The strict statement is available only for DHCPv6.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

service-profile (DHCP Local Server)

Syntax	<code>service-profile <i>dynamic-profile-name</i>;</code>
Hierarchy Level	<p>[edit system services dhcp-local-server], [edit system services dhcp-local-server dhcpv6], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i>], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> interface <i>interface-name</i>], [edit system services dhcp-local-server group <i>group-name</i>], [edit system services dhcp-local-server group <i>group-name</i> interface <i>interface-name</i>], [edit logical-systems <i>logical-system-name</i> system services dhcp-local-server ...], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server ...], [edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server ...]</p>
Release Information	<p>Statement introduced in Junos OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	<p>Specify the default subscriber service or DHCP client management service, which is activated when the subscriber or client logs in and no other service is activated by a RADIUS server or a provisioning server.</p> <ul style="list-style-type: none"> • To specify the default service for all DHCP local server clients, include the service-profile statement at the [edit system services dhcp-local-server] hierarchy level. • To specify the default service for a named group of interfaces, include the service-profile statement at the [edit system services dhcp-local-server group <i>group-name</i>] hierarchy level. • To specify the default service for a particular interface within a named group of interfaces, include the service-profile statement at the [edit system services dhcp-local-server group <i>group-name</i> interface <i>interface-name</i>] hierarchy level. • For DHCPv6 clients, use the service-profile statement at the [edit system services dhcp-local-server dhcpv6] hierarchy level.
Options	<i>dynamic-profile-name</i> —Name of the dynamic profile that defines the service.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

session-mode

Syntax	session-mode (automatic multihop singlehop);
Hierarchy Level	[edit system services dhcp-local-server liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 liveness-detection method bfd], [edit forwarding-options dhcp-relay liveness-detection], [edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd], [edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd]
Release Information	Statement introduced in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure the session mode.
Options	automatic —Configure single-hop BFD sessions if the peer is directly connected to the router interface and multihop BFD sessions if the peer is not directly connected to the router interface. multihop —Configure multihop BFD sessions. single-hop —Configure single hop BFD sessions.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 913• <i>Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients</i>

strict (DHCP Local Server)

Syntax	strict;
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure]</p>
Release Information	<p>Statement introduced in Junos OS Release 10.4.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Specify whether the server denies a client to bind when the client does not indicate that it accepts reconfigure messages. This feature is available only for DHCPv6.
Default	Accept solicit messages from clients that do not support reconfiguration and permit them to bind.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring Extended DHCP Local Server Dynamic Client Reconfiguration on page 936 • Preventing Binding of Clients That Do Not Support Reconfigure Messages on page 939

threshold (detection-time)

Syntax	<code>threshold <i>milliseconds</i>;</code>
Hierarchy Level	<p>[edit system services dhcp-local-server liveness-detection method bfd detection-time], [edit system services dhcp-local-server dhcpv6 liveness-detection method bfd detection-time], [edit forwarding-options dhcp-relay liveness-detection method bfd detection-time], [edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd detection-time], [edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd detection-time], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd detection-time], [edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd detection-time], [edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd detection-time]</p>
Release Information	<p>Statement introduced in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Specify the threshold for the adaptation of the detection time. When the BFD session detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.
<div style="display: flex; align-items: center;">  <div> <p>NOTE: The threshold time must be greater than or equal to the <code>minimum-interval</code> or the <code>minimum-receive-interval</code>.</p> </div> </div>	
Options	<p><i>milliseconds</i>— Value for the detection time adaptation threshold. Range: 1 through 255,000</p>
Required Privilege Level	<p>routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 913 • Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients

threshold (transmit-interval)

Syntax	<code>threshold <i>milliseconds</i>;</code>
Hierarchy Level	<p>[edit system services dhcp-local-server liveness-detection method bfd transmit-interval],</p> <p>[edit system services dhcp-local-server dhcpv6 liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd transmit-interval],</p> <p>[edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd transmit-interval],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd transmit-interval]</p>
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Specify the threshold for detecting the adaptation of the transmit interval. When the BFD session transmit interval adapts to a value greater than the threshold, a single trap and a single system message are sent.
Options	<p><i>milliseconds</i> — Threshold value.</p> <p>Range: 0 through 4,294,967,295 ($2^{32} - 1$)</p>
<div>  <p>NOTE: The threshold value specified in the <code>threshold</code> statement must be greater than the value specified in the <code>minimum-interval</code> statement for the <code>transmit-interval</code> statement.</p> </div>	
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 913 • Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients

timeout (DHCP Local Server)

Syntax	<code>timeout <i>timeout-value</i>;</code>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit system services dhcp-local-server reconfigure],</p> <p>[edit system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure]</p>
Release Information	<p>Statement introduced in Junos OS Release 10.0.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p> <p>Support at the [edit ... dhcpv6 ...] hierarchy levels introduced in Junos OS Release 10.4.</p>
Description	Configure the initial value in seconds between attempts to reconfigure all DHCP clients or only the DHCP clients serviced by the specified group of interfaces.
Options	<p><i>timeout-value</i>—Initial retry timeout value.</p> <p>Range: 1 through 10 seconds</p> <p>Default: 2 seconds</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

token (DHCP Local Server)

Syntax	<code>token <i>token-value</i>;</code>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure],</p> <p>[edit system services dhcp-local-server reconfigure],</p> <p>[edit system services dhcp-local-server dhcpv6 reconfigure],</p> <p>[edit system services dhcp-local-server group <i>group-name</i> reconfigure],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i> reconfigure]</p>
Release Information	<p>Statement introduced in Junos OS Release 10.0.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p> <p>Support at the [edit ... dhcpv6 ...] hierarchy levels introduced in Junos OS Release 10.4.</p>
Description	<p>Configure a plain-text token for all DHCP clients or only the DHCP clients serviced by the specified group of interfaces. The token enables rudimentary entity authentication to protect against inadvertently instantiated DHCP servers. A null token (empty string) indicates that the configuration token functionality is not enabled. A group configuration takes precedence over a DHCP local server configuration. For more information about tokens, see RFC 3118, <i>Authentication for DHCP Messages</i>, section 4.</p>
Options	<p><i>token-value</i>—Plain-text alphanumeric string.</p> <p>Default: null (empty string)</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring Extended DHCP Local Server Dynamic Client Reconfiguration on page 936 • Configuring a Token for DHCP Local Server Authentication on page 939

transmit-interval

Syntax	<pre>transmit-interval { threshold milliseconds; minimum-interval milliseconds; }</pre>
Hierarchy Level	[edit system services dhcp-local-server liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 liveness-detection method bfd], [edit forwarding-options dhcp-relay liveness-detection method bfd], [edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd], [edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd]
Release Information	Statement introduced in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure the Bidirectional Forwarding Detection (BFD) transmit interval. The remaining statements are explained separately.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 913• Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients

trigger (DHCP Local Server)

use-primary (DHCP Local Server)

Syntax	<code>use-primary <i>primary-profile-name</i>;</code>
Hierarchy Level	<code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server <i>dynamic-profile profile-name</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> <i>dynamic-profile profile-name</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server <i>dynamic-profile profile-name</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server group <i>group-name</i> <i>dynamic-profile profile-name</i>],</code> <code>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server <i>dynamic-profile profile-name</i>],</code> <code>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server group <i>group-name</i> <i>dynamic-profile profile-name</i>],</code> <code>[edit system services dhcp-local-server <i>dynamic-profile profile-name</i>]</code> <code>[edit system services dhcp-local-server group <i>group-name</i> <i>dynamic-profile profile-name</i>]</code>
Release Information	Statement introduced in Junos OS Release 9.3. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Specify the dynamic profile to configure as the primary dynamic profile. The primary dynamic profile is instantiated when the first subscriber or DHCP client logs in. Subsequent subscribers (or clients) are not assigned the primary dynamic profile; instead, they are assigned the dynamic profile specified for the interface. When the first subscriber (or client) logs out, the next subscriber (or client) that logs in is assigned the primary dynamic profile.
Options	<i>primary-profile-name</i> —Name of the dynamic profile to configure as the primary dynamic profile
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attaching Dynamic Profiles to DHCP Subscriber Interfaces or DHCP Client Interfaces on page 942

user-prefix (DHCP Local Server)

Syntax	<code>user-prefix <i>user-prefix-string</i>;</code>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group group-name authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server group group-name authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server dhcpv6 group group-name authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> system services dhcp-local-server group group-name authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group group-name authentication username-include],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> system services dhcp-local-server group group-name authentication username-include],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server authentication username-include],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 authentication username-include],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server dhcpv6 group group-name authentication username-include],</p> <p>[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server group group-name authentication username-include],</p> <p>[edit system services dhcp-local-server authentication username-include],</p> <p>[edit system services dhcp-local-server dhcpv6 authentication username-include],</p> <p>[edit system services dhcp-local-server dhcpv6 group group-name authentication username-include],</p> <p>[edit system services dhcp-local-server group group-name authentication username-include]</p>
Release Information	<p>Statement introduced in Junos OS Release 9.1.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Specify the user prefix that is concatenated with the username during the subscriber authentication or DHCP client authentication process.
Options	<i>user-prefix-string</i> —User prefix string.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

access (Dynamic Access Routes)

Syntax

```
access {
  route prefix {
    next-hop next-hop;
    metric route-cost;
    preference route-distance;
    tag route-tag;
  }
}
```

Hierarchy Level [\[edit dynamic-profiles routing-options\]](#)

Release Information Statement introduced in Junos OS Release 9.5.

Description Dynamically configure access routes.

BEST PRACTICE: We recommend that you always include the **access-internal** stanza in the dynamic-profile when the access stanza is present for framed-route support.

Options The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

- Related Documentation**

access-internal (Dynamic Access-Internal Routes)

Syntax `access-internal {
 route subscriber-ip-address {
 qualified-next-hop underlying-interface {
 mac-address address;
 }
 }
 }`

Hierarchy Level [edit dynamic-profiles routing-options]

Release Information Statement introduced in Junos OS Release 9.5.

Description Dynamically configure access-internal routes. Access-internal routes are optional, but are used instead of access routes if the next-hop address is not specified in the Framed-Route Attribute [22] for IPv4 or the Framed-IPv6-Route attribute [99] for IPv6.

.....
BEST PRACTICE: We recommend that you always include the `access-internal` stanza in the dynamic-profile when the `access` stanza is present for framed-route support.
.....

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
 routing-control—To add this statement to the configuration.

Release Information	Statement introduced in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	<p>Enable failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the one configured.</p> <p>The remaining statement is explained separately.</p>
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

Release Information Statement introduced in Junos OS Release 8.3.
 Statement introduced in Junos OS Release 12.1 for EX Series switches.

Description Configure extended Dynamic Host Configuration Protocol (DHCP) relay and DHCPv6 relay options on the router or switch and enable the router (or switch) to function as a DHCP relay agent. A DHCP relay agent forwards DHCP request and reply packets between a DHCP client and a DHCP server.

DHCP relay supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide subscriber authentication or client authentication. You can attach dynamic profiles and configure authentication support on a global basis or for a specific group of interfaces.

The extended DHCP and DHCPv6 relay agent options configured with the **dhcp-relay** and **dhcpv6** statements are incompatible with the DHCP/BOOTP relay agent options configured with the **bootp** statement. As a result, the extended DHCP or DHCPv6 relay agent and the DHCP/BOOTP relay agent cannot both be enabled on the router (or switch) at the same time.

The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

failure-action

Syntax	failure-action (clear-binding clear-binding-if-interface-up log-only);
Hierarchy Level	[edit system services dhcp-local-server liveness-detection], [edit system services dhcp-local-server dhcpv6 liveness-detection], [edit forwarding-options dhcp-relay liveness-detection], [edit forwarding-options dhcp-relay dhcpv6 liveness-detection], [edit system services dhcp-local-server group <i>group-name</i> liveness-detection], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection], [edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection], [edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection]
Release Information	Statement introduced in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure the action the router (or switch) takes when a liveness detection failure occurs.
Options	<p>clear-binding—The client session is cleared when a liveness detection failure occurs.</p> <p>clear-binding-if-interface-up—The client session is cleared only when a liveness detection failure occurs and the local interface is detected as being up.</p> <p>log-only—A message is logged to indicate the event; no action is taken and DHCP is left to manage the failure.</p>
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • DHCP Liveness Detection Overview on page 980 • Configuring Detection of DHCP Local Server Client Connectivity on page 941 • Configuring Detection of DHCP Relay or DHCP Relay Proxy Client Connectivity on page 981 • Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 913 • Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients

forward-snooped-clients (DHCP Relay Agent)

Syntax	forward-snooped-clients (all-interfaces configured-interfaces non-configured-interfaces);
Hierarchy Level	[edit forwarding-options dhcp-relay], [edit logical-systems <i>logical-system-name</i> forwarding-options dhcp-relay], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay], [edit routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay]
Release Information	Statement introduced in Junos OS Release 10.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	<p>Configure how DHCP relay agent handles DHCP snooped packets on specific interfaces. The router or switch determines the DHCP snooping action to perform based on a combination of the forward-snooped-clients configuration and the configuration of either the allow-snooped-clients statement or the no-allow-snooped-clients statement.</p> <p>The router (or switch) also uses this statement to determine how to handle snooped BOOTREPLY packets received on nonconfigured interfaces.</p>
Options	<p>all-interfaces—Perform the action on all interfaces.</p> <p>configured-interfaces—Perform the action only on configured interfaces.</p> <p>non-configured-interfaces—Perform the action only on nonconfigured interfaces.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 8.3.

Options **upto** and **exclude** introduced in Junos OS Release 9.1.

Support at the **[edit ... dhcpv6]** hierarchy levels introduced in Junos OS Release 11.4.

Statement introduced in Junos OS Release 12.1 for EX Series switches.

Description

Specify one or more interfaces, or a range of interfaces, that are within a specified group on which the DHCP or DHCPv6 relay agent is enabled. You can repeat the **interface *interface-name*** statement to specify multiple interfaces within a group, but you cannot specify the same interface in more than one group. Also, you cannot use an interface that is being used by the DHCP local server. Use the statement at the **[edit ... dhcpv6]** hierarchy levels to configure DHCPv6 support.

NOTE: DHCP values are supported in Integrated Routing and Bridging (IRB) configurations. When you configure an IRB interface in a network that is using DHCP, the DHCP information (for example, authentication, address assignment, and so on) is propagated in the associated bridge domain. This enables the DHCP server to configure client IP addresses residing within the bridge domain. IRB currently only supports static DHCP configurations. For additional information about how to configure IRB, see the *JUNOS® MX Series 3D Universal Edge Routers Solutions, Release 12.3*.

Options **exclude**—Exclude an interface or a range of interfaces from the group. This option and the **overrides** option are mutually exclusive.

interface-name—Name of the interface. You can repeat this option multiple times.

overrides—Override the specified default configuration settings for the interface. The **overrides** statement is described separately.

upto-interface-name—Upper end of the range of interfaces; the lower end of the range is the interface-name entry. The interface device name of the **upto-interface-name** must be the same as the device name of the **interface-name**.

The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
 interface-control—To add this statement to the configuration.

minimum-interval

Syntax	<code>minimum-interval <i>milliseconds</i>;</code>
Hierarchy Level	<p>[edit system services dhcp-local-server liveness-detection method bfd], [edit system services dhcp-local-server liveness-detection method bfd transmit-interval], [edit system services dhcp-local-server dhcpv6 liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 liveness-detection method bfd transmit-interval], [edit forwarding-options dhcp-relay liveness-detection method bfd], [edit forwarding-options dhcp-relay liveness-detection method bfd transmit-interval], [edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd], [edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd transmit-interval], [edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd], [edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd transmit-interval], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd transmit-interval], [edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd transmit-interval], [edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd transmit-interval]</p>
Release Information	<p>Statement introduced in Junos OS Release 12.1.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	<p>Configure the minimum intervals at which the local routing device transmits hello packets and then expects to receive a reply from a neighbor with which it has established a BFD session. This value represents the minimum interval at which the local routing device transmits hello packets as well as the minimum interval that the routing device expects to receive a reply from a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can specify the minimum transmit and receive intervals separately using the transmit-interval minimal-interval and minimum-receive-interval statements.</p>
Options	<p><i>milliseconds</i> — Specify the minimum interval value for BFD liveliness detection.</p> <p>Range: 1 through 255,000</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 913 • Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients

minimum-receive-interval

Syntax	<code>minimum-receive-interval <i>milliseconds</i>;</code>
Hierarchy Level	<p>[edit system services dhcp-local-server liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 liveness-detection method bfd], [edit forwarding-options dhcp-relay liveness-detection method bfd], [edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd], [edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd], [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd], [edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd]</p>
Release Information	<p>Statement introduced in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Configure the minimum interval at which the local routing device (or switch) must receive a reply from a neighbor with which it has established a BFD session.
Options	<p><i>milliseconds</i> — Specify the minimum receive interval value. Range: 1 through 255,000</p>
Required Privilege Level	<p>routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.</p>

Release Information Statement introduced in Junos OS Release 10.4.
 Support at the [edit ... dhcpv6] hierarchy levels introduced in Junos OS Release 11.4.
 Statement introduced in Junos OS Release 12.3 for EX Series switches.

Description Explicitly disable automatic binding of received DHCP request messages that have no entry in the database (*stray* requests). Use the statement at the [edit ... dhcpv6] hierarchy levels to configure DHCPv6 support.

M120 and M320 routers do not support DHCPv6.

NOTE: Beginning with Junos OS Release 10.4, automatic binding of stray requests is enabled by default. In Junos OS Release 10.3 and earlier releases, automatic binding of stray requests is disabled by default.

Required Privilege Level interface—To view this statement in the configuration.
 interface-control—To add this statement to the configuration.

prefix (DHCP Relay Agent)

Syntax	<code>prefix <i>prefix</i>;</code>
Hierarchy Level	<p>[edit forwarding-options dhcp-relay dhcpv6 <i>relay-agent-interface-id</i>],</p> <p>[edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> <i>relay-agent-interface-id</i>],</p> <p>[edit forwarding-options dhcp-relay relay-option-82 <i>circuit-id</i>],</p> <p>[edit forwarding-options dhcp-relay group <i>group-name</i> relay-option-82 <i>circuit-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> forwarding-options dhcp-relay dhcpv6 <i>relay-agent-interface-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> <i>relay-agent-interface-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> forwarding-options dhcp-relay relay-option-82 <i>circuit-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> forwarding-options dhcp-relay group <i>group-name</i> relay-option-82 <i>circuit-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay dhcpv6 <i>relay-agent-interface-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> <i>relay-agent-interface-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay relay-option-82 <i>circuit-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay group <i>group-name</i> relay-option-82 <i>circuit-id</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay dhcpv6 <i>relay-agent-interface-id</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> <i>relay-agent-interface-id</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay relay-option-82 <i>circuit-id</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> forwarding-options dhcp-relay group <i>group-name</i> relay-option-82 <i>circuit-id</i>]</p>
Release Information	<p>Statement introduced in Junos OS Release 8.3.</p> <p>Support at the [edit ... dhcpv6] hierarchy levels introduced in Junos OS Release 11.4.</p> <p>Statement introduced in Junos OS Release 12.3 for EX Series switches.</p>
Description	<p>Add a prefix to the base option 82 Agent Circuit ID information in DHCP packets destined for a DHCP server. The prefix can consist of any combination of the hostname, logical system name, and routing instance name. Use the statement at the [edit ... dhcpv6] hierarchy levels to configure DHCPv6 support.</p> <p>If you include only the hostname, only the logical system name, or only the routing instance name in the prefix, the format of the Agent Circuit ID information for Fast Ethernet or Gigabit Ethernet interfaces with stacked virtual LANs (S-VLANs) is one of the following:</p> <pre> host-name:(fe ge)-fpc/pic/port:svlan-id-vlan-id logical-system-name:(fe ge)-fpc/pic/port:svlan-id-vlan-id routing-instance-name:(fe ge)-fpc/pic/port:svlan-id-vlan-id </pre> <p>If you include both the logical system name and the routing instance name in the prefix, the format of the Agent Circuit ID information for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs is as follows:</p>

logical-system-name;routing-instance-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id

If you include the hostname, logical system name, and routing instance name in the prefix, the format of the Agent Circuit ID information for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs is as follows:

host-name/logical-system-name;routing-instance-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id

For Fast Ethernet or Gigabit Ethernet interfaces that use virtual LANs (VLANs) but not S-VLANs, only the **vlan-id** value appears in the Agent Circuit ID format. For Fast Ethernet or Gigabit Ethernet interfaces that do not use VLANs or S-VLANs, neither the **vlan-id** value nor the **svlan-id** value appears.

Options *prefix*—Any of the following:

- **host-name**—Prepend the hostname of the router configured with the **host-name** statement at the **[edit system]** hierarchy level to the Agent Circuit ID information.
- **logical-system-name**—Prepend the name of the logical system to the Agent Circuit ID information.
- **routing-instance-name**—Prepend the name of the routing instance to the Agent Circuit ID information.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

threshold (detection-time)

Syntax	<code>threshold <i>milliseconds</i>;</code>
Hierarchy Level	<p>[edit system services dhcp-local-server liveness-detection method bfd detection-time],</p> <p>[edit system services dhcp-local-server dhcpv6 liveness-detection method bfd detection-time],</p> <p>[edit forwarding-options dhcp-relay liveness-detection method bfd detection-time],</p> <p>[edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd detection-time],</p> <p>[edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd detection-time],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd detection-time],</p> <p>[edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd detection-time],</p> <p>[edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd detection-time]</p>
Release Information	<p>Statement introduced in Junos OS Release 12.1.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Specify the threshold for the adaptation of the detection time. When the BFD session detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.
<div>  <p>NOTE: The threshold time must be greater than or equal to the <code>minimum-interval</code> or the <code>minimum-receive-interval</code>.</p> </div>	
Options	<p><i>milliseconds</i>— Value for the detection time adaptation threshold.</p> <p>Range: 1 through 255,000</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 913 • Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients

threshold (transmit-interval)

Syntax	<code>threshold <i>milliseconds</i>;</code>
Hierarchy Level	<p>[edit system services dhcp-local-server liveness-detection method bfd transmit-interval],</p> <p>[edit system services dhcp-local-server dhcpv6 liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay dhcpv6 liveness-detection method bfd transmit-interval],</p> <p>[edit system services dhcp-local-server group <i>group-name</i> liveness-detection method bfd transmit-interval],</p> <p>[edit system services dhcp-local-server dhcpv6 group <i>group-name</i> liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay group <i>group-name</i> liveness-detection method bfd transmit-interval],</p> <p>[edit forwarding-options dhcp-relay dhcpv6 group <i>group-name</i> liveness-detection method bfd transmit-interval]</p>
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Specify the threshold for detecting the adaptation of the transmit interval. When the BFD session transmit interval adapts to a value greater than the threshold, a single trap and a single system message are sent.
Options	<p><i>milliseconds</i> — Threshold value.</p> <p>Range: 0 through 4,294,967,295 ($2^{32} - 1$)</p>
<div>  <p>NOTE: The threshold value specified in the <code>threshold</code> statement must be greater than the value specified in the <code>minimum-interval</code> statement for the <code>transmit-interval</code> statement.</p> </div>	
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

Release Information Statement introduced in Junos OS Release 9.6.
 Support at the [edit ... **dhcpv6**] hierarchy levels introduced in Junos OS Release 11.4.
 Statement introduced in Junos OS Release 12.3 for EX Series switches.

Description Use the textual interface description instead of the interface identifier when creating the agent-circuit-id suboption of the DHCP relay agent option 82. Use the statement at the [edit ... **dhcpv6**] hierarchy levels to configure DHCPv6 support.

If you specify that the textual description is used and no description is configured for the interface, DHCP relay defaults to using the interface identifier. The textual description is configured using the **description** statement at the [edit interfaces *interface-name*] hierarchy level.

NOTE: By default, DHCP relay accepts a maximum of 253 ASCII characters. If the textual interface description is longer than 253 characters, DHCP relay drops the packet, which results in the DHCP client failing to bind.

Options	logical —Use the textual description that is configured for the logical interface.
	device —Use the textual description that is configured for the device interface.
Required Privilege Level	interface—To view this statement in the configuration.
	interface-control—To add this statement to the configuration.

Release Information Statement introduced in Junos OS Release 9.1.
 Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
 Support at the [\[edit ... dhcpv6\]](#) hierarchy levels introduced in Junos OS Release 11.4.

Description Configure the username that the router (or switch) passes to the external AAA server. You must include at least one of the optional statements for the username to be valid. If you do not configure a username, the router (or switch) accesses the local authentication service only and does not use external authentication services, such as RADIUS. Use the statement at the [\[edit...dhcpv6\]](#) hierarchy levels to configure DHCPv6 support.

The following statements are not supported in the DHCPv6 hierarchy levels:

- mac-address
- option-60
- option-82

The following statements are supported in the DHCPv6 hierarchy levels only:

- relay-agent-interface-id
- relay-agent-remote-id
- relay-agent-subscriber-id

The remaining statements are explained separately.

Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

DHCP Local Server Monitoring Commands

clear dhcp server binding

Syntax `clear dhcp server binding`
 `<address>`
 `<all>`
 `<interface interface-name>`
 `<interfaces-vlan>`
 `<interfaces-wildcard>`
 `<logical-system logical-system-name>`
 `<routing-instance routing-instance-name>`

Release Information Command introduced in Junos OS Release 9.0.
 Options *interfaces-vlan* and *interfaces-wildcard* added in Junos OS Release 12.1.

Description Clear the binding state of a Dynamic Host Configuration Protocol (DHCP) client from the client table on the extended DHCP local server.

Options *address*—(Optional) Clear the binding state for the DHCP client, using one of the following entries:

- *ip-address*—The specified IP address.
- *mac-address*—The specified MAC address.
- *session-id*—The specified session ID.

all—(Optional) Clear the binding state for all DHCP clients.

interface interface-name—(Optional) Clear the binding state for DHCP clients on the specified interface.

.....

NOTE: This option clears all bindings whose initial login requests were received over the specified interface. Dynamic demux login requests are not received over the dynamic demux interface, but rather the underlying interface of the dynamic demux interface. To clear a specific dynamic demux interface, use the *ip-address* or *mac-address* options.

.....

interfaces-vlan—(Optional) Clear the binding state on the interface VLAN ID and S-VLAN ID.

interfaces-wildcard—(Optional) Clear bindings on a set of interfaces. This option supports the use of the wildcard character (*).

logical-system logical-system-name—(Optional) Clear the binding state for DHCP clients on the specified logical system.

routing-instance routing-instance-name—(Optional) Clear the binding state for DHCP clients on the specified routing instance.

Required Privilege Level view

Output Fields See [show dhcp server binding](#) for an explanation of output fields.

Sample Output

clear dhcp server binding <ip-address>

The following sample output displays the address bindings in the DHCP client table on the extended DHCP local server before and after the **clear dhcp server binding** command is issued.

```
user@host> show dhcp server binding
```

```
2 clients, (0 bound, 0 selecting, 0 renewing, 0 rebinding)
```

IP address	Hardware address	Type	Lease expires at
100.20.32.1	90:00:00:01:00:01	active	2007-01-17 11:38:47 PST
100.20.32.3	90:00:00:02:00:01	active	2007-01-17 11:38:41 PST

```
user@host> clear dhcp server binding 10.20.32.1
```

```
user@host> show dhcp server binding
```

```
1 clients, (0 bound, 0 selecting, 0 renewing, 0 rebinding)
```

IP address	Hardware address	Type	Lease expires at
100.20.32.3	90:00:00:02:00:01	active	2007-01-17 11:38:41 PST

clear dhcp server binding all

The following command clears all DHCP local server bindings:

```
user@host> clear dhcp server binding all
```

clear dhcp server binding interface

The following command clears DHCP local server bindings on a specific interface:

```
user@host> clear dhcp server binding interface fe-0/0/2
```

clear dhcp server binding <interfaces-vlan>

The following command uses the *interfaces-vlan* option to clear all DHCP local server bindings on top of the underlying interface **ae0**, which clears DHCP bindings on all demux VLANs on top of **ae0**:

```
user@host> clear dhcp server binding ae0
```

clear dhcp server binding <interfaces-wildcard>

The following command uses the *interfaces-wildcard* option to clear all DHCP local server bindings over a specific interface:

```
user@host> clear dhcp server binding ge-1/0/0.*
```

clear dhcp server statistics

Syntax	<code>clear dhcp server statistics</code> <code><interface <i>interface-name</i>></code> <code><logical-system <i>logical-system-name</i>></code> <code><routing-instance <i>routing-instance-name</i>></code>
Release Information	Command introduced in Junos OS Release 9.0.
Description	Clear all extended Dynamic Host Configuration Protocol (DHCP) local server statistics.
Options	<p>logical-system <i>logical-system-name</i>—(Optional) Clear the statistics for DHCP clients on the specified logical system. If you do not specify a logical system, statistics are cleared for the default logical system.</p> <p>routing-instance <i>routing-instance-name</i>—(Optional) Clear the statistics for DHCP clients on the specified routing instance. If you do not specify a routing instance, statistics are cleared for the default routing instance.</p>
Required Privilege Level	view
List of Sample Output	clear dhcp server statistics on page 1163
Output Fields	See show dhcp server statistics for an explanation of output fields.

Sample Output

clear dhcp server statistics

The following sample output displays the extended DHCP local server statistics before and after the **clear dhcp server statistics** command is issued.

```

user@host> show dhcp server statistics
Packets dropped:
  Total                               0

clear dhcpv6 server binding

Syntax	<pre>clear dhcpv6 server binding <address> <all> <interface interface-name> <interfaces-vlan> <interfaces-wildcard> <logical-system logical-system-name> <routing-instance routing-instance-name></pre>
Release Information	<p>Command introduced in Junos OS Release 9.6.</p> <p>Options <i>interfaces-vlan</i> and <i>interfaces-wildcard</i> added in Junos OS Release 12.1.</p>
Description	Clear the binding state of a Dynamic Host Configuration Protocol for IPv6 (DHCPv6) client from the client table on the extended DHCPv6 local server.
Options	<p>address—(Optional) Clear the binding state for the DHCPv6 client, using one of the following entries:</p> <ul style="list-style-type: none"> • <i>CID</i>—The specified Client ID (CID). • <i>ipv6-prefix</i>—The specified IPv6 prefix. • <i>session-id</i>—The specified session ID. <p>all—(Optional) Clear the binding state for all DHCPv6 clients.</p> <p>interface interface-name—(Optional) Clear the binding state for DHCPv6 clients on the specified interface.</p> <p>interfaces-vlan—(Optional) Clear the binding state on the interface VLAN ID and S-VLAN ID.</p> <p>interfaces-wildcard—(Optional) Clear bindings on a set of interfaces. This option supports the use of the wildcard character (*).</p> <p>logical-system logical-system-name—(Optional) Clear the binding state for DHCPv6 clients on the specified logical system.</p> <p>routing-instance routing-instance-name—(Optional) Clear the binding state for DHCPv6 clients on the specified routing instance.</p>
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none"> • Clearing DHCP Bindings for Subscriber Access • show dhcpv6 server binding on page 1185
List of Sample Output	<p>clear dhcpv6 server binding all on page 1166</p> <p>clear dhcpv6 server binding <ipv6-prefix> on page 1166</p>

[clear dhcpv6 server binding <interfaces-wildcard> on page 1166](#)

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

clear dhcpv6 server binding all

The following command clears all DHCPv6 local server bindings:

```
user@host> clear dhcpv6 server binding all
```

clear dhcpv6 server binding <ipv6-prefix>

The following command clears DHCPv6 local server bindings for a specific IPv6 prefix:

```
user@host> clear dhcpv6 server binding 14/0x00010001/0x02b3be8f/0x00109400/0x0005
```

clear dhcpv6 server binding interface

The following command clears DHCPv6 local server bindings on a specific interface:

```
user@host> clear dhcpv6 server binding interface fe-0/0/2
```

clear dhcpv6 server binding <interfaces-vlan>

The following command uses the *interfaces-vlan* option to clear all DHCPv6 local server bindings on top of the underlying interface **ae0**, which clears DHCPv6 bindings on all demux VLANs on top of **ae0**:

```
user@host> clear dhcpv6 server binding interface ae0
```

clear dhcpv6 server binding <interfaces-wildcard>

The following command uses the *interfaces-wildcard* option to clear all DHCPv6 local server bindings over a specific interface:

```
user@host> clear dhcpv6 server binding ge-1/0/0.*
```

clear dhcpv6 server statistics

Syntax	<pre>clear dhcpv6 server statistics <interface <i>interface-name</i>> <logical-system <i>logical-system-name</i>> <routing-instance <i>routing-instance-name</i>></pre>
Release Information	Command introduced in Junos OS Release 9.6.
Description	Clear all extended Dynamic Host Configuration Protocol for IPv6 (DHCPv6) local server statistics.
Options	<p>logical-system <i>logical-system-name</i>—(Optional) Clear the statistics for DHCPv6 clients on the specified logical system. If you do not specify a logical system, statistics are cleared for the default logical system.</p> <p>routing-instance <i>routing-instance-name</i>—(Optional) Clear the statistics for DHCPv6 clients on the specified routing instance. If you do not specify a routing instance, statistics are cleared for the default routing instance.</p>
Required Privilege Level	clear

Sample Output

clear dhcpv6 server statistics

```
user@host> clear dhcpv6 server statistics
```

request dhcp server reconfigure

Syntax	<code>request dhcp server reconfigure (all <i>address</i> interface <i>interface-name</i> logical-system <i>logical-system-name</i> routing-instance <i>routing-instance-name</i>)</code>
Release Information	Command introduced in Junos OS Release 10.0. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	<p>Initiate reconfiguration processing for the specified DHCP clients if they are in the bound state. If the clients are in the reconfiguring state, this command has no effect. If the clients are in any state other than bound or reconfiguring, this command has the same effect as the clear dhcp server binding command.</p> <p>When the local server state machine starts the reconfiguration process on a bound client, the client transitions to the reconfiguring state and the local server sends a forcerenew message to the client. Because the client was in the bound state before entering the reconfiguring state, all subscriber (or DHCP client) services, such as forwarding and statistics, continue to work. An exponential back-off timer determines the interval at which the forcerenew message is sent. If the final attempt is unsuccessful, the client is returned to its original state by default. You can optionally include the clear-on-abort statement to configure the client to be cleared when reconfiguration fails.</p>
Options	<p>all—Initiate reconfiguration for all DHCP clients.</p> <p><i>address</i>—Initiate reconfiguration for DHCP client with the specified IP address or MAC address.</p> <p>interface <i>interface-name</i>—Initiate reconfiguration for all DHCP clients on this logical interface (clients whose initial login requests were received over the specified interface).</p> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p> NOTE: You cannot use the interface <i>interface-name</i> option with the request dhcp server reconfigure command for DHCP passive clients (clients that are added as a result of DHCP snooped packets). For passive clients, the interface is not guaranteed to be the next-hop interface to the client, as is the case for active clients.</p> </div> <p>logical-system <i>logical-system-name</i>—Initiate reconfiguration for all DHCP clients on the specified logical system.</p> <p>routing-instance <i>routing-instance-name</i>—Initiate reconfiguration reconfigured for all DHCP clients in the specified routing instance.</p>
Required Privilege Level	view

request system reboot

Syntax	request system reboot <at <i>time</i> > <both-routing-engines> <in <i>minutes</i> > <media (compact-flash disk removable-compact-flash usb)> <message " <i>text</i> "> <other-routing-engine>
Syntax (EX Series Switches)	request system reboot <all-members> <at <i>time</i> > <both-routing-engines> <in <i>minutes</i> > <local> <media (external internal)> <member <i>member-id</i> > <message " <i>text</i> "> <other-routing-engine> <slice <i>slice</i> >
Syntax (TX Matrix Router)	request system reboot <all-chassis all-lcc lcc <i>number</i> scc> <at <i>time</i> > <both-routing-engines> <in <i>minutes</i> > <media (compact-flash disk)> <message " <i>text</i> "> <other-routing-engine>
Syntax (TX Matrix Plus Router)	request system reboot <all-chassis all-lcc lcc <i>number</i> sfc <i>number</i> > <at <i>time</i> > <both-routing-engines> <in <i>minutes</i> > <media (compact-flash disk)> <message " <i>text</i> "> <other-routing-engine> <partition (1 2 alternate)>
Syntax (MX Series Router)	request system reboot <all-members> <at <i>time</i> > <both-routing-engines> <in <i>minutes</i> > <local> <media (external internal)> <member <i>member-id</i> > <message " <i>text</i> "> <other-routing-engine>
Release Information	Command introduced before Junos OS Release 7.4.

Option **other-routing-engine** introduced in Junos OS Release 8.0.
 Command introduced in Junos OS Release 9.0 for EX Series switches.
 Option **sfc** introduced for the TX Matrix Plus router in Junos OS Release 9.6.
 Option **both-routing-engines** introduced in Junos OS Release 12.1.

Description Reboot the software.

Options **none**—Reboot the software immediately.

all-chassis—(TX Matrix and TX Matrix Plus routers only) (Optional) On a TX Matrix router or TX Matrix Plus router, reboot all routers connected to the TX Matrix or TX Matrix Plus router, respectively.

all-lcc—(TX Matrix and TX Matrix Plus routers only) (Optional) On a TX Matrix router or TX Matrix Plus router, reboot all line card chassis connected to the TX Matrix or TX Matrix Plus router, respectively.

all-members—(EX4200 switches and MX Series routers only) (Optional) Reboot the software on all members of the Virtual Chassis configuration.

at time—(Optional) Time at which to reboot the software, specified in one of the following ways:

- **now**—Stop or reboot the software immediately. This is the default.
- **+minutes**—Number of minutes from now to reboot the software.
- **yymmddhhmm**—Absolute time at which to reboot the software, specified as year, month, day, hour, and minute.
- **hh:mm**—Absolute time on the current day at which to stop the software, specified in 24-hour time.

both-routing-engines—(Optional) Reboot both Routing Engines at the same time.

in minutes—(Optional) Number of minutes from now to reboot the software. This option is an alias for the **at +minutes** option.

lcc number—(TX Matrix and TX Matrix Plus routers only) (Optional) On a TX Matrix router or TX Matrix Plus router, the number of a specified line card chassis connected to the TX Matrix or TX Matrix Plus router, respectively. Replace **number** with a value from 0 through 3.

local—(EX4200 switches and MX Series routers only) (Optional) Reboot the software on the local Virtual Chassis member.

media (compact-flash | disk | removable-compact-flash | usb)—(Optional) Boot medium for next boot. (The options **removable-compact-flash** and **usb** pertain to the J Series routers only.)

media (external | internal)—(EX Series switches and MX Series routers only) (Optional) Reboot the boot media:

- **external**—Reboot the external mass storage device.

- **internal**—Reboot the internal flash device.

member *member-id*—(EX4200 switches and MX Series routers only) (Optional) Reboot the software on the specified member of the Virtual Chassis configuration. For EX4200 switches, replace *member-id* with a value from 0 through 9. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.

message "*text*"—(Optional) Message to display to all system users before stopping or rebooting the software.

other-routing-engine—(Optional) Reboot the other Routing Engine from which the command is issued. For example, if you issue the command from the master Routing Engine, the backup Routing Engine is rebooted. Similarly, if you issue the command from the backup Routing Engine, the master Routing Engine is rebooted.

partition—(TX Matrix Plus routers only) (Optional) Reboot using the specified partition on the boot media. This option has the following suboptions:

- **1**—Reboot from partition 1.
- **2**—Reboot from partition 2.
- **alternate**—Reboot from the alternate partition.

scc—(TX Matrix routers only) (Optional) Reboot the Routing Engine on the TX Matrix switch-card chassis. If you issue the command from re0, re0 is rebooted. If you issue the command from re1, re1 is rebooted.

sfc *number*—(TX Matrix Plus routers only) (Optional) Reboot the Routing Engine on the TX Matrix Plus switch-fabric chassis. If you issue the command from re0, re0 is rebooted. If you issue the command from re1, re1 is rebooted. Replace *number* with 0.

slice *slice*—(EX Series switches only) (Optional) Reboot a partition on the boot media. This option has the following suboptions:

- **1**—Power off partition 1.
- **2**—Power off partition 2.
- **alternate**—Reboot from the alternate partition.

Additional Information Reboot requests are recorded in the system log files, which you can view with the **show log** command (see [show log](#)). Also, the names of any running processes that are scheduled to be shut down are changed. You can view the process names with the **show system processes** command (see [show system processes](#)).

On a TX Matrix or TX Matrix Plus router, if you issue the **request system reboot** command on the master Routing Engine, all the master Routing Engines connected to the routing matrix are rebooted. If you issue this command on the backup Routing Engine, all the backup Routing Engines connected to the routing matrix are rebooted.

NOTE: Before issuing the `request system reboot` command on a TX Matrix Plus router with no options or the all-chassis, all-lcc, lcc *number*, or sfc options, verify that master Routing Engine for all routers in the routing matrix are in the same slot number. If the master Routing Engine for a line-card chassis is in a different slot number than the master Routing Engine for a TX Matrix Plus router, the line-card chassis might become logically disconnected from the routing matrix after the `request system reboot` command.

NOTE: To reboot a router that has two Routing Engines, reboot the backup Routing Engine (if you have upgraded it) first, and then reboot the master Routing Engine.

Required Privilege Level maintenance

List of Sample Output

- [request system reboot on page 1175](#)
- [request system reboot \(at 2300\) on page 1175](#)
- [request system reboot \(in 2 Hours\) on page 1176](#)
- [request system reboot \(Immediately\) on page 1176](#)
- [request system reboot \(at 1:20 AM\) on page 1176](#)

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

`request system reboot`

```
user@host> request system reboot
Reboot the system ? [yes,no] (no)
```

`request system reboot (at 2300)`

```
user@host> request system reboot at 2300 message ?Maintenance time!?
Reboot the system ? [yes,no] (no) yes

shutdown: [pid 186]
*** System shutdown message from root@berry.network.net ***
System going down at 23:00
```

request system reboot (in 2 Hours)

The following example, which assumes that the time is 5 PM (17:00), illustrates three different ways to request the system to reboot in two hours:

```
user@host> request system reboot at +120
user@host> request system reboot in 120
user@host> request system reboot at 19:00
```

request system reboot (Immediately)

```
user@host> request system reboot at now
```

request system reboot (at 1:20 AM)

To reboot the system at 1:20 AM, enter the following command. Because 1:20 AM is the next day, you must specify the absolute time.

```
user@host> request system reboot at 06060120
request system reboot at 120
Reboot the system at 120? [yes,no] (no) yes
```

show dhcp server binding

Syntax	<pre>show dhcp server binding <address> <brief detail summary> <interface interface-name> <interfaces-vlan> <interfaces-wildcard> <logical-system logical-system-name> <routing-instance routing-instance-name></pre>
Release Information	<p>Command introduced in Junos OS Release 9.0.</p> <p>Options <i>interfaces-vlan</i> and <i>interfaces-wildcard</i> added in Junos OS Release 12.1.</p>
Description	Display the address bindings in the client table on the extended Dynamic Host Configuration Protocol (DHCP) local server.
Options	<p>address—(Optional) Display DHCP binding information for a specific client identified by one of the following entries:</p> <ul style="list-style-type: none"> • <i>ip-address</i>—The specified IP address. • <i>mac-address</i>—The specified MAC address. • <i>session-id</i>—The specified session ID. <p>brief detail summary—(Optional) Display the specified level of output about active client bindings. The default is brief, which produces the same output as show dhcp server binding.</p> <p>interface interface-name—(Optional) Display information about active client bindings on the specified interface. You can optionally filter on VLAN ID and SVLAN ID.</p> <p>interfaces-vlan—(Optional) Show the binding state information on the interface VLAN ID and S-VLAN ID.</p> <p>interfaces-wildcard—(Optional) The set of interfaces on which to show the binding state information. This option supports the use of the wildcard character (*).</p> <p>logical-system logical-system-name—(Optional) Display information about active client bindings for DHCP clients on the specified logical system.</p> <p>routing-instance routing-instance-name—(Optional) Display information about active client bindings for DHCP clients on the specified routing instance.</p>
Required Privilege Level	view

Output Fields Table 80 on page 1178 lists the output fields for the **show dhcp server binding** command. Output fields are listed in the approximate order in which they appear.

Table 80: show dhcp server binding Output Fields

Field Name	Field Description	Level of Output
<i>number</i> clients, (<i>number</i> init, <i>number</i> bound, <i>number</i> selecting, <i>number</i> requesting, <i>number</i> renewing, <i>number</i> releasing)	Summary counts of the total number of DHCP clients and the number of DHCP clients in each state.	summary
IP address	IP address of the DHCP client.	brief detail
Session Id	Session ID of the subscriber session.	brief detail
Hardware address	Hardware address of the DHCP client.	brief detail
Expires	Number of seconds in which lease expires.	brief detail
State	State of the address binding table on the extended DHCP local server: <ul style="list-style-type: none"> • BOUND—Client has active IP address lease. • FORCERENEW—Client has received forcere Renew message from server. • INIT—Initial state. • RELEASE—Client is releasing IP address lease. • RENEWING—Client sending request to renew IP address lease. • REQUESTING—Client requesting a DHCP server. • SELECTING—Client receiving offers from DHCP servers. 	brief detail
Interface	Interface on which the request was received.	brief

Table 80: show dhcp server binding Output Fields (*continued*)

Field Name	Field Description	Level of Output
Lease Expires	Date and time at which the client's IP address lease expires.	detail
Lease Expires in	Number of seconds in which lease expires.	detail
Lease Start	Date and time at which the client's IP address lease started.	detail
Last Packet Received	Date and time at which the router received the last packet.	detail
Incoming Client Interface	Client's incoming interface.	detail
Client Interface Svlan Id	S-VLAN ID of the client's incoming interface.	detail
Client Interface Vlan Id	VLAN ID of the client's incoming interface.	detail
Demux Interface	Name of the IP demultiplexing (demux) interface.	detail
Server IP Address or Server Identifier	IP address of DHCP server.	detail
Server Interface	Interface of DHCP server.	detail
Client Pool Name	Name of address pool used to assign client IP address lease.	detail
ACI Interface Set Name	Internally generated name of the dynamic agent circuit identifier (ACI) interface set.	detail
ACI Interface Set Index	Index number of the dynamic ACI interface set.	detail
ACI Interface Set Session ID	Identifier of the dynamic ACI interface set entry in the session database.	detail

show dhcp server statistics

Syntax	show dhcp server statistics <logical-system <i>logical-system-name</i>> <routing-instance <i>routing-instance-name</i>>
Release Information	Command introduced in Junos OS Release 9.0.
Description	Display extended Dynamic Host Configuration Protocol (DHCP) local server statistics.
Options	logical-system <i>logical-system-name</i> —(Optional) Display information about extended DHCP local server statistics on the specified logical system. If you do not specify a logical system, statistics are displayed for the default logical system. routing-instance <i>routing-instance-name</i> —(Optional) Display information about extended DHCP local server statistics on the specified routing instance. If you do not specify a routing instance, statistics are displayed for the default routing instance.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• clear dhcp server statistics on page 1163
List of Sample Output	show dhcp server statistics on page 1183
Output Fields	Table 81 on page 1183 lists the output fields for the show dhcp server statistics command. Output fields are listed in the approximate order in which they appear.

Table 81: show dhcp server statistics Output Fields

Field Name	Field Description
Packets dropped	<p>Number of packets discarded by the extended DHCP local server because of errors. Only nonzero statistics appear in the Packets dropped output. When all of the Packets dropped statistics are 0 (zero), only the Total field appears.</p> <ul style="list-style-type: none"> • Total—Total number of packets discarded by the extended DHCP local server • Authentication—Number of packets discarded because they could not be authenticated • Bad hardware address—Number of packets discarded because an invalid hardware address was specified • Bad opcode—Number of packets discarded because an invalid operation code was specified • Bad options—Number of packets discarded because invalid options were specified • Dynamic profile—Number of packets discarded due to dynamic profile information • Invalid server address—Number of packets discarded because an invalid server address was specified • No available addresses—Number of packets discarded because there were no addresses available for assignment • No interface match—Number of packets discarded because they did not belong to a configured interface • No routing instance match—Number of packets discarded because they did not belong to a configured routing instance • No valid local address—Number of packets discarded because there was no valid local address • Packet too short—Number of packets discarded because they were too short • Read error—Number of packets discarded because of a system read error • Send error—Number of packets that the extended DHCP local server could not send
Messages received	<p>Number of DHCP messages received.</p> <ul style="list-style-type: none"> • BOOTREQUEST—Number of BOOTP protocol data units (PDUs) received • DHCPDECLINE—Number of DHCP PDUs of type DECLINE received • DHCPDISCOVER—Number of DHCP PDUs of type DISCOVER received • DHCPINFORM—Number of DHCP PDUs of type INFORM received • DHCPRELEASE—Number of DHCP PDUs of type RELEASE received • DHCPREQUEST—Number of DHCP PDUs of type REQUEST received
Messages sent	<p>Number of DHCP messages sent.</p> <ul style="list-style-type: none"> • BOOTREPLY—Number of BOOTP PDUs transmitted • DHCPOFFER—Number of DHCP OFFER PDUs transmitted • DHCPACK—Number of DHCP ACK PDUs transmitted • DHCPNACK—Number of DHCP NACK PDUs transmitted • DHCPFORCERENEW—Number of DHCP FORCERENEW PDUs transmitted

show dhcpv6 server binding

Syntax	<pre>show dhcpv6 server binding <address> <brief detail summary> <interface interface-name> <interfaces-vlan> <interfaces-wildcard> <logical-system logical-system-name> <routing-instance routing-instance-name></pre>
Release Information	<p>Command introduced in Junos OS Release 9.6.</p> <p>Options <i>interfaces-vlan</i> and <i>interfaces-wildcard</i> added in Junos OS Release 12.1.</p>
Description	Display the address bindings in the client table on the extended Dynamic Host Configuration Protocol for IPv6 (DHCPv6) local server.
Options	<p>address—(Optional) Clear the binding state for the DHCPv6 client, using one of the following entries:</p> <ul style="list-style-type: none"> • <i>CID</i>—The specified Client ID (CID). • <i>ipv6-prefix</i>—The specified IPv6 prefix. • <i>session-id</i>—The specified session ID. <p>brief detail summary—(Optional) Display the specified level of output about active client bindings. The default is brief, which produces the same output as show dhcpv6 server binding.</p> <p>interface interface-name—(Optional) Display information about active client bindings on the specified interface. You can optionally filter on VLAN ID and SVLAN ID.</p> <p>interfaces-vlan—(Optional) Show the binding state information on the interface VLAN ID and S-VLAN ID.</p> <p>interfaces-wildcard—(Optional) The set of interfaces on which to show binding state information. This option supports the use of the wildcard character (*).</p> <p>logical-system logical-system-name—(Optional) Display information about active client bindings for DHCPv6 clients on the specified logical system.</p> <p>routing-instance routing-instance-name—(Optional) Display information about active client bindings for DHCPv6 clients on the specified routing instance.</p>
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • <i>Clearing DHCP Bindings for Subscriber Access</i> • clear dhcpv6 server binding on page 1165

Output Fields [Table 82 on page 1186](#) lists the output fields for the **show dhcpv6 server binding** command. Output fields are listed in the approximate order in which they appear.

Table 82: show dhcpv6 server binding Output Fields

Field Name	Field Description	Level of Output
<i>number clients</i> , (<i>number init</i> , <i>number bound</i> , <i>number selecting</i> , <i>number requesting</i> , <i>number renewing</i> , <i>number releasing</i>)	Summary counts of the total number of DHCPv6 clients and the number of DHCPv6 clients in each state.	summary
Prefix	Client's DHCPv6 prefix, or prefix used to support multiple address assignment.	brief detail
Session Id	Session ID of the subscriber session.	brief detail
Expires	Number of seconds in which lease expires.	brief detail
State	State of the address binding table on the extended DHCPv6 local server: <ul style="list-style-type: none"> • BOUND—Client has active IP address lease. • INIT—Initial state. • RECONFIGURE—Server has sent reconfigure message to client. • RELEASE—Client is releasing IP address lease. • RENEWING—Client sending request to renew IP address lease. • REQUESTING—Client requesting a DHCPv6 server. • SELECTING—Client receiving offers from DHCPv6 servers. 	brief detail
Interface	Interface on which the DHCPv6 request was received.	brief
Client IPv6 Address	Client's IPv6 address.	detail
Client IPv6 Prefix	Client's IPv6 prefix.	detail
Client DUID	Client's DHCP Unique Identifier (DUID).	brief detail

Table 82: show dhcpv6 server binding Output Fields (*continued*)

Field Name	Field Description	Level of Output
Lease expires	Date and time at which the client's IP address lease expires.	detail
Lease expires in	Number of seconds in which lease expires.	detail
Lease Start	Date and time at which the client's address lease was obtained.	detail
Incoming Client Interface	Client's incoming interface.	detail
Server IP Address	IP address of DHCPv6 server.	detail
Server Interface	Interface of DHCPv6 server.	detail
Client Pool Name	Address pool used to assign IPv6 address.	detail
Client Prefix Pool Name	Address pool used to assign IPv6 prefix.	detail
Client Id length	Length of the DHCPv6 client ID, in bytes.	detail
Client Id	ID of the DHCPv6 client.	detail

Output Fields See [show dhcp relay binding](#) for an explanation of output fields.

Sample Output

clear dhcp relay binding

The following sample output displays the address bindings in the DHCP client table before and after the **clear dhcp relay binding** command is issued.

```
user@host> show dhcp relay binding
IP address      Hardware address  Type    Lease expires at
100.20.32.1     90:00:00:01:00:01 active    2007-02-08 16:41:17 EST
192.168.14.8    90:00:01:01:02:01 active    2007-02-10 10:01:06 EST
```

```
user@host> clear dhcp relay binding 100.20.32.1
```

```
user@host> show dhcp relay binding
IP address      Hardware address  Type    Lease expires at
192.168.14.8    90:00:01:01:02:01 active    2007-02-10 10:01:06 EST
```

clear dhcp relay binding all

The following command clears all DHCP relay agent bindings:

```
user@host> clear dhcp relay binding all
```

clear dhcp relay binding interface

The following command clears DHCP relay agent bindings on a specific interface:

```
user@host> clear dhcp relay binding interface fe-0/0/3
```

clear dhcp relay binding <interfaces-vlan>

The following command uses the *interfaces-vlan* option to clear all DHCP relay agent bindings on top of the underlying interface **ae0**, which clears DHCP bindings on all demux VLANs on top of **ae0**:

```
user@host> clear dhcp relay binding interface ae0
```

clear dhcp relay binding <interfaces-wildcard>

The following command uses the *interfaces-wildcard* option to clear all DHCP relay agent bindings over a specific interface:

```
user@host> clear dhcp relay binding ge-1/0/0.*
```

clear dhcp relay statistics

Syntax	<pre>clear dhcp relay statistics <logical-system <i>logical-system-name</i>> <routing-instance <i>routing-instance-name</i>></pre>
Syntax	<p>Syntax for EX Series switches:</p> <pre>show dhcp relay statistics <routing-instance <i>routing-instance-name</i>></pre>
Release Information	<p>Command introduced in Junos OS Release 8.3.</p> <p>Statement introduced in Junos OS Release 12.1 for EX Series switches.</p> <p>Command introduced in Junos OS Release 12.1X48R3 for PTX Series Packet Transport Switches.</p>
Description	Clear all Dynamic Host Configuration Protocol (DHCP) relay statistics.
Options	<p>logical-system <i>logical-system-name</i>—(On routers only) (Optional) Perform this operation on the specified logical system. If you do not specify a logical system name, statistics are cleared for the default logical system.</p> <p>routing-instance <i>routing-instance-name</i>—(Optional) Perform this operation on the specified routing instance. If you do not specify a routing instance name, statistics are cleared for the default routing instance.</p>

clear dhcpv6 relay binding all

The following command clears all DHCP relay agent bindings:

```
user@host> clear dhcpv6 relay binding all
```

clear dhc6p relay binding interface

The following command clears DHCPv6 relay agent bindings on a specific interface:

```
user@host> clear dhcpv6 relay binding interface fe-0/0/2
```

clear dhcpv6 relay binding <interfaces-vlan>

The following command uses the *interfaces-vlan* option to clear all DHCPv6 relay agent bindings on top of the underlying interface **ae0**, which clears DHCPv6 bindings on all demux VLANs on top of **ae0**:

```
user@host> clear dhcpv6 relay binding interface ae0
```

clear dhcpv6 relay binding <interfaces-wildcard>

The following command uses the *interfaces-wildcard* option to clear all DHCPv6 relay agent bindings over a specific interface:

```
user@host> clear dhcpv6 relay binding ge-1/0/0.*
```

clear dhcpv6 relay statistics

Syntax	<code>clear dhcpv6 relay statistics</code> <code><logical-system <i>logical-system-name</i>></code> <code><routing-instance <i>routing-instance-name</i>></code>
Release Information	Command introduced in Junos OS Release 11.4. Command introduced in Junos OS Release 12.1X48R3 for PTX Series Packet Transport Switches. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Clear all Dynamic Host Configuration Protocol for IPv6 (DHCPv6) relay statistics.
Options	logical-system <i>logical-system-name</i> —(Optional) Perform this operation on the specified logical system. If you do not specify a logical system name, statistics are cleared for the default logical system. routing-instance <i>routing-instance-name</i> —(Optional) Perform this operation on the specified routing instance. If you do not specify a routing instance name, statistics are cleared for the default routing instance.

Output Fields Table 85 on page 1204 lists the output fields for the **show dhcp relay binding** command. Output fields are listed in the approximate order in which they appear.

Table 85: show dhcp relay binding Output Fields

Field Name	Field Description	Level of Output
<i>number</i> clients, (<i>number</i> init, <i>number</i> bound, <i>number</i> selecting, <i>number</i> requesting, <i>number</i> renewing, <i>number</i> rebinding, <i>number</i> releasing)	Summary counts of the total number of DHCP clients and the number of DHCP clients in each state.	summary
IP address	IP address of the DHCP client.	briefdetail
Session Id	Session ID of the subscriber session.	briefdetail
Hardware address	Hardware address of the DHCP client.	briefdetail
Expires	Number of seconds in which the lease expires.	briefdetail
State	State of the DHCP relay address binding table on the DHCP client: <ul style="list-style-type: none"> • BOUND—Client has an active IP address lease. • INIT—Initial state. • REBINDING—Client is broadcasting a request to renew the IP address lease. • RELEASE—Client is releasing the IP address lease. • RENEWING—Client is sending a request to renew the IP address lease. • REQUESTING—Client is requesting a DHCP server. • SELECTING—Client is receiving offers from DHCP servers. 	briefdetail

Table 85: show dhcp relay binding Output Fields (*continued*)

Field Name	Field Description	Level of Output
Interface	Incoming client interface.	brief
Lease Expires	Date and time at which the client's IP address lease expires.	detail
Lease Expires in	Number of seconds in which the lease expires.	detail
Lease Start	Date and time at which the client's IP address lease started.	detail
Incoming Client Interface	Client's incoming interface.	detail
Server IP Address	IP address of the DHCP server.	detail
Server Interface	Interface of the DHCP server.	detail
Bootp Relay Address	IP address of BOOTP relay.	detail
Type	Type of DHCP packet processing performed on the router: <ul style="list-style-type: none"> active—Router actively processes and relays DHCP packets. passive—Router passively snoops DHCP packets passing through the router. 	All levels
Lease expires at	Date and time at which the client's IP address lease expires.	All levels

show dhcp relay statistics

Syntax	<code>show dhcp relay statistics</code> <code><logical-system <i>logical-system-name</i>></code> <code><routing-instance <i>routing-instance-name</i>></code>
Syntax	Syntax for EX Series switches: <code>show dhcp relay statistics</code> <code><routing-instance <i>routing-instance-name</i>></code>
Release Information	Command introduced in Junos OS Release 8.3. Command introduced in Junos OS Release 12.1 for EX Series switches. Command introduced in Junos OS Release 12.1X48R3 for PTX Series Packet Transport Switches.
Description	Display Dynamic Host Configuration Protocol (DHCP) relay statistics.
Options	<code>logical-system <i>logical-system-name</i></code> —(On routers only) (Optional) Perform this operation on the specified logical system. If you do not specify a logical system name, statistics are displayed for the default logical system. <code>routing-instance <i>routing-instance-name</i></code> —(Optional) Perform this operation on the specified routing instance. If you do not specify a routing instance name, statistics are displayed for the default routing instance.
Required Privilege Level	view

Output Fields Table 87 on page 1212 lists the output fields for the **show dhcpv6 relay binding** command. Output fields are listed in the approximate order in which they appear.

Table 87: show dhcpv6 relay binding Output Fields

Field Name	Field Description	Level of Output
<i>number</i> clients, (<i>number</i> init, <i>number</i> bound, <i>number</i> selecting, <i>number</i> requesting, <i>number</i> renewing, <i>number</i> rebinding, <i>number</i> releasing)	Summary counts of the total number of DHCPv6 clients and the number of DHCPv6 clients in each state.	summary
Client IPv6 Prefix	Prefix of the DHCPv6 client.	briefdetail
Client DUID	DHCP for IPv6 Unique Identifier (DUID) of the client.	briefdetail
Session Id	Session ID of the subscriber (DHCP client) session.	briefdetail
Expires	Number of seconds in which the lease expires.	briefdetail
State	State of the DHCPv6 relay address binding table on the DHCPv6 client: <ul style="list-style-type: none"> • BOUND—Client has an active IP address lease. • INIT—Initial state. • REBINDING—Client is broadcasting a request to renew the IP address lease. • RELEASE—Client is releasing the IP address lease. • RENEWING—Client is sending a request to renew the IP address lease. • REQUESTING—Client is requesting a DHCPv6 server. • SELECTING—Client is receiving offers from DHCPv6 servers. 	briefdetail
Interface	Incoming client interface.	brief

Table 87: show dhcpv6 relay binding Output Fields (*continued*)

Field Name	Field Description	Level of Output
Lease Expires	Date and time at which the client's IP address lease expires.	detail
Lease Expires in	Number of seconds in which the lease expires.	detail
Lease Start	Date and time at which the client's IP address lease started.	detail
Incoming Client Interface	Client's incoming interface.	detail
Server Address	IP address of the DHCPv6 server. Displays unknown for a DHCPv6 relay agent in a multi-relay topology that is not directly adjacent to the DHCPv6 server and does not detect the IP address of the server. In that case, the output instead displays the Next Hop Server Facing Relay field.	detail
Next Hop Server Facing Relay	Next-hop address in the direction of the DHCPv6 server.	detail
Server Interface	Interface of the DHCPv6 server.	detail
Relay Address	IP address of the relay.	detail
Client Pool Name	Address pool that granted the client lease.	
Client ID Length	Length of client ID.	All levels
Client Id	Client ID.	All levels

show dhcpv6 relay statistics

Syntax	show dhcpv6 relay statistics <logical-system <i>logical-system-name</i>> <routing-instance <i>routing-instance-name</i>>
Release Information	Command introduced in Junos OS Release 11.4. Command introduced in Junos OS Release 12.1X48R3 for PTX Series Packet Transport Switches. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Display Dynamic Host Configuration Protocol for IPv6 (DHCPv6) relay statistics.
Options	logical-system <i>logical-system-name</i> —(Optional) Perform this operation on the specified logical system. If you do not specify a logical system name, statistics are displayed for the default logical system. routing-instance <i>routing-instance-name</i> —(Optional) Perform this operation on the specified routing instance. If you do not specify a routing instance name, statistics are displayed for the default routing instance.

show route extensive

Syntax	show route extensive <destination-prefix> <logical-system (all logical-system-name)>
Syntax (EX Series Switches)	show route extensive <destination-prefix>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Display extensive information about the active entries in the routing tables.
Options	<p>none—Display all active entries in the routing table.</p> <p>destination-prefix—(Optional) Display active entries for the specified address or range of addresses.</p> <p>logical-system (all logical-system-name)—(Optional) Perform this operation on all logical systems or on a particular logical system.</p>
Required Privilege Level	view
List of Sample Output	show route extensive on page 1224 show route extensive (Access Route) on page 1230 show route extensive (Route Reflector) on page 1231 show route extensive (FRR and LFA) on page 1231 show route extensive (FRR and LFA) on page 1232
Output Fields	Table 89 on page 1219 describes the output fields for the show route extensive command. Output fields are listed in the approximate order in which they appear.

Table 89: show route extensive Output Fields

Field Name	Field Description
<i>routing-table-name</i>	Name of the routing table (for example, inet.0).
<i>number destinations</i>	Number of destinations for which there are routes in the routing table.
<i>number routes</i>	Number of routes in the routing table and total number of routes in the following states: <ul style="list-style-type: none"> active (routes that are active). holddown (routes that are in the pending state before being declared inactive). hidden (routes that are not used because of a routing policy).

Table 89: show route extensive Output Fields (*continued*)

Field Name	Field Description
<i>route-destination</i> (entry, announced)	<p>Route destination (for example: 10.0.0.1/24). The entry value is the number of route for this destination, and the announced value is the number of routes being announced for this destination. Sometimes the route destination is presented in another format, such as:</p> <ul style="list-style-type: none"> • MPLS-label (for example, 80001). • interface-name (for example, ge-1/0/2). • neighbor-address:control-word-status:encapsulation type:vc-id:source (Layer 2 circuit only; for example, 10.1.1.195:NoCtrlWord:1:1:Local/96). • neighbor-address—Address of the neighbor. • control-word-status—Whether the use of the control word has been negotiated for this virtual circuit: NoCtrlWord or CtrlWord. • encapsulation type—Type of encapsulation, represented by a number: (1) Frame Relay DLCI, (2) ATM AAL5 VCC transport, (3) ATM transparent cell transport, (4) Ethernet, (5) VLAN Ethernet, (6) HDLC, (7) PPP, (8) ATM VCC cell transport, (10) ATM VPC cell transport. • vc-id—Virtual circuit identifier. • source—Source of the advertisement: Local or Remote.
TSI	Protocol header information.
label stacking	<p>(Next-to-the-last-hop routing device for MPLS only) Depth of the MPLS label stack, where the label-popping operation is needed to remove one or more labels from the top of the stack. A pair of routes is displayed, because the pop operation is performed only when the stack depth is two or more labels.</p> <ul style="list-style-type: none"> • S=0 route indicates that a packet with an incoming label stack depth of two or more exits this router with one fewer label (the label-popping operation is performed). • If there is no S= information, the route is a normal MPLS route, which has a stack depth of 1 (the label-popping operation is not performed).
[<i>protocol, preference</i>]	<p>Protocol from which the route was learned and the preference value for the route.</p> <ul style="list-style-type: none"> • +—A plus sign indicates the active route, which is the route installed from the routing table into the forwarding table. • -—A hyphen indicates the last active route. • *—An asterisk indicates that the route is both the active and the last active route. An asterisk before a to line indicates the best subpath to the route. <p>In every routing metric except for the BGP LocalPref attribute, a lesser value is preferred. In order to use common comparison routines, Junos OS stores the 1's complement of the LocalPref value in the Preference2 field. For example, if the LocalPref value for Route 1 is 100, the Preference2 value is -101. If the LocalPref value for Route 2 is 155, the Preference2 value is -156. Route 2 is preferred because it has a higher LocalPref value and a lower Preference2 value.</p>
Level	<p>(IS-IS only). In IS-IS, a single autonomous system (AS) can be divided into smaller groups called areas. Routing between areas is organized hierarchically, allowing a domain to be administratively divided into smaller areas. This organization is accomplished by configuring Level 1 and Level 2 intermediate systems. Level 1 systems route within an area. When the destination is outside an area, they route toward a Level 2 system. Level 2 intermediate systems route between areas and toward other ASs.</p>
Route Distinguisher	IP subnet augmented with a 64-bit prefix.

Table 89: show route extensive Output Fields (*continued*)

Field Name	Field Description
Next-hop type	Type of next hop. For a description of possible values for this field, see the Output Field table in the show route detail command.
Next-hop reference count	Number of references made to the next hop.
Flood nexthop branches exceed maximum message	Indicates that the number of flood next-hop branches exceeded the system limit of 32 branches, and only a subset of the flood next-hop branches were installed in the kernel.
Source	IP address of the route source.
Next hop	Network layer address of the directly reachable neighboring system.
via	<p>Interface used to reach the next hop. If there is more than one interface available to the next hop, the name of the interface that is actually used is followed by the word Selected. This field can also contain the following information:</p> <ul style="list-style-type: none"> • Weight—Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible. • Balance—Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a routing device is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.
Label-switched-path <i>lsp-path-name</i>	Name of the LSP used to reach the next hop.
Label operation	MPLS label and operation occurring at this routing device. The operation can be pop (where a label is removed from the top of the stack), push (where another label is added to the label stack), or swap (where a label is replaced by another label).
Offset	Whether the metric has been increased or decreased by an offset value.
Interface	(Local only) Local interface name.
Protocol next hop	Network layer address of the remote routing device that advertised the prefix. This address is used to recursively derive a forwarding next hop.
<i>label-operation</i>	MPLS label and operation occurring at this routing device. The operation can be pop (where a label is removed from the top of the stack), push (where another label is added to the label stack), or swap (where a label is replaced by another label).
Indirect next hops	When present, a list of nodes that are used to resolve the path to the next-hop destination, in the order that they are resolved.
State	State of the route (a route can be in more than one state). See the Output Field table in the show route detail command.

Table 89: show route extensive Output Fields (*continued*)

Field Name	Field Description
Session ID	The BFD session ID number that represents the protection using MPLS fast reroute (FRR) and loop-free alternate (LFA).
Inactive reason	<p>If the route is inactive, the reason for its current state is indicated. Typical reasons include:</p> <ul style="list-style-type: none"> • Active preferred—Currently active route was selected over this route. • Always compare MED—Path with a lower multiple exit discriminator (MED) is available. • AS path—Shorter AS path is available. • Cisco Non-deterministic MED selection—Cisco nondeterministic MED is enabled and a path with a lower MED is available. • Cluster list length—Path with a shorter cluster list length is available. • Forwarding use only—Path is only available for forwarding purposes. • IGP metric—Path through the next hop with a lower IGP metric is available. • IGP metric type—Path with a lower OSPF link-state advertisement type is available. • Interior > Exterior > Exterior via Interior—Direct, static, IGP, or EBGP path is available. • Local preference—Path with a higher local preference value is available. • Next hop address—Path with a lower metric next hop is available. • No difference—Path from a neighbor with a lower IP address is available. • Not Best in its group—Occurs when multiple peers of the same external AS advertise the same prefix and are grouped together in the selection process. When this reason is displayed, an additional reason is provided (typically one of the other reasons listed). • Number of gateways—Path with a higher number of next hops is available. • Origin—Path with a lower origin code is available. • OSPF version—Path does not support the indicated OSPF version. • RIB preference—Route from a higher-numbered routing table is available. • Route distinguisher—64-bit prefix added to IP subnets to make them unique. • Route metric or MED comparison—Route with a lower metric or MED is available. • Route preference—Route with a lower preference value is available. • Router ID—Path through a neighbor with a lower ID is available. • Unusable path—Path is not usable because of one of the following conditions: the route is damped, the route is rejected by an import policy, or the route is unresolved. • Update source—Last tiebreaker is the lowest IP address value.
Local AS	Autonomous system (AS) number of the local routing device.
Age	How long the route has been known.
AIGP	Accumulated interior gateway protocol (AIGP) BGP attribute.
Metric	Cost value of the indicated route. For routes within an AS, the cost is determined by IGP and the individual protocol metrics. For external routes, destinations, or routing domains, the cost is determined by a preference value.
MED-plus-IGP	Metric value for BGP path selection to which the IGP cost to the next-hop destination has been added.

Table 89: show route extensive Output Fields (*continued*)

Field Name	Field Description
TTL-Action	<p>For MPLS LSPs, state of the TTL propagation attribute. Can be enabled or disabled for all RSVP-signaled and LDP-signaled LSPs or for specific VRF routing instances.</p> <p>For sample output, see show route table.</p>
Task	Name of the protocol that has added the route.
Announcement bits	List of protocols that announce this route. n-Resolve inet indicates that the route is used for route resolution for next hops found in the routing table. n is an index used by Juniper Networks customer support only.
AS path	<p>AS path through which the route was learned. The letters at the end of the AS path indicate the path origin, providing an indication of the state of the route at the point at which the AS path originated:</p> <ul style="list-style-type: none"> I—IGP. E—EGP. Recorded—The AS path is recorded by the sample process (sampled). ?—Incomplete; typically, the AS path was aggregated. <p>When AS path numbers are included in the route, the format is as follows:</p> <ul style="list-style-type: none"> []—Brackets enclose the local AS number associated with the AS path if more than one AS number is configured on the routing device, or if AS path prepending is configured. { }—Braces enclose AS sets, which are groups of AS numbers in which the order does not matter. A set commonly results from route aggregation. The numbers in each AS set are displayed in ascending order. ()—Parentheses enclose a confederation. ([])—Parentheses and brackets enclose a confederation set. <p>NOTE: In Junos OS Release 10.3 and later, the AS path field displays an unrecognized attribute and associated hexadecimal value if BGP receives attribute 128 (attribute set) and you have not configured an independent domain in any routing instance.</p>
AS path: I <Originator>	(For route reflected output only) Originator ID attribute set by the route reflector.
VC Label	MPLS label assigned to the Layer 2 circuit virtual connection.
MTU	Maximum transmission unit (MTU) of the Layer 2 circuit.
VLAN ID	VLAN identifier of the Layer 2 circuit.
Cluster list	(For route reflected output only) Cluster ID sent by the route reflector.
Originator ID	(For route reflected output only) Address of router that originally sent the route to the route reflector.
Prefixes bound to route	Forwarding equivalent class (FEC) bound to this route. Applicable only to routes installed by LDP.
Communities	Community path attribute for the route. See the Output Field table in the show route detail command for all possible values for this field.

Table 89: show route extensive Output Fields (*continued*)

Field Name	Field Description
Layer2-info: encaps	Layer 2 encapsulation (for example, VPLS).
control flags	Control flags: none or Site Down.
mtu	Maximum transmission unit (MTU) information.
Label-Base, range	First label in a block of labels and label block size. A remote PE routing device uses this first label when sending traffic toward the advertising PE routing device.
status vector	Layer 2 VPN and VPLS network layer reachability information (NLRI).
Localpref	Local preference value included in the route.
Router ID	BGP router ID as advertised by the neighbor in the open message.
Primary Routing Table	In a routing table group, the name of the primary routing table in which the route resides.
Secondary Tables	In a routing table group, the name of one or more secondary tables in which the route resides.
Originating RIB	Name of the routing table whose active route was used to determine the forwarding next-hop entry in the resolution database. For example, in the case of inet.0 resolving through inet.0 and inet.3, this field indicates which routing table, inet.0 or inet.3, provided the best path for a particular prefix.
Node path count	Number of nodes in the path.
Forwarding nexthops	Number of forwarding next hops. The forwarding next hop is the network layer address of the directly reachable neighboring system (if applicable) and the interface used to reach it.

Sample Output

show route protocol

Syntax	<code>show route protocol <i>protocol</i></code> <code><brief detail extensive terse></code> <code><logical-system (all <i>logical-system-name</i>)></code>
Syntax (EX Series Switches)	<code>show route protocol <i>protocol</i></code> <code><brief detail extensive terse></code>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches. ospf2 and ospf3 options introduced in Junos OS Release 9.2. ospf2 and ospf3 options introduced in Junos OS Release 9.2 for EX Series switches. flow option introduced in Junos OS Release 10.0. flow option introduced in Junos OS Release 10.0 for EX Series switches.
Description	Display the route entries in the routing table that were learned from a particular protocol.
Options	brief detail extensive terse —(Optional) Display the specified level of output. If you do not specify a level of output, the system defaults to brief . logical-system (all <i>logical-system-name</i>) —(Optional) Perform this operation on all logical systems or on a particular logical system. <i>protocol</i> —Protocol from which the route was learned: <ul style="list-style-type: none">• access—Access route for use by DHCP application• access-internal—Access-internal route for use by DHCP application• aggregate—Locally generated aggregate route• arp—Route learned through the Address Resolution Protocol• atmvpn—Asynchronous Transfer Mode virtual private network• bgp—Border Gateway Protocol• ccc—Circuit cross-connect• direct—Directly connected route• dvmrp—Distance Vector Multicast Routing Protocol• esis—End System-to-Intermediate System• flow—Locally defined flow-specification route• frr—Precomputed protection route or backup route used when a link goes down• isis—Intermediate System-to-Intermediate System• ldp—Label Distribution Protocol• l2circuit—Layer 2 circuit• l2vpn—Layer 2 virtual private network

- **local**—Local address
- **mpls**—Multiprotocol Label Switching
- **msdp**—Multicast Source Discovery Protocol
- **ospf**—Open Shortest Path First versions 2 and 3
- **ospf2**—Open Shortest Path First versions 2 only
- **ospf3**—Open Shortest Path First version 3 only
- **pim**—Protocol Independent Multicast
- **rip**—Routing Information Protocol
- **ripng**—Routing Information Protocol next generation
- **rsvp**—Resource Reservation Protocol
- **rtarget**—Local route target virtual private network
- **static**—Statically defined route
- **tunnel**—Dynamic tunnel
- **vpn**—Virtual private network

NOTE: EX Series switches run a subset of these protocols. See the switch CLI for details.

Acquiring Troubleshooting Information

- [Tracing Extended DHCP Operations on page 1245](#)
- [Tracing Extended DHCP Operations for Specific Interfaces on page 1251](#)

Tracing Extended DHCP Operations

Both the extended DHCP local server and the extended DHCP relay agent support tracing operations. DHCP tracing operations track extended DHCP operations and record them in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

You can configure DHCP trace operations at the global level and at the interface level. Global DHCP tracing logs all DHCP-related events, whereas interface-level tracing logs only interface-specific DHCP events. If you configure interface-level trace operations, you can specify tracing for a range of interfaces or an individual interface. However, only a single interface-level log file is supported. That is, you cannot specify different interface-level log files for different interfaces or groups of interfaces.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

- Important events for both global and per-interface tracing are logged in a file located in the `/var/log` directory. By default, the router uses the filename, `jdhcpd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
- When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

- By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure global DHCP tracing operations.

- Specify tracing operations for DHCP local server and DHCP relay:

```
[edit system processes dhcp-service]
user@host# edit traceoptions
```

The tracing configuration is applied globally to all DHCP applications in every LS:RI. Configuration of event tracing on a per-LS:RI basis is not supported. DHCP tracing is configurable only in the default LS:RI. However, DHCP applications (local server or relay) do not have to be configured in the default LS:RI. This behavior was different in software releases before Junos OS Release 11.4, where you had to configure a DHCP application in the default LS:RI in order to configure DHCP tracing, even when you wanted to run DHCP and trace its operations only in a nondefault LS:RI.

In the earlier software releases, you configured tracing statements at the **[edit system services dhcp-local-server]** and **[edit forwarding-options dhcp-relay]** hierarchy levels. These statements have been deprecated and hidden in favor of the statements at the **[edit system processes dhcp-service]** hierarchy level.

NOTE: The deprecated statements may be removed from a future release; we recommend that you transition to the new statements.

Because you can configure DHCP tracing at three different hierarchy levels (one new and recommended, two old and deprecated), the following rules apply to manage the interaction:

- When you configure a filename or any other options for the trace log file, the configuration at the **[edit system processes dhcp-service]** hierarchy level has the highest precedence, followed by the configuration at the **[edit system services dhcp-local-server]** hierarchy level, and finally with the lowest precedence, the configuration at the **[edit forwarding-options dhcp-relay]** hierarchy level.
- The flag configurations for multiple hierarchy levels are merged and applied to all trace log events.
- The deprecated statements do not support filtering the generation of DHCP trace log events by severity level. If you use these statements, trace logging operates with an implicit severity of **all**, regardless of the severity level configured at the **[edit system processes dhcp-service]** hierarchy level.

For information about configuring per-interface tracing options, see [“Tracing Extended DHCP Operations for Specific Interfaces” on page 1250](#).

The extended DHCP traceoptions operations are described in the following sections:

- [Configuring the Extended DHCP Log Filename on page 1247](#)
- [Configuring the Number and Size of Extended DHCP Log Files on page 1247](#)
- [Configuring Access to the Extended DHCP Log File on page 1248](#)
- [Configuring a Regular Expression for Extended DHCP Messages to Be Logged on page 1248](#)

- [Configuring the Extended DHCP Tracing Flags on page 1249](#)
- [Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged on page 1249](#)
- [Tracing Extended DHCP Operations for Specific Interfaces on page 1250](#)

Configuring the Extended DHCP Log Filename

By default, the name of the file that records trace output is **jdhcpd**. You can specify a different name by including the **file** option. DHCP local server and DHCP relay agent both support the **file** option for the **traceoptions** statement and the **interface-traceoptions** statement.

To change the filename:

- Specify a filename for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename
```

- Specify a filename for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename
```

Configuring the Number and Size of Extended DHCP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, **filename.19.gz**, is simply overwritten when the next oldest file, **filename.18.gz** is compressed and renamed to **filename.19.gz**.

DHCP local server and DHCP relay agent both support the **files** and **size** options for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename files number size maximum-file-size
```

- Specify the name, number, and size of the file used for the trace output for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set file filename files number size maximum-file-size
```

Configuring Access to the Extended DHCP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

DHCP local server and DHCP relay agent both support the **world-readable** option and the **no-world-readable** option for the **traceoptions** statement and the **interface-traceoptions** statement. To specify that all users can read the log file:

- Configure the log file to be world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set file filename world-readable
```

- Configure the log file to be world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set file filename world-readable
```

To explicitly set the default behavior, in which the log file can only be read by the user who configured tracing:

- Configure the log file to be no-world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set file filename no-world-readable
```

- Configure the log file to be no-world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set file filename no-world-readable
```

Configuring a Regular Expression for Extended DHCP Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events. You can refine the output by including regular expressions to be matched.

DHCP local server and DHCP relay agent both support the **match** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure regular expressions to be matched:

- Specify the regular expression for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set file filename match regular-expression
```

- Specify the regular expression for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set file filename match regular-expression
```

Configuring the Extended DHCP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

DHCP local server and DHCP relay agent both support the **flag** option for the **traceoptions** statement and the **interface-traceoptions** statement. A smaller set of flags is supported for interface-level tracing than for global tracing. To configure the flags for the events to be logged:

- Specify the flags for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set flag flag
```

- Specify the flags for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set flag flag
```

Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. A low severity level is less restrictive—filters out fewer messages—than a higher level. When you configure a severity level, all messages at that level and all higher (more restrictive) levels are logged.

The following list presents severity levels in order from lowest (least restrictive) to highest (most restrictive). This order also represents the significance of the messages; for example, **error** messages are of greater concern than **info** messages.

- **verbose**
- **info**
- **notice**
- **warning**
- **error**

The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all**. You can also specify **verbose** with the same result, because **verbose** is the lowest (least restrictive) severity level; it has nothing to do with the terseness or verbosity of the messages. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

DHCP local server and DHCP relay agent both support the **level** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the flags for the events to be logged:

- Specify the severity level for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set level severity
```

- Specify the severity level for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set level severity
```

Tracing Extended DHCP Operations for Specific Interfaces

In addition to the global DHCP tracing operations, subscriber management enables you to trace extended DHCP operations for a specific interface or for a range of interfaces.

Configuring per-interface tracing is a two-step procedure. In the first step, you specify the tracing options that you want to use, such as file information and flags. In the second step, you enable the tracing operation on the specific interfaces.

To configure per-interface tracing operations:

1. Specify the tracing options you want to use.

NOTE: Per-interface tracing uses the same default tracing behavior as the global extended DHCP tracing operation. The default behavior is described in [“Tracing Extended DHCP Operations” on page 1245](#).

- a. Specify that you want to configure per-interface tracing options.

- For DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent:

```
[edit system processes dhcp-service]  
user@host# edit interface-traceoptions
```

- b. (Optional) Specify the tracing file options.

- Configure the name for the file used for the trace output.

See [“Configuring the Extended DHCP Log Filename” on page 1247](#).

- Configure the number and size of the log files.

See [“Configuring the Number and Size of Extended DHCP Log Files” on page 1247](#).

- Configure access to the log file.

See [“Configuring Access to the Extended DHCP Log File” on page 1248](#).

- Configure a regular expression to filter logging events.

See [“Configuring a Regular Expression for Extended DHCP Messages to Be Logged” on page 1248](#).

- c. (Optional) Specify tracing flag options.

See [“Configuring the Extended DHCP Tracing Flags” on page 1249](#).

- d. (Optional) Configure a severity level for messages to specify which event messages are logged.

See [“Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged” on page 1249](#).

2. Enable tracing on an interface or interface range.

The following examples show a DHCP local server configuration. You can also use the **trace** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level and at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

- Enable tracing on a specific interface.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name trace
```

- Enable tracing on a range of interfaces.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name upto interface
interface-name trace
```

Tracing Extended DHCP Operations for Specific Interfaces

In addition to the global DHCP tracing operations, subscriber management enables you to trace extended DHCP operations for a specific interface or for a range of interfaces.

Configuring per-interface tracing is a two-step procedure. In the first step, you specify the tracing options that you want to use, such as file information and flags. In the second step, you enable the tracing operation on the specific interfaces.

To configure per-interface tracing operations:

1. Specify the tracing options you want to use.

NOTE: Per-interface tracing uses the same default tracing behavior as the global extended DHCP tracing operation. The default behavior is described in [“Tracing Extended DHCP Operations” on page 1245](#).

- a. Specify that you want to configure per-interface tracing options.

- For DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent:

```
[edit system processes dhcp-service]
user@host# edit interface-traceoptions
```

- b. (Optional) Specify the tracing file options.

- Configure the name for the file used for the trace output.

See [“Configuring the Extended DHCP Log Filename”](#) on page 1247.

- Configure the number and size of the log files.

See [“Configuring the Number and Size of Extended DHCP Log Files”](#) on page 1247.

- Configure access to the log file.

See [“Configuring Access to the Extended DHCP Log File”](#) on page 1248.

- Configure a regular expression to filter logging events.

See [“Configuring a Regular Expression for Extended DHCP Messages to Be Logged”](#) on page 1248.

- c. (Optional) Specify tracing flag options.

See [“Configuring the Extended DHCP Tracing Flags”](#) on page 1249.

- d. (Optional) Configure a severity level for messages to specify which event messages are logged.

See [“Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged”](#) on page 1249.

- 2. Enable tracing on an interface or interface range.

The following examples show a DHCP local server configuration. You can also use the **trace** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level and at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

- Enable tracing on a specific interface.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name trace
```

- Enable tracing on a range of interfaces.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name upto interface
interface-name trace
```

Troubleshooting Configuration Statements

interface-traceoptions (DHCP)

Syntax	<pre>interface-traceoptions { file <i>filename</i> <files <i>number</i>> <match <i>regular-expression</i> > <size <i>maximum-file-size</i>> <world-readable no-world-readable>; flag <i>flag</i>; level (all error info notice verbose warning); no-remote-trace; }</pre>
Hierarchy Level	[edit system processes dhcp-service]
Release Information	Statement introduced in Junos OS Release 11.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	<p>Configure extended DHCP tracing operations that can be enabled on a specific interface or group of interfaces.</p> <p>Replaces deprecated interface-traceoptions statements at the [edit forwarding-options dhcp-relay] and [edit system services dhcp-local-server] hierarchy levels.</p> <p>To enable the tracing operation on the specific interfaces, you use the interface <i>interface-name</i> trace statement.</p>
Options	<p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log.</p> <p>files <i>number</i>—(Optional) Maximum number of trace files to create before overwriting the oldest one. If you specify a maximum number of files, you also must specify a maximum file size with the size option.</p> <p>Range: 2 through 1000</p> <p>Default: 3 files</p> <p>flag <i>flag</i>—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements</p> <ul style="list-style-type: none">• all—Trace all events• packet—Trace packet and option decoding operations• state—Trace changes in state <p>level—Level of tracing to perform; also known as severity level. The option you configure enables tracing of events at that level and all higher (more restrictive) levels. You can specify any of the following levels:</p> <ul style="list-style-type: none">• all—Match messages of all levels.• error—Match error messages.• info—Match informational messages.• notice—Match notice messages about conditions requiring special handling.

- **verbose**—Match verbose messages. This is the lowest (least restrictive) severity level; when you configure **verbose**, messages at all higher levels are traced. Therefore, the result is the same as when you configure **all**.

- **warning**—Match warning messages.

match *regular-expression*—(Optional) Refine the output to include lines that contain the regular expression.

no-remote-trace—Disable remote tracing.

no-world-readable—(Optional) Disable unrestricted file access.

size *maximum-file-size*—(Optional) Maximum size of each trace file. By default, the number entered is treated as bytes. Alternatively, you can include a suffix to the number to indicate kilobytes (KB), megabytes (MB), or gigabytes (GB). If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option.

Syntax: *sizek* to specify KB, *sizem* to specify MB, or *sizeg* to specify GB

Range: 10240 through 1073741824

world-readable—(Optional) Enable unrestricted file access.

Required Privilege Level	trace—To view this statement in the configuration. trace-control—To add this statement to the configuration.

CoS Overview

When a network experiences congestion and delay, some packets must be dropped. The Juniper Networks® Junos® operating system (Junos OS) class of service (CoS) enables you to divide traffic into classes and offer various levels of throughput and packet loss when congestion occurs. This allows packet loss to happen according to rules that you configure.

For interfaces that carry IPv4, IPv6, and MPLS traffic, you can configure the Junos OS CoS features to provide multiple classes of service for different applications. On the routing device, you can configure multiple forwarding classes for transmitting packets, define which packets are placed into each output queue, schedule the transmission service level for each queue, and manage congestion using a random early detection (RED) algorithm.

The Junos OS CoS features provide a set of mechanisms that you can use to provide differentiated services when best-effort traffic delivery is insufficient. In designing CoS applications, you must give careful consideration to your service needs, and you must thoroughly plan and design your CoS configuration to ensure consistency across all routing devices in a CoS domain. You must also consider all the routing devices and other networking equipment in the CoS domain to ensure interoperability among all equipment.

Because Juniper Networks routing devices implement CoS in hardware rather than in software, you can experiment with and deploy CoS features without adversely affecting packet forwarding and routing performance.

CoS Standards

The standards for Juniper Networks® Junos® operating system (Junos OS) class of service (CoS) capabilities are defined in the following RFCs:

- RFC 2474, *Definition of the Differentiated Services Field in the IPv4 and IPv6 Headers*
- RFC 2597, *Assured Forwarding PHB Group*
- RFC 2598, *An Expedited Forwarding PHB*
- RFC 2698, *A Two Rate Three Color Marker*

Understanding Packet Flow Across a Network

CoS works by examining traffic entering at the edge of your network. The edge routing devices classify traffic into defined service groups, to provide the special treatment of traffic across the network. For example, voice traffic can be sent across certain links, and data traffic can use other links. In addition, the data traffic streams can be serviced differently along the network path to ensure that higher-paying customers receive better service. As the traffic leaves the network at the far edge, you can reclassify the traffic.

To support CoS, you must configure each routing device in the network. Generally, each routing device examines the packets that enter it to determine their CoS settings. These settings then dictate which packets are first transmitted to the next downstream routing device. In addition, the routing devices at the edges of the network might be required to alter the CoS settings of the packets that enter the network from the customer or peer networks.

In [Figure 5 on page 1265](#), Router A is receiving traffic from a customer network. As each packet enters, Router A examines the packet's current CoS settings and classifies the traffic into one of the groupings defined by the Internet service provider (ISP). This definition allows Router A to prioritize its resources for servicing the traffic streams it is receiving. In addition, Router A might alter the CoS settings (forwarding class and loss priority) of the packets to better match the ISP's traffic groups. When Router B receives the packets, it examines the CoS settings, determines the appropriate traffic group, and processes the packet according to those settings. It then transmits the packets to Router C, which performs the same actions. Router D also examines the packets and determines the appropriate group. Because Router D sits at the far end of the network, the ISP might decide once again to alter the CoS settings of the packets before Router D transmits them to the neighboring network.

Figure 5: Packet Flow Across the Network

Junos CoS Components

The Juniper Networks® Junos® operating system (Junos OS) CoS consists of many components that you can combine and tune to provide the level of services required by customers.

The Junos OS CoS components include:

- **Code-point aliases**—A *code-point alias* assigns a name to a pattern of code-point bits. You can use this name instead of the bit pattern when you configure other CoS components, such as classifiers, drop-profile maps, and rewrite rules.
- **Classifiers**—*Packet classification* refers to the examination of an incoming packet. This function associates the packet with a particular CoS servicing level. In the Junos OS, classifiers associate incoming packets with a forwarding class and loss priority and, based on the associated forwarding class, assign packets to output queues. Two general types of classifiers are supported:
 - **Behavior aggregate or CoS value traffic classifiers**—A *behavior aggregate* (BA) is a method of classification that operates on a packet as it enters the routing device. The CoS value in the packet header is examined, and this single field determines the CoS settings applied to the packet. BA classifiers allow you to set the forwarding class and loss priority of a packet based on the Differentiated Services code point (DSCP) value, DSCP IPv6 value, IP precedence value, MPLS EXP bits, and IEEE 802.1p value. The default classifier is based on the IP precedence value.
 - **Multifield traffic classifiers**—A *multifield* classifier is a second method for classifying traffic flows. Unlike a behavior aggregate, a multifield classifier can examine multiple fields in the packet. Examples of some fields that a multifield classifier can examine include the source and destination address of the packet as well as the source and destination port numbers of the packet. With multifield classifiers, you set the forwarding class and loss priority of a packet based on firewall filter rules.
- **Forwarding classes**—The *forwarding classes* affect the forwarding, scheduling, and marking policies applied to packets as they transit a routing device. The forwarding class plus the loss priority define the per-hop behavior. Four categories of forwarding classes are supported: best effort, assured forwarding, expedited forwarding, and network control. For Juniper Networks M Series Multiservice Edge Routers, four forwarding classes are supported. You can configure up to one each of the four types of forwarding classes. For M120 and M320 Multiservice Edge Routers, Juniper Networks MX Series 3D Universal Edge Routers, Juniper Networks T Series Core Routers and EX Series switches, 16 forwarding classes are supported, so you can classify packets more granularly. For example, you can configure multiple classes of expedited forwarding (EF) traffic: EF, EF1, and EF2.
- **Loss priorities**—*Loss priorities* allow you to set the priority of dropping a packet. Loss priority affects the scheduling of a packet without affecting the packet's relative ordering. You can use the packet loss priority (PLP) bit as part of a congestion control strategy. You can use the loss priority setting to identify packets that have experienced congestion. Typically you mark packets exceeding some service level with a high loss priority. You set loss priority by configuring a classifier or a policer. The loss priority is used later in the workflow to select one of the drop profiles used by RED.

- Forwarding policy options—These options allow you to associate forwarding classes with next hops. Forwarding policy also allows you to create classification overrides, which assign forwarding classes to sets of prefixes.
- Transmission scheduling and rate control—These parameters provide you with a variety of tools to manage traffic flows:
 - Queuing—After a packet is sent to the outgoing interface on a routing device, it is queued for transmission on the physical media. The amount of time a packet is queued on the routing device is determined by the availability of the outgoing physical media as well as the amount of traffic using the interface.
 - Schedulers—An individual routing device interface has multiple queues assigned to store packets. The routing device determines which queue to service based on a particular method of scheduling. This process often involves a determination of which type of packet should be transmitted before another. The Junos OS schedulers allow you to define the priority, bandwidth, delay buffer size, rate control status, and RED drop profiles to be applied to a particular queue for packet transmission.
 - Fabric schedulers—For M320 and T Series routers only, fabric schedulers allow you to identify a packet as high or low priority based on its forwarding class, and to associate schedulers with the fabric priorities.
 - Policers for traffic classes—*Policers* allow you to limit traffic of a certain class to a specified bandwidth and burst size. Packets exceeding the policer limits can be discarded, or can be assigned to a different forwarding class, a different loss priority, or both. You define policers with filters that can be associated with input or output interfaces.
- Rewrite rules—A *rewrite rule* sets the appropriate CoS bits in the outgoing packet. This allows the next downstream routing device to classify the packet into the appropriate service group. Rewriting, or marking, outbound packets is useful when the routing device is at the border of a network and must alter the CoS values to meet the policies of the targeted peer.

Default CoS Settings

If you do not configure any CoS settings on your routing device, the software performs some CoS functions to ensure that user traffic and protocol packets are forwarded with minimum delay when the network is experiencing congestion. Some default mappings are automatically applied to each logical interface that you configure. Other default mappings, such as explicit default classifiers and rewrite rules, are in operation only if you explicitly associate them with an interface.

You can display default CoS settings by issuing the **show class-of-service** operational mode command. This section includes sample output displaying the default CoS settings. The sample output is truncated for brevity.

show class-of-service

```
user@host> show class-of-service
```

Default Forwarding Classes

CoS Applications Overview

You can configure CoS features to meet your application needs. Because the components are generic, you can use a single CoS configuration syntax across multiple routing devices. CoS mechanisms are useful for two broad classes of applications. These applications can be referred to as *in the box* and *across the network*.

In-the-box applications use CoS mechanisms to provide special treatment for packets passing through a single node on the network. You can monitor the incoming traffic on each interface, using CoS to provide preferred service to some interfaces (that is, to some customers) while limiting the service provided to other interfaces. You can also filter outgoing traffic by the packet's destination, thus providing preferred service to some destinations.

Across-the-network applications use CoS mechanisms to provide differentiated treatment to different classes of packets across a set of nodes in a network. In these types of applications, you typically control the ingress and egress routing devices to a routing domain and all the routing devices within the domain. You can use the Junos OS CoS

features to modify packets traveling through the domain to indicate the packet's priority across the domain.

Specifically, you modify the CoS code points in packet headers, remapping these bits to values that correspond to levels of service. When all routing devices in the domain are configured to associate the precedence bits with specific service levels, packets traveling across the domain receive the same level of service from the ingress point to the egress point. For CoS to work in this case, the mapping between the precedence bits and service levels must be identical across all routing devices in the domain.

The Junos OS CoS applications support the following range of mechanisms:

- **Differentiated Services (DiffServ)**—The CoS application supports DiffServ, which uses 6-bit IPv4 and IPv6 header type-of-service (ToS) byte settings. The configuration uses CoS values in the IP and IPv6 ToS fields to determine the forwarding class associated with each packet.
- **Layer 2 to Layer 3 CoS mapping**—The CoS application supports mapping of Layer 2 (IEEE 802.1p) packet headers to routing device forwarding class and loss-priority values. Layer 2 to Layer 3 CoS mapping involves setting the forwarding class and loss priority based on information in the Layer 2 header. Output involves mapping the forwarding class and loss priority to a Layer 2-specific marking. You can mark the Layer 2 and Layer 3 headers simultaneously.
- **MPLS EXP**—Supports configuration of mapping of MPLS experimental (EXP) bit settings to routing device forwarding classes and vice versa.
- **VPN outer-label marking**—Supports setting of outer-label EXP bits, also known as CoS bits, based on MPLS EXP mapping.

Interface Types That Do Not Support CoS

For original Channelized OC12 PICs, limited CoS functionality is supported. For more information, contact Juniper Networks customer support.

NOTE: Transmission scheduling is not supported on 8-port, 12-port, and 48-port Fast Ethernet PICs.

You can configure CoS on all interfaces, except the following:

- **cau4**—Channelized STM1 IQ interface (configured on the Channelized STM1 IQ PIC).
- **coc1**—Channelized OC1 IQ interface (configured on the Channelized OC12 IQ PIC).
- **coc12**—Channelized OC12 IQ interface (configured on the Channelized OC12 IQ PIC).
- **cstm-1**—Channelized STM1 IQ interface (configured on the Channelized STM1 IQ PIC).
- **ct1**—Channelized T1 IQ interface (configured on the Channelized DS3 IQ PIC or Channelized OC12 IQ PIC).
- **ct3**—Channelized T3 IQ interface (configured on the Channelized DS3 IQ PIC or Channelized OC12 IQ PIC).

- **ce1**—Channelized E1 IQ interface (configured on the Channelized E1 IQ PIC or Channelized STM1 IQ PIC).
- **dsc**—Discard interface.
- **fxp**—Management and internal Ethernet interfaces.
- **lo**—Loopback interface. This interface is internally generated.
- **pe**—Encapsulates packets destined for the rendezvous point routing device. This interface is present on the first-hop routing device.
- **pd**—De-encapsulates packets at the rendezvous point. This interface is present on the rendezvous point.
- **vt**—Virtual loopback tunnel interface.

NOTE: For channelized interfaces, you can configure CoS on channels, but not at the controller level. For a complex configuration example, see the *Junos OS Feature Guides*.

VPLS and Default CoS Classification

A VPLS routing instance with the **no-tunnel-services** option configured has a default classifier applied to the label-switched interface for all VPLS packets coming from the remote VPLS PE. This default classifier is modifiable only on MX Series routers. On T Series, when **no-tunnel-services** option is configured, the custom classifier for VPLS instances is not supported.

NOTE: With **no-tunnel-services** configured, custom classifier for VPLS routing instances on T Series and LMNR based FPC for M320 is not supported. When a wild card configuration or an explicit routing instances are configured for VPLS on CoS CLI, the custom classifier binding results in default classifier binding on Packet Forwarding Engine (PFE).

For example, on routing devices with eight queues (Juniper Networks M120 and M320 Multiservice Edge Routers, MX Series Ethernet Services Routers, and T Series Core Routers), the default classification applied to **no-tunnel-services** VPLS packets are shown in [Table 90 on page 1271](#).

Table 90: Default VPLS Classifiers

MPLS Label EXP Bits	Forwarding Class/Queue
000	0
001	1
010	2

Table 90: Default VPLS Classifiers (*continued*)

MPLS Label EXP Bits	Forwarding Class/Queue
011	3
100	4
101	5
110	6
111	7

NOTE: Forwarding class to queue number mapping is not always one-to-one. Forwarding classes and queues are only the same when default forwarding-class-to-queue mapping is in effect. For more information about configuring forwarding class and queues, see [“Configuring Forwarding Classes” on page 1530](#).

On MX Series routers, VPLS filters and policers act on a Layer 2 frame that includes the media access control (MAC) header (after any VLAN rewrite or other rules are applied), but does not include the cyclical redundancy check (CRC) field.

NOTE: On MX Series routers, if you apply a counter in a firewall for egress MPLS or VPLS packets with the EXP bits set to 0, the counter will not tally these packets.

CoS Input and Output Configuration

- [CoS Inputs and Outputs Overview on page 1272](#)

CoS Inputs and Outputs Overview

Some CoS components map one set of values to another set of values. Each mapping contains one or more inputs and one or more outputs.

Some CoS components map one set of values to another set of values. Each mapping contains one or more inputs and one or more outputs. When you configure a mapping, you set the outputs for a given set of inputs, as shown in [Table 91 on page 1272](#).

Table 91: CoS Mappings—Inputs and Outputs

CoS Mappings	Inputs	Outputs	Comments
classifiers	code-points	forwarding-class loss-priority	The map sets the forwarding class and PLP for a specific set of code points.
drop-profile-map	loss-priority protocol	drop-profile	The map sets the drop profile for a specific PLP and protocol type.

Table 91: CoS Mappings—Inputs and Outputs (*continued*)

CoS Mappings	Inputs	Outputs	Comments
rewrite-rules	loss-priority	code-points	The map sets the code points for a specific forwarding class and PLP.

Packet Flow Through the CoS Process Overview

Perhaps the best way to understand Junos CoS is to examine how a packet is treated on its way through the CoS process. This topic includes a description of each step and figures illustrating the process.

The following steps describe the CoS process:

1. A logical interface has one or more classifiers of different types applied to it (at the **[edit class-of-service interfaces]** hierarchy level). The types of classifiers are based on which part of the incoming packet the classifier examines (for example, EXP bits, IEEE 802.1p bits, or DSCP bits). You can use a translation table to rewrite the values of these bits on ingress.

NOTE: You can only rewrite the values of these bits on ingress on the Juniper Networks M40e, M120, M320 Multiservice Edge Routers, and T Series Core Routers with IQE PICs. For more information about rewriting the values of these bits on ingress, see *Configuring ToS Translation Tables*.

2. The classifier assigns the packet to a forwarding class and a loss priority (at the **[edit class-of-service classifiers]** hierarchy level).
3. Each forwarding class is assigned to a queue (at the **[edit class-of-service forwarding-classes]** hierarchy level).
4. Input (and output) policers meter traffic and might change the forwarding class and loss priority if a traffic flow exceeds its service level.
5. The physical or logical interface has a scheduler map applied to it (at the **[edit class-of-service interfaces]** hierarchy level).

At the **[edit class-of-service interfaces]** hierarchy level, the **scheduler-map** and **rewrite-rules** statements affect the outgoing packets, and the **classifiers** statement affects the incoming packets.

6. The scheduler defines how traffic is treated in the output queue—for example, the transmit rate, buffer size, priority, and drop profile (at the **[edit class-of-service schedulers]** hierarchy level).
7. The scheduler map assigns a scheduler to each forwarding class (at the **[edit class-of-service scheduler-maps]** hierarchy level).
8. The drop-profile defines how aggressively to drop packets that are using a particular scheduler (at the **[edit class-of-service drop-profiles]** hierarchy level).
9. The rewrite rule takes effect as the packet leaves a logical interface that has a rewrite rule configured (at the **[edit class-of-service rewrite-rules]** hierarchy level). The rewrite rule writes information to the packet (for example, EXP or DSCP bits) according to the forwarding class and loss priority of the packet.

Figure 6 on page 1274 and Figure 7 on page 1274 show the components of the Junos CoS features, illustrating the sequence in which they interact.

Figure 6: CoS Classifier, Queues, and Scheduler

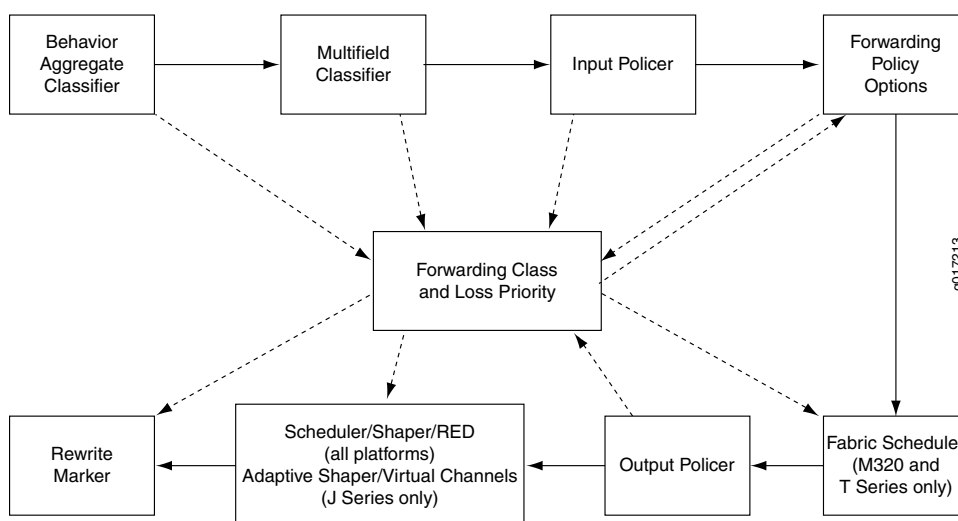

Figure 7: Packet Flow Through CoS Configurable Components

Each outer box in [Figure 7 on page 1274](#) represents a process component. The components in the upper row apply to inbound packets, and the components in the lower row apply to outbound packets. The arrows with the solid lines point in the direction of packet flow.

The middle box (forwarding class and loss priority) represents two data values that can either be inputs to or outputs of the process components. The arrows with the dotted lines indicate inputs and outputs (or settings and actions based on settings). For example, the multifield classifier sets the forwarding class and loss priority of incoming packets. This means that the forwarding class and loss priority are outputs of the classifier; thus, the arrow points away from the classifier. The scheduler receives the forwarding class and loss priority settings, and queues the outgoing packet based on those settings. This means that the forwarding class and loss priority are inputs to the scheduler; thus, the arrow points to the scheduler.

Typically, only a combination of some components (not all) is used to define a CoS service offering.

[edit firewall] Hierarchy Level

Several statements in the **[edit firewall]** hierarchy are valid at numerous locations within the hierarchy. To make the complete hierarchy easier to read, the repeated statements are listed in the following sections, which are referenced at the appropriate locations in [“Complete \[edit firewall\] Hierarchy” on page 325](#).

- [Common Firewall Actions on page 1288](#)
- [Common IP Firewall Actions on page 1288](#)
- [Common IPv4 Firewall Actions on page 1288](#)
- [Common IP Firewall Match Conditions on page 1289](#)
- [Common IPv4 Firewall Match Conditions on page 1290](#)
- [Common Layer 2 Firewall Match Conditions on page 1290](#)
- [Complete \[edit firewall\] Hierarchy on page 1292](#)

Common Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family (any | ccc | ethernet-switching | inet | inet6 | mpls | vpls) filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common firewall actions are as follows:

```
count counter-name;  
forwarding-class class-name;  
loss-priority (high | low | medium-high | medium-low);  
next term;  
policer policer-name;  
three-color-policer policer-name {  
    (single-rate single-rate-policer-name | two-rate two-rate-policer-name);  
}
```

Common IP Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet filter *filter-name* term *term-name* then]
- [edit firewall family inet6 filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common IP firewall actions are as follows:

```
log;  
logical-system logical-system-name <routing-instance routing-instance-name>  
    <topology topology-name>;  
port-mirror;  
port-mirror-instance instance-name;  
routing-instance routing-instance-name <topology topology-name>;  
sample;  
service-filter-hit;  
syslog;  
topology topology-name;
```

Common IPv4 Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common IP version 4 (IPv4) firewall actions are as follows:

```
(accept | discard <accounting collector-name> | reject <administratively-prohibited |
  bad-host-tos | bad-network-tos | fragmentation-needed | host-prohibited |
  host-unknown | host-unreachable | network-prohibited | network-unknown |
  network-unreachable | port-unreachable | precedence-cutoff | precedence-violation |
  protocol-unreachable | source-host-isolated | source-route-failed | tcp-reset>);
ipsec-sa sa-name;
load-balance sa-name;
next-hop-group group-name;
prefix-action action-name;
```

Common IP Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- **[edit firewall family inet dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in “[Complete \[edit firewall\] Hierarchy](#)” on page 325)
- **[edit firewall family inet filter *filter-name* term *term-name* from]**
- **[edit firewall family inet6 dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in “[Complete \[edit firewall\] Hierarchy](#)” on page 325)
- **[edit firewall family inet6 filter *filter-name* term *term-name* from]**
- **[edit firewall filter *filter-name* term *term-name* from]**

The common IP firewall match conditions are as follows:

```
address {
  ip-prefix </prefix-length> <except>;
}
destination-address {
  ip-prefix </prefix-length> <except>;
}
destination-class [ class-names ] | destination-class-except [ class-names ];
(destination-port [ port-names ] | destination-port-except [ port-names ]);
destination-prefix-list {
  list-name <except>;
}
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);
 icmp-code [ codes ] | icmp-code-except [ codes ];
 icmp-type [ types ] | icmp-type-except [ types ];
interface interface-name;
(interface-group [ group-names ] | interface-group-except [ group-names ]);
interface-set set-name;
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(packet-length [ values ] | packet-length-except [ values ]);
(port [ port-names ] | port-except [ port-names ]);
prefix-list {
  list-name <except>;
}
service-filter-hit;
source-address {
```

```
    ip-prefix </prefix-length> <except>;  
  }  
  (source-class [ class-names ] | source-class-except [ class-names ] );  
  (source-port [ port-names ] | source-port-except [ port-names ] );  
  source-prefix-list {  
    list-name <except>;  
  }  
  tcp-established;  
  tcp-flags flag;  
  tcp-initial;
```

Common IPv4 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet dialer-filter *filter-name* term *term-name* from] (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- [edit firewall family inet filter *filter-name* term *term-name* from]
- [edit firewall filter *filter-name* term *term-name* from]

The common IPv4 firewall match conditions are as follows:

```
(ah-spi [ values ] | ah-spi-except [ values ] );  
(dscp [ code-point-values ] | dscp-except [ code-point-values ] );  
(esp-spi [ values ] | esp-spi-except [ values ] );

Common Layer 2 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family ethernet-switching filter *filter-name* term *term-name* from]
- [edit firewall family vpls filter *filter-name* term *term-name* from]

The common Layer 2 firewall match conditions are as follows:

```
destination-mac-address {  
  mac-address <except>;  
}  
(destination-port [ port-names ] | destination-port-except [ port-names ] );  
(dscp [ code-point-values ] | dscp-except [ code-point-values ] );  
(ether-type [ protocol-types ] | ether-type-except [ protocol-types ] );  
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ] );
```

```

icmp-code [ codes ] | icmp-code-except [ codes ];
icmp-type [ types ] | icmp-type-except [ types ];
(interface-group [ group-names ] | interface-group-except [ group-names ]);
ip-address {
    ip-prefix </prefix-length> <except>;
}
ip-destination-address {
    ip-prefix </prefix-length> <except>;
}
(ip-precedence [ precedence-names ] | ip-precedence-except [ precedence-names ]);
(ip-protocol [ protocol-names ] | ip-protocol-except [ protocol-names ]);
ip-source-address ip-prefix </prefix-length>;
(learn-vlan-lp-priority [ priorities ] | learn-vlan-lp-priority [ priorities ]);
(learn-vlan-id [ vlan-ids ] | learn-vlan-id-except [ vlan-ids ]);
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(port [ port-names ] | port-except [ port-names ]);
source-mac-address {
    mac-address <except>;
}
(source-port [ port-names ] | source-port-except [ port-names ]);
tcp-flags flag;
(traffic-type [ broadcast known-unicast multicast unknown-unicast ] |
    traffic-type-except [ broadcast known-unicast multicast unknown-unicast ]);
(user-vlan-lp-priority [ priorities ] | user-vlan-lp-priority [ priorities ]);
(user-vlan-id [ vlan-ids ] | user-vlan-id-except [ vlan-ids ]);
(vlan-ether-type [ protocol-types ] | vlan-ether-type-except [ protocol-types ]);

```

CoS for L2TP Tunnels on Ethernet Interface Overview

For effective packet tunneling, CoS is implemented over L2TP tunnels. For Ethernet interfaces, CoS is supported for L2TP session traffic to a LAC on platforms configured as an LNS that include egress IQ2 or IQ2E PICs.

This feature is supported on the following platforms:

- EX Series switches
- M7i and M10i routers
- M120 routers

To enable session-aware CoS on an L2TP interface, include the **per-session-scheduler** statement at the **[edit interfaces unit logical-unit-number]** hierarchy level.

After CoS is configured on an L2TP tunnel, Junos OS dynamically creates a traffic shaper for the traffic-shaping-profile and the L2TP tunnel based on the tunnel identification number. This ensures that the packets are monitored at the LAC and classified to allow the traffic flow to be adjusted on congested networks.

This feature has the following limitations:

- Only 991 shapers are supported on each IQ2 or IQ2E PIC.
- For a 4-port IQ2E PIC, you can configure up to 1976 shapers for an 8-queue session and 3952 shapers for a 4-queue session.
- For an 8-port IQ2E PIC, you can configure up to 1912 shapers for an 8-queue session and up to 3824 shapers for a 4-queue session.
- Sessions in excess of the maximum supported values specified for the PICs cannot be shaped (but they can be policed).
- The overall traffic rate cannot exceed the L2TP traffic rate, or else random drops result.
- There is no support for logical interface scheduling and shaping at the ingress because all schedulers are now reserved for L2TP.
- There is no support for physical interface rate shaping at the ingress.
- You cannot delete or deactivate the primary Ethernet interface on which the tunnel is established.

You can provide policing support for sessions with more than the maximum supported value on each IQ2 or IQ2E PIC. Each session can have four or eight different classes of traffic (queues). Each class needs its own policer; for example, one for voice and one for data traffic.

Configuring CoS for L2TP Tunnels on Ethernet Interfaces

The Layer 2 Tunneling Protocol (L2TP) is often used to carry traffic securely between an L2TP Network Server (LNS) to an L2TP Access Concentrator (LAC). CoS is supported for L2TP session traffic to a LAC on platforms configured as an LNS that include egress IQ2 and IQ2E Ethernet PICs.

This feature is supported on the following platforms:

- EX Series switches
- M7i and M10i routers

- M120 routers

To configure CoS for L2TP on Ethernet interfaces:

1. Configure L2TP services on the Ethernet interface.
2. On the Ethernet interface, enable session-aware CoS for L2TP sessions.

```
[[edit interfaces interface-name unit logical-unit-number]
user@host# set per-session-scheduler
```
3. Configure the traffic manager in the IQ2 or IQ2E PIC to enable per-session CoS support.

```
[edit chassis fpc slot-number pic pic-number]
user@host# set traffic-manager mode-session-shaping
```
4. (Optional) To fine tune the system, you may also set the traffic-manager mode to session-shaping and configure the value of ingress-shaping-overhead parameter from 50 through 130 depending on your network requirement.

```
[edit chassis fpc slot-number pic pic-number]
user@host# set traffic-manager ingress-shaping-overhead value mode-session-shaping
```

NOTE: If you deactivate or delete the primary Ethernet interface on which the L2TP tunnel is configured, the tunnel with sessions having CoS is torn down.

After CoS is enabled for L2TP tunnels on Ethernet interface, you can run the **show class-of-service l2tp-session** command to verify the mapping of CoS with the configured L2TP session.

Configuring LNS CoS for Link Redundancy

You can configure multiple ports on the same IQ2 and IQ2E PICs to support link redundancy for CoS on L2TP tunnels configured on an Ethernet interface. Link redundancy is useful when the active port is unavailable due to events such as:

- Disconnection of the cable
- Rebooting of the remote end system
- Traffic re-routing through a different port due to network conditions

When link redundancy is enabled in such scenarios, the L2TP tunnels and its session are maintained by switching traffic to another port configured on the same IQ2 or IQ2E PIC.

To configure multiple ports (IQ and IQ2PE PIC) on an Ethernet interface for redundancy with CoS, configure per-session-scheduler for all Ethernet ports:

```
user@host#edit interfaces ge-2/0/0 unit 0 per-session-scheduler
user@host#edit interfaces ge-2/0/1 unit 0 per-session-scheduler
```

You can similarly configure all the ports on the IQ2 or IQ2E PIC to support link redundancy for CoS on L2TP tunnels.

NOTE:

- If one or more redundancy ports is removed from the configuration, the tunnels established through those redundancy ports also go down.
 - You must configure per-session-scheduler for all the ports that are to be used for redundancy. If you do not do so, new tunnels or sessions with CoS do not get established.
-

**Related
Documentation**

- [per-session-scheduler](#)

Example: L2TP LNS CoS Support for Link Redundancy

This example shows how link redundancy is supported when CoS for L2TP is configured on Ethernet interfaces.

NOTE: In this example, support for link redundancy is demonstrated by manually disabling the interface. However, link redundancy is also supported when the interface goes down due to events such as disconnection of the cable or rebooting of the remote end system.

- [Requirements on page 1314](#)
- [Overview on page 1315](#)
- [Configuration on page 1315](#)
- [Verification on page 1316](#)

Requirements

Before you begin:

- Configure service and loopback interfaces.
- Configure CoS for L2TP.

This feature applies to M Series Multiservice Edge Router running Junos OS Release 12.1 or later and EX Series switches.

Overview

Junos OS now supports link redundancy for CoS configured on an L2TP LNS. In this example, we verify that an L2TP tunnel does not go down when the Ethernet interface, through which the tunnels and its sessions with CoS are established, goes down.

Figure 8 on page 1315 shows a sample scenario in which L2TP access concentrator (LAC) devices operate on one side of an L2TP tunnel. LAC devices are configured with the address range of 192.168.100.0 with a subnet mask of 24. The LAC devices are connected to two backbone routers, P1 and P2. These two routers, P1 and P2, are connected over two Gigabit Ethernet ports on a single Ethernet IQ2 PIC to an L2TP network server (LNS). The LNS device is a router running Junos OS that supports redundancy for terminating L2TP sessions configured with CoS parameters. The CoS settings are applied on the interfaces using a RADIUS server when the L2TP session is set up. One of the Gigabit Ethernet interfaces on the IQ2 PIC present on the LNS device, ge-0/3/1, is connected to P1, while the other interface, ge-0/3/3, is linked to P2. Such a method of connection enables the subscriber sessions that reach the LAC devices to be forwarded to one of the two ports of the IQ2 PIC on the LNS device.

Figure 8: Topology to Verify Link Redundancy Support for L2TP LNS CoS

Configuration

Step-by-Step Procedure

To configure Ethernet interfaces for redundancy:

1. Configure Gigabit Ethernet interfaces.

```
[edit interfaces]
```

```
user@host# set ge-0/3/1 unit 0 family inet address 192.168.1.1/30
```

```
user@host# set ge-0/3/3 unit 0 family inet address 192.168.1.5/30
```

```
user@host# set ge-0/3/1 unit 0 per-session-scheduler
```

```
user@host# set ge-0/3/3 unit 0 per-session-scheduler
```

2. Configure static routing options.

```
[edit routing-options]
```

```
user@host# set static route 192.168.100.0/24 next-hop [ 192.168.1.2 192.168.1.6 ]
```

Step-by-Step Procedure Verify that CoS is now implemented over L2TP on an Ethernet interface and the LAC is reachable.

1. Verify that LAC is reachable.

```
user@host> show route 192.168.100.1
inet.0: 14 destinations, 14 routes (14 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.0/24    *[Static/5] 1d 02:09:09
                  to 192.168.1.2 via ge-0/3/1.0
                  > to 192.168.1.6 via ge-0/3/3.0
```

2. Bring up an L2TP session and verify that L2TP sessions come up.

```
user@host> show services l2tp session
Interface: sp-1/3/0, Tunnel group: GEN-TUN-GRP-BIO, Tunnel local ID: 44806
Local Remote Interface State      Bundle Username
ID   ID   unit
12491 33795      1 Established      - test1
```

3. Send a traffic stream towards the subscriber.
4. Verify that the shaping at the subscriber end is as per the shaping rate configured.

```
user@host# show class-of-service l2tp-session
L2TP Session Username: test1, Index: 12491
Physical interface: ge-0/3/3, Index: 131
Queues supported: 4, Queues in use: 4
Scheduler map: GEN-SCHED-MAP-EF-65%, Index: 5212
Shaping rate: 2162200 bps
Encapsulation Overhead: 6, Cell Overhead: Enabled
```

In the output of the **show class-of-service l2tp-session** command, ge-0/3/3, index 131 represents the port used to establish the L2TP tunnel to which the current L2TP session belongs. It does not represent the port that was active when the L2TP session came up.

Verification

Verify that, when CoS is configured on an L2TP tunnel, link redundancy works if one of the ports on which the L2TP tunnel is established goes down.

- [Bring Down ge-0/3/3 Interface Through Which the L2TP Tunnel Is Established on page 1316](#)
- [Verify LAC Reachability and the Status of L2TP Sessions on page 1317](#)

Bring Down ge-0/3/3 Interface Through Which the L2TP Tunnel Is Established

Purpose Bring down the interface through which the L2TP session and its tunnels are established.

Action [edit interfaces]
 user@host# set ge-0/3/3 disable
 user@host# commit

Verify LAC Reachability and the Status of L2TP Sessions

Purpose Verify that link redundancy works and the L2TP session does not go down when the active port on the IQ2 PIC is down. Verify that the traffic flow is unaffected after it is switched to another port configured on the same IQ2 or IQ2E PIC.

Action

```

user@host> show route 192.168.100.1
inet.0: 14 destinations, 14 routes (14 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.100.0/24    *[Static/5] 1d 02:35:09
                  to 192.168.1.2 via ge-0/3/1.0

user@host> show services l2tp session
Interface: sp-1/3/0, Tunnel group: GEN-TUN-GRP-BIO, Tunnel local ID: 44806
Local Remote Interface State          Bundle Username
ID    ID    unit
12491 33795    1 Established          - test1

```

CoS for MPLS Overview

When IP traffic enters a label-switched path (LSP) tunnel, the ingress routing device marks all packets with a class-of-service (CoS) value, which is used to place the traffic into a transmission priority queue. On the routing device, each interface has up to eight transmit queues. The CoS value is encoded as part of the Multiprotocol Label Switching (MPLS) header and remains in the packets until the MPLS header is removed when the packets exit from the egress routing device. The routing devices within the LSP utilize the CoS value set at the ingress routing device. The CoS value is encoded by means of the CoS bits (also known as the EXP or experimental bits).

MPLS class of service works in conjunction with the routing device's general CoS functionality. If you do not configure any CoS features, the default general CoS settings are used. For MPLS class of service, you might want to prioritize how the transmit queues are serviced by configuring weighted round-robin, and to configure congestion avoidance using random early detection (RED).

The next-hop label-switching router (LSR) uses the default classification shown in [Table 92 on page 1318](#).

Table 92: LSR Default Classification

Code Point	Forwarding Class	Loss Priority
000	best-effort	low
001	best-effort	high
010	expedited-forwarding	low
011	expedited-forwarding	high
100	assured-forwarding	low
101	assured-forwarding	high
110	network-control	low
111	network-control	high

Configuration

- [Configuration Task on page 1318](#)

Configuration Task

- [Configuring CoS for MPLS Traffic on page 1318](#)

Configuring CoS for MPLS Traffic

To configure CoS for MPLS packets in an LSP, include the **class-of-service** statement with the appropriate CoS value:

```
class-of-service cos-value;
```

If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit protocols mpls interface *interface-name* label-map *label-value*]
- [edit protocols mpls label-switched-path *path-name*]
- [edit protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit protocols mpls static-path *prefix*]
- [edit protocols rsvp interface *interface-name* link-protection]

- [edit protocols rsvp interface *interface-name* link-protection bypass *destination*]
- [edit logical-systems *logical-system-name* protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-path *prefix*]
- [edit logical-systems *logical-system-name* protocols mpls interface *interface-name* label-map *label-value*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *destination*]

The **class-of-service** statement at the [edit protocols mpls label-switched-path] hierarchy level assigns an initial EXP value for the MPLS shim header of packets in the LSP. This value is initialized at the ingress routing device only and overrides the rewrite configuration established for that forwarding class. However, the CoS processing (weighted round robin [WRR] and RED) of packets entering the ingress routing device is not changed by the **class-of-service** statement on an MPLS LSP. Classification is still based on the behavior aggregate (BA) classifier at the [edit class-of-service] hierarchy level or the multifield classifier at the [edit firewall] hierarchy level.

We recommend configuring all routing devices along the LSP to have the same input classifier for EXP, and, if a rewrite rule is configured, all routing devices should have the same rewrite configuration. Otherwise, traffic at the next LSR might be classified into a different forwarding class, resulting in a different EXP value being written to the EXP header.

For more information, see the *Junos OS MPLS Applications Configuration Guide*.

BA Classifier Overview

The behavior aggregate (BA) classifier maps a class-of-service (CoS) value to a forwarding class and loss priority. The forwarding class determines the output queue. The loss priority is used by schedulers in conjunction with the random early discard (RED) algorithm to control packet discard during periods of congestion.

The types of BA classifiers are based on which part of the incoming packet the classifier examines:

- Differentiated Services code point (DSCP) for IP DiffServ
- DSCP for IPv6 DiffServ
- IP precedence bits
- MPLS EXP bits
- IEEE 802.1p CoS bits
- IEEE 802.1ad drop eligible indicator (DEI) bit

Unlike multifield classifiers (which are discussed in [“Multifield Classifier Overview” on page 1387](#)), BA classifiers are based on fixed-length fields, which makes them computationally more efficient than multifield classifiers. For this reason, core devices are normally configured to perform BA classification, because of the higher traffic volumes they handle.

In most cases, you need to rewrite a given marker (IP precedence, DSCP, IEEE 802.1p, IEEE 802.1ad, or MPLS EXP settings) at the ingress node to accommodate BA classification by core and egress devices. For more information about rewrite markers, see [“Rewriting Packet Header Information Overview” on page 1690](#).

For Juniper Networks M Series Multiservice Edge Routers, four classes can forward traffic independently. For M320 Multiservice Edge Routers and Juniper Networks T Series Core Routers, eight classes can forward traffic independently. Therefore, you must configure additional classes to be aggregated into one of these classes. You use the BA classifier to configure class aggregation.

For Juniper Networks MX Series 3D Universal Edge Routers and Intelligent Queuing 2 (IQ2) PICs, the following restrictions apply:

- You cannot use BA classifiers for IPv4 DSCP bits for Layer 2 VPNs.

- You cannot use BA classifiers for IPv6 DSCP bits for VPLS.
- You cannot use BA classifiers for IPv6 DSCP bits for Layer 2 VPNs.

For the 10-port 10-Gigabit Oversubscribed Ethernet (OSE) PICs, the following restrictions on BA classifiers apply:

- Multiple classifiers can be configured to a single logical interface. However, there are some restrictions on which the classifiers can coexist.

For example, the DSCP and IP precedence classifiers cannot be configured on the same logical interface. The DSCP and IP precedence classifiers can coexist with the DSCP IPv6 classifier on the same logical interface. An IEEE 802.1 classifier can coexist with other classifiers and is applicable only if a packet does not match any of the configured classifiers. For information about the supported combinations, see [“Applying Classifiers to Logical Interfaces” on page 1331](#).

- If the classifiers are not defined explicitly, then the default classifiers are applied as follows:
 - All MPLS packets are classified using the MPLS (EXP) classifier. If there is no explicit MPLS (EXP) classifier, then the default MPLS (EXP) classifier is applied.
 - All IPv4 packets are classified using the IP precedence and DSCP classifiers. If there is no explicit IP precedence or DSCP classifier, then the default IP precedence classifier is applied.
 - All IPv6 packets are classified using a DSCP IPv6 classifier. If there is no explicit DSCP IPv6 classifier, then the default DSCP IPv6 classifier is applied.
 - If the IEEE 802.1p classifier is configured and a packet does not match any explicitly configured classifier, then the IEEE 802.1p classifier is applied.

NOTE: For a specified interface, you can configure both a multifield classifier and a BA classifier without conflicts. Because the classifiers are always applied in sequential order, the BA classifier followed by the multifield classifier, any BA classification result is overridden by a multifield classifier if they conflict. For more information about multifield classifiers, see [“Multifield Classifier Overview” on page 1387](#).

Overview of BA Classifier Types

The idea behind class of service (CoS) is that packets are not treated identically by the routers or switches on the network. In order to selectively apply service classes to specific packets, the packets of interest must be classified in some fashion.

The simplest way to classify a packet is to use behavior aggregate classification. The DSCP, DSCP IPv6, or IP precedence bits of the IP header convey the behavior aggregate class information. The information might also be found in the MPLS EXP bits, IEEE 802.1ad, or IEEE 802.1p CoS bits.

You can configure the following classifier types:

- DSCP, DSCP IPv6, or IP precedence—IP packet classification (Layer 3 headers)
- MPLS EXP—MPLS packet classification (Layer 2 headers)
- IEEE 802.1p—Packet classification (Layer 2 headers)
- IEEE 802.1ad—Packet classification for IEEE 802.1ad formats (including DEI bit)

If you apply an IEEE 802.1 classifier to a logical interface, this classifier takes precedence and is not compatible with any other classifier type. On Juniper Networks MX Series Ethernet Services Routers and EX Series switches using IEEE 802.1ad frame formats, you can apply classification on the basis of the IEEE 802.1p bits (three bits in either the inner virtual LAN (VLAN) tag or the outer VLAN tag) and the drop eligible indicator (DEI) bit. On routers with IQ2 PICs using IEEE 802.1ad frame format, you can apply classification based on the IEEE 802.1p bits and the DEI bit. Classifiers for IP (DSCP or IP precedence) and MPLS (EXP) can coexist on a logical interface if the hardware requirements are met. (See [“Applying Classifiers to Logical Interfaces”](#) on page 1331.)

The Enhanced Queuing DPC (EQ DPC) does not support BA classification for packets received from a Layer 3 routing interface or a virtual routing and forwarding (VRF) interface and routed to an integrated routing and bridging interface (IRB) to reach the remote end of a pseudowire connection. The EQ DPC also does not support BA classification for Layer 2 frames received from a Virtual Private LAN Service (VPLS) pseudowire connection from a remote site and routed to a Layer 3 routing interface through an IRB interface.

Default Behavior Aggregate Classification Overview

The software automatically assigns an implicit default IP precedence classifier to all logical interfaces.

NOTE: Only the IEEE 802.1p classifier is supported in Layer 2 interfaces. You must explicitly apply this classifier to the interface as shown in [“Default IEEE 802.1p Classifier”](#) on page 1327.

If you enable the MPLS protocol family on a logical interface, a default MPLS EXP classifier is automatically applied to that logical interface.

Other default classifiers (such as those for IEEE 802.1p bits and DSCP) require that you explicitly associate a default classification table with a logical interface. When you explicitly associate a default classifier with a logical interface, you are in effect overriding the implicit default classifier with an explicit default classifier.

NOTE: Although several code points map to the expedited-forwarding (ef) and assured-forwarding (af) classes, by default no resources are assigned to these forwarding classes. All af classes other than af1x are mapped to best-effort, because RFC 2597, *Assured Forwarding PHB Group*, prohibits a node from aggregating classes.

You can apply IEEE 802.1p classifiers to interfaces that are part of VPLS routing instances.

Understanding DSCP Classification for VPLS

You can perform Differentiated Services Code Point (DSCP) classification for IPv4 packets on Ethernet interfaces that are part of a virtual private LAN service (VPLS) routing instance on the ingress provider edge (PE) router. This is supported on the M320 router with Enhanced type III FPC and the M120 router. On the Intelligent Queuing 2 (IQ2) or Intelligent Queuing 2 Enhanced (IQ2E) PICs, the **vlan-vpls** encapsulation statement is required. DSCP for IPv6 and Internet precedence for IPv6 are not supported.

In order to perform DSCP classification for IPv4 packets on Ethernet interfaces that are part of a VPLS routing instance on the ingress PE router, you must make sure of the following:

- The correct encapsulation statement based on PIC type is configured for the interface.
- The DSCP classifier is defined (default is allowed) at the **[edit class-of-service classifiers]** hierarchy level.
- The defined DSCP classifier is applied to the interface.
- The interface is included in the VPLS routing instance on the ingress of the PE router.

Related Documentation

- [BA Classifier Overview on page 1320](#)

BA Classifiers and ToS Translation Tables

On some PICs, the behavior aggregate (BA) translation tables are included for every logical interface (unit) protocol family configured on the logical interface. The proper default translation table is active even if you do not include any explicit translation tables. You can display the current translation table values with the **show class-of-service classifiers** command.

On Juniper Networks M40e, M120, M320 Multiservice Edge Routers, and T Series Core Routers with Enhanced IQ (IQE) PICs, or on any router or switch with IQ2 or Enhanced IQ2 (IQ2E) PICs, you can replace the type-of-service (ToS) bit value on the incoming packet header on a logical interface with a user-defined value. The new ToS value is used for all class-of-service processing and is applied before any other class-of-service or firewall treatment of the packet. The PIC uses the **translation-table** statement to determine the new ToS bit values.

You can configure a physical interface (port) or logical interface (unit) with up to three translation tables. For example, you can configure a port or unit with BA classification

for IPv4 DSCP, IPv6 DSCP, and MPLS EXP. The number of frame relay data-link connection identifiers (DLCIs) (units) that you can configure on each PIC varies based on the number and type of BA classification tables configured on the interfaces.

For more information on configuring ToS translation tables, along with examples, see *Configuring ToS Translation Tables*.

Classifiers and Rewrite Rules at the Global and Physical Interface Levels Overview

On ACX Series Universal Access Routers and EX Series switches, CoS supports classification and rewrite at the global level and physical interface levels.

At a global level, you can define EXP classification.

At a physical interface level, you can define the following features:

- DSCP and inet-precedence classifiers
- DSCP and inet-precedence rewrites
- ieee-802.1 classifiers (inner and outer)
- ieee-802.1 rewrites (outer)

At a logical interface level, you can define the fixed classification and EXP rewrites.

To configure global EXP classifiers, include the **classifiers exp classifier-name** statement at the **[edit class-of-service] system-defaults** hierarchy level.

To configure classifiers or rewrite rules at the physical interface, include either the **classifiers** statement or the **rewrite-rules** statement at the **[edit class-of-service] interfaces interface-name]** hierarchy level.

To display classifiers configured under **system-defaults**, enter the **show class-of-service system-defaults** command.

To display classifiers and rewrite rules bound to physical interfaces, enter the **show class-of-service interfaces interface-name** command.

- [Default IEEE 802.1ad Classifier on page 1328](#)
- [Default IP Precedence Classifier \(ipprec-default\) on page 1329](#)

Default IP Precedence Classifier (*ipprec-compatibility*)

By default, all logical interfaces are automatically assigned an implicit IP precedence classifier called **ipprec-compatibility**. The **ipprec-compatibility** IP precedence classifier maps IP precedence bits to forwarding classes and loss priorities, as shown in [Table 93 on page 1325](#).

Table 93: Default IP Precedence Classifier

IP Precedence CoS Values	Forwarding Class	Loss Priority
000	best-effort	low
001	best-effort	high
010	best-effort	low
011	best-effort	high
100	best-effort	low
101	best-effort	high
110	network-control	low
111	network-control	high

Default MPLS EXP Classifier

For all PICs except PICs mounted on Juniper Networks M Series Multiservice Edge Router standard (nonenhanced) FPCs, if you enable the MPLS protocol family on a logical interface, the default MPLS EXP classifier is automatically applied to that logical interface. The default MPLS classifier maps EXP bits to forwarding classes and loss priorities, as shown in [Table 94 on page 1325](#).

Table 94: Default MPLS Classifier

Code Point	Forwarding Class	Loss Priority
000	best-effort	low
001	best-effort	high
010	expedited-forwarding	low
011	expedited-forwarding	high
100	assured-forwarding	low
101	assured-forwarding	high
110	network-control	low

Table 94: Default MPLS Classifier (*continued*)

Code Point	Forwarding Class	Loss Priority
111	network-control	high

Default DSCP and DSCP IPv6 Classifier

Table 95 on page 1326 shows the forwarding class and packet loss priority (PLP) that are assigned to each well-known DSCP when you apply the explicit default DSCP or DSCP IPv6 classifier. To do this, include the **default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* classifiers (dscp | dscp-ipv6)]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number classifiers (dscp
| dscp-ipv6)]
default;
```

NOTE: If you deactivate or delete dscp-ipv6 statement from the configuration, the default IPv6 classifier is not activated on the on the M5, M10, M7i, M10i, M20, M40, M40e, and M160 routing platforms. As a workaround, explicitly specify the default option to the dscp-ipv6 statement.

Table 95: Default DSCP Classifier

DSCP and DSCP IPv6	Forwarding Class	PLP

Default IEEE 802.1p Classifier

Table 96 on page 1327 shows the forwarding class and PLP that are assigned to the IEEE 802.1p CoS bits when you apply the explicit default IEEE 802.1p classifier. To do this, include the **default** statement at the [edit class-of-service interfaces *interface-name* unit *logical-unit-number* classifiers ieee-802.1] hierarchy level:

NOTE: Only the IEEE 802.1p classifier is supported in Layer 2 interfaces. You must explicitly apply this classifier as shown.

```
[edit class-of-service interfaces interface-name unit logical-unit-number classifiers
  ieee-802.1]
  default;
```

Table 96: Default IEEE 802.1p Classifier

Code Point	Forwarding Class	PLP
000	best-effort	low
001	best-effort	high
010	expedited-forwarding	low
011	expedited-forwarding	high

Table 96: Default IEEE 802.1p Classifier (*continued*)

Code Point	Forwarding Class	PLP
100	assured-forwarding	low
101	assured-forwarding	high
110	network-control	low
111	network-control	high

Default IEEE 802.1ad Classifier

Table 97 on page 1328 shows the code point, forwarding class alias, and PLP that are assigned to the IEEE 802.1ad bits when you apply the explicit default IEEE 802.1ad classifier. The table is very similar to the IEEE 802.1p default table, but the loss priority is determined by the DEI bit. To apply the default table, include the **default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* classifiers ieee-802.1]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number classifiers
  ieee-802.1ad]
  default;
```

Table 97: Default IEEE 802.1ad Classifier

IEEE 802.1ad Code Point	Forwarding Class Alias	PLP
0000	be	low
0010	be1	low
0100	ef	low
0110	ef1	low
1000	af11	low
1010	af12	low
1100	nc1	low
1110	nc2	low
0001	be-dei	high
0011	be1-dei	high
0101	ef-dei	high
0111	ef1-dei	high

Table 97: Default IEEE 802.1ad Classifier (*continued*)

IEEE 802.1ad Code Point	Forwarding Class Alias	PLP
1001	af11-dei	high
1011	af12-dei	high
1101	nc1-dei	high
1111	nc2-dei	high

Default IP Precedence Classifier (*ipprec-default*)

There are two separate tables for default IP precedence classification. All logical interfaces are implicitly assigned the **ipprec-compatibility** classifier by default, as described in [Table 93 on page 1325](#).

The other default IP precedence classifier (called **ipprec-default**) overrides the **ipprec-compatibility** classifier when you explicitly associate it with a logical interface. To do this, include the **default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* classifiers inet-precedence]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number classifiers
  inet-precedence]
  default;
```

[Table 98 on page 1329](#) shows the forwarding class and PLP that are assigned to the IP precedence CoS bits when you apply the default IP precedence classifier.

Table 98: Default IP Precedence (*ipprec-default*) Classifier

Code Point	Forwarding Class	PLP
000	best-effort	low
001	assured-forwarding	low
010	best-effort	low
011	best-effort	low
100	best-effort	low
101	expedited-forwarding	low
110	network-control	low
111	network-control	high

Configuration

- [Configuration Statements on page 1347](#)

Configuration Tasks for Classifiers

- [Defining Classifiers on page 1330](#)
- [Applying Classifiers to Logical Interfaces on page 1331](#)
- [DSCP Classifier Configuration Examples on page 1335](#)
- [Setting Packet Loss Priority on page 1337](#)

Defining Classifiers

You can override the default IP precedence classifier by defining a classifier and applying it to a logical interface. To define new classifiers for all code point types, include the **classifiers** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
classifiers {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) classifier-name {
    import [classifier-name | default];
    forwarding-class class-name {
      loss-priority level code-points [ aliases ] [ bit-patterns ];
    }
  }
}
```

The map sets the forwarding class and PLP for a specific set of code-point aliases and bit patterns. The inputs of the map are code-point aliases and bit patterns. The outputs of the map are the forwarding class and the PLP. For more information about how CoS maps work, see “[CoS Inputs and Outputs Overview](#)” on page 1272.

The classifiers work as follows:

- **dscp**—Handles incoming IPv4 packets.
- **dscp-ipv6**—Handles incoming IPv6 packets. For more information, see “[Applying DSCP IPv6 Classifiers](#)” on page 1341.
- **exp**—Handles MPLS packets using Layer 2 headers.
- **ieee-802.1**—Handles Layer 2 CoS.
- **inet-precedence**—Handles incoming IPv4 packets. IP precedence mapping requires only the upper three bits of the DSCP field.

A classifier takes a specified bit pattern as either the literal pattern or as a defined alias and attempts to match it to the type of packet arriving on the interface. If the information in the packet's header matches the specified pattern, the packet is sent to the appropriate queue, defined by the forwarding class associated with the classifier.

The code-point aliases and bit patterns are the input for the map. The loss priority and forwarding class are outputs of the map. In other words, the map sets the PLP and forwarding class for a given set of code-point aliases and bit patterns.

NOTE: On M Series, MX Series, and T Series routers, and EX Series switches that do not have tricolor marking enabled, the loss priority can be configured only by setting the PLP within a multifield classifier. This setting can then be used by the appropriate drop profile map and rewrite rule. For more information, see [“Setting Packet Loss Priority” on page 1337](#).

Importing a Classifier

You can use any table, including the default, in the definition of a new classifier by including the **import** statement. The imported classifier is used as a template and is not modified. Whenever you commit a configuration that assigns a new **class-name** and **loss-priority** value to a code-point alias or set of bits, it replaces that entry in the imported classifier template. As a result, you must explicitly specify every CoS value in every designation that requires modification.

To do this, include the **import default** statement at the **[edit class-of-service classifiers type classifier-name]** hierarchy level:

```
[edit class-of-service classifiers type classifier-name]
import default;
```

For instance, to import the default DSCP classifier, include the **dscp default** statement at the **[edit class-of-service classifiers dscp classifier-name]** hierarchy level:

```
[edit class-of-service classifiers dscp classifier-name]
import default;
```

Applying Classifiers to Logical Interfaces

To apply the classification map to a logical interface:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
user@host#set classifiers (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence)
(classifier-name | default);
```

You can use interface wildcards for **interface-name** and **logical-unit-number**.

For most PICs, if you apply an IEEE 802.1p classifier to a logical interface, you cannot apply non-IEEE classifiers to other logical interfaces on the same physical interface. This restriction does not apply to Gigabit Ethernet IQ2 PICs.

There are some restrictions on applying multiple BA classifiers to a single logical interface. [Table 99 on page 1332](#) shows the supported combinations. In this table, the OSE PICs refer to the 10-port 10-Gigabit OSE PICs.

Table 99: Logical Interface Classifier Combinations

Classifier Combinations	Gigabit Ethernet IQ2 PICs	OSE PICs	Other PICs on M320, MX Series, T Series routers and on EX Series Switches	Other M Series with Regular FPCs	Other M Series with Enhanced FPCs
dscp and inet-precedence	No	No	No	No	No
dscp-ipv6 and (dscp inet-precedence)	Yes	Yes	Yes	No	No
exp and ieee 802.1	Yes	Yes	No	No	No
ieee 802.1 and (dscp dscp-ipv6 exp inet-precedence)	Yes	Yes	No	No	Yes
exp and (dscp dscp-ipv6 inet-precedence)	Yes	Yes	Yes	No	Yes

For Gigabit Ethernet IQ2 and 10-port 10-Gigabit Oversubscribed Ethernet (OSE) interfaces, family-specific classifiers take precedence over IEEE 802.1p BA classifiers. For example, if you configure a logical interface to use both an MPLS EXP and an IEEE 802.1p classifier, the EXP classifier takes precedence. MPLS-labeled packets are evaluated by the EXP classifier, and all other packets are evaluated by the IEEE 802.1p classifier. The same is true about other classifiers when combined with IEEE 802.1p classifiers on the same logical interface.

In Junos OS Releases 9.6 and later, the DSCP and IPv6 DSCP classifiers are not compatible with older formats. You cannot directly replace the old classifier with the new one. You must first delete the old classifier and then apply the new one, although both steps can be done in one configuration session. Otherwise, the commit will fail.

NOTE: If an interface is mounted on an M Series router FPC, you can apply only the default **exp** classifier. If an interface is mounted on an enhanced FPC, you can create a new **exp** classifier and apply it to an interface.

On MX960, MX480, MX240, MX80, M120, and M320 routers and EX Series switches with Enhanced Type III FPCs only, you can configure user-defined DSCP-based BA classification for MPLS interfaces (this feature is not available for IQE PICs or on MX Series routers and EX Series switches when ingress queuing is used) or VPLS/L3VPN routing instances (LSI interfaces). The DSCP-based classification for MPLS packets for Layer 2 VPNs is not supported. To classify MPLS packets on the routing instance at the egress PE, include the **dscp** or **dscp-ipv6** statements at the **[edit class-of-service routing-instances routing-instance-name classifiers]** hierarchy level. To classify MPLS packets at the core-facing interface, apply the classifier at the **[edit class-of-service interface**

interface-name unit *unit-name* classifiers (dscp | dscp-ipv6) *classifier-name* family mpls] hierarchy level.

NOTE: If you do not apply a DSCP classifier, the default EXP classifier is applied to MPLS traffic.

You can apply DSCP classification for MPLS traffic in the following usage scenarios:

- In a Layer 3 VPN (L3VPN) using an LSI routing instance.
 - Supported on the M120, M320, MX960, MX480, MX240, and MX80 routers.
 - DSCP classifier configured under **[edit class-of-service routing-instances]** on the egress PE router.
- In VPLS using an LSI routing instance.
 - Supported on the M120, M320, MX960, MX480, MX240, and MX80 routers.
 - DSCP classifier configured under **[edit class-of-service routing-instances]** on the egress PE router.
- In a Layer 3 VPN (L3VPN) using a VT routing instance.
 - Supported on the M120, M320, MX960, MX480, MX240, and MX80 routers.
 - DSCP classifier configured under **[edit class-of-service interfaces]** on the core-facing interface on the egress PE router.
- In VPLS using the VT routing instance.
- MPLS forwarding.
 - Supported on the M120, M320, MX960, MX480, MX240, and MX80 routers (not supported on IQE and MX when ingress queuing is enabled).
 - DSCP classifier configured under **[edit class-of-service interfaces]** on the ingress core-facing interface on the P or egress PE router.

MPLS forwarding when the label stacking is greater than 2 is not supported:

The following example configures a DSCP classifier for IPv4 named **dscp-ipv4-classifier** for the **fc-af11-class** forwarding class and a corresponding IPv6 DSCP classifier:

```
class-of-service {
  routing-instances routing-instance-one {
    classifiers {
      dscp dscp-ipv4-classifier {
        loss-priority low code-points 000100;
      }
      dscp dscp-ipv6-classifier {
        forwarding-class fc-af11-class {
          loss-priority low {
            code-points af11;
          }
        }
      }
    }
  }
}
```

```

    }
  }
}

```

NOTE: This is not a complete configuration.

This example applies the IPv4 classifier to MPLS traffic and the IPv6 classifier to Internet traffic on interface **ge-2/0/3.0**:

```

class-of-service {
  interfaces ge-2/0/3 {
    unit 0 {
      classifiers {
        dscp dscp-ipv4-classifier {
          family mpls;
        }
        dscp-ipv6 dscp-ipv6-classifier {
          family inet; # This is the default if not present.
        }
      }
    }
  }
}

```

NOTE: This is not a complete configuration.

This example applies the same classifier to both MPLS and IP traffic on interface **ge-2/2/0**.

```

[edit class-of-services interface ge-2/2/0]
unit 0 {
  classifiers {
    dscp dscp-mpls {
      family [ mpls inet ];
    }
  }
}

```

NOTE: This is not a complete configuration.

NOTE: You can apply DSCP and DSCP IPv6 classifiers to explicit null MPLS packets. The **family mpls** statement works the same on both explicit null and non-null MPLS labels.

**Related
Documentation**

DSCP Classifier Configuration Examples

On MX960, MX480, MX240, MX80, M120, and M320 routers with Enhanced Type III FPCs and EX Series switches only, you can configure user-defined DSCP-based BA classification for MPLS interfaces (this feature is not available for IQE PICs or on MX Series routers or EX Series switches when ingress queuing is used) or VPLS/L3VPN routing instances (LSI interfaces). The following examples show how you can apply DSCP classifiers for MPLS traffic in these cases.

**Applying a DSCP
Classifier to MPLS
Packets on the
Core-facing Interface**

Configure the core-facing interface and associated logical interfaces:

```
interfaces ge-5/3/1 {
  unit 0 {
    family inet {
      address 1.1.1.1/24;
    }
    family iso;
    family inet6 {
      address 2000::1/64;
    }
    family mpls
  }
}
```

Configure the DSCP classifier.

```
class-of-service {
  classifiers {
    dscp dscp11 {
      forwarding-class expedited-forwarding {
        loss-priority low code-points [ ef cs5 ];
      }
      forwarding-class assured-forwarding {
        loss-priority low code-points [ af21 af31 af41 cs4 ];
        loss-priority high code-points [ af23 af33 af43 cs2 af22 af32 af42 cs3 ];
      }
      forwarding-class best-effort {
        loss-priority low code-points [ af11 cs1 af12 ];
        loss-priority high code-points af13;
      }
      forwarding-class network-control {
        loss-priority low code-points [ cs6 cs7 ];
      }
    }
  }
}
```

Attach the classifier to the logical interface for the mpls family. You cannot configure more than one classifier per family.

```
class-of-service {
  interfaces {
    ge-5/3/1 {
      unit 0 {
        classifiers {
          dscp dscp11 {
            family mpls;
          }
        }
      }
    }
  }
}
```

```

    }
  }
}

```

The above classifiers are applicable on egress PE routers for VPLS and L3VPN cases. For plain interfaces (not VPLS/L3VPN (LSI) interfaces), these classifiers are applicable on P and egress PE routers on core facing interfaces.

Applying a DSCP Classifier to MPLS Traffic for L3VPN/VPLS

Configure routing instances of type either vrf or vpls.

```

routing-instances {
  vpls1 {
    instance-type vpls;
    interface ge-2/2/2.0; #customer facing interface for VPLS
    route-distinguisher 10.255.245.51:1;
    vrf-target target:1234:1;
    protocols {
      vpls {
        site-range 10;
        no-tunnel-services;
        site vpls-1-site-1 {
          site-identifier 1;
        }
      }
    }
  }
}

```

Configure the DSCP classifier.

```

class-of-service {
  classifiers {
    dscp dscp11 {
      forwarding-class expedited-forwarding {
        loss-priority low code-points [ ef cs5 ];
      }
      forwarding-class assured-forwarding {
        loss-priority low code-points [ af21 af31 af41 cs4 ];
        loss-priority high code-points [ af23 af33 af43 cs2 af22 af32 af42 cs3 ];
      }
      forwarding-class best-effort {
        loss-priority low code-points [ af11 cs1 af12 ];
        loss-priority high code-points af13;
      }
      forwarding-class network-control {
        loss-priority low code-points [ cs6 cs7 ];
      }
    }
  }
}

```

Attach the classifier to a routing instance. You cannot configure more than one classifier per routing instance.

```

class-of-service {
  routing-instances {
    vpls1 {
      classifiers {
        dscp dscp11;
      }
    }
  }
}

```

Related Documentation

- [Applying Classifiers to Logical Interfaces on page 1331](#)

Setting Packet Loss Priority

By default, the least significant bit of the CoS value sets the packet loss priority (PLP) value. For example, CoS value 000 is associated with PLP **low**, and CoS value 001 is associated with PLP **high**. In general, you can change the PLP by configuring a behavior aggregate (BA) or multifield classifier, as discussed in “[Overview of BA Classifier Types](#)” on page 1321 and “[Multifield Classifier Overview](#)” on page 1387.

However, on Juniper Networks M320 Multiservice Edge Routers, MX Series 3D Universal Edge Routers, and T Series Core Routers and EX Series switches that do not have tricolor marking enabled, the loss priority can be configured by setting the PLP within a multifield classifier or by behavior aggregate (BA) classifier. This setting can then be used by the appropriate drop profile map and rewrite rule.

On M320 routers and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and tricolor marking enabled, you can set the PLP with a BA or multifield classifier, as described in “[Using BA Classifiers to Set PLP](#)” on page 1460 and “[Using Multifield Classifiers to Set PLP](#)” on page 1461.

On T Series routers with different Packet Forwarding Engines (non-Enhanced Scaling and Enhanced Scaling FPCs), you can configure PLP bit copying for ingress and egress unicast and multicast traffic. To configure, include the **copy-plp-all** statement at the **[edit class-of-service]** hierarchy level.

Example: Overriding the Default PLP on M320 Routers

The following example shows a two-step procedure to override the default PLP settings on M320 routers:

1. The following example specifies that while the DSCP code points are 110, the loss priority is set to **high**; however, on M320 routers, overriding the default PLP this way has no effect.

```

class-of-service {
  classifiers {
    dscp ba-classifier {
      forwarding-class expedited-forwarding {
        loss-priority high code-points 110;
      }
    }
  }
}

```

2. For M320 routers, this multifield classifier sets the PLP.

```
firewall {
  filter ef-filter {
    term ef-multifield {
      from {
        precedence 6;
      }
      then {
        loss-priority high;
        forwarding-class expedited-forwarding;
      }
    }
  }
}
```

Configuration Tasks for BA Classifiers

- [Example: DSCP IPv6 Rewrites and Forwarding Class Maps on page 1338](#)
- [Tunneling and BA Classifiers on page 1339](#)
- [Configuring Classifiers and Rewrite Rules at the Global and Physical Interface Levels on page 1339](#)

Example: DSCP IPv6 Rewrites and Forwarding Class Maps

You cannot configure a DSCP IPv6 rewrite rule and output forwarding class map on the same logical interface (unit). These must be used on different logical interfaces. Although a warning is issued, there is nothing in the CLI that prevents this configuration. An error message appears when you attempt to commit the configuration.

This example shows the warning and error message that results when the default DSCP IPv6 rewrite rule is configured on logical interface **ge-1/0/4.0** with output forwarding class map **vg1**.

```
[edit class-of-service]
interfaces {
  ge-1/0/4 {
    unit 0 {
      ##
      ## Warning: DSCP-IPv6 rewrite and forwarding class map not allowed on same unit
      ##
      output-forwarding-class-map vg1;
      rewrite-rules {
        dscp-ipv6 default;
      }
    }
  }
}

user@router# commit
[edit class-of-service interfaces ge-1/0/4 unit 0 output-forwarding-class-map]
'output-forwarding-class-map vg1'
DSCP-IPv6 rewrite and forwarding class map not allowed on same unit
error: commit failed: (statements constraint check failed)
```

Related Documentation • [Applying Forwarding Classes to Interfaces on page 1531](#)

Tunneling and BA Classifiers

BA classifiers can be used with GRE and IP-IP tunnels on the following routers and switches:

- EX Series switches
- M7i and M10i routers
- M Series routers with E-FPC or EP-FPC
- M120 routers
- M320 routers
- T Series routers

When a GRE or IP-IP tunnel is configured on an incoming (core-facing) interface, the queue number and PLP information are carried through the tunnel. At the egress (customer-facing) interface, the packet is queued and the CoS bits rewritten based on the information carried through the tunnel.

If no BA classifier is configured in the incoming interface, the default classifier is applied. If no rewrite rule is configured, the default rewrite rule is applied.

Configuring Classifiers and Rewrite Rules at the Global and Physical Interface Levels

On ACX Series Universal Access Routers and EX Series switches, CoS supports classification and rewrite at the global and physical interface levels.

To configure the global EXP classifier, include the following statements at the **[edit class-of-service] system-defaults** hierarchy level.

```
[edit class-of-service]
{
  system-defaults
  {
    classifiers exp classifier-name
  }
}
```

CoS supports one global system default classifier of the EXP type, as shown in the following example:

```
[edit class-of-service]
{
  system-defaults {
    classifiers {
      exp exp-classf-core;
    }
  }
}
```

To configure classifiers and rewrite rules at the physical interface level, include the following statements at the **[edit class-of-service] interfaces** hierarchy level.

```
[edit class-of-service]
interfaces {
  interface-name
    classifiers dscp classifier-name
    classifiers inet-precedence classifier-name
    classifiers ieee-802.1 [vlan-tag (outer | inner)] classifier-name
    rewrite-rules dscp rewrite-name
    rewrite-rules inet-prec rewrite-name
    rewrite-rules ieee-802.1 rewrite-name
}
```

The following example shows classifiers and rewrite rules configured on physical interfaces:

```
ge-0/1/0 {
  unit 0 {
    rewrite-rules {
      exp custom-exp;
    }
  }
  classifiers {
    dscp d1;
    ieee-802.1 ci;
  }
  rewrite-rules {
    dscp default;
  }
}
ge-0/1/2 {
  classifiers {
    ieee-802.1 ci;
  }
  rewrite-rules {
    ieee-802.1 ri;
  }
}
ge-0/1/3 {
  unit 0 {
    rewrite-rules {
      exp custom-exp2;
    }
  }
}
ge-0/1/7 {
  classifiers {
    dscp d1;
  }
}
ge-0/1/8 {
  classifiers {
    dscp d1;
  }
}
```

**Related
Documentation**

- [Classifiers and Rewrite Rules at the Global and Physical Interface Levels Overview on page 1324](#)

Configuration Task for DSCP IPv6 Classifiers

- [Applying DSCP IPv6 Classifiers on page 1341](#)

Applying DSCP IPv6 Classifiers

For M320 and T Series routers and forEX Series switches, you can apply separate classifiers for IPv4 and IPv6 packets per logical interface by including the **classifiers** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level and specifying the **dscp** and **dscp-ipv6** classifier types:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
  classifiers dscp (classifier-name | default) family (mpls | inet);
  classifiers dscp-ipv6 (classifier-name | default) family (mpls | inet));
```

For M Series router enhanced FPCs, you cannot apply separate classifiers for IPv4 and IPv6 packets on a single logical interface. Instead, classifier assignment works as follows:

- If you assign a DSCP classifier only, IPv4 and IPv6 packets are classified using the DSCP classifier.
- If you assign an IP precedence classifier only, IPv4 and IPv6 packets are classified using the IP precedence classifier. In this case, the lower three bits of the DSCP field are ignored because IP precedence mapping requires the upper three bits only.
- If you assign either the DSCP or the IP precedence classifier in conjunction with the DSCP IPv6 classifier, the commit fails.
- If you assign a DSCP IPv6 classifier only, IPv4 and IPv6 packets are classified using the DSCP IPv6 classifier, but the commit displays a warning message.

For more information, see “[Applying Classifiers to Logical Interfaces](#)” on page 1331. For a complex configuration example, see the *Junos OS Feature Guides*.

Configuration Tasks for MPLS EXP Classifiers

- [Applying MPLS EXP Classifiers to Routing Instances on page 1341](#)
- [Applying MPLS EXP Classifiers for Explicit-Null Labels on page 1345](#)

Applying MPLS EXP Classifiers to Routing Instances

When you enable VRF table labels and you do not explicitly apply a classifier configuration to the routing instance, the default MPLS EXP classifier is applied to the routing instance. For detailed information about VRF table labels, see the *Junos OS VPNs Configuration Guide*.

The default MPLS EXP classification table contents are shown in [Table 100 on page 1341](#).

Table 100: Default MPLS EXP Classification Table

Forwarding Class	Loss Priority	CoS Value
best-effort	low	000
best-effort	high	001

Table 100: Default MPLS EXP Classification Table (*continued*)

Forwarding Class	Loss Priority	CoS Value
expedited-forwarding	low	010
expedited-forwarding	high	011
assured-forwarding	low	100
assured-forwarding	high	101
network-control	low	110
network-control	high	111

For PICs that are installed on enhanced FPCs, you can override the default MPLS EXP classifier and apply a custom classifier to the routing instance. To do this, perform the following configuration tasks:

1. Filter traffic based on the IP header by including the **vrf-table-label** statement at the **[edit routing-instances *routing-instance-name*]** hierarchy level:

```
[edit routing-instances routing-instance-name]
vrf-table-label;
```

2. Configure a custom MPLS EXP classifier by including the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
classifiers {
  exp classifier-name {
    import (classifier-name | default);
    forwarding-class class-name {
      loss-priority level code-points [ aliases ] [ bit-patterns ];
    }
  }
}
forwarding-classes {
  queue queue-number class-name priority (high | low);
}
```

3. Configure the routing instance to use the custom MPLS EXP classifier by including the **exp** statement at the **[edit class-of-service routing-instances *routing-instance-name* classifiers]** hierarchy level:

```
[edit class-of-service routing-instances routing-instance-name classifiers]
exp classifier-name;
```

To display the MPLS EXP classifiers associated with all routing instances, issue the **show class-of-service routing-instances** command.

NOTE: The following caveats apply to custom MPLS EXP classifiers for routing instances:

- An enhanced FPC is required.
- Logical systems are not supported.

For more details, see the following sections:

- [Configuring Global Classifiers and Wildcard Routing Instances on page 1343](#)
- [Examples: Applying MPLS EXP Classifiers to Routing Instances on page 1344](#)

Configuring Global Classifiers and Wildcard Routing Instances

To configure a global routing instance classifier, include the **all** statement at the **[edit class-of-service routing-instances]** hierarchy level:

```
[edit class-of-service routing-instances]
all {
  classifiers {
    exp classifier-name;
  }
}
```

For routing instances associated with specific classifiers, the global configuration is ignored.

To use a wildcard in the routing instance classifier configuration, include an asterisk (*) in the name of the routing instance:

```
[edit class-of-service routing-instances]
routing-instance-name* {
  classifiers {
    exp classifier-name;
  }
}
```

The wildcard configuration follows the longest match. If there is a specific configuration, it is given precedence over the wildcard configuration.

NOTE: Wildcards and the all keyword are supported at the [edit class-of-service routing-instances] hierarchy level but not at the [edit routing-instances] hierarchy level.

If you configure a routing instance at the [edit routing-instances] hierarchy level with, for example, the name `vpn*`, the Junos OS treats `vpn*` as a valid and distinct routing instance name. If you then try to apply a classifier to the `vpn*` routing instance at the [edit class-of-service routing-instances] hierarchy level, the Junos OS treats the `vpn*` routing instance name as a wildcard, and all the routing instances that start with `vpn` and do not have a specific classifier applied receive the classifier associated with `vpn*`. This same behavior applies with the all keyword.

Examples: Applying MPLS EXP Classifiers to Routing Instances

Configure a global classifier for all routing instances and override the global classifier for a specific routing instance. In this example, there are three routing instances: `vpn1`, `vpn2`, and `vpn3`, each with VRF table label enabled. The classifier `exp-classifier-global` is applied to `vpn1` and `vpn2` (that is, all but `vpn3`, which is listed separately). The classifier `exp-classifier-3` is applied to `vpn3`.

Configuring a Global Classifier

```
[edit routing-instances]
vpn1 {
  vrf-table-label;
}
vpn2 {
  vrf-table-label;
}
vpn3 {
  vrf-table-label;
}

[edit class-of-service routing-instances]
all {
  classifiers {
    exp exp-classifier-global;
  }
}
vpn3 {
  classifiers {
    exp exp-classifier-3;
  }
}
```

Configure a wildcard routing instance and override the wildcard with a specific routing instance. In this example, there are three routing instances: `vpn-red`, `vpn-yellow`, and `vpn-green`, each with VRF table label enabled. The classifier `exp-class-wildcard` is applied to `vpn-yellow` and `vpn-green`. The classifier `exp-class-red` is applied to `vpn-red`.

Configuring a Wildcard Routing Instance

```
[edit routing-instances]
vpn-red {
  vrf-table-label;
```

```

}
vpn-yellow {
    vrf-table-label;
}
vpn-green {
    vrf-table-label;
}

[edit class-of-service routing-instances]
vpn* {
    classifiers {
        exp exp-class-wildcard;
    }
}
vpn-red {
    classifiers {
        exp exp-class-red;
    }
}

```

Display the MPLS EXP classifiers associated with two routing instances:

Monitoring a Configuration

```

[edit class-of-service routing-instances]
vpn1 {
    classifiers {
        exp default;
    }
}
vpn2 {
    classifiers {
        exp class2;
    }
}

```

```
user@host> show class-of-service routing-instances
```

```

Routing Instance : vpn1
  Object      Name      Type      Index
  Classifier   exp-default  exp       8

Routing Instance : vpn2
  Object      Name      Type      Index
  Classifier   class2     exp       57507

```

Applying MPLS EXP Classifiers for Explicit-Null Labels

When you configure MPLS explicit-null labels, label 0 is advertised to the egress router of an LSP. When label 0 is advertised, the egress router (instead of the penultimate router) removes the label. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label. For more information about explicit-null labels and ultimate-hop popping, see the *Junos OS MPLS Applications Configuration Guide*.

On M320 and T Series routers, when you configure MPLS explicit-null labels with an MPLS EXP classifier, the MPLS EXP classifier can be different from an IPv4 or IPv6 classifier configured on the same logical interface. In other words, you can apply separate classifiers for MPLS EXP, IPv4, and IPv6 packets per logical interface. To combine an

EXP classifier with a distinct IPv6 classifier, the PIC must be mounted on an Enhanced FPC.

NOTE: For J Series routers and other M Series routers, MPLS explicit-null labels with MPLS EXP classification are supported if you set the same classifier for EXP and IPv4 traffic, or EXP and IPv6 traffic.

For more information about how IPv4 and IPv6 packet classification is handled, see [“Applying DSCP IPv6 Classifiers” on page 1341](#).

To configure an MPLS EXP classifiers for explicit-null labels, include the **exp** statement at the **[edit class-of-service classifiers]** and **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* classifiers]** hierarchy levels:

```
[edit class-of-service classifiers]
exp classifier-name {
  import (classifier-name | default);
  forwarding-class class-name {
    loss-priority level code-points [ aliases ] [ bit-patterns ];
  }
}
[edit class-of-service interfaces interface-name unit logical-unit-number classifiers]
exp (classifier-name | default);
```

Configuration Task for IEEE 802.1ad Classifiers

- [Configuring and Applying IEEE 802.1ad Classifiers on page 1346](#)

Configuring and Applying IEEE 802.1ad Classifiers

For Juniper Network MX Series 3D Universal Edge Router interfaces or IQ2 PICs with IEEE 802.1ad frame formats or EX Series switches, you can set the forwarding class and loss priority for traffic on the basis of the three IEEE 802.1p bits and the DEI bit. You can apply the default map or customize one or more of the default values.

You then apply the classifier to the interface on which you configure IEEE 802.1ad frame formats.

Defining Custom IEEE 802.1ad Maps

You can customize the default IEEE 802.1ad map by defining values for IEEE 802.1ad code points.

```
class-of-service {
  classifiers {
    ieee-802.1ad dot1p_dei_class {
      forwarding-class best-effort {
        loss-priority low code-points [ 0000 1101 ];
      }
    }
  }
}
```

Applying Custom IEEE 802.1ad Maps

You then apply the classifier map to the logical interface:

```

interfaces {
  ge-2/0/0 {
    unit 0 {
      classifiers {
        ieee-802.1ad dot1p_dei_class;
      }
    }
  }
}

```

Verifying Custom IEEE 802.1ad Map Configuration

To verify your configuration, you can issue the following operational mode commands:

- `show class-of-service forwarding-table loss-priority-map`
- `show class-of-service forwarding-table loss-priority-map mapping`
- `show chassis forwarding`
- `show pfe fwdd`

Configuration Statements

exp

Syntax	<code>exp (rewrite-name default) protocol protocol-types;</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS Release 12.2. for ACX series
Description	Apply an MPLS experimental (EXP) rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules exp] hierarchy level.</p> <p>default—The default mapping.</p> <p>By default, IP precedence rewrite rules alter the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged. This default behavior applies to rewrite rules you configure for MPLS packets with IPv4 payloads. You configure these types of rewrite rules by including the mpls-inet-both or mpls-inet-both-non-vpn option at the [edit class-of-service interfaces <i>interface</i> <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules exp <i>rewrite-rule-name</i> protocol] hierarchy level. The IP precedence rewrite rules explanation does not apply to ACX Series Universal Access routers.</p> <p>On interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series Ethernet Services Routers and EX Series switches, we highly recommend that you configure the default option when you configure a behavior aggregate (BA) classifier that does not include a specific rewrite rule for MPLS packets. Doing so ensures that MPLS exp value is rewritten according to the BA classifier rules configured for forwarding or packet loss priority. This does not apply to ACX Series Universal Access routers.</p> <p>The remaining statement is explained separately.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

forwarding-class (BA Classifiers)

Syntax	<code>forwarding-class <i>class-name</i> { loss-priority <i>level</i> code-points [<i>aliases</i>] [<i>bit-patterns</i>]; }</code>
Hierarchy Level	[edit class-of-service classifiers <i>type classifier-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Define forwarding class name and option values.
Options	<p><i>class-name</i>—Name of the forwarding class.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Defining Classifiers on page 1330 • <i>Example: Configuring CoS for a PBB Network</i>

ieee-802.1 (Rewrite Rules on Logical Interface)

Syntax	ieee-802.1 (<i>rewrite-name</i> default) vlan-tag (outer outer-and-inner);
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4. vlan-tag statement introduced in Junos OS Release 8.1.
Description	Apply an IEEE-802.1 rewrite rule. For IQ PICs, you can only configure one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.
Options	rewrite-name —Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules ieee-802.1] hierarchy level. default —The default mapping.
Required Privilege Level	interface —To view this statement in the configuration. interface-control —To add this statement to the configuration.

ieee-802.1 (Classifier on Physical Interface)

Syntax	ieee-802.1 (<i>classifier-name</i> default) vlan-tag (inner outer);
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> classifiers]
Release Information	Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Access routers.
Description	For ACX Series Universal Access routers and EX Series switches, map the ieee-802.1p field of the incoming packet to the forwarding class and packet loss priority based on the specified 802.1p classifier. In the case of double tagged packets, you can configure whether to use the 802.1p of the outer or inner VLAN tag.
Options	<p>vlan-tag inner—In the case of double tagged packets, classify based on the 802.1p of the inner VLAN tag.</p> <p>vlan-tag outer—Classify based on the 802.1p of the outermost VLAN tag.</p> <p>classifier-name—Name of the previously defined ieee-802.1p behavior aggregate classifier.</p> <p>default—Default ieee-802.1p behavior aggregate classifier.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

ieee-802.1ad

Syntax	ieee-802.1ad (<i>rewrite-name</i> default) vlan-tag (outer outer-and-inner);
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced in Junos OS Release 9.2.
Description	Apply a IEEE-802.1ad rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules ieee-802.1ad] hierarchy level.</p> <p>default—The default rewrite bit mapping.</p> <p>vlan-tag—The rewrite rule is applied to the outer or outer-and-inner VLAN tag.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

import (Classifiers)

Syntax	<code>import (classifier-name default);</code>
Hierarchy Level	<code>[edit class-of-service classifiers type classifier-name]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify a default or previously defined classifier.
Options	<p>classifier-name—Name of the classifier mapping configured at the <code>[edit class-of-service classifiers]</code> hierarchy level.</p> <p>default—The default classifier mapping.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Overview of BA Classifier Types on page 1321

inet-precedence

Syntax	<code>inet-precedence (rewrite-name default);</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Apply a IPv4 precedence rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules inet-precedence] hierarchy level.</p> <p>default—The default mapping. By default, IP precedence rewrite rules alter the first three bits on the type of service (ToS) byte while leaving the last three bits unchanged.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

inet-precedence (Classifier on Physical Interface)

Syntax	<code>inet-precedence (<i>classifier-name</i> default);</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> classifiers]
Release Information	Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Access routers.
Description	On ACX Series Universal Access routers and EX Series switches, map the inet-precedence field of the incoming packet to the forwarding class and packet loss priority, based on the specified inet-precedence classifier. When no classifier is configured on the physical interface, the default ipprec-compatibility inet-precedence classifier is applied on the physical interface.
Options	<p><i>classifier-name</i>—Name of the previously defined inet-precedence behavior aggregate classifier.</p> <p>default—Default inet-precedence behavior aggregate classifier.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

Hierarchy Level [edit class-of-service]

Release Information Statement introduced before Junos OS Release 7.4.
Interface-set level added in Junos OS Release 8.5.

Description Configure interface-specific CoS properties for incoming packets.

NOTE: The `dscp-ipv6` and `ieee-802.1ad` classifier types are not supported on ACX Series routers. For further information about support on ACX Series routers, see *Understanding CoS CLI Configuration Statements on ACX Series Universal Access Routers*.

Options The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Defining Code-Point Aliases

- [Overview on page 1371](#)
- [Configuration on page 1375](#)

Overview

- [Code-Point Alias on page 1372](#)

Code-Point Alias

- [Default Code-Point Alias Overview on page 1372](#)
- [Default CoS Values on page 1372](#)

Default Code-Point Alias Overview

Behavior aggregate (BA) classifiers use class-of-service (CoS) values such as Differentiated Services code points (DSCPs), DSCP IPv6, IP precedence, IEEE 802.1 and MPLS experimental (EXP) bits to associate incoming packets with a particular CoS servicing level. On a Services Router or EX Series switch, you can assign a meaningful name or alias to the CoS values and use this alias instead of bits when configuring CoS components. These aliases are not part of the specifications but are well known through usage. For example, the alias for DSCP 101110 is widely accepted as **ef** (expedited forwarding).

NOTE: The code point aliases must begin with a letter and can be up to 64 characters long.

When you configure classes and define classifiers, you can refer to the markers by alias names. You can configure user-defined classifiers in terms of alias names. If the value of an alias changes, it alters the behavior of any classifier that references it.

To configure class-of-service (CoS) code point aliases, include the **code-point-aliases** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
code-point-aliases {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) {
    alias-name bits;
  }
}
```

Configuration

- [Configuration Task on page 1375](#)
- [Configuration Statements on page 1376](#)

Configuration Task

- [Defining Code Point Aliases for Bit Patterns on page 1375](#)

Defining Code Point Aliases for Bit Patterns

To define a code-point alias, include the **code-point-aliases** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
code-point-aliases {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) {
    alias-name bit-pattern;
  }
}
```

The CoS marker types are as follows:

- **dscp**—Handles incoming IPv4 packets.
- **dscp-ipv6**—Handles incoming IPv6 packets.
- **exp**—Handles MPLS packets using Layer 2 headers.
- **ieee-802.1**—Handles Layer 2 CoS.
- **inet-precedence**—Handles incoming IPv4 packets. IP precedence mapping requires only the upper three bits of the DSCP field.

For example, you might configure the following aliases:

```
[edit class-of-service]
code-point-aliases {
  dscp {
    my1 110001;
    my2 101110;
    be 000001;
    cs7 110000;
  }
}
```

This configuration produces the following mapping:

```
user@host> show class-of-service code-point-aliases dscp
Code point type: dscp

Alias           Bit pattern
ef/my2          101110
af11             001010
af12             001100
af13             001110
```

af21	010010
af22	010100
af23	010110
af31	011010
af32	011100
af33	011110
af41	100010
af42	100100
af43	100110
be	000001
cs1	001000
cs2	010000
cs3	011000
cs4	100000
cs5	101000
nc1/cs6/cs7	110000
nc2	111000
my1	110001

The following notes explain certain results in the mapping:

- **my1 110001:**
 - 110001 was not mapped to anything before, and **my1** is a new alias.
 - Nothing in the default mapping table is changed by this statement.
- **my2 101110:**
 - 101110 is now mapped to **my2** as well as **ef**.
- **be 000001:**
 - **be** is now mapped to 000001.
 - The old value of **be**, 000000, is not associated with any alias. Packets with this DSCP value are now mapped to the default forwarding class.
- **cs7 110000:**
 - **cs7** is now mapped to 110000, as well as **nc1** and **cs6**.
 - The old value of **cs7**, 111000, is still mapped to **nc2**.

Multifield Classifier Overview

A multifield classifier is a method of classifying traffic flows. Devices that sit at the edge of a network usually classify packets according to codings that are located in multiple packet header fields. Multifield classification is normally performed at the network edge because of the general lack of DiffServ code point (DSCP) or IP precedence support in end-user applications.

In an edge router, a multifield classifier provides the filtering functionality that scans through a variety of packet fields to determine the forwarding class for a packet. Typically, a classifier performs matching operations on the selected fields against a configured value.

Unlike a behavior aggregate (BA), which classifies packets based on class-of-service (CoS) bits in the packet header, a multifield classifier can examine multiple fields in the packet header—for example, the source and destination address of the packet, and the source and destination port numbers of the packet. A multifield classifier typically matches one or more of the six packet header fields: destination address, source address, IP protocol, source port, destination port, and DSCP. Multifield classifiers are used when a simple BA classifier is insufficient to classify a packet.

In the Juniper Networks® Junos® operating system (Junos OS), you configure a multifield classifier with a firewall filter and its associated match conditions. This enables you to use any filter match criteria to locate packets that require classification. From a CoS perspective, multifield classifiers (or firewall filter rules) provide the following services:

- Classify packets to a forwarding class and loss priority. The forwarding class determines the output queue. The loss priority is used by schedulers in conjunction with the random early discard (RED) algorithm to control packet discard during periods of congestion.
- Police traffic to a specific bandwidth and burst size. Packets exceeding the policer limits can be discarded, or can be assigned to a different forwarding class, to a different loss priority, or to both.

NOTE: You *police* traffic on input to conform to established CoS parameters, setting loss handling and forwarding class assignments as needed. You *shape* traffic on output to make sure that router resources, especially bandwidth, are distributed fairly. However, input policing and output shaping are two different CoS processes, each with their own configuration statements.

Overview of Simple Filters

Simple filters are recommended for metropolitan Ethernet applications. They are supported on Gigabit Ethernet intelligent queuing 2 (IQ2) and Enhanced Queuing Dense Port Concentrator (DPC) interfaces only.

Unlike normal filters, simple filters are for IPv4 traffic only and have the following restrictions:

- The **next term** action is not supported.
- Qualifiers, such as the **except** and **protocol-except** statements, are not supported.
- Noncontiguous masks are not supported.
- Multiple source addresses and destination addresses in a single term are not supported. If you configure multiple addresses, only the last one is used.
- Ranges are only valid as source or destination ports. For example, **source-port 400-500** or **destination-port 600-700**.
- Output filters are not supported. You can apply a simple filter to ingress traffic only.
- Simple filters are not supported for interfaces in an aggregated-Ethernet bundle.
- Explicitly configurable terminating actions, such as **accept**, **reject**, and **discard**, are not supported. Simple filters always accept packets.

NOTE: On the MX Series routers with the Enhanced Queuing DPC, the forwarding class is not supported as a **from** match condition.

Two-Color Policers and Shaping Rate Changes

When you configure a change in shaping rate, it is important to consider the effect on the bandwidth limit. Whenever the shaping rate changes, the bandwidth limit is adjusted based on whether a logical interface (unit) or bandwidth percentage policer is configured.

When a logical interface bandwidth policer is configured, the order of priority for the shaping rate (if configured at that level) is:

- The shaping rate applied to the logical interface (unit).
- The shaping rate applied to the physical interface (port).
- The physical interface speed.

When a bandwidth percentage policer is configured, the order of priority for the shaping rate (if configured at that level) is:

- The shaping rate applied to the physical interface (port).
- The physical interface speed.

These guidelines must be kept in mind when calculating the logical link speed and link speed from the configured shaping rate, which determines the rate-limited bandwidth after the policer is applied.

Understanding IEEE 802.1p Inheritance push and swap from a Transparent Tag

MX Series routers with Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) and M320 routers and EX Series switches support configurable IEEE 802.1p inheritance of push and swap bits from the transparent tag of each incoming packet which allows you to classify incoming packets based on the IEEE 802.1p bits from the transparent tag.

During a tagging operation, Junos OS by default inherits the IEEE 802.1p bits from incoming tags in swap and push operations from the known tags configured on the interface.

It can be useful to override the default behavior by configuring Junos OS to inherit the IEEE 802.1p bits from a transparent tag, and to classify incoming packets based on the IEEE 802.1p bits of the incoming transparent tag. The configuration statements **swap-by-poppush** and **transparent** enable Junos OS to do this.

By default, during a swap operation, the IEEE 802.1p bits of the VLAN tag remain unchanged. When the **swap-by-poppush** operation is enabled on a logical interface, the swap operation is treated as a **pop** operation followed by **push** operation. The **pop** operation removes the existing tag and the associated IEEE 802.1p bits and the push operation copies the inner VLAN IEEE 802.1p bits to the IEEE bits of the VLAN or VLANs being pushed. As a result, the IEEE 802.1p bits are inherited from the incoming transparent tag.

To classify incoming packets based on the IEEE 802.1p bits from the transparent tag, include the **transparent** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* classifiers ieee-802.1 vlan-tag]** hierarchy level.

To configure Junos OS to inherit the IEEE 802.1p bits from the transparent tag, include the **swap-by-poppush** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

NOTE: IEEE 802.1p Inheritance push and swap is only supported on untagged and single-tagged logical interfaces, and is not supported on dual-tagged logical interfaces.

Configuring Multifield Classifiers

If you configure both a behavior aggregate (BA) classifier and a multifield classifier, BA classification is performed first; then multifield classification is performed. If they conflict, any BA classification result is overridden by the multifield classifier.

NOTE: For a specified interface, you can configure both a multifield classifier and a BA classifier without conflicts. Because the classifiers are always applied in sequential order, the BA classifier followed by the multifield classifier, any BA classification result is overridden by a multifield classifier if they conflict.

To activate a multifield classifier, you must configure it on a logical interface. There is no restriction on the number of multifield classifiers you can configure.

NOTE: For MX Series routers and EX Series switches, if you configure a firewall filter with a DSCP action or traffic-class action on a DPC, the commit does not fail, but a warning displays and an entry is made in the syslog.

For an L2TP LNS on MX Series routers, you can attach firewall for static LNS sessions by configuring these at logical interfaces directly on the inline services device (si-fpc/pic/port). RADIUS-configured firewall attachments are not supported.

To configure multifield classifiers, include the following statements at the **[edit firewall]** hierarchy level:

```
[edit firewall]
family family-name {
  filter filter-name {
    term term-name {
      from {
```

```

        match-conditions;
    }
    then {
        dscp 0;
        forwarding-class class-name;
        loss-priority (high | low);
    }
}
}
simple-filter filter-name {
    term term-name {
        from {
            match-conditions;
        }
        then {
            forwarding-class class-name;
            loss-priority (high | low | medium);
        }
    }
}
}
}

```

Configuring Logical Bandwidth Policers

When you configure a policer as a percentage (using the **bandwidth-percent** statement), the bandwidth is calculated as a percentage of either the physical interface media rate or the logical interface shaping rate. To specify that the bandwidth be calculated based on the logical interface shaping rate and not the physical interface media rate, include the **logical-bandwidth-policer** statement. If a shaping rate is not configured for the logical interface, the physical interface media rate is used, even if you include the **logical-bandwidth-policer**. You can configure the shaping rate on the logical interface using class-of-service statements.

```

[edit firewall policer policer-name]
logical-bandwidth-policer;

```

Configuring IEEE 802.1p Inheritance push and swap from the Transparent Tag

To classify incoming packets based on the IEEE 802.1p bits from the transparent tag, include the **transparent** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number classifiers ieee-802.1 vlan-tag]** hierarchy level.

Tagged Interface Example

The following example configuration specifies the classification based on the transparent VLAN tag.

```

edit
class-of-service {
    interfaces {
        ge-3/0/1 {
            unit 0 {
                classifiers {
                    ieee-802.1 default vlan-tag transparent;
                }
            }
        }
    }
}

```

```
}
```

To configure Junos OS to inherit the IEEE 802.1p bits from the transparent tag, include the **swap-by-poppush** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

The following is a configuration to swap and push VLAN tags and allow inheritance of the IEEE 802.1p value from the transparent VLAN tag in incoming packets.

```
edit
ge-3/0/0 {
  vlan-tagging;
  encapsulation vlan-ccc;
  unit 0 {
    encapsulation vlan-ccc;
    vlan-id 100;
    swap-by-poppush;
    input-vlan-map {
      swap-push;
      tag-protocol-id 0x9100;
      inner-tag-protocol-id 0x9100;
      vlan-id 500;
      inner-vlan-id 400;
    }
    output-vlan-map {
      pop-swap;
      inner-vlan-id 100;
      inner-tag-protocol-id 0x88a8;
    }
  }
}
```

The **swap-by-poppush** statement causes a swap operation to be done as a pop followed by a push operation. So for the outer tag, the incoming S-Tag is popped and a new tag is pushed. As a result, the S-Tag inherits the IEEE 802.1p bits from the transparent tag. The inner tag is then pushed, which results in the inner tag inheriting the IEEE 802.1p bits from the transparent tag.

Untagged Interface Example

The following is a configuration to push two VLAN tags and allow inheritance of the IEEE 802.1p value from the transparent VLAN tag in the incoming packet.

```
[edit]
ge-3/0/1 {
  encapsulation ccc;
  unit 0 {
    input-vlan-map {
      push-push;
      tag-protocol-id 0x9100;
      inner-tag-protocol-id 0x9100;
      vlan-id 500;
      inner-vlan-id 400;
    }
    output-vlan-map {
      pop-pop;
    }
  }
}
```

```
}
```

No additional configuration is required to inherit the IEEE 802.1p value, as the **push** operation inherits the IEEE 802.1p values by default.

The following configuration specifies the classification based on the transparent VLAN tag.

```
[edit]
class-of-service {
  interfaces {
    ge-3/0/1 {
      unit 0 {
        classifiers {
          ieee-802.1 default vlan-tag transparent;
        }
      }
    }
  }
}
```

Example: Classifying Packets Based on Their Destination Address

Configure a multifield classifier that ensures that all IPv4 packets destined for the **10.10.10.0/24** network are placed into the **platinum** forwarding class. This assignment occurs regardless of the received CoS bit values in the packet. Apply this filter to the inbound interface **ge-1/2/2.0**.

To verify that your configuration is attached to the correct interface, issue the **show interfaces filters** command.

```
[edit]
firewall {
```

```
family inet {
  filter set-FC-to-platinum {
    term match-a-single-route {
      from {
        destination-address {
          10.10.10.0/24;
        }
      }
      then {
        forwarding-class platinum;
        accept;
      }
    }
    term accept-all {
      then accept;
    }
  }
}
interfaces {
  ge-1/2/2 {
    unit 0 {
      family inet {
        filter {
          input set-FC-to-platinum;
        }
      }
    }
  }
}
```

Example: Configuring and Verifying a Complex Multifield Filter

In this example, SIP signaling (VoIP) messages use TCP/UDP, port 5060, and RTP media channels use UDP with port assignments from 16,384 through 32,767. See the following sections:

- [Configuring a Complex Multifield Filter on page 1394](#)
- [Verifying a Complex Multifield Filter on page 1396](#)

Configuring a Complex Multifield Filter

To configure the multifield filter, perform the following actions:

- Classify SIP signaling messages (VoIP network control traffic) as NC with a firewall filter.
- Classify VoIP traffic as EF with the same firewall filter.
- Police all remaining traffic with IP precedence 0 and make it BE.
- Police BE traffic to 1 Mbps with excess data marked with PLP high.
- Apply the firewall filter with policer to the interface.

The firewall filter called **classify** matches on the transport protocol and ports identified in the incoming packets and classifies packets into the forwarding classes specified by your criteria.

The first term, **sip**, classifies SIP signaling messages as network control messages. The **port** statement matches any source port or destination port (or both) that is coded to 5060.

Classifying SIP Signaling Messages

```

firewall {
  family inet {
    filter classify {
      interface-specific;
      term sip {
        from {
          protocol [ udp tcp ];
          port 5060;
        }
        then {
          forwarding-class network-control;
          accept;
        }
      }
    }
  }
}

```

The second term, **rtp**, classifies VoIP media channels that use UDP-based transport.

Classifying VoIP Channels That Use UDP

```

term rtp {
  from {
    protocol udp;
    port 16384-32767;
  }
  then {
    forwarding-class expedited-forwarding;
    accept;
  }
}

```

The policer's burst tolerance is set to the recommended value for a low-speed interface, which is ten times the interface MTU. For a high-speed interface, the recommended burst size is the transmit rate of the interface times 3 to 5 milliseconds.

Configuring the Policer

```

policer be-policer {
  if-exceeding {
    bandwidth-limit 1m;
    burst-size-limit 15k;
  }
  then loss-priority high;
}

```

The third term, **be**, ensures that all remaining traffic is policed according to a bandwidth restriction.

Policing All Remaining Traffic

```
term be {
  then policer be-policer;
}
```

The **be** term does not include a **forwarding-class** action modifier. Furthermore, there is no explicit treatment of network control (NC) traffic provided in the **classify** filter. You can configure explicit classification of NC traffic and all remaining IP traffic, but you do not need to, because the default IP precedence classifier correctly classifies the remaining traffic.

Apply the **classify** classifier to the **fe-0/0/2** interface:

Applying the Classifier

```
interfaces {
  fe-0/0/2 {
    unit 0 {
      family inet {
        filter {
          input classify;
        }
        address 10.12.0.13/30;
      }
    }
  }
}
```

Verifying a Complex Multifield Filter

Before the configuration is committed, display the default classifiers in effect on the interface using the **show class-of-service interface interface-name** command. The display confirms that the **ipprec-compatibility** classifier is in effect by default.

Verifying Default Classification

```
user@host> show class-of-service fe-0/0/2
Physical interface: fe-0/0/2, Index: 135
Queues supported: 8, Queues in use: 4
Scheduler map: <default>, Index: 2032638653
```

```
Logical interface: fe-0/0/2.0, Index: 68
Shaping rate: 32000
Object      Name                                Type      Index
Scheduler-map <default>                               27
Rewrite     exp-default                             exp       21
Classifier   exp-default                             exp        5
Classifier   ipprec-compatibility                     ip         8
```

To view the default classifier mappings, use the **show class-of-service classifier name name** command. The highlighted output confirms that traffic with IP precedence setting of 0 is correctly classified as BE, and NC traffic, with precedence values of 6 or 7, is properly classified as NC.

Displaying Default Classifier Mappings

```

user@host> show class-of-service classifier name ipprec-compatibility
Classifier: ipprec-compatibility, Code point type: inet-precedence, Index: 12
  Code point      Forwarding class      Loss priority
  ---
  000             best-effort          low
  001             best-effort          high
  010             best-effort          low
  011             best-effort          high
  100             best-effort          low
  101             best-effort          high
  110             network-control    low
  111             network-control    high

```

After your configuration is committed, verify that your multifield classifier is working correctly. You can monitor the queue counters for the routing device's **egress** interface used when forwarding traffic received from the peer. Displaying the queue counters for the ingress interface (**fe-0/0/2**) does not allow you to check your ingress classification, because queuing generally occurs only at egress in the Junos OS. (Ingress queuing is supported on Gigabit Ethernet IQ2 PICs and Enhanced IQ2 PICs only.)

To verify the operation of the multifield filter:

1. To determine which egress interface is used for the traffic, use the **traceroute** command.
2. After you identify the egress interface, clear its associated queue counters by issuing the **clear interfaces statistics interface-name** command.
3. Confirm the default forwarding class-to-queue number assignment. This allows you to predict which queues are used by the VoIP, NC, and other traffic. To do this, issue the **show class-of-service forwarding-class** command.
4. Display the queue counts on the interface by issuing the **show interfaces queue** command.

Example: Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets

On Juniper Networks M320 Multiservice Edge Routers and T Series Core Routers and on EX Series switches, you can selectively set the DSCP field of MPLS-tagged IPv4 and IPv6 packets to **000000**. In the same packets, you can set the MPLS EXP field according to a configured rewrite table, which is based on the forwarding classes that you set in incoming packets using a BA or multifield classifier.

Queue selection is based on the forwarding classes you assign in scheduler maps. This means that you can direct traffic to a single output queue, regardless of whether the DSCP field is unchanged or rewritten to **000000**. To do this, you must configure a multifield classifier that matches selected packets and modifies them with the **dscp 0** action.

Selective marking of DSCP fields to **0**, without affecting output queue assignment, can be useful. For example, suppose you need to use the MPLS EXP value to configure CoS applications for core provider routing devices. At the penultimate egress provider edge (PE) router where the MPLS labels are removed, the CoS bits need to be provided by another value, such as DSCP code points. This case illustrates why it is useful to mark both the DSCP and MPLS EXP fields in the packet. Furthermore, it is useful to be able to

mark the two fields differently, because the CoS rules of the core provider routing device might differ from the CoS rules of the egress penultimate router. At egress, as always, you can use a rewrite table to rewrite the MPLS EXP values corresponding to the forwarding classes that you need to set.

NOTE: When both customer-facing and core-facing interfaces exist, you can derive the EXP value in the following precedence order, while adding the MPLS label:

1. EXP value provided by the CoS rewrite action.
2. EXP value derived from the top label of the stack (MPLS label stacking).
3. IPv4 or IPv6 precedence (Layer 3 VPN, Layer 2 VPN, and VPLS scenarios).

For IPv4 traffic, the **dscp 0** action modifier at the **[edit firewall family inet filter *filter-name* term *term-name* then]** hierarchy level is valid. However, for IPv6 traffic, you configure this feature by including the **traffic-class 0** action modifier at the **[edit firewall family inet6 filter *filter-name* term *term-name* then]** hierarchy level.

In the following IPv4 example, term 1 of the multifield classifier matches packets with DSCP **001100** code points coming from a certain VRF, rewrites the bits to DSCP **000000**, and sets the forwarding class to **best-effort**. In term 2, the classifier matches packets with DSCP **010110** code points and sets the forwarding class to **best-effort**. Because term 2 does not include the **dscp 0** action modifier, the DSCP **010110** bits remain unchanged. Because the classifier sets the forwarding class for both code points to **best-effort**, both traffic types are directed to the same output queue.

NOTE: If you configure a bit string in a DSCP match condition in a firewall filter, then you must include the letter “b” in front of the string, or the match rule creation fails on commit.

```
[edit]
firewall {
  family inet {
    filter vrf-rewrite {
      term 1 {
        from {
          dscp b001100;
        }
        then {
          dscp 0;
          forwarding-class best-effort;
        }
      }
      term 2 {
        from {
          dscp b010110;
        }
        then {
```

```

        forwarding-class best-effort;
    }
}
}
}
}

```

Applying the Multifield Classifier

Apply the filter to an input interface corresponding to the VRF:

```

[edit]
interfaces {
  ge-0/1/0 {
    unit 0 {
      family inet {
        filter input vrf-rewrite;
      }
    }
  }
}

```

NOTE: The `dscp 0` action is supported in both input and output filters. You can use this action for non-MPLS packets as well as for IPv4 and IPv6 packets entering an MPLS network. All IPv4 and IPv6 firewall filter match conditions are supported with the `dscp 0` action.

The following limitations apply:

- You can use a multifield classifier to rewrite DSCP fields to value 0 only. Other values are not supported.
- If a packet matches a filter that has the `dscp 0` action, then the outgoing DSCP value of the packet is 0, even if the packet matches a rewrite rule, and the rewrite rule is configured to mark the packet to a non-zero value. The `dscp 0` action overrides any other rewrite rule actions configured on the routing device.
- Although you can use the `dscp 0` action on an input filter, the output filter and other classifiers do not see the packet as being marked `dscp 0`. Instead, they classify the packet based on its original incoming DSCP value. The DSCP value of the packet is set to 0 after all other classification actions have completed on the packet.

Example: Configuring a Simple Filter

This simple filter sets the loss priority to low for TCP traffic with source address 1.1.1.1, sets the loss priority to high for HTTP (web) traffic with source addresses in the 4.0.0.0/8 range, and sets the loss priority to low for all traffic with destination address 6.6.6.6. The simple filter is applied as an input filter (arriving packets are checking for destination address 6.6.6.6, not queued output packets) on interface `ge-0/0/1.0`.

```

[edit]
firewall {
  family inet {

```

```
simple-filter filter1 {
  term 1 {
    from {
      source-address {
        1.1.1.1/32;
      }
      protocol {
        tcp;
      }
    }
    then loss-priority low;
  }
  term 2 {
    from {
      source-address {
        4.0.0.0/8;
      }
      source-port {
        http;
      }
    }
    then loss-priority high;
  }
  term 3 {
    from {
      destination-address {
        6.6.6.6/32;
      }
    }
    then {
      loss-priority low;
      forwarding-class best-effort;
    }
  }
}

interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        simple-filter {
          input filter1;
        }
        address 10.1.2.3/30;
      }
    }
  }
}
```

Example: Configuring a Logical Bandwidth Policer

This example applies a logical bandwidth policer rate to two logical interfaces on interface **ge-0/2/7**. The policed rate on **unit 0** is 2 Mbps (50 percent of 4 Mbps) and the policed rate on **unit 1** is 1 Mbps (50 percent of 2 Mbps).

```

[edit firewall]
policer Logical_Policer {
  logical-bandwidth-policer; # This applies the policer to logical interfaces
  if-exceeding {
    bandwidth-percent 50; # This applies 50 percent to the shaping-rate
    burst-size-limit 125k;
  }
  then discard;
}

[edit class-of-service]
interfaces {
  ge-0/2/7 {
    unit 0 {
      shaping-rate 4m # This establishes the rate to be policed on unit 0
    }
    unit 1 {
      shaping-rate 2m # This establishes the rate to be policed on unit 1
    }
  }
}
[edit interfaces ge-0/2/7]
per-unit-scheduler;
vlan-tagging;
unit 0 {
  vlan-id 100;
  family inet {
    policer {
      input Logical_Policer;
      output Logical_Policer;
    }
    address 172.1.1.1/30;
  }
}
unit 1 {
  vlan-id 200;
  family inet {
    policer {
      input Logical_Policer;
      output Logical_Policer;
    }
    address 172.2.1.1/30;
  }
}

```

Example: Two-Color Policers and Shaping Rate Changes

In this example, the shaping rate has been configured for the logical interface, but a bandwidth percentage policer is also configured. Therefore policing is based on the physical interface speed of 1 Gbps.

If both a shaping rate and a bandwidth percentage policer is configured on the same logical interface, the policing is based on the physical interface speed. Here is the example configuration:

```

[edit interfaces]

```

```
ge-0/1/0 {
  per-unit-scheduler;
  vlan-tagging;
  unit 0 {
    vlan-id 1;
    family inet {
      policer {
        output policer_test;
      }
      address 10.0.7.1/24;
    }
  }
}
```

```
[edit firewall]
policer policer_test {
  if-exceeding {
    bandwidth-percent 75;
    burst-size-limit 256k;
  }
  then discard;
}
```

```
[edit]
class-of-service {
  interfaces {
    ge-0/1/0 {
      unit 0 {
        shaping-rate 15m;
      }
    }
  }
}
```

[edit firewall] Hierarchy Level

Several statements in the **[edit firewall]** hierarchy are valid at numerous locations within the hierarchy. To make the complete hierarchy easier to read, the repeated statements are listed in the following sections, which are referenced at the appropriate locations in “Complete **[edit firewall]** Hierarchy” on page 325.

- [Common Firewall Actions on page 1407](#)
- [Common IP Firewall Actions on page 1407](#)
- [Common IPv4 Firewall Actions on page 1408](#)

- [Common IP Firewall Match Conditions on page 1408](#)
- [Common IPv4 Firewall Match Conditions on page 1409](#)
- [Common Layer 2 Firewall Match Conditions on page 1409](#)
- [Complete \[edit firewall\] Hierarchy on page 1411](#)

Common Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- **[edit firewall family (any | ccc | ethernet-switching | inet | inet6 | mpls | vpls) filter *filter-name* term *term-name* then]**
- **[edit firewall filter *filter-name* term *term-name* then]**

The common firewall actions are as follows:

```
count counter-name;
forwarding-class class-name;
loss-priority (high | low | medium-high | medium-low);
next term;
policer policer-name;
three-color-policer policer-name {
    (single-rate single-rate-policer-name | two-rate two-rate-policer-name);
}
```

Common IP Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- **[edit firewall family inet filter *filter-name* term *term-name* then]**
- **[edit firewall family inet6 filter *filter-name* term *term-name* then]**
- **[edit firewall filter *filter-name* term *term-name* then]**

The common IP firewall actions are as follows:

```
log;
logical-system logical-system-name <routing-instance routing-instance-name>
    <topology topology-name>;
port-mirror;
port-mirror-instance instance-name;
routing-instance routing-instance-name <topology topology-name>;
sample;
service-filter-hit;
syslog;
topology topology-name;
```

Common IPv4 Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common IP version 4 (IPv4) firewall actions are as follows:

```
(accept | discard <accounting collector-name> | reject <administratively-prohibited |
  bad-host-tos | bad-network-tos | fragmentation-needed | host-prohibited |
  host-unknown | host-unreachable | network-prohibited | network-unknown |
  network-unreachable | port-unreachable | precedence-cutoff | precedence-violation |
  protocol-unreachable | source-host-isolated | source-route-failed | tcp-reset>);
ipsec-sa sa-name;
load-balance sa-name;
next-hop-group group-name;
prefix-action action-name;
```

Common IP Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet dialer-filter *filter-name* term *term-name* from] (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- [edit firewall family inet filter *filter-name* term *term-name* from]
- [edit firewall family inet6 dialer-filter *filter-name* term *term-name* from] (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- [edit firewall family inet6 filter *filter-name* term *term-name* from]
- [edit firewall filter *filter-name* term *term-name* from]

The common IP firewall match conditions are as follows:

```
address {
  ip-prefix</prefix-length> <except>;
}
destination-address {
  ip-prefix</prefix-length> <except>;
}
destination-class [ class-names ] | destination-class-except [ class-names ];
(destination-port [ port-names ] | destination-port-except [ port-names ]);
destination-prefix-list {
  list-name <except>;
}
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);
icmp-code [ codes ] | icmp-code-except [ codes ];
icmp-type [ types ] | icmp-type-except [ types ];
interface interface-name;
```

```

(interface-group [ group-names ] | interface-group-except [ group-names ]);
interface-set set-name;
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(packet-length [ values ] | packet-length-except [ values ]);
(port [ port-names ] | port-except [ port-names ]);
prefix-list {
    list-name <except>;
}
service-filter-hit;
source-address {
    ip-prefix/prefix-length> <except>;
}
(source-class [ class-names ] | source-class-except [ class-names ]);
(source-port [ port-names ] | source-port-except [ port-names ]);
source-prefix-list {
    list-name <except>;
}
tcp-established;
tcp-flags flag;
tcp-initial;

```

Common IPv4 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- [edit firewall family inet dialer-filter *filter-name* term *term-name* from] (with the exceptions noted at this level in “[Complete \[edit firewall\] Hierarchy](#)” on page 325)
- [edit firewall family inet filter *filter-name* term *term-name* from]
- [edit firewall filter *filter-name* term *term-name* from]

The common IPv4 firewall match conditions are as follows:

```

(ah-spi [ values ] | ah-spi-except [ values ]);
(dscp [ code-point-values ] | dscp-except [ code-point-values ]);
(esp-spi [ values ] | esp-spi-except [ values ]);
first-fragment;
fragment-flags flag;
(fragment-offset [ offsets ] | fragment-offset-except [ offsets ]);
(ip-options [ option-names ] | ip-options-except [ option-names ]);
is-fragment;
(precedence [ precedence-names ] | precedence-except [ precedence-names ]);
(protocol [ protocol-names ] | protocol-except [ protocol-names ]);
(ttl [ ttl-values ] | ttl-except [ ttl-values ]);

```

Common Layer 2 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- [edit firewall family ethernet-switching filter *filter-name* term *term-name* from]
- [edit firewall family vpls filter *filter-name* term *term-name* from]

The common Layer 2 firewall match conditions are as follows:

```
destination-mac-address {
    mac-address <except>;
}
(destination-port [ port-names ] | destination-port-except [ port-names ]);
(dscp [ code-point-values ] | dscp-except [ code-point-values ]);
(ether-type [ protocol-types ] | ether-type-except [ protocol-types ]);
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);
icmp-code [ codes ] | icmp-code-except [ codes ];
icmp-type [ types ] | icmp-type-except [ types ];
(interface-group [ group-names ] | interface-group-except [ group-names ]);
ip-address {
    ip-prefix</prefix-length> <except>;
}
ip-destination-address {
    ip-prefix</prefix-length> <except>;
}
(ip-precedence [ precedence-names ] | ip-precedence-except [ precedence-names ]);
(ip-protocol [ protocol-names ] | ip-protocol-except [ protocol-names ]);
ip-source-address ip-prefix</prefix-length>;
(learn-vlan-lp-priority [ priorities ] | learn-vlan-lp-priority [ priorities ]);
(learn-vlan-id [ vlan-ids ] | learn-vlan-id-except [ vlan-ids ]);
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(port [ port-names ] | port-except [ port-names ]);
source-mac-address {
    mac-address <except>;
}
(source-port [ port-names ] | source-port-except [ port-names ]);
tcp-flags flag;
(traffic-type [ broadcast known-unicast multicast unknown-unicast ] |
    traffic-type-except [ broadcast known-unicast multicast unknown-unicast ]);
(user-vlan-lp-priority [ priorities ] | user-vlan-lp-priority [ priorities ]);
(user-vlan-id [ vlan-ids ] | user-vlan-id-except [ vlan-ids ]);
(vlan-ether-type [ protocol-types ] | vlan-ether-type-except [ protocol-types ]);
```

Complete [edit firewall] Hierarchy

dscp (Multifield Classifier)

Syntax	<code>dscp [0 <i>value</i>];</code>
Hierarchy Level	<code>[edit firewall family <i>family-name</i> filter <i>filter-name</i> term <i>term-name</i> then]</code>
Release Information	Statement introduced in Junos OS Release 7.4.
Description	<p>For M320 and T Series routers, set the DSCP field of incoming or outgoing packets to 000000. On the same packets, you can use a behavior aggregate (BA) classifier and a rewrite rule to rewrite the MPLS EXP field.</p> <p>For MX Series routers with MPCs and EX Series switches, the DSCP field can be set from a numeric range.</p> <p>For MX Series routers and EX Series switches, if you configure a firewall filter with a DSCP action or traffic-class action on a DPC, the commit does not fail, but the filter is not applied to the interface, a warning displays, and an entry is made in the syslog.</p>
Options	value —For MX Series routers with MPCs and EX Series switches, specify the field of incoming or outgoing packets in the range from 0 through 63 .
Required Privilege Level	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>

            }
        }
    }
```

Hierarchy Level [edit [firewall](#)]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure a firewall filter for IP version 4 (IPv4) or IP version 6 (IPv6) traffic.

Options *family-name*—Protocol family:

- **ccc**—Circuit cross-connect parameters
- **inet**—IPv4 parameters
- **inet6**—IPv6 protocol parameters
- **iso**—OSI ISO protocol parameters
- **mpls**—MPLS protocol parameters
- **tcc**—Translational cross-connect parameters
- **vpls**—Virtual private LAN service parameters.

The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

filter (Configuring)

Syntax	<pre>filter <i>filter-name</i> { accounting-profile <i>name</i>; enhanced-mode; interface-shared; interface-specific; physical-interface-filter; term <i>term-name</i> { filter <i>filter-name</i>; from { match-conditions; } then { actions; } } }</pre>
Hierarchy Level	[edit dynamic-profiles <i>profile-name</i> firewall family <i>family-name</i>], [edit firewall family <i>family-name</i>], [edit logical-systems <i>logical-system-name</i> firewall family <i>family-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Logical systems support introduced in Junos OS Release 9.3. physical-interface-filter statement introduced in Junos OS Release 9.6. Support at the [edit dynamic-profiles ... family <i>family-name</i>] hierarchy level introduced in Junos OS Release 11.4. Support for the interface-shared > statement introduced in Junos OS Release 12.2. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure firewall filters.
Options	<p><i>filter-name</i>—Name that identifies the filter. This must be a non-reserved string of not more than 64 characters. To include spaces in the name, enclose it in quotation marks (" "). In Junos OS Release 9.0 and later, you can no longer use special characters within the name of a firewall filter. Firewall filter names are restricted from having the form _.* (beginning and ending with underscores) or _.* (beginning with an underscore).</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	firewall —To view this statement in the configuration. firewall-control —To add this statement to the configuration.

forwarding-class (Multifield Classifiers)

Syntax	<code>forwarding-class <i>class-name</i>;</code>
Hierarchy Level	<code>[edit firewall family <i>family-name</i> filter <i>filter-name</i> term <i>term-name</i> then]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Set the forwarding class of incoming packets.
Options	<i>class-name</i> —Name of the forwarding class.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	• Configuring Multifield Classifiers on page 1390

from

Syntax	<code>from { applications [<i>application-name</i>]; application-sets [<i>set-name</i>]; destination-address (CoS) <i>address</i>; source-address <i>address</i>; }</code>
Hierarchy Level	<code>[edit services cos rule <i>rule-name</i> term <i>term-name</i>]</code>
Release Information	Statement introduced in Junos OS Release 8.1.
Description	Specify input conditions for a CoS term.
Options	The remaining statements are explained separately.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	• Configuring CoS Rule Sets

loss-priority (Normal Filter)

Syntax	loss-priority (high low);
Hierarchy Level	[edit firewall family <i>family-name</i> filter <i>filter-name</i> term <i>term-name</i> then]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Set the loss priority of incoming packets.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Multifield Classifiers on page 1390

loss-priority (Simple Filter)

Syntax	loss-priority (high low medium);
Hierarchy Level	[edit firewall family <i>family-name</i> simple-filter <i>filter-name</i> term <i>term-name</i> then]
Release Information	Statement introduced in Junos OS Release 7.6.
Description	Set the loss priority of incoming packets.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Multifield Classifiers on page 1390

simple-filter (Configuring)

Syntax	<pre> simple-filter <i>filter-name</i> { term <i>term-name</i> { from { match-conditions; } then { forwarding-class <i>class-name</i>; loss-priority (high low medium); } } } </pre>
Hierarchy Level	[edit firewall family inet filter <i>filter-name</i>]
Release Information	Statement introduced in Junos OS Release 7.6.
Description	Define a simple filter. Simple filters are recommended for metropolitan Ethernet applications.
Options	<p>from—Match packet fields to values. If the from option is not included, all packets are considered to match and the actions and action modifiers in the then statement are taken.</p> <p>match-conditions—One or more conditions to use to make a match.</p> <p>term-name—Name that identifies the term. The name can contain letters, numbers, and hyphens (-), and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" ").</p> <p>then—Actions to take on matching packets. If the then option is not included and a packet matches all the conditions in the from statement, the packet is accepted.</p> <p>The remaining statements are explained separately. Only forwarding-class and loss-priority are valid in a simple filter configuration.</p>
Required Privilege Level	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>

Traffic Policing Overview

This topic covers the following information:

- [Congestion Management for IP Traffic Flows on page 1441](#)
- [Traffic Limits on page 1441](#)
- [Traffic Color Marking on page 1442](#)

- [Forwarding Classes and PLP Levels on page 1443](#)
- [Policer Application to Traffic on page 1444](#)

Congestion Management for IP Traffic Flows

Traffic policing, also known *rate limiting*, is an essential component of network access security that is designed to thwart denial-of-service (DoS) attacks. Traffic policing enables you to control the maximum rate of IP traffic sent or received on an interface and also to partition network traffic into multiple priority levels, also known as *classes of service*. A policer defines a set of traffic rate limits and sets consequences for traffic that does not conform to the configured limits. Packets in a traffic flow that does not conform to traffic limits are either discarded or marked with a different forwarding class or packet loss priority (PLP) level.

With the exception of policers configured to rate-limit aggregate traffic (all protocol families and logical interfaces configured on a physical interface), you can apply a policer to all IP packets in a Layer 2 or Layer 3 traffic flow at a logical interface.

With the exception of policers configured to rate-limit based on physical interface media rate, you can apply a policer to specific IP packets in a Layer 3 traffic flow at a logical interface by using a stateless firewall filter.

You can apply a policer to inbound or outbound interface traffic. Policers applied to inbound traffic help to conserve resources by dropping traffic that does not need to be routed through a network. Dropping inbound traffic also helps to thwart denial-of-service (DoS) attacks. Policers applied to outbound traffic control the bandwidth used.

NOTE: Traffic policers are instantiated on a per-PIC basis. Traffic policing does not work when the traffic for one local policy decision function (L-PDF) subscriber is distributed over multiple Multiservices PICs in an AMS group.

Traffic Limits

Junos[®] OS policers use the *token-bucket* algorithm to enforce a limit on average transmit or receive rate of IP traffic at an interface while allowing bursts of traffic up to a maximum value based on the overall traffic load. The token-bucket algorithm offers more flexibility than the *leaky-bucket* algorithm in that you can allow a specified amount of bursting before starting to discard packets or apply a penalty to packet output-queuing priority or packet drop priority.

In the token-bucket model, the bucket represents the policing function. Tokens are added to the bucket at a fixed rate, but only up to the specified depth of the bucket. Each token represents a “credit” for some number of bits, and tokens in the bucket are “cached in” for the ability to transmit or receive traffic at the interface. When sufficient tokens are present in the bucket, a traffic flow continues unrestricted. Otherwise, packets might be dropped or else re-marked with a lower forwarding class, a higher packet loss priority (PLP) level, or both.

- The rate at which tokens are added to the bucket represents the highest average transmit or receive rate in bits per second allowed for a given service level. You specify

this highest average traffic rate as the *bandwidth limit* of the policer. If the traffic arrival rate is so high that at some point insufficient tokens are present in the bucket, then the traffic flow is no longer conforming to the traffic limit.

- The depth of the bucket in bytes controls the amount of back-to-back bursting allowed. You specify this factor as the *burst-size limit* of the policer. This second limit affects the average transmit or receive rate by limiting the number of bytes permitted in a transmission burst for a given interval of time. Bursts exceeding the current burst-size limit are dropped until there are sufficient tokens available to permit the burst to proceed.

Figure 9: Network Traffic and Burst Rates

As shown in the figure above, a UPC bar code is a good facsimile of what traffic looks like on the line; an interface is either transmitting (bursting at full rate) or it is not. The black lines represent periods of data transmission and the white space represents periods of silence when the token bucket can replenish.

Depending on the type of policer used, packets in a policed traffic flow that surpasses the defined limits might be implicitly set to a higher PLP level, assigned to a configured forwarding class or set to a configured PLP level (or both), or simply discarded. If packets encounter downstream congestion, packets with a **low** PLP level are less likely to be discarded than those with a **medium-low**, **medium-high**, or **high** PLP level.

Traffic Color Marking

Based on the particular set of traffic limits configured, a policer identifies a traffic flow as belonging to one of either two or three categories that are similar to the colors of a traffic light used to control automobile traffic.

A *two-color-marking* policer categorizes traffic as either conforming to the traffic limits (green) or violating the traffic limits (red):

- **Green**—Two-color-marking policers implicitly set the packets in a green flow to the low PLP level, and you cannot configure any policer actions for conforming traffic.
- **Red**—Two-color-marking policers do not perform any implicit actions on packets in a red flow. Instead, those packets are handled according to the actions specified in the policer configuration. You can configure a two-color-marking policer to simply discard packets if the traffic flow is red. Alternatively, you can configure a two-color-marking policer to handle the packets in a red flow by setting the PLP level to either **low** or **high**, assigning the packets to any forwarding class already configured, or both.

On MX Series, M120, and M320 routers and M7i and M10i routers with the Enhanced CFEB (CFEB-E) and EX Series switches only, you can specify two additional PLP levels for packets in a red flow: **medium-low** or **medium-high**.

Three-color-marking policers categorize traffic as conforming to the traffic limits (green), violating the traffic limits (red), or exceeding the traffic limits but within an allowed range (yellow):

- **Green**—Like two-color-marking policers, three-color-marking policers implicitly set the packets in a green flow to the low PLP level, and you cannot configure any policer actions for conforming traffic.
- **Yellow**—Unlike two-color-marking policers, three-color-marking policers categorize a second type of nonconforming traffic: yellow.

Single-rate three-color policing categorizes as yellow traffic that exceeds the traffic limits while conforming to a second defined burst-size limit. Two-rate three-color policing categorizes as yellow traffic that exceeds the traffic limits while conforming to both a second defined burst-size limit and a second defined bandwidth limit.

Three-color-marking policers implicitly set the packets in a yellow flow to the medium-high PLP level so that the packets incur a less severe penalty than those in a red flow. You cannot configure any policer actions for yellow traffic.

- **Red**—Unlike two-color-marking policers, three-color-marking policers implicitly set the packets in a red flow to the high PLP level, which is the highest PLP value. You can also configure a three-color-marking policer to discard the packets in a red flow instead of forwarding them with a high PLP setting.

Two-color-marking policers allows bursts of traffic for short periods, whereas three-color-marking policers allow more sustained bursts of traffic.

Forwarding Classes and PLP Levels

A packet's forwarding class assignment and PLP level are used by the Junos OS class of service (CoS) features. The Junos CoS features include a set of mechanisms that you can use to provide differentiated services when best-effort traffic delivery is insufficient. For router (and switch) interfaces that carry IPv4, IPv6, and MPLS traffic, you can configure CoS features to take in a single flow of traffic entering at the edge of your network and provide different levels of service across the network—internal forwarding and scheduling (queuing) for output—based on the forwarding class assignments and PLP levels of the individual packets.

NOTE: Forwarding-class or loss-priority assignments performed by a policer or a stateless firewall filter override any such assignments performed on the ingress by the CoS default IP precedence classification at all logical interfaces or by any configured behavior aggregate (BA) classifier that is explicitly mapped to a logical interface.

Based on CoS configurations, packets of a given forwarding class are transmitted through a specific output queue, and each output queue is associated with a transmission service level defined in a *scheduler*.

Based on other CoS configurations, when packets in an output queue encounter congestion, packets with higher loss-priority values are more likely to be dropped by the random early detection (RED) algorithm. Packet loss priority values affect the scheduling of a packet without affecting the packet's relative ordering within the traffic flow.

Policer Application to Traffic

After you have defined and named a policer, it is stored as a template. You can later use the same policer name to provide the same policer configuration each time you want to use it. This eliminates the need to define the same policer values more than once.

You can apply a policer to a traffic flow in either of two ways:

- You can configure a standard stateless firewall filter that specifies the **policer *policer-name*** nonterminating action or the **three-color-policer (single-rate | two-rate) *policer-name*** nonterminating action. When you apply the standard filter to the input or output at a logical interface, the policer is applied to all packets of the filter-specific protocol family that match the conditions specified in the filter configuration.

With this method of applying a policer, you can define specific classes of traffic on an interface and apply traffic rate-limiting to each class.

- You can apply a policer directly to an interface so that traffic rate-limiting applies to all traffic on that interface, regardless of protocol family or any match conditions.

You can configure policers at the queue, logical interface, or Layer 2 (MAC) level. Only a single policer is applied to a packet at the egress queue, and the search for policers occurs in this order:

- Queue level
- Logical interface level
- Layer 2 (MAC) level

Tricolor Marking Architecture

Policers provide two functions: metering and marking.

The policer meters each packet and passes the packet and the metering result to the marker, as shown in [Figure 10 on page 1445](#).

Figure 10: Flow of Tricolor Marking Policer Operation

9017049

The meter operates in two modes. In the color-blind mode, the meter treats the packet stream as uncolored. Any preset loss priorities are ignored. In the color-aware mode, the meter inspects the packet loss priority (PLP) field, which has been set by an upstream device as PLP high, medium-high, medium-low, or low; in other words, the PLP field has already been set by a behavior aggregate (BA) or multifield classifier. The marker changes the PLP of each incoming IP packet according to the results of the meter. For more information, see [“Configuring Two-Rate Tricolor Marking” on page 1452](#).

This chapter emphasizes configuration and use of TCM policers. For more information about configuring and using two-color policers (“policers”), see the *Traffic Policers Configuration Guide*.

Single-rate TCM is so called because traffic is policed according to one rate—the CBR—and two burst sizes: the CBS and EBS. The CBS specifies the usual burst size in bytes and the EBS specifies the maximum burst size in bytes for packets that are admitted to the network. The EBS is greater than or equal to the CBS, and neither can be 0. As each packet enters the network, its bytes are counted. Packets that do not exceed the CBS are marked low PLP. Packets that exceed the CBS but are below the EBS are marked medium-high PLP. Packets that exceed the EBS are marked high PLP.

Two-rate TCM is so called because traffic is policed according to two rates: the CIR and the PIR. The PIR is greater than or equal to the CIR. The CIR specifies the average rate at which bits are admitted to the network and the PIR specifies the maximum rate at which bits are admitted to the network. As each packet enters the network, its bits are counted. Bits in packets that do not exceed the CIR have their packets marked low PLP. Bits in packets that exceed the CIR but are below the PIR have their packets marked medium-high PLP. Bits in packets that exceed the PIR have their packets marked high PLP.

For information about how to use marking policers with BA and multifield classifiers, see [“Using BA Classifiers to Set PLP” on page 1460](#) and [“Using Multifield Classifiers to Set PLP” on page 1461](#).

Tricolor Marking Limitations

Tricolor Marking (TCM) has some limitations that must be kept in mind during configuration and operation.

The following limitations apply to TCM:

- When you enable TCM on a 10-port Gigabit Ethernet PIC or a 10-Gigabit Ethernet PIC, for queues 6 and 7 only, the output of the **show interfaces queue *interface-name*** command does not display the number of queued bytes and packets, or the number of bytes and packets dropped due to RED. If you do not configure tricolor marking on the interface, these statistics are available for all queues.
- When you enable TCM, Transmission Control Protocol (TCP)-based configurations for drop profiles are rejected. In other words, you cannot include the **protocol** statement at the **[edit class-of-service schedulers *scheduler-name* drop-profile-map]** hierarchy level. The result is that drop profiles are applied to packets with the specified PLP and any protocol type.
- On Gigabit Ethernet IQ PICs, for IEEE 802.1 rewrite rules, only two loss priorities are supported. Exiting packets with medium-high loss priority are treated as high, and packets with medium-low loss priority are treated as low. In other words rewrite rules corresponding to high and low apply instead of those corresponding to medium-high and medium-low. For IQ PICs, you can only configure one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.
- When some PICs with Frame Relay encapsulation mark a packet with high loss priority, the packet is treated as having medium-high loss priority on M320 Multiservice Edge Routers and T Series Core Routers with Enhanced II FPCs and T640 Core Routers with Enhanced Scaling FPC4.
- In a single firewall filter term, you cannot configure both the **loss-priority** action modifier and the **three-color-policer** action modifier. These statements are mutually exclusive.

Policer Support for Aggregated Ethernet Bundle Overview

Aggregated interfaces support single-rate policers, three-color marking policers, two-rate three-color marking policers, hierarchical policers, and percentage-based policers. By default, policer bandwidth and burst-size applied on aggregated bundles is not matched to the user-configured bandwidth and burst-size.

You can configure interface-specific policers applied on an aggregated Ethernet bundle to match the effective bandwidth and burst-size to user-configured values. The **shared-bandwidth-policer** statement is required to achieve this match behavior.

This capability applies to all interface-specific policers of the following types: single-rate policers, single-rate three-color marking policers, two-rate three-color marking policers, and hierarchical policers. Percentage-based policers match the bandwidth to the user-configured values by default, and do not require shared-bandwidth-policer configuration. The **shared-bandwidth-policer** statement causes a split in burst-size for percentage-based policers.

NOTE: This feature is supported on the following platforms: T Series routers, M120, M10i, M7i (CFEB-E only), M320 (SFPC only), MX240, MX480, and MX960 (DPC only), and EX Series switches.

The following usage scenarios are supported:

- Interface policers used by the following configuration:

[edit] interfaces (aeX | asX) unit *unit-num* family *family* policer [input | output | arp]

- Policers and three-color policers (both single-rate three-color marking and two-rate three-color marking) used inside interface-specific filters; that is, filters that have an interface-specific keyword and are used by the following configuration:

[edit] interfaces (aeX | asX) unit *unit-num* family *family* filter [input | output]

- Common-edge service filters, which are derived from CLI-configured filters and thus inherit interface-specific properties. All policers and three-color policers used by these filters are also affected.

The following usage scenarios are not supported:

- Policers and three-color policers used inside filters that are not interface specific; such a filter is meant to be shared across multiple interfaces.
- Any implicit policers or policers that are part of implicit filters; for example, the default ARP policer applied to an aggregate Ethernet interface. Such a policer is meant to be shared across multiple interfaces.
- Prefix-specific action policers.

To configure this feature, include the **shared-bandwidth-policer** statement at the following hierarchy levels: **[edit firewall policer *policer-name*]**, **[edit firewall three-color-policer *policer-name*]**, or **[edit firewall hierarchical-policer *policer-name*]**.

Configuring Tricolor Marking

You configure marking policers by defining the policer and multiple levels of PLP for classifiers, rewrite rules, random early detection (RED) drop profiles, and firewall filters.

To configure marking policers, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
tri-color;
classifiers {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) classifier-name {
    import classifier-name | default;
    forwarding-class class-name {
      loss-priority (low | medium-low | medium-high | high) code-points [ aliases ]
        [ bit-patterns ];
    }
  }
}
rewrite-rules {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) rewrite-name {
    import (rewrite-name | default);
    forwarding-class class-name {
      loss-priority (low | medium-low | medium-high | high) code-point (aliases |
        bit-patterns;
    }
  }
}
schedulers {
  scheduler-name {
    drop-profile-map loss-priority (any | low | medium-low | medium-high | high) protocol
      any drop-profile profile-name;
  }
}

[edit firewall]
policer name {
  then loss-priority (low | medium-low | medium-high | high);
}
three-color-policer policer-name {
  action {
    loss-priority high then discard; # Only for IQ2 PICs
  }
  logical-interface-policer;
  single-rate {
    (color-aware | color-blind);
    committed-information-rate bps;
    committed-burst-size bytes;
    excess-burst-size bytes;
  }
  two-rate {
    (color-aware | color-blind);
    committed-information-rate bps;
    committed-burst-size bytes;
    peak-information-rate bps;
    peak-burst-size bytes;
  }
}
filter filter-name {
  <family family> {
```

```

term rule-name {
  then {
    three-color-policer (single-rate | two-rate) policer-name;
  }
}

```

Configuring Single-Rate Tricolor Marking

With TCM, you can configure traffic policing according to two separate modes—color-blind and color-aware. In color-blind mode, the current PLP value is ignored. In color-aware mode, the current PLP values are considered by the policer and can only be increased.

- [Configuring Color-Blind Mode for Single-Rate Tricolor Marking on page 1449](#)
- [Configuring Color-Aware Mode for Single-Rate Tricolor Marking on page 1450](#)

Configuring Color-Blind Mode for Single-Rate Tricolor Marking

All packets are evaluated by the CBS. If a packet exceeds the CBS, it is evaluated by the EBS. In color-blind mode, the policer supports three loss priorities only: low, medium-high, and high.

In color-blind mode, packets that exceed the CBS but are below the EBS are marked yellow (medium-high). Packets that exceed the EBS are marked red (high), as shown in [Table 102 on page 1449](#).

Table 102: Color-Blind Mode TCM Color-to-PLP Mapping

Color	PLP	Meaning
Green	low	Packet does not exceed the CBS.
Yellow	medium-high	Packet exceeds the CBS but does not exceed the EBS.
Red	high	Packet exceeds the EBS.

If you are using color-blind mode and you wish to configure an output policer that marks packets to have medium-low loss priority, you must configure a policer at the **[edit firewall policer policer-name]** hierarchy level. For example:

```

firewall {
  policer 4PLP {
    if-exceeding {
      bandwidth-limit 40k;
      burst-size-limit 4k;
    }
    then loss-priority medium-low;
  }
}

```

Apply this policer at one or both of the following hierarchy levels:

- **[edit firewall family family filter filter-name term rule-name then policer policer-name]**

- [edit interfaces *interface-name* unit *logical-unit-number* family *family* filter *filter-name*]

Configuring Color-Aware Mode for Single-Rate Tricolor Marking

In color-aware mode, the metering treatment the packet receives depends on its classification. Metering can increase a packet's preassigned PLP, but cannot decrease it, as shown in [Table 103 on page 1450](#).

Table 103: Color-Aware Mode TCM PLP Mapping

Incoming PLP	Packet Metered Against	Possible Cases	Outgoing PLP
low	CBS and EBS	Packet does not exceed the CBS.	low
		Packet exceeds the CBS but not the EBS.	medium-high
		Packet exceeds the EBS.	high
medium-low	EBS only	Packet does not exceed the CBS.	medium-low
		Packet does not exceed the EBS.	medium-low
		Packet exceeds the EBS.	high
medium-high	EBS only	Packet does not exceed the CBS.	medium-high
		Packet does not exceed the EBS.	medium-high
		Packet exceeds the EBS.	high
high	Not metered by the policer.	All cases.	high

The following sections describe single-rate color-aware PLP mapping in more detail.

Effect on Low PLP of Single-Rate Policer

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to medium-high or high. Therefore, these packets are metered against both the CBS and the EBS.

For example, if a BA or multifield classifier marks a packet with low PLP according to the type-of-service (ToS) bits in the IP header, and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CBS, packets remain marked as low PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, some of the packets are marked as medium-high PLP, and some of the packets remain marked as low PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP, and some of the packets remain marked as low PLP.

Effect on Medium-Low PLP of Single-Rate Policer

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to high. Therefore, these packets are metered against the EBS only.

For example, if a BA or multifield classifier marks a packet with medium-low PLP according to the ToS bits in the IP header, and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CBS, packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP, and some of the packets remain marked as medium-low PLP.

Effect on Medium-High PLP of Single-Rate Policer

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to high. Therefore, these packets are metered against the EBS only.

For example, if a BA or multifield classifier marks a packet with medium-high PLP according to the ToS bits in the IP header, and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CBS, packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CBS but less than the EBS, packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the EBS, some of the packets are marked as high PLP, and some of the packets remain marked as medium-high PLP.

Effect on High PLP of Single-Rate Policer

Packets belonging to the red class have already been marked by a classifier with high PLP. The marking policer can only leave the packet's PLP unchanged. Therefore, these packets are not metered against the CBS or the EBS and all the packets remain marked as high PLP.

Configuring Two-Rate Tricolor Marking

With TCM, you can configure traffic policing according to two separate modes—color-blind and color-aware. In color-blind mode, the current PLP value is ignored. In color-aware mode, the current PLP values are considered by the policer and can only be increased.

- [Configuring Color-Blind Mode for Two-Rate Tricolor Marking on page 1452](#)
- [Configuring Color-Aware Mode for Two-Rate Tricolor Marking on page 1453](#)

Configuring Color-Blind Mode for Two-Rate Tricolor Marking

All packets are evaluated by the CIR. If a packet exceeds the CIR, it is evaluated by the PIR. In color-blind mode, the policer supports three loss priorities only: low, medium-high, and high.

In color-blind mode, packets that exceed the CIR but are below the PIR are marked yellow (medium-high). Packets that exceed the PIR are marked red (high), as shown in [Table 104 on page 1452](#).

Table 104: Color-Blind Mode TCM Color-to-PLP Mapping

Color	PLP	Meaning
Green	low	Packet does not exceed the CIR.
Yellow	medium-high	Packet exceeds the CIR but does not exceed the PIR.
Red	high	Packet exceeds the PIR.

If you are using color-blind mode and you wish to configure an output policer that marks packets to have medium-low loss priority, you must configure a policer at the **[edit firewall policer *policer-name*]** hierarchy level. For example:

```
firewall {
  policer 4PLP {
    if-exceeding {
      bandwidth-limit 40k;
      burst-size-limit 4k;
    }
    then loss-priority medium-low;
  }
}
```

Apply this policer at one or both of the following hierarchy levels:

- **[edit firewall family *family* filter *filter-name* term *rule-name* then policer *policer-name*]**

- [edit interfaces *interface-name* unit *logical-unit-number* family *family* filter *filter-name*]

Configuring Color-Aware Mode for Two-Rate Tricolor Marking

In color-aware mode, the metering treatment the packet receives depends on its classification. Metering can increase a packet's preassigned PLP, but cannot decrease it, as shown in [Table 105 on page 1453](#).

Table 105: Color-Aware Mode TCM Mapping

Incoming PLP	Packet Metered Against	Possible Cases	Outgoing PLP
low	CIR and PIR	Packet does not exceed the CIR.	low
		Packet exceeds the CIR but not the PIR.	medium-high
		Packet exceeds the PIR.	high
medium-low	PIR only	Packet does not exceed the CIR.	medium-low
		Packet does not exceed the PIR.	medium-low
		Packet exceeds the PIR.	high
medium-high	PIR only	Packet does not exceed the CIR.	medium-high
		Packet does not exceed the PIR.	medium-high
		Packet exceeds the PIR.	high
high	Not metered by the policer.	All cases.	high

The following sections describe color-aware two-rate PLP mapping in more detail.

Effect on Low PLP of Two-Rate Policer

Packets belonging to the green class have already been marked by a classifier with low PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to medium-high or high. Therefore, these packets are metered against both the CIR and the PIR.

For example, if a BA or multifield classifier marks a packet with low PLP according to the ToS bits in the IP header, and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, packets remain marked as low PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, some of the packets are marked as medium-high PLP, and some of the packets remain marked as low PLP.

- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP, and some of the packets remain marked as low PLP.

Effect on Medium-Low PLP of Two-Rate Policer

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to high. Therefore, these packets are metered against the PIR only.

For example, if a BA or multifield classifier marks a packet with medium-low PLP according to the ToS bits in the IP header, and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the CIR/CBS but less than the PIR, packets remain marked as medium-low PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP, and some of the packets remain marked as medium-low PLP.

Effect on Medium-High PLP of Two-Rate Policer

Packets belonging to the yellow class have already been marked by a classifier with medium-low or medium-high PLP. The marking policer can leave the packet's PLP unchanged or increase the PLP to high. Therefore, these packets are metered against the PIR only.

For example, if a BA or multifield classifier marks a packet with medium-high PLP according to the ToS bits in the IP header, and the two-rate TCM policer is in color-aware mode, the output loss priority is as follows:

- If the rate of traffic flow is less than the CIR, packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the CIR but less than the PIR, packets remain marked as medium-high PLP.
- If the rate of traffic flow is greater than the PIR, some of the packets are marked as high PLP, and some of the packets remain marked as medium-high PLP.

Effect on High PLP of Two-Rate Policer

Packets belonging to the red class have already been marked by a classifier with high PLP. The marking policer can only leave the packet's PLP unchanged. Therefore, these packets are not metered against the CIR or the PIR and all the packets remain marked as high PLP.

Enabling Tricolor Marking

By default, TCM is enabled on M120, MX Series, and T4000 routers, and EX Series switches. To enable TCM on other routers, include the **tri-color** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
tri-color;
```

This statement is necessary on the following routers:

- M320 and T Series routers with Enhanced II FPCs
- T640 routers with Enhanced Scaling FPC4s

If you do not include this statement in the configuration on platforms that require it, you cannot configure medium-low or medium-high PLP for classifiers, rewrite rules, drop profiles, or firewall filters.

Configuring Tricolor Marking Policers

A tricolor marking policer polices traffic on the basis of metering rates, including the CIR, the PIR, their associated burst sizes, and any policing actions configured for the traffic. To configure a tricolor marking policer, include the following statements at the **[edit firewall]** hierarchy level:

```
[edit firewall]
three-color-policer name {
  action {
    loss-priority high then discard; # Only for IQ2 PICs
  }
  logical-interface-policer;
  single-rate {
    (color-aware | color-blind);
    committed-information-rate bps;
    committed-burst-size bytes;
    excess-burst-size bytes;
  }
  two-rate {
    (color-aware | color-blind);
    committed-information-rate bps;
    committed-burst-size bytes;
    peak-information-rate bps;
    peak-burst-size bytes;
  }
}
```

You can configure a tricolor policer to discard high loss priority traffic on a logical interface in the ingress or egress direction. To configure a policer on a logical interface using tricolor marking policing to discard high loss priority traffic, include the **logical-interface-policer** statement and **action** statement.

In all cases, the range of allowable bits-per-second or byte values is 1500 to 100,000,000,000. You can specify the values for bps and bytes either as complete decimal numbers or as decimal numbers followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

The color-aware policer implicitly marks packets into four loss priority categories:

- Low
- Medium-low
- Medium-high
- High

The color-blind policer implicitly marks packets into three loss priority categories:

- Low
- Medium-high
- High

Table 106 on page 1456 describes all the configurable TCM statements.

Table 106: Tricolor Marking Policer Statements

Statement	Meaning	Configurable Values
single-rate	Marking is based on the CIR, CBS, and EBS.	—
two-rate	Marking is based on the CIR, PIR, and rated burst sizes.	—
color-aware	Metering depends on the packet's preclassification. Metering can increase a packet's assigned PLP, but cannot decrease it.	—
color-blind	All packets are evaluated by the CIR or CBS. If a packet exceeds the CIR or CBS, it is evaluated by the PIR or EBS.	—
committed-information-rate	Guaranteed bandwidth under normal line conditions and the average rate up to which packets are marked green.	1500 through 100,000,000,000 bps
committed-burst-size	Maximum number of bytes allowed for incoming packets to burst above the CIR, but still be marked green.	1500 through 100,000,000,000 bytes
excess-burst-size	Maximum number of bytes allowed for incoming packets to burst above the CIR, but still be marked yellow.	1500 through 100,000,000,000 bytes
peak-information-rate	Maximum achievable rate. Packets that exceed the CIR but are below the PIR are marked yellow. Packets that exceed the PIR are marked red.	1500 through 100,000,000,000 bps
peak-burst-size	Maximum number of bytes allowed for incoming packets to burst above the PIR, but still be marked yellow.	1500 through 100,000,000,000 bytes

Applying Tricolor Marking Policers to Firewall Filters

To rate-limit traffic by applying a tricolor marking policer to a firewall filter, include the **three-color-policer** statement:

```
three-color-policer {
```

```
(single-rate | two-rate) policer-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit firewall family *family* filter *filter-name* term *rule-name* then]
- [edit firewall filter *filter-name* term *rule-name* then]

In the **family** statement, the protocol family can be **any**, **ccc**, **inet**, **inet6**, **mpls**, or **vpls**.

You must identify the referenced policer as a **single-rate** or **two-rate** policer, and this statement must match the configured TCM policer. Otherwise, an error message appears in the configuration listing.

For example, if you configure **srTCM** as a single-rate TCM policer and try to apply it as a two-rate policer, the following message appears:

```
[edit firewall]
user@host# show three-color-policer srTCM
single-rate {
  color-aware;
  ...
}
user@host# show filter TESTER
term A {
  then {
    three-color-policer {
      ##
      ## Warning: Referenced two-rate policer does not exist
      ##
      two-rate srTCM;
    }
  }
}
```

Example: Applying a Two-Rate Tricolor Marking Policer to a Firewall Filter

Apply the **trtcm1-cb** policer to a firewall filter:

```
firewall {
  three-color-policer trtcm1-cb { # Configure the trtcm1-cb policer.
    two-rate {
      color-blind;
      committed-information-rate 1048576;
      committed-burst-size 65536;
      peak-information-rate 10485760;
      peak-burst-size 131072;
    }
  }
  filter fil { # Configure the fil firewall filter, applying the trtcm1-cb policer.
    term default {
      then {
        three-color-policer {
          two-rate trtcm1-cb;
        }
      }
    }
  }
}
```

```
}
```

**Related
Documentation**

- *Firewall Filters Configuration Guide*

Applying Firewall Filter Tricolor Marking Policers to Interfaces

To apply a tricolor marking policer to an interface, you must reference the filter name in the interface configuration. To do this, include the **filter** statement:

```
filter {  
    input filter-name;  
    output filter-name;  
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family *family*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family *family*]

The filter name that you reference should have an attached tricolor marking policer, as shown in [“Applying Tricolor Marking Policers to Firewall Filters” on page 1456](#).

Example: Applying a Single-Rate Tricolor Marking Policer to an Interface

Apply the **trtcm1-cb** policer to an interface:

```
firewall {  
    three-color-policer srtcm1 { # Configure the srtcm1-cb policer.  
        single-rate {  
            color-blind;  
            committed-information-rate 1048576;  
            committed-burst-size 65536;  
            excess-burst-size 131072;  
        }  
    }  
    filter fil { # Configure the fil firewall filter, applying the srtcm1-cb policer.  
        term default {  
            then {  
                three-color-policer {  
                    single-rate srtcm1-cb; # The TCM policer must be single-rate.  
                }  
            }  
        }  
    }  
    interfaces { # Configure the interface, which attaches the fil firewall filter.  
        ge-1/0/0 {  
            unit 0 {  
                family inet {  
                    filter {  
                        input fil;  
                    }  
                }  
            }  
        }  
    }  
}
```

Applying Layer 2 Policers to Gigabit Ethernet Interfaces

To rate-limit traffic by applying a policer to a Gigabit Ethernet interface (or a 10-Gigabit Ethernet interface [xe-fpc/pic/port]), include the **layer2-policer** statement with the direction, type, and name of the policer:

```
[edit interfaces ge-fpc/pic/port unit 0]
layer2-policer {
  input-policer policer-name;
  input-three-color policer-name;
  output-policer policer-name;
  output-three-color policer-name;
}
```

The direction (input or output) and type (policer or three-color) are combined into one statement and the policer named must be properly configured.

One input or output policer of either type can be configured on the interface.

Examples: Applying Layer 2 Policers to a Gigabit Ethernet Interface

Apply color-blind and color-aware two-rate TCM policers as input and output policers to a Gigabit Ethernet interface:

```
ge-1/0/0 {
  unit 0
  layer2-policer {
    input-three-color trTCM1-cb; # Apply the trTCM1-color-blind policer.
    output-three-color trTCM1-ca; # Apply the trTCM1-color-aware policer.
  }
}
```

Apply two-level and color-blind single-rate TCM policers as input and output policers to a Gigabit Ethernet interface:

```
ge-1/0/0 {
  unit 1
  layer2-policer {
    input-policer two-color-policer; # Apply a two-color policer.
    output-three-color srTCM2-cb; # Apply the srTCM1-color-blind policer.
  }
}
```

Apply a color-aware single-rate TCM policer as output policer on a Gigabit Ethernet interface:

```
ge-1/0/0 {
  unit 2
  layer2-policer {
    output-three-color srTCM3-ca { # Apply the srTCM3-color-aware policer.
  }
}
```

Configuration Tasks for Packet Loss Priority

- [Using BA Classifiers to Set PLP on page 1460](#)
- [Using Multifield Classifiers to Set PLP on page 1461](#)
- [Configuring PLP for Drop-Profile Maps on page 1462](#)
- [Configuring Rewrite Rules Based on PLP on page 1462](#)

Using BA Classifiers to Set PLP

Behavior aggregate (BA) classifiers take action on incoming packets. When TCM is enabled, Juniper Networks M320 Multiservice Edge Routers and T Series Core Routers support four classifier PLP designations: **low**, **medium-low**, **medium-high**, and **high**. To configure the PLP for a classifier, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
classifiers {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) classifier-name {
    import (classifier-name | default);
    forwarding-class class-name {
      loss-priority (low | medium-low | medium-high | high) code-points [ aliases ]
        [ bit-patterns ];
    }
  }
}
```

The inputs for a classifier are the CoS values. The outputs for a classifier are the forwarding class and the loss priority (PLP). A classifier sets the forwarding class and the PLP for each packet entering the interface with a specific set of CoS values.

For example, in the following configuration, the **assured-forwarding** forwarding class and **medium-low** PLP are assigned to all packets entering the interface with the **101110** CoS values:

```
class-of-service {
  classifiers {
    dscp dscp-cl {
      forwarding-class assured-forwarding {
        loss-priority medium-low {
          code-points 101110;
        }
      }
    }
  }
}
```

To use this classifier, you must configure the settings for the **assured-forwarding** forwarding class at the **[edit class-of-service forwarding-classes queue queue-number assured-forwarding]** hierarchy level. For more information, see [“Overview of Forwarding Classes” on page 1526](#).

Using Multifield Classifiers to Set PLP

Multifield classifiers take action on incoming or outgoing packets, depending whether the firewall rule is applied as an input filter or an output filter. When TCM is enabled, Juniper Networks M320 Multiservice Edge Routers and T Series Core Routers support four multifield classifier PLP designations: **low**, **medium-low**, **medium-high**, and **high**.

To configure the PLP for a multifield classifier, include the **loss-priority** statement in a policer or firewall filter that you configure at the **[edit firewall]** hierarchy level:

```
[edit firewall]
family family-name {
  filter filter-name {
    term term-name {
      from {
        match-conditions;
      }
      then {
        loss-priority (low | medium-low | medium-high | high);
        forwarding-class class-name;
      }
    }
  }
}
```

The inputs (match conditions) for a multifield classifier are one or more of the six packet header fields: destination address, source address, IP protocol, source port, destination port, and DSCP. The outputs for a multifield classifier are the forwarding class and the loss priority (PLP). In other words, a multifield classifier sets the forwarding class and the PLP for each packet entering or exiting the interface with a specific destination address, source address, IP protocol, source port, destination port, or DSCP.

For example, in the following configuration, the forwarding class **expedited-forwarding** and PLP **medium-high** are assigned to all IPv4 packets with the **10.1.1.0/24** or **10.1.2.0/24** source address:

```
firewall {
  family inet {
    filter classify-customers {
      term isp1-customers {
        from {
          source-address 10.1.1.0/24;
          source-address 10.1.2.0/24;
        }
        then {
          loss-priority medium-high;
          forwarding-class expedited-forwarding;
        }
      }
    }
  }
}
```

To use this classifier, you must configure the settings for the **expedited-forwarding** forwarding class at the **[edit class-of-service forwarding-classes queue queue-number]**

expedited-forwarding] hierarchy level. For more information, see [“Overview of Forwarding Classes” on page 1526](#).

Configuring PLP for Drop-Profile Maps

RED drop profiles take action on outgoing packets. When TCM is enabled, M320 and T Series routers support four drop-profile map PLP designations: **low**, **medium-low**, **medium-high**, and **high**.

To configure the PLP for the drop-profile map, include the **schedulers** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
schedulers {
  scheduler-name {
    drop-profile-map loss-priority (any | low | medium-low | medium-high | high) protocol
    any drop-profile profile-name;
  }
}
```

When you configure TCM, the drop-profile map's protocol type must be **any**.

The inputs for a drop-profile map are the loss priority and the protocol type. The output for a drop-profile map is the drop profile name. In other words, the map sets the drop profile for each packet with a specific PLP and protocol type exiting the interface.

For example, in the following configuration, the **dp** drop profile is assigned to all packets exiting the interface with a medium-low PLP and belonging to any protocol:

```
class-of-service {
  schedulers {
    af {
      drop-profile-map loss-priority medium-low protocol any drop-profile dp;
    }
  }
}
```

To use this drop-profile map, you must configure the settings for the **dp** drop profile at the **[edit class-of-service drop-profiles dp]** hierarchy level. For more information, see [“RED Drop Profiles Overview” on page 1674](#).

Configuring Rewrite Rules Based on PLP

Rewrite rules take action on outgoing packets. When TCM is enabled, M320 and T Series routers support four rewrite PLP designations: **low**, **medium-low**, **medium-high**, and **high**. To configure the PLP for a rewrite rule, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
rewrite-rules {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) rewrite-name {
    import (rewrite-name | default);
    forwarding-class class-name {
      loss-priority (low | medium-low | medium-high | high) code-point (alias | bits);
    }
  }
}
```

```
}
```

The inputs for a rewrite rule are the forwarding class and the loss priority (PLP). The output for a rewrite rule are the CoS values. In other words, a rewrite rule sets the CoS values for each packet exiting the interface with a specific forwarding class and PLP.

For example, if you configure the following, the **000000** CoS values are assigned to all packets exiting the interface with the **assured-forwarding** forwarding class and **medium-high** PLP:

```
class-of-service {
  rewrite-rules {
    dscp dscp-rw {
      forwarding-class assured-forwarding {
        loss-priority medium-high code-point 000000;
      }
    }
  }
}
```

To use this classifier, you must configure the settings for the **assured-forwarding** forwarding class at the **[edit class-of-service forwarding-classes queue *queue-number* assured-forwarding]** hierarchy level. For more information, see [“Overview of Forwarding Classes” on page 1526](#).

classifiers (Definition)

Syntax	<pre> classifiers { type classifier-name { import (classifier-name default); forwarding-class class-name { loss-priority level code-points [aliases] [bit-patterns]; } } } </pre>
Hierarchy Level	[edit class-of-service], [edit class-of-service routing-instances <i>routing-instance-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4. ieee-802.1ad option introduced in Junos OS Release 9.2.
Description	Define a CoS behavior aggregate (BA) classifier for classifying packets. You can associate the classifier with a forwarding class or code-point mapping, and import a default classifier or one that is previously defined.
<div>  <p>NOTE: The [edit class-of-service routing-instances <i>routing-instance-name</i>] hierarchy level and the dscp-ipv6 and ieee-802.1ad classifier types are not supported on ACX Series routers.</p> </div>	
Options	<p>classifier-name—Name of the aggregate behavior classifier.</p> <p>type—Traffic type: dscp, dscp-ipv6, exp, ieee-802.1, ieee-802.1ad, inet-precedence.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

exp

Syntax	<code>exp (rewrite-name default) protocol protocol-types;</code>
Hierarchy Level	<code>[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]</code>
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS Release 12.2. for ACX series
Description	Apply an MPLS experimental (EXP) rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the <code>[edit class-of-service rewrite-rules exp]</code> hierarchy level.</p> <p>default—The default mapping.</p> <p>By default, IP precedence rewrite rules alter the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged. This default behavior applies to rewrite rules you configure for MPLS packets with IPv4 payloads. You configure these types of rewrite rules by including the mpls-inet-both or mpls-inet-both-non-vpn option at the <code>[edit class-of-service interfaces interface interface-name unit logical-unit-number rewrite-rules exp rewrite-rule-name protocol]</code> hierarchy level. The IP precedence rewrite rules explanation does not apply to ACX Series Universal Access routers.</p> <p>On interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series Ethernet Services Routers and EX Series switches, we highly recommend that you configure the default option when you configure a behavior aggregate (BA) classifier that does not include a specific rewrite rule for MPLS packets. Doing so ensures that MPLS exp value is rewritten according to the BA classifier rules configured for forwarding or packet loss priority. This does not apply to ACX Series Universal Access routers.</p> <p>The remaining statement is explained separately.</p>
Required Privilege Level	interface —To view this statement in the configuration. interface-control —To add this statement to the configuration.

import (Classifiers)

Syntax	<code>import (classifier-name default);</code>
Hierarchy Level	<code>[edit class-of-service classifiers type classifier-name]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify a default or previously defined classifier.
Options	classifier-name —Name of the classifier mapping configured at the <code>[edit class-of-service classifiers]</code> hierarchy level. default —The default classifier mapping.
Required Privilege Level	interface —To view this statement in the configuration. interface-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Overview of BA Classifier Types on page 1321

import (Rewrite Rules)

Syntax	<code>import (rewrite-name default);</code>
Hierarchy Level	<code>[edit class-of-service rewrite-rules type rewrite-name]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify a default or previously defined rewrite-rules mapping to import.
Options	rewrite-name —Name of a rewrite-rules mapping configured at the <code>[edit class-of-service rewrite-rules]</code> hierarchy level. default —The default rewrite-rules mapping.
Required Privilege Level	interface —To view this statement in the configuration. interface-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Rewrite Rules on page 1694

inet-precedence

Syntax	<code>inet-precedence (rewrite-name default);</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Apply a IPv4 precedence rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules inet-precedence] hierarchy level.</p> <p>default—The default mapping. By default, IP precedence rewrite rules alter the first three bits on the type of service (ToS) byte while leaving the last three bits unchanged.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Configuring Rewrite Rules on page 1694• dscp (Rewrite Rules) on page 1382• dscp-ipv6 (Class-of-Service) on page 1357• exp on page 1358• exp-push-push-push on page 1723• exp-swap-push-push on page 1724• ieee-802.1 (Rewrite Rules on Logical Interface) on page 1360• ieee-802.1ad on page 1362• rewrite-rules (Definition) on page 1481

loss-priority (Scheduler Drop Profiles)

Syntax	loss-priority (any high low medium-high medium-low);
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i> drop-profile-map]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches. Statement introduced in Junos OS Release 12.2 for ACX Series Routers.
Description	Specify a loss priority to which to apply a drop profile. The drop profile map sets the drop profile for a specific PLP and protocol type. The inputs for the map are the PLP designation and the protocol type. The output is the drop profile.
Options	any —The drop profile applies to packets with any PLP.

NOTE: On ACX Series Routers, only the **any** option is supported when you configure the **non-tcp** option for [protocol](#).

high—The drop profile applies to packets with high PLP.

low—The drop profile applies to packets with low PLP.

medium-high—The drop profile applies to packets with medium-high PLP.

medium-low—The drop profile applies to packets with medium-low PLP.

Required Privilege	interface—To view this statement in the configuration.
Level	interface-control—To add this statement to the configuration.

Related Documentation	<ul style="list-style-type: none"> • Default Schedulers Overview on page 1575 • Configuring Drop Profile Maps for Schedulers on page 1590 • Configuring Schedulers for Priority Scheduling on page 1594 • Configuring Tricolor Marking on page 1447 • protocol (Schedulers) on page 1480
------------------------------	---

protocol (Schedulers)

Syntax	protocol (any non-tcp tcp);
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i> drop-profile-map]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches. Statement introduced in Junos OS Release 12.2 for ACX Series Routers.
Description	Specify the protocol type for the specified scheduler.
Options	any —Accept any protocol type. non-tcp —(ACX Series Routers, M Series and T Series (except T4000) routers only) Accept any protocol type other than TCP/IP.

NOTE: On ACX Series Routers, when you configure the **non-tcp** option, only the **any** option is supported for [loss-priority](#).

	tcp —(ACX Series Routers, M Series and T Series (except T4000) routers only) Accept TCP/IP protocol type.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Schedulers on page 1579

rewrite-rules (Definition)

Syntax	<pre>rewrite-rules { type <i>rewrite-name</i>{ import (<i>rewrite-name</i> default); forwarding-class <i>class-name</i> { loss-priority <i>level</i> <i>code-point</i> [<i>aliases</i>] [<i>bit-patterns</i>]; } } }</pre>
Hierarchy Level	[edit class-of-service]
Release Information	<p>Statement introduced before Junos OS Release 7.4.</p> <p>ieee-802.1ad option introduced in Junos OS Release 9.2.</p>
Description	Specify a rewrite-rules mapping for the traffic that passes through all queues on the interface.
Options	<p><i>rewrite-name</i>—Name of a rewrite-rules mapping.</p> <p><i>type</i>—Traffic type.</p> <p>Values: dscp, dscp-ipv6, exp, frame-relay-de (J Series routers only), ieee-802.1, ieee-802.1ad, inet-precedence</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring Rewrite Rules on page 1694 • <i>Example: Configuring CoS for a PBB Network</i> • J Series router documentation

schedulers (Class of Service)

Syntax	<pre>schedulers { scheduler-name { adjust-minimum <i>rate</i>; adjust-percent <i>percentage</i>; buffer-size (<i>seconds</i> percent <i>percentage</i> remainder temporal <i>microseconds</i>); drop-profile-map loss-priority (any low medium-low medium-high high) <i>protocol</i> (any non-tcp tcp) drop-profile <i>profile-name</i>; excess-priority [low medium-low medium-high high none]; excess-rate (percent <i>percentage</i> proportion <i>value</i>); priority <i>priority-level</i>; shaping-rate (percent <i>percentage</i> <i>rate</i>); transmit-rate (percent <i>percentage</i> <i>rate</i> remainder) <exact rate-limit>; } }</pre>
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.1X48 for PTX Series switches.
Description	Specify the scheduler name and parameter values.
Options	<i>scheduler-name</i> —Name of the scheduler to be configured. The remaining statements are explained separately.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Schedulers Overview on page 1573• Default Schedulers Overview on page 1575• Configuring Schedulers on page 1579• Configuring a Scheduler• Example: Configuring CoS for a PBB Network

tri-color

Syntax	tri-color;
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced in Junos OS Release 7.4.
Description	For IPv4 packets on M320, MX Series, T Series routers with Enhanced II Flexible PIC Concentrators (FPCs), and EX Series switches, enable two-rate tricolor marking (TCM), as defined in RFC 2698.
Default	If you do not include this statement, tricolor marking is not enabled and the medium packet loss priority (PLP) is not configurable.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Tricolor Marking on page 1447

[edit firewall] Hierarchy Level

Several statements in the **[edit firewall]** hierarchy are valid at numerous locations within the hierarchy. To make the complete hierarchy easier to read, the repeated statements are listed in the following sections, which are referenced at the appropriate locations in “[Complete \[edit firewall\] Hierarchy](#)” on page 325.

- [Common Firewall Actions on page 1483](#)
- [Common IP Firewall Actions on page 1484](#)
- [Common IPv4 Firewall Actions on page 1484](#)
- [Common IP Firewall Match Conditions on page 1485](#)
- [Common IPv4 Firewall Match Conditions on page 1486](#)
- [Common Layer 2 Firewall Match Conditions on page 1486](#)
- [Complete \[edit firewall\] Hierarchy on page 1488](#)

Common Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- **[edit firewall family (any | ccc | ethernet-switching | inet | inet6 | mpls | vpls) filter *filter-name* term *term-name* then]**
- **[edit firewall filter *filter-name* term *term-name* then]**

The common firewall actions are as follows:

```
count counter-name;  
forwarding-class class-name;  
loss-priority (high | low | medium-high | medium-low);  
next term;  
policer policer-name;  
three-color-policer policer-name {  
    (single-rate single-rate-policer-name | two-rate two-rate-policer-name);  
}
```

Common IP Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet filter *filter-name* term *term-name* then]
- [edit firewall family inet6 filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common IP firewall actions are as follows:

```
log;  
logical-system logical-system-name <routing-instance routing-instance-name>  
    <topology topology-name>;  
port-mirror;  
port-mirror-instance instance-name;  
routing-instance routing-instance-name <topology topology-name>;  
sample;  
service-filter-hit;  
syslog;  
topology topology-name;
```

Common IPv4 Firewall Actions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- [edit firewall family inet filter *filter-name* term *term-name* then]
- [edit firewall filter *filter-name* term *term-name* then]

The common IP version 4 (IPv4) firewall actions are as follows:

```
(accept | discard <accounting collector-name> | reject <administratively-prohibited |  
    bad-host-tos | bad-network-tos | fragmentation-needed | host-prohibited |  
    host-unknown | host-unreachable | network-prohibited | network-unknown |  
    network-unreachable | port-unreachable | precedence-cutoff | precedence-violation |  
    protocol-unreachable | source-host-isolated | source-route-failed | tcp-reset>);  
ipsec-sa sa-name;  
load-balance sa-name;  
next-hop-group group-name;  
prefix-action action-name;
```

Common IP Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in “[Complete \[edit firewall\] Hierarchy](#)” on page 325 instead of the statements being repeated.

- `[edit firewall family inet dialer-filter filter-name term term-name from]` (with the exceptions noted at this level in “[Complete \[edit firewall\] Hierarchy](#)” on page 325)
- `[edit firewall family inet filter filter-name term term-name from]`
- `[edit firewall family inet6 dialer-filter filter-name term term-name from]` (with the exceptions noted at this level in “[Complete \[edit firewall\] Hierarchy](#)” on page 325)
- `[edit firewall family inet6 filter filter-name term term-name from]`
- `[edit firewall filter filter-name term term-name from]`

The common IP firewall match conditions are as follows:

```

address {
    ip-prefix</prefix-length> <except>;
}
destination-address {
    ip-prefix</prefix-length> <except>;
}
destination-class [ class-names ] | destination-class-except [ class-names ];
(destination-port [ port-names ] | destination-port-except [ port-names ]);
destination-prefix-list {
    list-name <except>;
}
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);
icmp-code [ codes ] | icmp-code-except [ codes ];
icmp-type [ types ] | icmp-type-except [ types ];
interface interface-name;
(interface-group [ group-names ] | interface-group-except [ group-names ]);
interface-set set-name;
(loss-priority [ priorities ] | loss-priority-except [ priorities ]);
(packet-length [ values ] | packet-length-except [ values ]);
(port [ port-names ] | port-except [ port-names ]);
prefix-list {
    list-name <except>;
}
service-filter-hit;
source-address {
    ip-prefix</prefix-length> <except>;
}
(source-class [ class-names ] | source-class-except [ class-names ]);
(source-port [ port-names ] | source-port-except [ port-names ]);
source-prefix-list {
    list-name <except>;
}
tcp-established;
tcp-flags flag;
tcp-initial;

```

Common IPv4 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family inet dialer-filter *filter-name* term *term-name* from]** (with the exceptions noted at this level in [“Complete \[edit firewall\] Hierarchy” on page 325](#))
- **[edit firewall family inet filter *filter-name* term *term-name* from]**
- **[edit firewall filter *filter-name* term *term-name* from]**

The common IPv4 firewall match conditions are as follows:

```
(ah-spi [ values ] | ah-spi-except [ values ]);
(dscp [ code-point-values ] | dscp-except [ code-point-values ]);
(esp-spi [ values ] | esp-spi-except [ values ]);
first-fragment;
fragment-flags flag;
(fragment-offset [ offsets ] | fragment-offset-except [ offsets ]);
(ip-options [ option-names ] | ip-options-except [ option-names ]);
is-fragment;
(precedence [ precedence-names ] | precedence-except [ precedence-names ]);
(protocol [ protocol-names ] | protocol-except [ protocol-names ]);
(ttl [ tll-values ] | ttl-except [ tll-values ]);
```

Common Layer 2 Firewall Match Conditions

This section lists statements that are valid at the following hierarchy levels, and is referenced at those levels in [“Complete \[edit firewall\] Hierarchy” on page 325](#) instead of the statements being repeated.

- **[edit firewall family ethernet-switching filter *filter-name* term *term-name* from]**
- **[edit firewall family vpls filter *filter-name* term *term-name* from]**

The common Layer 2 firewall match conditions are as follows:

```
destination-mac-address {
    mac-address <except>;
}
(destination-port [ port-names ] | destination-port-except [ port-names ]);
(dscp [ code-point-values ] | dscp-except [ code-point-values ]);
(ether-type [ protocol-types ] | ether-type-except [ protocol-types ]);
(forwarding-class [ class-names ] | forwarding-class-except [ class-names ]);
(icmp-code [ codes ] | icmp-code-except [ codes ]);
(icmp-type [ types ] | icmp-type-except [ types ]);
(interface-group [ group-names ] | interface-group-except [ group-names ]);
ip-address {
    ip-prefix</prefix-length> <except>;
}
ip-destination-address {
    ip-prefix</prefix-length> <except>;
}
(ip-precedence [ precedence-names ] | ip-precedence-except [ precedence-names ]);
```

```
(ip-protocol [ protocol-names ] | ip-protocol-except [ protocol-names ] );
ip-source-address ip-prefix </prefix-length>;
(learn-vlan-1p-priority [ priorities ] | learn-vlan-1p-priority [ priorities ] );
(learn-vlan-id [ vlan-ids ] | learn-vlan-id-except [ vlan-ids ] );
(loss-priority [ priorities ] | loss-priority-except [ priorities ] );
(port [ port-names ] | port-except [ port-names ] );
source-mac-address {
    mac-address <except>;
}
(source-port [ port-names ] | source-port-except [ port-names ] );
tcp-flags flag;
(traffic-type [ broadcast known-unicast multicast unknown-unicast ] |
    traffic-type-except [ broadcast known-unicast multicast unknown-unicast ] );
(user-vlan-1p-priority [ priorities ] | user-vlan-1p-priority [ priorities ] );
(user-vlan-id [ vlan-ids ] | user-vlan-id-except [ vlan-ids ] );
(vlan-ether-type [ protocol-types ] | vlan-ether-type-except [ protocol-types ] );
```

Complete [edit firewall] Hierarchy

 }
 }
 }
 }
 }`

Hierarchy Level [edit [firewall](#)]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure a firewall filter for IP version 4 (IPv4) or IP version 6 (IPv6) traffic.

Options *family-name*—Protocol family:

- **ccc**—Circuit cross-connect parameters
- **inet**—IPv4 parameters
- **inet6**—IPv6 protocol parameters
- **iso**—OSI ISO protocol parameters
- **mpls**—MPLS protocol parameters
- **tcc**—Translational cross-connect parameters
- **vpls**—Virtual private LAN service parameters.

The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
 interface-control—To add this statement to the configuration.

loss-priority (Normal Filter)

Syntax	loss-priority (high low);
Hierarchy Level	[edit firewall family <i>family-name</i> filter <i>filter-name</i> term <i>term-name</i> then]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Set the loss priority of incoming packets.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Multifield Classifiers on page 1390

loss-priority (Simple Filter)

Syntax	loss-priority (high low medium);
Hierarchy Level	[edit firewall family <i>family-name</i> simple-filter <i>filter-name</i> term <i>term-name</i> then]
Release Information	Statement introduced in Junos OS Release 7.6.
Description	Set the loss priority of incoming packets.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Multifield Classifiers on page 1390

policer (Configuring)

Syntax	<pre>policer <i>policer-name</i> { filter-specific; if-exceeding { bandwidth-limit <i>bps</i>; bandwidth-percent <i>number</i>; burst-size-limit <i>bytes</i>; } logical-bandwidth-policer; logical-interface-policer; physical-interface-policer; shared-bandwidth-policer; then { <i>policer-action</i>; } }</pre>
Hierarchy Level	[edit dynamic-profiles <i>profile-name</i> firewall], [edit firewall], [edit logical-systems <i>logical-system-name</i> firewall]
Release Information	Statement introduced before Junos OS Release 7.4. The out-of-profile policer action added in Junos OS Release 8.1. The logical-bandwidth-policer statement added in Junos OS Release 8.2. Logical systems support introduced in Junos OS Release 9.3. The physical-interface-policer statement introduced in Junos OS Release 9.6. The shared-bandwidth-policer statement added in Junos OS Release 11.2. Support at the [edit dynamic-profiles ... firewall] hierarchy level introduced in Junos OS Release 11.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Configure policer rate limits and actions. When included at the [edit firewall] hierarchy level, the policer statement creates a template, and you do not have to configure a policer individually for every firewall filter or interface. To activate a policer, you must include the policer-action modifier in the then statement in a firewall filter term or on an interface.
Options	<i>policer-action</i> —One or more actions to take: <ul style="list-style-type: none">• discard—Discard traffic that exceeds the rate limits.• forwarding-class <i>class-name</i>—Specify the particular forwarding class.• loss-priority—Set the packet loss priority (PLP) to low, medium-low, medium-high, or high.• out-of-profile—On J Series routers with strict priority queuing, prevent starvation of other queues by rate limiting the data stream entering the strict priority queue, marking the packets that exceed the rate limit as out-of-profile, and dropping the out-of-profile packets if the physical interface is congested.

policer-name—Name that identifies the policer. The name can contain letters, numbers, and hyphens (-), and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" "). Policer names cannot begin with an underscore in the form `__.*`.

then—Actions to take on matching packets.

The remaining statements are explained separately.

Required Privilege	firewall—To view this statement in the configuration.
Level	firewall-control—To add this statement to the configuration.

shared-bandwidth-policer

Syntax	shared-bandwidth-policer;
Hierarchy Level	[edit firewall policer <i>policer-name</i>] [edit firewall three-color-policer <i>policer-name</i>] [edit firewall hierarchical-policer <i>policer-name</i>]
Release Information	Statement introduced in Junos OS Release 11.2. Support for MX Series MPC and MIC interfaces added in Junos OS Release 12.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Policer instances share bandwidth. This enables configuration of interface-specific policers applied on an aggregated Ethernet bundle or an aggregated SONET bundle to match the effective bandwidth and burst-size to user-configured values. This feature is supported on the following platforms: T Series routers, M120, M10i, M7i (CFEB-E only), M320 (SFPC only), MX240, MX480, and MX960 with DPC, MPC, and MIC interfaces, and EX Series switches.
	<div> NOTE: This statement is not supported on T4000 Type 5 FPCs.</div>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Policer Support for Aggregated Ethernet Bundle Overview on page 1446

term (Normal Filter)

Syntax	<pre> term <i>term-name</i> { from { <i>match-conditions</i>; } then { forwarding-class <i>class-name</i>; loss-priority (high low); three-color-policer { (single-rate two-rate) <i>policer-name</i>; } } } </pre>
Hierarchy Level	[edit firewall family <i>family-name</i> filter <i>filter-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Define a firewall filter term.
Options	<p>from—Match packet fields to values. If not included, all packets are considered to match and the actions and action modifiers in the then statement are taken.</p> <p>match-conditions—One or more conditions to use to make a match.</p> <p>term-name—Name that identifies the term. The name can contain letters, numbers, and hyphens (-), and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" ").</p> <p>then—Actions to take on matching packets. If not included and a packet matches all the conditions in the from statement, the packet is accepted. For CoS, only the actions listed are allowed. These statements are explained separately.</p>
Required Privilege Level	<p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring Multifield Classifiers on page 1390

filter (Applying to an Interface)

Syntax	<pre>filter { input <i>filter-name</i>; output <i>filter-name</i>; }</pre>
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i>], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Apply a filter to an interface. You can also use filters for encrypted traffic. When you configure filters, you can configure the family inet , inet6 , mpls , or vpls only.
Options	<p>input <i>filter-name</i>—Name of one filter to evaluate when packets are received on the interface.</p> <p>output <i>filter-name</i>—Name of one filter to evaluate when packets are transmitted on the interface.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• simple-filter on page 1440• <i>Applying Firewall Filter Tricolor Marking Policers to Interfaces</i>• <i>Example: Classifying Packets Based on Their Destination Address</i>• Example: Configuring and Verifying a Complex Multifield Filter on page 1394• <i>Example: Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets</i>• Example: Configuring a Simple Filter on page 1399• Example: Configuring a Logical Bandwidth Policer on page 1400• Example: Two-Color Policers and Shaping Rate Changes on page 1401

input-policer

Syntax	<code>input-policer <i>policer-name</i>;</code>
Hierarchy Level	<code>[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> layer2-policer]</code> <code>[edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> layer2-policer]</code>
Release Information	Statement introduced in Junos OS Release 8.2. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Apply a single-rate two-color policer to the Layer 2 input traffic at the logical interface. The input-policer and input-three-color statements are mutually exclusive.
Options	<i>policer-name</i> —Name of the single-rate two-color policer that you define at the [edit firewall] hierarchy level.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

Overview of Forwarding Classes

This topic covers the following information:

- [Output Queue Assignments Based on Forwarding Class on page 1526](#)
- [Devices That Support Up to Four Forwarding Classes on page 1526](#)
- [Devices That Support Up to 16 Forwarding Classes on page 1527](#)
- [Default and Configurable Packet Loss Priority Values on page 1527](#)
- [Configuration Statements Used to Configure and Apply Forwarding Classes on page 1527](#)

Output Queue Assignments Based on Forwarding Class

It is helpful to think of forwarding classes as output queues. In effect, the end result of classification is the identification of an output queue for a particular packet.

CoS packet classification assigns an incoming packet to an output queue based on the packet's forwarding class. Each packet is associated with one of the following default forwarding classes:

- Expedited forwarding (EF)—Provides a low-loss, low-latency, low-jitter, assured bandwidth, end-to-end service.
- Assured forwarding (AF)—Provides a group of values you can define and includes four subclasses: AF1, AF2, AF3, and AF4, each with three drop probabilities: low, medium, and high.
- Best effort (BE)—Provides no service profile. For the best effort forwarding class, loss priority is typically not carried in a class-of-service (CoS) value and random early detection (RED) drop profiles are more aggressive.
- Network control (NC)—This class is typically high priority because it supports protocol control.

Devices That Support Up to Four Forwarding Classes

Some of the Juniper Networks routing platforms support up to four forwarding classes for classifying customer traffic. On these platforms, you can configure one of each type of default forwarding class. The following Juniper Networks platforms support up to four forwarding classes:

- M7i Multiservice Edge Routers with Compact Forwarding Engine Boards (CFEBs)
- M10i Multiservice Edge Routers with CFEBs

NOTE: This list does not reference any Juniper Networks device that has reached its End of Life (EOL) period and its End of Support (EOS) milestone date.

Devices That Support Up to 16 Forwarding Classes

Other Juniper Networks routing platforms support up to 16 forwarding classes, which enables you to classify packets more granularly. For example, you can configure multiple classes of EF traffic: EF, EF1, and EF2. On these platforms, the Junos OS software supports up to eight output queues; therefore, if you configure more than eight forwarding classes, you must map multiple forwarding classes to single output queues. The following Juniper Networks routing and switching platforms support up to 16 forwarding classes and up to 8 output queues:

- EX Series switches
- M7i Multiservices Edge Routers with Enhanced Compact Forwarding Engine Boards (CFEB-Es)
- M10i Multiservices Edge Routers with CFEB-Es
- M120 Multiservices Edge Routers
- M320 Multiservices Edge Routers
- MX Series 3D Universal Edge Routers
- T Series Core Routers
- PTX Packet Transport Switches

Default and Configurable Packet Loss Priority Values

By default, the loss priority is low. On most devices, you can configure high or low loss priority. On the following devices, you can configure high, low, medium-high, or medium-low loss priority:

- J Series Services Router interfaces
- M320 routers and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs)
- T640 routers with Enhanced Scaling FPC4s
- PTX Series Packet Transport Switches

Configuration Statements Used to Configure and Apply Forwarding Classes

To configure CoS forwarding classes, include the **forwarding-classes** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
forwarding-classes {
  class class-name queue-num queue-number priority (high | low);
  queue queue-number class-name priority (high | low);
}
forwarding-classes-interface-specific forwarding-class-map-name {
  class class-name queue-num queue-number [ restricted-queue queue-number ];
}
interfaces {
  interface-name {
    unit logical-unit-number {
      forwarding-class class-name;
```

```

        forwarding-classes-interface-specific forwarding-class-map-name;
    }
}
restricted-queues {
    forwarding-class class-name queue queue-number;
}

```

- *Policer Overview*

Default Forwarding Classes

By default, four queues are assigned to four forwarding classes, each with a queue number, name, and abbreviation.

These default mappings apply to all routers. The four forwarding classes defined by default are shown in [Table 107 on page 1528](#).

If desired, you can rename the forwarding classes associated with the queues supported on your hardware. Assigning a new class name to an output queue does not alter the default classification or scheduling that is applicable to that queue. CoS configurations can be quite complicated, so unless it is required by your scenario, we recommend that you not alter the default class names or queue number associations.

Some routers support eight queues. Queues 4 through 7 have no default mappings to forwarding classes. To use queues 4 through 7, you must create custom forwarding class names and map them to the queues. For more information, see the Juniper Networks J Series Services Router documentation.

Table 107: Default Forwarding Classes

Queue	Forwarding Class Name	Comments
Queue 0	best-effort (be)	The software does not apply any special CoS handling to packets with 000000 in the DiffServ field, a backward compatibility feature. These packets are usually dropped under congested network conditions.
Queue 1	expedited-forwarding (ef)	<p>The software delivers assured bandwidth, low loss, low delay, and low delay variation (jitter) end-to-end for packets in this service class.</p> <p>Routers accept excess traffic in this class, but in contrast to assured forwarding, out-of-profile expedited-forwarding packets can be forwarded out of sequence or dropped.</p>

Table 107: Default Forwarding Classes (*continued*)

Queue	Forwarding Class Name	Comments
Queue 2	assured-forwarding (af)	<p>The software offers a high level of assurance that the packets are delivered as long as the packet flow from the customer stays within a certain service profile that you define.</p> <p>The software accepts excess traffic, but applies a RED drop profile to determine if the excess packets are dropped and not forwarded.</p> <p>Depending on router type, up to four drop probabilities (low, medium-low, medium-high, and high) are defined for this service class.</p>
Queue 3	network-control (nc)	<p>The software delivers packets in this service class with a low priority. (These packets are not delay sensitive.)</p> <p>Typically, these packets represent routing protocol hello or keepalive messages. Because loss of these packets jeopardizes proper network operation, delay is preferable to discard.</p>

The following rules govern queue assignment:

- If classifiers fail to classify a packet, the packet always receives the default classification to the class associated with queue 0.
- The number of queues is dependent on the hardware plugged into the chassis. CoS configurations are inherently contingent on the number of queues on the system. Only two classes, **best-effort** and **network-control**, are referenced in the default configuration. The default configuration works on all routers.
- CoS configurations that specify more queues than the router can support are not accepted. The commit fails with a detailed message that states the total number of queues available.
- All default CoS configuration is based on queue number. The name of the forwarding class that shows up when the default configuration is displayed is the forwarding class currently associated with that queue.

This is the default configuration for the **forwarding-classes** statement:

```
[edit class-of-service]
forwarding-classes {
  queue 0 best-effort;
  queue 1 expedited-forwarding;
  queue 2 assured-forwarding;
  queue 3 network-control;
}
```

If you reassign the forwarding-class names, the **best-effort** forwarding-class name appears in the locations in the configuration previously occupied by **network-control** as follows:

```
[edit class-of-service]
forwarding-classes {
  queue 0 network-control;
```

```
queue 1 assured-forwarding;  
queue 2 expedited-forwarding;  
queue 3 best-effort;  
}
```

All the default rules of classification and scheduling that applied to Queue 3 still apply. Queue 3 is simply now renamed **best-effort**.

On Juniper Networks M320 Multiservice Edge Routers and T Series Core Routers, you can assign multiple forwarding classes to a single queue. If you do so, the first forwarding class that you assign to queue 0 acquires the default BE classification and scheduling. The first forwarding class that you assign to queue 1 acquires the default EF classification and scheduling. The first forwarding class that you assign to queue 2 acquires the default AF classification and scheduling. The first forwarding class that you assign to queue 3 acquires the default NC classification and scheduling. For more information, see *Configuring Up to 16 Forwarding Classes*.

- In the current default configuration:
 - Only IP precedence classifiers are associated with interfaces.
 - The only classes designated are **best-effort** and **network-control**.
 - Schedulers are not defined for the **expedited-forwarding** or **assured-forwarding** forwarding classes.
- You must explicitly classify packets to the **expedited-forwarding** or **assured-forwarding** forwarding class and define schedulers for these classes.

For more information, see *Hardware Capabilities and Limitations*.

Configuration

- [Overriding Fabric Priority Queuing on page 1535](#)
- [Configuring Up to 16 Forwarding Classes on page 1535](#)

Configuring Forwarding Classes

You assign each forwarding class to an internal queue number by including the **forwarding-classes** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]  
forwarding-classes {  
  class queue-num queue-number priority (high | low);
```

```

queue queue-number class-name priority (high | low) [ policing-priority (premium |
normal) ];
}

```

You cannot commit a configuration that assigns the same forwarding class to two different queues.

CAUTION: We do not recommend classifying packets into a forwarding class that has no associated scheduler on the egress interface. Such a configuration can cause unnecessary packet drops because an unconfigured scheduling class might lack adequate buffer space. For example, if you configure a custom scheduler map that does not define queue 0, and the default classifier assigns incoming packets to the best-effort class (queue 0), the unconfigured egress queue for the best-effort forwarding class might not have enough space to accommodate even short packet bursts.

A default congestion and transmission control mechanism is used when an output interface is not configured for a certain forwarding class, but receives packets destined for that unconfigured forwarding class. This default mechanism uses the delay buffer and weighted round robin (WRR) credit allocated to the designated forwarding class, with a default drop profile. Because the buffer and WRR credit allocation is minimal, packets might be lost if a larger number of packets are forwarded without configuring the forwarding class for the interface.

Applying Forwarding Classes to Interfaces

You can configure *fixed classification* on a logical interface by specifying a forwarding class to be applied to all packets received by the logical interface, regardless of the packet contents.

NOTE: On the T4000 router, BA classification and fixed classification are mutually exclusive. That is, only one of the classifications can be configured.

To apply a forwarding class configuration to the input logical interface, include the **forwarding-class** statement at the [edit class-of-service interfaces *interface-name* unit *logical-unit-number*] hierarchy level:

```

[edit class-of-service interfaces interface-name unit logical-unit-number]
  forwarding-class class-name;

```

You can include interface wildcards for *interface-name* and *logical-unit-number*.

In the following example, all packets coming into the router from the **ge-3/0/0.0** interface are assigned to the **assured-forwarding** forwarding class:

```

[edit class-of-service]
interfaces {
  ge-3/0/0 {
    unit 0 {

```

```

        forwarding-class assured-forwarding;
    }
}

```

- [forwarding-class on page 1547](#)

Classifying Packets by Egress Interface

For Juniper Networks EX Series switches, M320 Multiservice Edge Routers, and T Series Core Routers with the Intelligent Queuing (IQ), IQ2, Enhanced IQ (IQE), or Multiservices link services intelligent queuing (LSQ) interfaces,, you can classify unicast and multicast packets based on the egress interface. For unicast traffic, you can also use a multifield filter, but only egress interface classification applies to multicast traffic as well as unicast traffic. If you configure egress classification of an interface, you cannot perform Differentiated Services code point (DSCP) rewrites on the interface. By default, the system will not perform any classification based on the egress interface.

To enable packet classification by the egress interface, you first configure a forwarding class map and one or more queue numbers for the egress interface at the **[edit class-of-service forwarding-classes-interface-specific forwarding-class-map-name]** hierarchy level:

```

[edit class-of-service]
  forwarding-classes-interface-specific forwarding-class-map-name {
    class class-name queue-num queue-number [ restricted-queue queue-number ];
  }

```

For T Series routers that are restricted to only four queues, you can control the queue assignment with the **restricted-queue** option, or you can allow the system to automatically determine the queue in a modular fashion. For example, a map assigning packets to queue 6 would map to queue 2 on a four-queue system.

NOTE: If you configure an output forwarding class map associating a forwarding class with a queue number, this map is not supported on multiservices link services intelligent queuing (lsq-) interfaces.

Once the forwarding class map has been configured, you apply the map to the logical interface by using the **output-forwarding-class-map** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy level:

```

[edit class-of-service interfaces interface-name unit logical-unit-number]
  output-forwarding-class-map forwarding-class-map-name;

```

All parameters relating to the queues and forwarding class must be configured as well. For more information about configuring forwarding classes and queues, see [“Configuring Forwarding Classes” on page 1530](#).

This example shows how to configure an interface-specific forwarding-class map named **FCMAP1** that restricts queues 5 and 6 to different queues on four-queue systems and then applies **FCMAP1** to **unit 0** of interface **ge-6/0/0**:

```

[edit class-of-service]

```

```

forwarding-classes-interface-specific FCMAP1 {
  class FC1 queue-num 6 restricted-queue 3;
  class FC2 queue-num 5 restricted-queue 2;
  class FC3 queue-num 3;
  class FC4 queue-num 0;
  class FC3 queue-num 0;
  class FC4 queue-num 1;
}

```

```

[edit class-of-service]
interfaces {
  ge-6/0/0 unit 0 {
    output-forwarding-class-map FCMAP1;
  }
}

```

Note that without the **restricted-queue** option in **FCMAP1**, the example would assign **FC1** and **FC2** to queues 2 and 1, respectively, on a system restricted to four queues.

Use the **show class-of-service forwarding-class *forwarding-class-map-name*** command to display the forwarding-class map queue configuration:

```
user@host> show class-of-service forwarding-class FCMAP2
```

Forwarding class	ID	Queue	Restricted queue
FC1	0	6	3
FC2	1	5	2
FC3	2	3	3
FC4	3	0	0
FC5	4	0	0
FC6	5	1	1
FC7	6	6	2
FC8	7	7	3

Use the **show class-of-service interface *interface-name*** command to display the forwarding-class maps (and other information) assigned to a logical interface:

```
user@host> show class-of-service interface ge-6/0/0
```

```

Physical interface: ge-6/0/0, Index: 128
Queues supported: 8, Queues in use: 8

```

Object	Name	Type	Index
Scheduler-map	<default>	Output	2
Scheduler-map	<default>	Input	3

Assigning Forwarding Class and DSCP Value for Routing Engine–Generated Traffic

You can set the forwarding class and differentiated service code point (DSCP) value for traffic originating in the Routing Engine. To configure forwarding class and DSCP values that apply to Routing Engine–generated traffic only, apply an output filter to the loopback (lo.0) interface and set the appropriate forwarding class and DSCP bit configuration for various protocols. For example, you can set the DSCP value on OSPF packets that originate in the Routing Engine to **10** and assign them to the AF (assured forwarding) forwarding class while the DSCP value on ping packets are set to **0** and use forwarding class BE (best effort).

This particular classification ability applies to packets generated by the Routing Engine only.

The following example assigns Routing Engine sourced ping packets (using ICMP) a DSCP value of **38** and a forwarding class of **af17**, OSPF packets a DSCP value of **12** and a forwarding class of **af11**, and BGP packets (using TCP) a DSCP value of **10** and a forwarding class of **af16**.

```
[edit class-of-service]
forwarding-classes {
  class af11 queue-num 7;
  class af12 queue-num 1;
  class af13 queue-num 2;
  class af14 queue-num 4;
  class af15 queue-num 5;
  class af16 queue-num 4;
  class af17 queue-num 6;
  class af18 queue-num 7;
}

[edit firewall filter family inet]
filter loopback-filter {
  term t1 {
    from {
      protocol icmp; # For pings
    }
    then {
      forwarding-class af17;
      dscp 38;
    }
  }
  term t2 {
    from {
      protocol ospf; # For OSPF
    }
    then {
      forwarding-class af11;
      dscp 12;
    }
  }
}
```

```

term t3 {
  from {
    protocol tcp; # For BGP
  }
  then {
    forwarding-class af16;
    dscp 10;
  }
}
term t4 {
  then accept; # Do not forget!
}
}

[edit interfaces]
lo0 {
  unit 0 {
    family inet {
      filter {
        output loopback-filter;
      }
    }
  }
}

```

NOTE: This is not a complete router configuration. You still have to assign resources to the queues, configure the routing protocols, addresses, and so on.

Overriding Fabric Priority Queuing

On EX Series switches, and on M320 and T Series routers, the default behavior is for fabric priority queuing on egress interfaces to match the scheduling priority you assign. High-priority egress traffic is automatically assigned to high-priority fabric queues. Likewise, low-priority egress traffic is automatically assigned to low-priority fabric queues.

You can override the default fabric priority queuing of egress traffic by including the **priority** statement at the **[edit class-of-service forwarding-classes queue queue-number class-name]** hierarchy level:

```

[edit class-of-service forwarding-classes queue queue-number class-name]
priority (high | low);

```

For information about associating a scheduler with a fabric priority, see [“Associating Schedulers with Fabric Priorities” on page 1612](#).

Configuring Up to 16 Forwarding Classes

By default on all routers and switches, four output queues are mapped to four forwarding classes, as shown in the topic *Default Forwarding Classes*. On Juniper Networks J Series Services Routers, M120 and M320 Multiservice Edge Routers, and T Series Core Routers, you can configure more than four forwarding classes and queues. For information about configuring J Series routers, see the J Series router documentation.

NOTE: You cannot use CoS-based forwarding features if you configure more than eight forwarding classes on the device.

On M120, M320, MX Series, T Series routers, EX Series switches and PTX Series Packet Transport Switches, you can configure up to 16 forwarding classes and eight queues, with multiple forwarding classes assigned to single queues. The concept of assigning multiple forwarding classes to a queue is sometimes referred to as creating *forwarding-class aliases*. This section explains how to configure M320 and T Series routers.

Mapping multiple forwarding classes to single queues is useful. Suppose, for example, that forwarding classes are set based on multifield packet classification, and the multifield classifiers are different for core-facing interfaces and customer-facing interfaces. Suppose you need four queues for a core-facing interface and five queues for a customer-facing interface, where **fc0** through **fc4** correspond to the classifiers for the customer-facing interface, and **fc5** through **fc8** correspond to classifiers for the core-facing interface, as shown in [Figure 11 on page 1536](#).

Figure 11: Customer-Facing and Core-Facing Forwarding Classes

9016702

In this example, there are nine classifiers and, therefore, nine forwarding classes. The forwarding class-to-queue mapping is shown in [Table 108 on page 1536](#).

Table 108: Sample Forwarding Class-to-Queue Mapping

Forwarding Class Names	Queue Number
fc0	0
fc5	
fc1	1
fc6	
fc2	2
fc7	
fc3	3
fc8	
fc4	4

To configure up to 16 forwarding classes, include the **class** and **queue-num** statements at the **[edit class-of-service forwarding-classes]** hierarchy level:

```
[edit class-of-service forwarding-classes]
class class-name queue-num queue-number;
```

You can configure up to 16 different forwarding-class names. The corresponding output queue number can be from 0 through 7. Therefore, you can map multiple forwarding classes to a single queue. If you map multiple forwarding classes to a queue, the multiple forwarding classes must refer to the same scheduler (at the **[edit class-of-service scheduler-maps *map-name* forwarding-class *class-name* scheduler *scheduler-name*]** hierarchy level).

When you configure up to 16 forwarding classes, you can use them as you can any other forwarding class—in classifiers, schedulers, firewall filters (multifield classifiers), policers, and rewrite rules.

When you configure up to 16 forwarding classes, the following limitations apply:

- The **class** and **queue** statements at the **[edit class-of-service forwarding-classes]** hierarchy level are mutually exclusive. In other words, you can include one or the other of the following configurations, but not both:

```
[edit class-of-service forwarding-classes]
queue queue-number class-name;
```

```
[edit class-of-service forwarding-classes]
class class-name queue-num queue-number;
```

- On T Series routers only, when you configure IEEE 802.1p rewrite marking on Gigabit Ethernet IQ, Gigabit Ethernet IQ2, Gigabit Ethernet Enhanced IQ (IQE), and Gigabit Ethernet Enhanced IQ2 (IQ2E) PICs, you cannot configure more than eight forwarding classes. This limitation does not apply to M Series routers. On M Series routers, you can configure up to 16 forwarding classes when you configure IEEE 802.1p rewrite marking on any of these PICs.
- For GRE and IP-IP tunnels, IP precedence and DSCP rewrite marking of the inner header do not work with more than eight forwarding classes.
- When you use CoS-based forwarding features, you cannot configure more than eight forwarding classes with a forwarding policy. However, if you try to configure CoS-based forwarding with more than eight forwarding classes configured, commit fails with a message. Therefore, you can configure CBF on a router with eight or less than eight forwarding classes only. Under this condition, the forwarding class to queue mapping can be either one-to-one or one-to-many.
- A scheduler map that maps eight different forwarding classes to eight different schedulers can only be applied to interfaces that support eight queues. If you apply this type of scheduler map to an interface that only supports four queues, then the commit will fail.
- We recommend that you configure the statements changing PICs to support eight queues and then applying an eight queue scheduler map in two separate steps. Otherwise, the commit might succeed but the PIC might not have eight queues when the scheduler map is applied, generating an error.

You can determine the ID number assigned to a forwarding class by issuing the **show class-of-service forwarding-class** command. You can determine whether the classification is fixed by issuing the **show class-of-service forwarding-table classifier mapping** command. In the command output, if the **Table Type** field appears as **Fixed**, the classification is fixed. For more information about fixed classification, see [“Applying Forwarding Classes to Interfaces” on page 1531](#).

This section discusses the following topics:

- [Enabling Eight Queues on Interfaces on page 1538](#)
- [Multiple Forwarding Classes and Default Forwarding Classes on page 1539](#)
- [PICs Restricted to Four Queues on page 1540](#)
- [Examples: Configuring Up to 16 Forwarding Classes on page 1541](#)

Enabling Eight Queues on Interfaces

By default, Intelligent Queuing (IQ), Intelligent Queuing 2 (IQ2), Intelligent Queuing Enhanced (IQE), and Intelligent Queuing 2 Enhanced (IQ2E) PICs on M320 and T Series routers are restricted to a maximum of four egress queues per interface. To configure a maximum of eight egress queues on these interfaces, include the **max-queues-per-interface** statement at the **[edit chassis fpc slot-number pic pic-number]** hierarchy level:

```
[edit chassis fpc slot-number pic pic-number]
max-queues-per-interface (4 | 8);
```

On a TX Matrix or TX Matrix Plus router, include the **max-queues-per-interface** statement at the **[edit chassis lcc number fpc slot-number pic pic-number]** hierarchy level:

```
[edit chassis lcc number fpc slot-number pic pic-number]
max-queues-per-interface (4 | 8);
```

The numerical value can be 4 or 8.

For Juniper Networks J Series routers, this statement is not supported. J Series routers always have eight queues available.

NOTE: In addition to configuring eight queues at the **[edit chassis]** hierarchy level, the configuration at the **[edit class-of-service]** hierarchy level must support eight queues per interface.

The maximum number of queues per IQ PIC can be 4 or 8. If you include the **max-queues-per-interface** statement, all ports on the IQ PIC use configured mode and all interfaces on the IQ PIC have the same maximum number of queues.

To determine how many queues an interface supports, you can check the **CoS queues** output field of the **show interfaces interface-name extensive** command:

```
user@host> show interfaces ge-1/0/0 extensive
CoS queues: 8 supported
```

If you include the **max-queues-per-interface 4** statement, you can configure all four ports and configure up to four queues per port.

For 4-port OC3c/STM1 Type I and Type II PICs on M320 and T Series routers, when you include the **max-queues-per-interface 8** statement, you can configure up to eight queues on ports 0 and 2. After you commit the configuration, the PIC goes offline and comes back online with only ports 0 and 2 operational. No interfaces can be configured on ports 1 and 3.

For Quad T3 and Quad E3 PICs, when you include the **max-queues-per-interface 8** statement, you can configure up to eight queues on ports 0 and 2. After you commit the configuration, the PIC goes offline and comes back online with only ports 0 and 2 operational. No interfaces can be configured on ports 1 and 3.

When you include the **max-queues-per-interface** statement and commit the configuration, all physical interfaces on the IQ PIC are deleted and readded. Also, the PIC is taken offline and then brought back online immediately. You do not need to take the PIC offline and online manually. You should change modes between four queues and eight queues only when there is no active traffic going to the IQ PIC.

Multiple Forwarding Classes and Default Forwarding Classes

For queues 0 through 3, if you assign multiple forwarding classes to a single queue, default forwarding class assignment works as follows:

- The first forwarding class that you assign to queue 0 acquires the default BE classification and scheduling.
- The first forwarding class that you assign to queue 1 acquires the default EF classification and scheduling.
- The first forwarding class that you assign to queue 2 acquires the default AF classification and scheduling.
- The first forwarding class that you assign to queue 3 acquires the default NC classification and scheduling.

Of course you can override the default classification and scheduling by configuring custom classifiers and schedulers.

If you do not explicitly map forwarding classes to queues 0 through 3, then the respective default classes are automatically assigned to those queues. When you are counting the 16 forwarding classes, you must include in the total any default forwarding classes automatically assigned to queues 0 through 3. As a result, you can map up to 13 forwarding classes to a single queue when the single queue is queue 0, 1, 2, or 3. You can map up to 12 forwarding classes to a single queue when the single queue is queue 4, 5, 6, or 7. In summary, there must be at least one forwarding class each (default or otherwise) assigned to queue 0 through 3, and you can assign the remaining 12 forwarding classes (16–4) to any queue.

For example, suppose you assign two forwarding classes to queue 0 and you assign no forwarding classes to queues 1 through 3. The software automatically assigns one default

forwarding class each to queues 1 through 3. This means 11 forwarding classes (16–5) are available for you to assign to queues 4 through 7.

For more information about forwarding class defaults, see *Default Forwarding Classes*.

PICs Restricted to Four Queues

Some Juniper Networks T Series Core Router PICs support up to 16 forwarding classes and are restricted to 4 queues. Contact Juniper Networks customer support for a current list of T Series router PICs that are restricted to four queues. To determine how many queues an interface supports, you can check the **CoS queues** output field of the **show interfaces interface-name extensive** command:

```
user@host> show interfaces ge-1/0/0 extensive
CoS queues: 8 supported
```

By default, for T Series router PICs that are restricted to four queues, the router overrides the global configuration based on the following formula:

$$Q_r = Q_d \bmod R_{max}$$

Q_r is the queue number assigned if the PIC is restricted to four queues.

Q_d is the queue number that would have been mapped if this PIC were not restricted.

R_{max} is the maximum number of restricted queues available. Currently, this is four.

For example, assume you map the forwarding class **ef** to queue 6. For a PIC restricted to four queues, the queue number for forwarding class **ef** is **Q_r = 6 mod 4 = 2**.

To determine which queue is assigned to a forwarding class, use the **show class-of-service forwarding-class** command from the top level of the CLI. The output shows queue assignments for both global queue mappings and restricted queue mappings:

```
user@host> show class-of-service forwarding-class
```

Forwarding class	Queue	Restricted Queue	Fabric priority	
be		0	2	low
ef		1	2	low
assured-forwarding		2	2	low
network-control		3	3	low

For T Series router PICs restricted to four queues, you can override the formula-derived queue assignment by including the **restricted-queues** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
restricted-queues {
  forwarding-class class-name queue queue-number;
}
```

You can configure up to 16 forwarding classes. The output queue number can be from 0 through 3. Therefore, for PICs restricted to four queues, you can map multiple forwarding classes to single queues. If you map multiple forwarding classes to a queue, the multiple forwarding classes must refer to the same scheduler. This requirement applies to all PICs. The class name you configure at the **[edit class-of-service restricted-queues]** hierarchy level must be either a default forwarding class name or a forwarding class you configure at the **[edit class-of-service forwarding-classes]** hierarchy level.

Examples: Configuring Up to 16 Forwarding Classes

Configure 16 forwarding classes:

**Configuring 16
Forwarding Classes**

```
[edit class-of-service]
forwarding-classes {
  class fc0 queue-num 0;
  class fc1 queue-num 0;
  class fc2 queue-num 1;
  class fc3 queue-num 1;
  class fc4 queue-num 2;
  class fc5 queue-num 2;
  class fc6 queue-num 3;
  class fc7 queue-num 3;
  class fc8 queue-num 4;
  class fc9 queue-num 4;
  class fc10 queue-num 5;
  class fc11 queue-num 5;
  class fc12 queue-num 6;
  class fc13 queue-num 6;
  class fc14 queue-num 7;
  class fc15 queue-num 7;
}
```

For PICs restricted to four queues, map four forwarding classes to each queue:

**Restricted Queues:
Mapping Two
Forwarding Classes to
Each Queue**

```
[edit class-of-service]
restricted-queues {
  forwarding-class fc0 queue 0;
  forwarding-class fc1 queue 0;
  forwarding-class fc2 queue 0;
  forwarding-class fc3 queue 0;
  forwarding-class fc4 queue 1;
  forwarding-class fc5 queue 1;
  forwarding-class fc6 queue 1;
  forwarding-class fc7 queue 1;
  forwarding-class fc8 queue 2;
  forwarding-class fc9 queue 2;
  forwarding-class fc10 queue 2;
  forwarding-class fc11 queue 2;
  forwarding-class fc12 queue 3;
  forwarding-class fc13 queue 3;
  forwarding-class fc14 queue 3;
  forwarding-class fc15 queue 3;
}
```

If you map multiple forwarding classes to a queue, the multiple forwarding classes must refer to the same scheduler:

**Configuring a
Scheduler Map
Applicable to an
Interface Restricted to
Four Queues**

```
[edit class-of-service]
scheduler-maps {
  interface-restricted {
    forwarding-class be scheduler Q0;
    forwarding-class ef scheduler Q1;
    forwarding-class ef1 scheduler Q1;
    forwarding-class ef2 scheduler Q1;
    forwarding-class af1 scheduler Q2;
  }
}
```

```
    forwarding-class af scheduler Q2;
    forwarding-class nc scheduler Q3;
    forwarding-class nc1 scheduler Q3;
  }
}
[edit class-of-service]
restricted-queues {
  forwarding-class be queue 0;
  forwarding-class ef queue 1;
  forwarding-class ef1 queue 1;
  forwarding-class ef2 queue 1;
  forwarding-class af queue 2;
  forwarding-class af1 queue 2;
  forwarding-class nc queue 3;
  forwarding-class nc1 queue 3;
}
```

forwarding-class (Interfaces)

Syntax	<code>forwarding-class class-name;</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.2 for ACX Series routers.
Description	Associate a forwarding class configuration or default mapping with a specific interface.
Options	<i>class-name</i> —Name of the forwarding class.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Applying Forwarding Classes to Interfaces on page 1531 • Configuring Fixed Classification on an ATM IMA Pseudowire • Example: Configuring Fixed Classification on an ATM IMA Pseudowire

forwarding-class (Restricted Queues)

Syntax	<code>forwarding-class class-name queue queue-number;</code>
Hierarchy Level	[edit class-of-service restricted-queues]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For M320 and T Series routers only, map forwarding classes to restricted queues. You can map up to eight forwarding classes to restricted queues.
Options	<i>class-name</i> —Name of the forwarding class. The remaining statement is explained separately.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

forwarding-classes (Class-of-Service)

Syntax	<pre>forwarding-classes { class queue-num queue-number priority (high low); queue queue-number class-name priority (high low) [policing-priority (premium normal)]; }</pre>
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced before Junos OS Release 7.4. policing-priority option introduced in Junos OS Release 9.5. Statement introduced on PTX Series Packet Transport Switches in Junos OS Release 12.1.
Description	Associate the forwarding class with a queue name and number. For M320, MX Series, T Series routers and EX Series switches only, you can configure fabric priority queuing by including the priority statement. For Enhanced IQ PICs, you can include the policing-priority option.
<div> NOTE: The priority and policing-priority options are not supported on PTX Series Packet Transport Switches.</div>	
<p>The statements are explained separately.</p> <p>See “Configuring Forwarding Classes” on page 1530, “Overriding Fabric Priority Queuing” on page 1535, and <i>Example: Configuring CoS for a PBB Network</i>. For the policing-priority option, see <i>Configuring Layer 2 Policers on IQE PICs</i>. For classification by egress interface, see <i>Classifying Packets by Egress Interface</i>.</p>	
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

forwarding-classes-interface-specific

Syntax	forwarding-classes-interface-specific <i>forwarding-class-map-name</i> { class <i>class-name</i> queue-num <i>queue-number</i> [restricted-queue <i>queue-number</i>]; }
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced in Junos OS Release 9.6.
Description	For the IQ, IQE, LSQ and ATM2 PICs in the T Series routers only and for EX Series switches, configure a forwarding class map for unicast and multicast traffic and a user-configured queue number for an egress interface.
Options	<p><i>class-name</i>—Name of the forwarding class.</p> <p><i>forwarding-class-map-name</i>—Name of the forwarding class map for traffic.</p> <p><i>queue-number</i>—Number of the egress queue.</p> <p>Range: 0 through 3 or 7, depending on chassis and configuration</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

Hierarchy Level [edit class-of-service]

Release Information Statement introduced before Junos OS Release 7.4.
Interface-set level added in Junos OS Release 8.5.

Description Configure interface-specific CoS properties for incoming packets.

NOTE: The dscp-ipv6 and ieee-802.1ad classifier types are not supported on ACX Series routers. For further information about support on ACX Series routers, see *Understanding CoS CLI Configuration Statements on ACX Series Universal Access Routers*.

Options The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Forwarding Policy Options Overview

Class-of-service (CoS)-based forwarding (CBF) enables you to control next-hop selection based on a packet's class of service and, in particular, the value of the IP packet's precedence bits.

For example, you might want to specify a particular interface or next hop to carry high-priority traffic while all best-effort traffic takes some other path. When a routing protocol discovers equal-cost paths, it can pick a path at random or load-balance across the paths through either hash selection or round robin. CBF allows path selection based on class.

To configure CBF properties, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
forwarding-policy {
  next-hop-map map-name {
    forwarding-class class-name {
      next-hop [ next-hop-name ];
      lsp-next-hop [ lsp-regular-expression ];
      non-lsp-next-hop;
      discard;
    }
  }
  class class-name {
    classification-override {
      forwarding-class class-name;
    }
  }
}
```

Configuration Tasks

- [Configuring CoS-Based Forwarding on page 1557](#)
- [Overriding the Input Classification on page 1560](#)

Configuring CoS-Based Forwarding

You can apply CoS-based forwarding (CBF) only to a defined set of routes. Therefore you must configure a policy statement as in the following example:

```
[edit policy-options]
policy-statement my-cos-forwarding {
  from {
```

```

    route-filter destination-prefix match-type;
  }
  then {
    cos-next-hop-map map-name;
  }
}

```

This configuration specifies that routes matching the route filter are subject to the CoS next-hop mapping specified by *map-name*. For more information about configuring policy statements, see the *Routing Policy Configuration Guide*.

NOTE: On M Series routers (except the M120 and M320 routers), forwarding-class-based matching and CBF do not work as expected if the forwarding class has been set with a multifield filter on an input interface.

You can configure CBF on a routing device with eight or less than eight forwarding classes only. Under this condition, the forwarding class to queue mapping can be either one-to-one or one-to-many. However, you cannot configure CBF when the number of forwarding classes configured exceeds eight. Similarly, with CBF configured, you cannot configure more than eight forwarding classes.

To specify a CoS next-hop map, include the **forwarding-policy** statement at the **[edit class-of-service]** hierarchy level:

```

[edit class-of-service]
forwarding-policy {
  next-hop-map map-name {
    forwarding-class class-name {
      next-hop [ next-hop-name ];
      lsp-next-hop [ lsp-regular-expression ];
      discard;
    }
  }
}

```

When you configure CBF with OSPF as the interior gateway protocol (IGP), you must specify the next hop as an interface name or next-hop alias, not as an IP address. This is true because OSPF adds routes with the interface as the next hop for point-to-point interfaces; the next hop does not contain the IP address. For an example configuration, see *Example: Configuring CoS-Based Forwarding*.

For Layer 3 VPNs, when you use class-based forwarding for the routes received from the far-end provider-edge (PE) router within a VRF instance, the software can match the routes based on the attributes that come with the received route only. In other words, the matching can be based on the route within RIB-in. In this case, the **route-filter** statement you include at the **[edit policy-options policy-statement my-cos-forwarding from]** hierarchy level has no effect because the policy checks the **bgp.l3vpn.0** table, not the **vrf.inet.0** table.

The Junos OS applies the CoS next-hop map to the set of next hops previously defined; the next hops themselves can be located across any outgoing interfaces on the routing

device. For example, the following configuration associates a set of forwarding classes and next-hop identifiers:

```
[edit class-of-service forwarding-policy]
next-hop-map map1 {
  forwarding-class expedited-forwarding {
    next-hop next-hop1;
    next-hop next-hop2;
  }
  forwarding-class best-effort {
    next-hop next-hop3;
    lsp-next-hop lsp-next-hop4;
  }
}
```

In this example, **next-hop N** is either an IP address or an egress interface for some next hop, and **lsp-next-hop4** is a regular expression corresponding to any next hop with that label. Q1 through QN are a set of forwarding classes that map to the specific next hop. That is, when a packet is switched with Q1 through QN, it is forwarded out the interface associated with the associated next hop.

This configuration has the following implications:

- A single forwarding class can map to multiple standard next hops or LSP next hops. This implies that load sharing is done across standard next hops or LSP next hops servicing the same class value. To make this work properly, the Junos OS creates a list of the equal-cost next hops and forwards packets according to standard load-sharing rules for that forwarding class.
- If a forwarding class configuration includes LSP next hops and standard next hops, the LSP next hops are preferred over the standard next hops. In the preceding example, if both **next-hop3** and **lsp-next-hop4** are valid next hops for a route to which **map1** is applied, the forwarding table includes entry **lsp-next-hop4** only.
- If **next-hop-map** does not specify all possible forwarding classes, the default forwarding class is selected as the default. If the default forwarding class is not specified in the next-hop map, a default is designated randomly. The default forwarding class is the class associated with queue 0.
- For LSP next hops, the Junos OS uses UNIX **regex(3)**-style regular expressions. For example, if the following labels exist: **lsp**, **lsp1**, **lsp2**, **lsp3**, the statement **lsp-next-hop lsp** matches **lsp**, **lsp1**, **lsp2**, and **lsp3**. If you do not desire this behavior, you must use the anchor characters **lsp-next-hop " ^lsp\$"**, which match **lsp** only.
- The route filter does not work because the policy checks against the **bgp.l3vpn.0** table instead of the **vrf.inet.0** table.

The final step is to apply the route filter to routes exported to the forwarding engine. This is shown in the following example:

```
routing-options {
  forwarding-table {
    export my-cos-forwarding;
  }
}
```

This configuration instructs the routing process to insert routes to the forwarding engine matching **my-cos-forwarding** with the associated next-hop CBF rules.

The following algorithm is used when you apply a configuration to a route:

- If the route is a single next-hop route, all traffic goes to that route; that is, no CBF takes effect.
- For each next hop, associate the proper forwarding class. If a next hop appears in the route but not in the **cos-next-hop** map, it does not appear in the forwarding table entry.
- The default forwarding class is used if all forwarding classes are not specified in the next-hop map. If the default is not specified, one is chosen randomly.

Overriding the Input Classification

For IPv4 or IPv6 packets, you can override the incoming classification, assigning them to the same forwarding class based on their input interface, input precedence bits, or destination address. You do so by defining a policy class when configuring CoS properties and referencing this class when configuring a routing policy.

When you override the classification of incoming packets, any mappings you configured for associated precedence bits or incoming interfaces to output transmission queues are ignored. Also, if the packet loss priority (PLP) bit was set in the packet by the incoming interface, the PLP bit is cleared.

To override the input packet classification, do the following:

1. Define the policy class by including the **class** statement at the **[edit class-of-service policy]** hierarchy level:

```
[edit class-of-service]
forwarding-policy {
  class class-name {
    classification-override {
      forwarding-class class-name;
    }
  }
}
```

class-name is a name that identifies the class.

2. Associate the policy class with a routing policy by including it in a **policy-statement** statement at the **[edit policy-options]** hierarchy level. Specify the destination prefixes in the **route-filter** statement and the CoS policy class name in the **then** statement.

```
[edit policy-options]
policy-statement policy-name {
  term term-name {
    from {
      route-filter destination-prefix match-type <class class-name>
    }
    then class class-name;
  }
}
```

3. Apply the policy by including the **export** statement at the **[edit routing-options]** hierarchy level:

```
[edit routing-options]
forwarding-table {
  export policy-name;
}
```

Examples

- [Example: Configuring CoS-Based Forwarding for Different Traffic Types on page 1563](#)
- [Example: Configuring CoS-Based Forwarding for IPv6 on page 1564](#)

Example: Configuring CoS-Based Forwarding

Router A has two routes to destination **10.255.71.208** on Router D. One route goes through Router B, and the other goes through Router C, as shown in [Figure 12 on page 1561](#).

Configure Router A with CBF to select Router B for queue 0 and queue 2, and Router C for queue 1 and queue 3.

Figure 12: Sample CoS-Based Forwarding

When you configure CBF with OSPF as the IGP, you must specify the next hop as an interface name, not as an IP address. The next hops in this example are specified as **ge-2/0/0.0** and **ge-0/3/0.0**.

```
[edit class-of-service]
forwarding-policy {
  next-hop-map my_cbf {
    forwarding-class be {
      next-hop ge-2/0/0.0;
    }
    forwarding-class ef {
      next-hop ge-0/3/0.0;
    }
    forwarding-class af {
```

```
        next-hop ge-2/0/0.0;
      }
      forwarding-class nc {
        next-hop ge-0/3/0.0;
      }
    }
  }
  classifiers {
    inet-precedence inet {
      forwarding-class be {
        loss-priority low code-points [ 000 100 ];
      }
      forwarding-class ef {
        loss-priority low code-points [ 001 101 ];
      }
      forwarding-class af {
        loss-priority low code-points [ 010 110 ];
      }
      forwarding-class nc {
        loss-priority low code-points [ 011 111 ];
      }
    }
  }
  forwarding-classes {
    queue 0 be;
    queue 1 ef;
    queue 2 af;
    queue 3 nc;
  }
  interfaces {
    at-4/2/0 {
      unit 0 {
        classifiers {
          inet-precedence inet;
        }
      }
    }
  }
}

[edit policy-options]
policy-statement cbf {
  from {
    route-filter 10.255.71.208/32 exact;
  }
  then cos-next-hop-map my_cbf;
}

[edit routing-options]
graceful-restart;
forwarding-table {
  export cbf;
}

[edit interfaces]

  file trace-intf size 5m world-readable;
```

```

    flag all;
  }
  ge-0/3/0 {
    unit 0 {
      family inet {
        address 10.40.13.1/30;
      }
      family iso;
      family mpls;
    }
  }
  ge-2/0/0 {
    unit 0 {
      family inet {
        address 10.40.12.1/30;
      }
      family iso;
      family mpls;
    }
  }
  at-4/2/0 {
    atm-options {
      vpi 1 {
        maximum-vcs 1200;
      }
    }
    unit 0 {
      vci 1.100;
      family inet {
        address 10.40.11.2/30;
      }
      family iso;
      family mpls;
    }
  }
}

```

Example: Configuring CoS-Based Forwarding for Different Traffic Types

One common use for CoS-based forwarding and next-hop maps is to enforce different handling for different traffic types, such as voice and video. For example, an LSP-based next hop can be used for voice and video, and a non-LSP next-hop can be used for best effort traffic.

Only the forwarding policy is shown in this example:

```

[edit class-of-service]
forwarding-policy {
  next-hop-map ldp-map {
    forwarding-class expedited-forwarding {
      lsp-next-hop voice;
      non-lsp-next-hop;
    }
    forwarding-class assured-forwarding {
      lsp-next-hop video;
      non-lsp-next-hop;
    }
  }
}

```

```
        forwarding-class best-effort {
            non-lsp-next-hop;
            discard;
        }
    }
}
```

Example: Configuring CoS-Based Forwarding for IPv6

This example configures CoS-based forwarding (CBF) next-hop maps and CBF LSP next-hop maps for IPv6 addresses.

You can configure a next-hop map with both IPv4 and IPv6 addresses, or you can configure separate next-hop maps for IPv4 and IPv6 addresses and include the **from family (inet | inet6)** statements at the **[edit policy-options policy-options policy-statement *policy-name* term *term-name*]** hierarchy level to ensure that only next-hop maps of a specified protocol are applied to a specified route.

If you do not configure separate next-hop maps and include the **from family (inet | inet6)** statements in the configuration, when a route uses two next hops (whether IPv4, IPv6, interface, or LSP next hop) in at least two of the specified forwarding classes, CBF is used for the route; otherwise, the CBF policy is ignored.

1. Define the CBF next-hop map:

```
[edit class-of-service]
forwarding-policy {
    next-hop-map cbf-map {
        forwarding-class best-effort {
            next-hop [ ::192.168.139.38 192.168.139.38 ];
        }
        forwarding-class expedited-forwarding {
            next-hop [ ::192.168.140.5 192.168.140.5 ];
        }
        forwarding-class assured-forwarding {
            next-hop [ ::192.168.145.5 192.168.145.5 ];
        }
        forwarding-class network-control {
            next-hop [ ::192.168.141.2 192.168.141.2 ];
        }
    }
}
```

2. Define the CBF forwarding policy:

```
[edit policy-options]
policy-statement ls {
    then cos-next-hop-map cbf-map;
}
```

3. Export the CBF forwarding policy:

```
[edit routing-options]
forwarding-table {
    export ls;
}
```

- [Applying Scheduler Maps Overview on page 1577](#)
- [Applying a Shaping Rate to Physical Interfaces Overview on page 1578](#)
- [Default Fabric Priority Queuing on page 1578](#)

Schedulers Overview

You use *schedulers* to define the properties of output queues. These properties include the amount of interface bandwidth assigned to the queue, the size of the memory buffer allocated for storing packets, the priority of the queue, and the random early detection (RED) drop profiles associated with the queue.

You associate the schedulers with forwarding classes by means of *scheduler maps*. You can then associate each scheduler map with an interface, thereby configuring the hardware queues, packet schedulers, and RED processes that operate according to this mapping.

To configure class-of-service (CoS) schedulers, include the following statements at the `[edit class-of-service]` hierarchy level:

NOTE: For PTX Series Packet Transport Switches:

- The fabric and traffic-control-profiles statements at the [edit class-of-service] hierarchy level are not supported.

```
[edit class-of-service]
interfaces {
  interface-name {
    scheduler-map map-name;
    scheduler-map-chassis map-name;
    shaping-rate rate;
    unit {
      output-traffic-control-profile profile-name;
      scheduler-map map-name;
      shaping-rate rate;
    }
  }
}
fabric {
  scheduler-map {
    priority (high | low) scheduler scheduler-name;
  }
}
scheduler-maps {
  map-name {
    forwarding-class class-name scheduler scheduler-name;
  }
}
schedulers {
  scheduler-name {
    buffer-size (percent percentage | remainder | temporal microseconds );
    drop-profile-map loss-priority (any | low | medium-low | medium-high | high) protocol
      (any | non-tcp | tcp) drop-profile profile-name;
    excess-priority (low | high);
    excess-rate (percent percentage | proportion value);
    priority priority-level;
    transmit-rate (rate | percent percentage remainder) <exact | rate-limit>;
  }
}
traffic-control-profiles profile-name {
  delay-buffer-rate (percent percentage | rate);
  excess-rate percent percentage;
  guaranteed-rate (percent percentage | rate);
  scheduler-map map-name;
  shaping-rate (percent percentage | rate);
}
```

You cannot configure both the **shaping-rate** statement at the [edit class-of-service interfaces *interface-name*] hierarchy level and the **transmit-rate rate-limit** statement and option at the [edit class-of-service schedulers *scheduler-name*] hierarchy level. These statements are mutually exclusive. If you do configure both, you will not be able to commit the configuration:

```
[edit class-of-service]
'shaping-rate'
only one option (shaping-rate or transmit-rate rate-limit) can be configured at a time
error: commit failed (statements constraint check failed)
```

Default Schedulers Overview

Each forwarding class has an associated scheduler priority. Only two forwarding classes, best effort and network control (queue 0 and queue 3), are used in the Junos default scheduler configuration.

By default, the best effort forwarding class (queue 0) receives 95 percent of the bandwidth and buffer space for the output link, and the network control forwarding class (queue 3) receives 5 percent. The default drop profile causes the buffer to fill and then discard all packets until it has space.

The expedited-forwarding and assured-forwarding classes have no schedulers because, by default, no resources are assigned to queue 1 and queue 2. However, you can manually configure resources for the expedited-forwarding and assured-forwarding classes.

Also by default, each queue can exceed the assigned bandwidth if additional bandwidth is available from other queues. When a forwarding class does not fully use the allocated transmission bandwidth, the remaining bandwidth can be used by other forwarding classes if they receive a larger amount of the offered load than the bandwidth allocated. For more information, see [“Allocation of Leftover Bandwidth” on page 1593](#).

The following default scheduler is provided when you install the Junos OS. These settings are not visible in the output of the **show class-of-service** command; rather, they are implicit.

```
[edit class-of-service]
schedulers {
  network-control {
    transmit-rate percent 5;
    buffer-size percent 5;
    priority low;
    drop-profile-map loss-priority any protocol any drop-profile terminal;
  }
  best-effort {
    transmit-rate percent 95;
    buffer-size percent 95;
    priority low;
    drop-profile-map loss-priority any protocol any drop-profile terminal;
  }
}
drop-profiles {
  terminal {
    fill-level 100 drop-probability 100;
  }
}
```

Priority Scheduling Overview

The Junos OS supports multiple levels of transmission priority, which in order of increasing priority are **low**, **medium-low**, **medium-high**, and **high**, and **strict-high**. This allows the software to service higher-priority queues before lower-priority queues.

Priority scheduling determines the order in which an output interface transmits traffic from the queues, thus ensuring that queues containing important traffic are provided better access to the outgoing interface. This is accomplished through a procedure in which the software examines the priority of the queue. In addition, the software determines if the individual queue is within its defined bandwidth profile. The bandwidth profile is discussed in [“Configuring Scheduler Transmission Rate” on page 1591](#). This binary decision, which is reevaluated on a regular time cycle, compares the amount of data transmitted by the queue against the amount of bandwidth allocated to it by the scheduler. When the transmitted amount is less than the allocated amount, the queue is considered to be in profile. A queue is out of profile when its transmitted amount is larger than its allocated amount.

The queues for a given output physical interface (or output logical interface if per-unit scheduling is enabled on that interface) are divided into sets based on their priority. Any such set contains queues of the same priority.

The software traverses the sets in descending order of priority. If at least one of the queues in the set has a packet to transmit, the software selects that set. A queue from the set is selected based on the weighted round robin (WRR) algorithm, which operates within the set.

The Junos OS performs priority queuing using the following steps:

1. The software locates all high-priority queues that are currently in profile. These queues are serviced first in a weighted round-robin fashion.
2. The software locates all medium-high priority queues that are currently in profile. These queues are serviced second in a weighted round-robin fashion.
3. The software locates all medium-low priority queues that are currently in profile. These queues are serviced third in a weighted round-robin fashion.
4. The software locates all low-priority queues that are currently in profile. These queues are serviced fourth in a weighted round-robin fashion.
5. The software locates all high-priority queues that are currently out of profile and are not rate limited. The weighted round-robin algorithm is applied to these queues for servicing.
6. The software locates all medium-high priority queues that are currently out of profile and are not rate limited. The weighted round-robin algorithm is applied to these queues for servicing.

7. The software locates all medium-low priority queues that are currently out of profile and are not rate limited. The weighted round-robin algorithm is applied to these queues for servicing.
8. The software locates all low-priority queues that are currently out of profile and are also not rate limited. These queues are serviced last in a weighted round-robin manner.

Applying Scheduler Maps Overview

Physical interfaces (for example, **t3-0/0/0**, **t3-0/0/0:0**, and **ge-0/0/0**) support scheduling with any encapsulation type pertinent to that physical interface. For a single port, you cannot apply scheduling to the physical interface if you have applied scheduling to one or more of the associated logical interfaces.

Logical interfaces (for example, **t3-0/0/0 unit 0** and **ge-0/0/0 unit 0**) support scheduling on data link connection identifiers (DLCIs) or VLANs only.

In the Junos OS implementation, the term *logical interfaces* generally refers to interfaces you configure by including the **unit** statement at the **[edit interfaces interface-name]** hierarchy level. Logical interfaces have the **.logical** descriptor at the end of the interface name, as in **ge-0/0/0.1** or **t1-0/0/0:0.1**, where the logical unit number is 1.

Although channelized interfaces are generally thought of as logical or virtual, the Junos OS sees T3, T1, and NxDSO interfaces within a channelized IQ PIC as physical interfaces. For example, both **t3-0/0/0** and **t3-0/0/0:1** are treated as physical interfaces by the Junos OS. In contrast, **t3-0/0/0.2** and **t3-0/0/0:1.2** are considered logical interfaces because they have the **.2** at the end of the interface names.

Within the **[edit class-of-service]** hierarchy level, you cannot use the **.logical** descriptor when you assign properties to logical interfaces. Instead, you must include the **unit** statement in the configuration. For example:

```
[edit class-of-service]
user@host# set interfaces t3-0/0/0 unit 0 scheduler-map map1
```

Related Documentation

To apply a scheduler map to network traffic, you associate the map with an interface. See the following topics:

Applying a Shaping Rate to Physical Interfaces Overview

On T4000 routers with Type 5 FPCs and on EX Series switches, you can configure physical interfaces to shape traffic based on the rate-limited bandwidth of the total interface bandwidth. This allows you to shape the output of the physical interface, so that the interface transmits less traffic than it is physically capable of carrying.

If you do not configure a shaping rate on the physical interface, the default physical interface bandwidth is based on the channel bandwidth and the time slot allocation.

In general, the physical interface speed is the basis for calculating the various queue parameters for a physical interface such as delay buffer size, weighted round-robin (WRR) weight, drop profile, and so forth. However, when you apply a shaping rate by including the **shaping-rate** statement, the shaping rate on that physical interface becomes the basis for calculating all the queue parameters for that physical interface.

On T4000 routers with Type 5 FPCs, the shaping rate value for the physical interface must be a minimum of 292 Kbps. The maximum value of shaping rate is limited by the maximum transmission rate of the interface.

- [show interfaces extensive on page 2450](#)

Default Fabric Priority Queuing

On Juniper Networks EX Series switches, M320 Multiservice Edge Routers, and Juniper Networks T Series Core Routers, the default behavior is for fabric priority queuing on egress interfaces to match the scheduling priority you assign. High-priority egress traffic is automatically assigned to high-priority fabric queues. Likewise, low-priority egress traffic is automatically assigned to low-priority fabric queues.

For information about overriding automatic fabric priority queuing, see [“Overriding Fabric Priority Queuing” on page 1535](#) and [“Associating Schedulers with Fabric Priorities” on page 1612](#).

Configuring Schedulers

You configure a scheduler by including the **scheduler** statement at the **[edit class-of-service]** hierarchy level:

```
schedulers {
  scheduler-name {
    buffer-size (percent percentage | remainder | temporal microseconds);
    drop-profile-map loss-priority (any | low | medium-low | medium-high | high) protocol
      (any | non-tcp | tcp) drop-profile profile-name;
    priority priority-level;
    transmit-rate (rate | percent percentage remainder) <exact | rate-limit>;
  }
}
```

For detailed information about scheduler configuration statements, see the indicated topics:

- [Configuring the Scheduler Buffer Size on page 1579](#)
- [Configuring Drop Profile Maps for Schedulers on page 1590](#)
- [Configuring Scheduler Transmission Rate on page 1591](#)
- [Configuring Schedulers for Priority Scheduling on page 1594](#)

Configuring the Scheduler Buffer Size

To control congestion at the output stage, you can configure the delay-buffer bandwidth. The delay-buffer bandwidth provides packet buffer space to absorb burst traffic up to the specified duration of delay. Once the specified delay buffer becomes full, packets with 100 percent drop probability are dropped from the head of the buffer.

The default scheduler transmission rate for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent of the total available bandwidth.

The default buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent of the total available buffer. The total available buffer per queue differs by PIC type, as shown in [Table 109 on page 1580](#).

To configure the buffer size, include the **buffer-size** statement at the **[edit class-of-service schedulers**

scheduler-name] hierarchy level:

```
[edit class-of-service schedulers scheduler-name]
  buffer-size (percent percentage | remainder | temporal microseconds);
```

For each scheduler, you can configure the buffer size as one of the following:

- A percentage of the total buffer. The total buffer per queue is based on microseconds and differs by routing device type, as shown in [Table 109 on page 1580](#).
- The remaining buffer available. The remainder is the buffer percentage that is not assigned to other queues. For example, if you assign 40 percent of the delay buffer to queue 0, allow queue 3 to keep the default allotment of 5 percent, and assign the remainder to queue 7, then queue 7 uses approximately 55 percent of the delay buffer.
- A temporal value, in microseconds. For the temporal setting, the queuing algorithm starts dropping packets when it queues more than a computed number of bytes. This maximum is computed by multiplying the transmission rate of the queue by the configured temporal value. The buffer size temporal value per queue differs by routing device type, as shown in [Table 109 on page 1580](#). The maximums apply to the logical interface, not each queue.

For information about configuring large buffer sizes on IQ PICs, see “[Configuring Large Delay Buffers for Slower Interfaces](#)” on page 1581.

Table 109: Buffer Size Temporal Value Ranges by Routing Device Type

Routing Devices	Temporal Value Ranges
M320 and T Series router FPCs, Type 1 and Type 2	1 through 80,000 microseconds
M320 and T Series router FPCs, Type 3. All ES cards (Type 1, 2, 3, and 4).	1 through 50,000 microseconds For PICs with greater than 40 Gbps of total bandwidth, the maximum temporal buffer size that can be configured for a scheduler is 40,000 microseconds instead of 50,000 microseconds.
M120 router FEBs and MX Series router nonenhanced Queuing DPCs, and EX Series switches	1 through 100,000 microseconds
M5, M7i, M10, and M10i router FPCs	1 through 100,000 microseconds
Other M Series router FPCs	1 through 200,000 microseconds
PTX Series Packet Transport Switches	1 through 100,000 microseconds
IQ PICs on all routers	1 through 100,000 microseconds
With Large Buffer Sizes Enabled	
IQ PICs on all routers	1 through 500,000 microseconds
Gigabit Ethernet IQ VLANs	
With shaping rate up to 10 Mbps	1 through 400,000 microseconds
With shaping rate up to 20 Mbps	1 through 300,000 microseconds

Table 109: Buffer Size Temporal Value Ranges by Routing Device Type (*continued*)

Routing Devices	Temporal Value Ranges
With shaping rate up to 30 Mbps	1 through 200,000 microseconds
With shaping rate up to 40 Mbps	1 through 150,000 microseconds
With shaping rate above 40 Mbps	1 through 100,000 microseconds

For more information about configuring delay buffers, see the following subtopics:

- [Configuring Large Delay Buffers for Slower Interfaces on page 1581](#)
- [Enabling and Disabling the Memory Allocation Dynamic per Queue on page 1589](#)

Configuring Large Delay Buffers for Slower Interfaces

By default, T1, E1, and NxDS0 interfaces and DLCIs configured on channelized IQ PICs are limited to 100,000 microseconds of delay buffer. (The default average packet size on the IQ PIC is 40 bytes.) For these interfaces, it might be necessary to configure a larger buffer size to prevent congestion and packet dropping. You can do so on the following PICs:

- Channelized IQ
- 4-port E3 IQ
- Gigabit Ethernet IQ and IQ2

Congestion and packet dropping occur when large bursts of traffic are received by slower interfaces. This happens when faster interfaces pass traffic to slower interfaces, which is often the case when edge devices receive traffic from the core of the network. For example, a 100,000-microsecond T1 delay buffer can absorb only 20 percent of a 5000-microsecond burst of traffic from an upstream OC3 interface. In this case, 80 percent of the burst traffic is dropped.

[Table 110 on page 1581](#) shows some recommended buffer sizes needed to absorb typical burst sizes from various upstream interface types.

Table 110: Recommended Delay Buffer Sizes

Length of Burst	Upstream Interface	Downstream Interface	Recommended Buffer on Downstream Interface
5000 microseconds	OC3	E1 or T1	500,000 microseconds
5000 microseconds	E1 or T1	E1 or T1	100,000 microseconds
1000 microseconds	T3	E1 or T1	100,000 microseconds

To ensure that traffic is queued and transmitted properly on E1, T1, and NxDS0 interfaces and DLCIs, you can configure a buffer size larger than the default maximum. To enable

larger buffer sizes to be configured, include the **q-pic-large-buffer (large-scale | small-scale)** statement at the **[edit chassis fpc slot-number pic pic-number]** hierarchy level:

```
[edit chassis fpc slot-number pic pic-number]
q-pic-large-buffer large-scale;
```

If you specify the **large-scale** option, the feature supports a larger number of interfaces. If you specify **small-scale**, the default, then the feature supports a smaller number of interfaces.

When you include the **q-pic-large-buffer** statement in the configuration, the larger buffer is transparently available for allocation to scheduler queues. The larger buffer maximum varies by interface type, as shown in [Table 111 on page 1582](#).

Table 111: Maximum Delay Buffer with q-pic-large-buffer Enabled by Interface

Platform, PIC, or Interface Type	Maximum Buffer Size
With Large Buffer Sizes Not Enabled	
M320 and T Series router FPCs, Type 1 and Type 2	80,000 microseconds
M320 and T Series router FPCs, Type 3	50,000 microseconds
Other M Series router FPCs	200,000 microseconds
IQ PICs on all routers	100,000 microseconds
With Large Buffer Sizes Enabled	
Channelized T3 and channelized OC3 DLCIs—Maximum sizes vary by shaping rate:	
With shaping rate from 64,000 through 255,999 bps	4,000,000 microseconds
With shaping rate from 256,000 through 511,999 bps	2,000,000 microseconds
With shaping rate from 512,000 through 1,023,999 bps	1,000,000 microseconds
With shaping rate from 1,024,000 through 2,048,000 bps	500,000 microseconds
With shaping rate from 2,048,001 bps through 10 Mbps	400,000 microseconds
With shaping rate from 10,000,001 bps through 20 Mbps	300,000 microseconds
With shaping rate from 20,000,001 bps through 30 Mbps	200,000 microseconds
With shaping rate from 30,000,001 bps through 40 Mbps	150,000 microseconds
With shaping rate up to 40,000,001 bps and above	100,000 microseconds
NxDSO IQ Interfaces—Maximum sizes vary by channel size:	

Table 111: Maximum Delay Buffer with q-pic-large-buffer Enabled by Interface (*continued*)

Platform, PIC, or Interface Type	Maximum Buffer Size
1xDSO through 3xDSO	4,000,000 microseconds
4xDSO through 7xDSO	2,000,000 microseconds
8xDSO through 15xDSO	1,000,000 microseconds
16xDSO through 32xDSO	500,000 microseconds
Other IQ interfaces	500,000 microseconds

If you configure a delay buffer larger than the new maximum, the candidate configuration can be committed successfully. However, the setting is rejected by the packet forwarding component and a system log warning message is generated.

For interfaces that support DLCI queuing, the large buffer is supported for DLCIs on which the configured shaping rate is less than or equal to the physical interface bandwidth. For instance, when you configure a Frame Relay DLCI on a Channelized T3 IQ PIC, and you configure the shaping rate to be 1.5 Mbps, the amount of delay buffer that can be allocated to the DLCI is 500,000 microseconds, which is equivalent to a T1 delay buffer. For more information about DLCI queuing, see *Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs*.

For NxDSO interfaces, the larger buffer sizes can be up to 4,000,000 microseconds, depending on the number of DSO channels in the NxDSO interface. For slower NxDSO interfaces with fewer channels, the delay buffer can be relatively larger than for faster NxDSO interfaces with more channels. This is shown in [Table 113 on page 1585](#). To calculate specific buffer sizes for various NxDSO interfaces, see “[Maximum Delay Buffer for NxDSO Interfaces](#)” on page 1584.

You can allocate the delay buffer as either a percentage or a temporal value. The resulting delay buffer is calculated differently depending how you configure the delay buffer, as shown in [Table 112 on page 1584](#).

Table 112: Delay-Buffer Calculations

Delay Buffer Configuration	Formula	Example
Percentage	$\text{available interface bandwidth} * \text{configured percentage buffer-size} = \text{queue buffer}$	<p>If you configure a queue on a T1 interface to use 30 percent of the available delay buffer, the queue receives 28,125 bytes of delay buffer:</p> <pre> sched-expedited { transmit-rate percent 30; buffer-size percent 30; } </pre> <p>$1.5 \text{ Mbps} * 0.3 * 500,000 \text{ microseconds} = 225,000 \text{ bits}$ $= 28,125 \text{ bytes}$</p>
Temporal	$\text{available interface bandwidth} * \text{configured percentage transmit-rate} * \text{configured temporal buffer-size} = \text{queue buffer}$	<p>If you configure a queue on a T1 interface to use 500,000 microseconds of delay buffer and you configure the transmission rate to be 20 percent, the queue receives 18,750 bytes of delay buffer:</p> <pre> sched-best { transmit-rate percent 20; buffer-size temporal 500000; } </pre> <p>$1.5 \text{ Mbps} * 0.2 * 500,000 \text{ microseconds} = 150,000 \text{ bits}$ $= 18,750 \text{ bytes}$</p>
Percentage, with buffer size larger than transmit rate		<p>In this example, the delay buffer is allocated twice the transmit rate. Maximum delay buffer latency can be up to twice the 500,000-microsecond delay buffer if the queue's transmit rate cannot exceed the allocated transmit rate.</p> <pre> sched-extra-buffer { transmit-rate percent 10; buffer-size percent 20; } </pre>
FRF.16 LSQ bundles	<p>For total bundle bandwidth < T1 bandwidth, the delay-buffer rate is 1 second.</p> <p>For total bundle bandwidth >= T1 bandwidth, the delay-buffer rate is 200 milliseconds (ms).</p>	

For more information, see the following sections:

- [Maximum Delay Buffer for NxDSO Interfaces on page 1584](#)
- [Example: Configuring Large Delay Buffers for Slower Interfaces on page 1586](#)

Maximum Delay Buffer for NxDSO Interfaces

Because NxDSO interfaces carry less bandwidth than a T1 or E1 interface, the buffer size on an NxDSO interface can be relatively larger, depending on the number of DSO channels combined. The maximum delay buffer size is calculated with the following formula:

$$\text{Interface Speed} * \text{Maximum Delay Buffer Time} = \text{Delay Buffer Size}$$

For example, a 1xDS0 interface has a speed of 64 kilobits per second (Kbps). At this rate, the maximum delay buffer time is 4,000,000 microseconds. Therefore, the delay buffer size is 32 kilobytes (KB):

$$64 \text{ Kbps} * 4,000,000 \text{ microseconds} = 32 \text{ KB}$$

Table 113 on page 1585 shows the delay-buffer calculations for 1xDS0 through 32xDS0 interfaces.

Table 113: NxDS0 Transmission Rates and Delay Buffers

Interface Speed	Delay Buffer Size
1xDS0 Through 4xDS0: Maximum Delay Buffer Time Is 4,000,000 Microseconds	
1xDS0: 64 Kbps	32 KB
2xDS0: 128 Kbps	64 KB
3xDS0: 192 Kbps	96 KB
4xDS0 Through 7xDS0: Maximum Delay Buffer Time Is 2,000,000 Microseconds	
4xDS0: 256 Kbps	64 KB
5xDS0: 320 Kbps	80 KB
6xDS0: 384 Kbps	96 KB
7xDS0: 448 Kbps	112 KB
8xDS0 Through 15xDS0: Maximum Delay Buffer Time Is 1,000,000 Microseconds	
8xDS0: 512 Kbps	64 KB
9xDS0: 576 Kbps	72 KB
10xDS0: 640 Kbps	80 KB
11xDS0: 704 Kbps	88 KB
12xDS0: 768 Kbps	96 KB
13xDS0: 832 Kbps	104 KB
14xDS0: 896 Kbps	112 KB
15xDS0: 960 Kbps	120 KB
16xDS0 Through 32xDS0: Maximum Delay Buffer Time Is 500,000 Microseconds	
16xDS0: 1024 Kbps	64 KB
17xDS0: 1088 Kbps	68 KB

Table 113: NxDSO Transmission Rates and Delay Buffers (*continued*)

Interface Speed	Delay Buffer Size
18xDSO: 1152 Kbps	72 KB
19xDSO: 1216 Kbps	76 KB
20xDSO: 1280 Kbps	80 KB
21xDSO: 1344 Kbps	84 KB
22xDSO: 1408 Kbps	88 KB
23xDSO: 1472 Kbps	92 KB
24xDSO: 1536 Kbps	96 KB
25xDSO: 1600 Kbps	100 KB
26xDSO: 1664 Kbps	104 KB
27xDSO: 1728 Kbps	108 KB
28xDSO: 1792 Kbps	112 KB
29xDSO: 1856 Kbps	116 KB
30xDSO: 1920 Kbps	120 KB
31xDSO: 1984 Kbps	124 KB
32xDSO: 2048 Kbps	128 KB

Example: Configuring Large Delay Buffers for Slower Interfaces

Set large delay buffers on interfaces configured on a Channelized OC12 IQ PIC. The CoS configuration binds a scheduler map to the interface specified in the chassis configuration. For information about the delay-buffer calculations in this example, see [Table 112 on page 1584](#).

```
chassis {
  fpc 0 {
    pic 0 {
      q-pic-large-buffer; # Enabling large delay buffer
      max-queues-per-interface 8; # Eight queues (M320, T Series, and TX Matrix routers)
    }
  }
}
```

Configuring the Delay Buffer Value for a Scheduler

You can assign to a physical or logical interface a scheduler map that is composed of different schedulers (or queues). The physical interface's large delay buffer can be distributed to the different schedulers (or queues) using the **transmit-rate** and **buffer-size** statements at the `[edit class-of-service schedulers scheduler-name]` hierarchy level.

The example shows two schedulers, **sched-best** and **sched-exped**, with the delay buffer size configured as a percentage (20 percent) and temporal value (300,000 microseconds), respectively. The **sched-best** scheduler has a transmit rate of 10 percent. The **sched-exped** scheduler has a transmit rate of 20 percent.

The **sched-best** scheduler's delay buffer is twice that of the specified transmit rate of 10 percent. Assuming that the **sched-best** scheduler is assigned to a T1 interface, this scheduler receives 20 percent of the total 500,000 microseconds of the T1 interface's delay buffer. Therefore, the scheduler receives 18,750 bytes of delay buffer:

$$\text{available interface bandwidth} * \text{configured percentage buffer-size} * \text{maximum buffer} = \text{queue buffer}$$

$$1.5 \text{ Mbps} * 0.2 * 500,000 \text{ microseconds} = 150,000 \text{ bits} = 18,750 \text{ bytes}$$

Assuming that the **sched-exped** scheduler is assigned to a T1 interface, this scheduler receives 300,000 microseconds of the T1 interface's 500,000-microsecond delay buffer with the traffic rate at 20 percent. Therefore, the scheduler receives 11,250 bytes of delay buffer:

$$\text{available interface bandwidth} * \text{configured percentage transmit-rate} * \text{configured temporal buffer-size} = \text{queue buffer}$$

$$1.5 \text{ Mbps} * 0.2 * 300,000 \text{ microseconds} = 90,000 \text{ bits} = 11,250 \text{ bytes}$$

```
[edit]
class-of-service {
  schedulers {
    sched-best {
      transmit-rate percent 10;
      buffer-size percent 20;
    }
    sched-exped {
      transmit-rate percent 20;
      buffer-size temporal 300000;
    }
  }
}
```

Configuring the Physical Interface Shaping Rate

In general, the physical interface speed is the basis for calculating the delay buffer size. However, when you include the **shaping-rate** statement, the shaping rate becomes the basis for calculating the delay buffer size. This example configures the shaping rate on a T1 interface to 200 Kbps, which means that the T1 interface bandwidth is set to 200 Kbps instead of 1.5 Mbps. Because 200 Kbps is less than 4xDS0, this interface receives 4 seconds of delay buffer, or 800 Kbps of traffic, which is 800 KB for a full second. For more information, see [Table 113 on page 1585](#).

```
class-of-service {
  interfaces {
    t1-0/0/0:1 {
      shaping-rate 200k;
    }
  }
}
```

```
    }  
  }
```

Complete Configuration

This example shows a Channelized OC12 IQ PIC in FPC slot 0, PIC slot 0 and a channelized T1 interface with Frame Relay encapsulation. It also shows a scheduler map configuration on the physical interface.

```
chassis {  
  fpc 0 {  
    pic 0 {  
      q-pic-large-buffer;  
      max-queues-per-interface 8;  
    }  
  }  
}  
interfaces {  
  coc12-0/0/0 {  
    partition 1 oc-slice 1 interface-type coc1;  
  }  
  coc1-0/0/0:1 {  
    partition 1 interface-type t1;  
  }  
  t1-0/0/0:1:1 {  
    encapsulation frame-relay;  
    unit 0 {  
      family inet {  
        address 1.1.1.1/24;  
      }  
      dlci 100;  
    }  
  }  
}  
class-of-service {  
  interfaces {  
    t1-0/0/0:1:1 {  
      scheduler-map smap-1;  
    }  
  }  
}  
scheduler-maps {  
  smap-1 {  
    forwarding-class best-effort scheduler sched-best;  
    forwarding-class expedited-forwarding scheduler sched-exped;  
    forwarding-class assured-forwarding scheduler sched-assure;  
    forwarding-class network-control scheduler sched-network;  
  }  
}  
schedulers {  
  sched-best {  
    transmit-rate percent 40;  
    buffer-size percent 40;  
  }  
  sched-exped {  
    transmit-rate percent 30;  
    buffer-size percent 30;  
  }  
  sched-assure {  
    transmit-rate percent 30;  
    buffer-size percent 30;  
  }  
}
```

```

        transmit-rate percent 20;
        buffer-size percent 20;
    }
    sched-network {
        transmit-rate percent 10;
        buffer-size percent 10;
    }
}

```

Enabling and Disabling the Memory Allocation Dynamic per Queue

In the Junos OS, the memory allocation dynamic (MAD) is a mechanism that dynamically provisions extra delay buffer when a queue is using more bandwidth than it is allocated in the transmit rate setting. With this extra buffer, queues absorb traffic bursts more easily, thus avoiding packet drops. The MAD mechanism can provision extra delay buffer only when extra transmission bandwidth is being used by a queue. This means that the queue might have packet drops if there is no surplus transmission bandwidth available.

For Juniper Networks M320 Multiservice Edge Routers, MX Services Ethernet Services Routers, and T Series Core Routers and EX Series switches only, the MAD mechanism is enabled unless the delay buffer is configured with a temporal setting for a given queue. The MAD mechanism is particularly useful for forwarding classes carrying latency-immune traffic for which the primary requirement is maximum bandwidth utilization. In contrast, for latency-sensitive traffic, you might wish to disable the MAD mechanism because large delay buffers are not optimum.

MAD support is dependent on the FPC and Packet Forwarding Engine, not the PIC. All M320, MX Series, and T Series router and EX Series switches' FPCs and Packet Forwarding Engines support MAD. No Modular Port Concentrators (MPCs) and IQ, IQ2, IQ2E or IQE PICs support MAD.

To enable the MAD mechanism on supported hardware, include the **buffer-size percent** statement at the **[edit class-of-service schedulers *scheduler-name*]** hierarchy level:

```

[edit class-of-service schedulers scheduler-name]
  buffer-size percent percentage;

```

If desired, you can configure a buffer size that is greater than the configured transmission rate. The buffer can accommodate packet bursts that exceed the configured transmission rate, if sufficient excess bandwidth is available:

```

class-of-service {
  schedulers {
    sched-best {
      transmit-rate percent 20;
      buffer-size percent 30;
    }
  }
}

```

As stated previously, you can use a temporal delay buffer configuration to disable the MAD mechanism on a queue, thus limiting the size of the delay buffer. However, the effective buffer latency for a temporal queue is bounded not only by the buffer size value

but also by the associated drop profile. If a drop profile specifies a drop probability of 100 percent at a fill-level less than 100 percent, the effective maximum buffer latency is smaller than the buffer size setting. This is because the drop profile specifies that the queue drop packets before the queue's delay buffer is 100 percent full.

Such a configuration might look like the following example:

```
class-of-service {
  drop-profiles {
    plp-high {
      fill-level 70 drop-probability 100;
    }
    plp-low {
      fill-level 80 drop-probability 100;
    }
  }
  schedulers {
    sched {
      buffer-size temporal 500000;
      drop-profile-map loss-priority low protocol any drop-profile plp-low;
      drop-profile-map loss-priority high protocol any drop-profile plp-high;
      transmit-rate percent 20;
    }
  }
}
```

Configuring Drop Profile Maps for Schedulers

Drop-profile maps associate drop profiles with a scheduler. The map examines the current loss priority setting of the packet (high, low, or any) and assigns a drop profile according to these values. For example, you can specify that all TCP packets with low loss priority are assigned a drop profile that you name **low-drop**. You can associate multiple drop-profile maps with a single queue.

The scheduler drop profile defines the drop probabilities across the range of delay-buffer occupancy, thereby supporting the RED process. Depending on the drop probabilities, RED might drop packets aggressively long before the buffer becomes full, or it might drop only a few packets even if the buffer is almost full. For information on how to configure drop profiles, see [“RED Drop Profiles Overview” on page 1674](#).

By default, the drop profile is mapped to packets with low PLP and any protocol type. To configure how packet types are mapped to a specified drop profile, include the **drop-profile-map** statement at the **[edit class-of-service schedulers scheduler-name]** hierarchy level:

```
[edit class-of-service schedulers scheduler-name ]
  drop-profile-map loss-priority (any | low | medium-low | medium-high | high) protocol
    (any | non-tcp | tcp) drop-profile profile-name;
```

The map sets the drop profile for a specific PLP and protocol type. The inputs for the map are the PLP and the protocol type. The output is the drop profile. For more information about how CoS maps work, see [“CoS Inputs and Outputs Overview” on page 1272](#).

NOTE: On Juniper Network MX Series 3D Universal Edge Routers, T4000 Core Routers, EX Series switches, and PTX Series Packet Transport Switches, you can configure only the `any` option for the protocol statement.

For each scheduler, you can configure separate drop profile maps for each loss priority.

You can configure a maximum of 32 different drop profiles.

Configuring Scheduler Transmission Rate

The transmission rate control determines the actual traffic bandwidth from each forwarding class you configure. The rate is specified in bits per second (bps). Each queue is allocated some portion of the bandwidth of the outgoing interface.

This bandwidth amount can be a fixed value, such as 1 megabit per second (Mbps), a percentage of the total available bandwidth, or the rest of the available bandwidth. You can limit the transmission bandwidth to the exact value you configure, or allow it to exceed the configured rate if additional bandwidth is available from other queues. This property allows you to ensure that each queue receives the amount of bandwidth appropriate to its level of service.

On M Series routers other than the M120 and M320 routers, you should not configure a **buffer-size** larger than the **transmit-rate** for a rate-limited queue in a scheduler. If you do, the Packet Forwarding Engine will reject the CoS configuration. However, you can achieve the same effect by removing the **exact** option from the transmit rate or specifying the buffer size using the **temporal** option.

NOTE: For 8-port, 12-port, and 48-port Fast Ethernet PICs, transmission scheduling is not supported.

On Juniper Networks J Series Services Routers, you can include the **transmit-rate** statement described in this section to assign the WRR weights within a given priority level and not between priorities. For more information, see [“Configuring Schedulers for Priority Scheduling” on page 1594](#).

To configure transmission scheduling, include the **transmit-rate** statement at the **[edit class-of-service schedulers scheduler-name]** hierarchy level:

```
[edit class-of-service schedulers scheduler-name]
  transmit-rate (rate | percent percentage | remainder) <exact | rate-limit>;
```

You can specify the transmit rate as follows:

- **rate**—Transmission rate, in bits per second. For all MX Series router and EX Series switch interfaces, the rate can be from 65,535 through 160,000,000,000 bps. On all other platforms, the rate can be from 3200 through 160,000,000,000 bps.
- **percent *percentage***—Percentage of transmission capacity.
- **remainder**—Use remaining rate available. In the configuration, you cannot combine the **remainder** and **exact** options.
- **exact**—(Optional) Enforce the exact transmission rate or percentage you configure with the **transmit-rate *rate*** or **transmit-rate percent** statement. Under sustained congestion, a rate-controlled queue that goes into negative credit fills up and eventually drops packets. You specify the **exact** option as follows:

```
[edit class-of-service schedulers scheduler-name]
transmit-rate rate exact;
```

```
[edit class-of-service schedulers scheduler-name]
transmit-rate percent percentage exact;
```

In the configuration, you cannot combine the **remainder** and **exact** options.

NOTE:

- Including the **exact** option is not supported on Enhanced Queuing Dense Port Concentrators (DPCs) on Juniper Network MX Series 3D Universal Edge Routers.
- The configuration of the **transmit-rate percent 0 exact** statement at the `[edit class-of-service schedulers scheduler-name]` hierarchy is ineffective on T4000 routers with Type 5 FPCs.

- **rate-limit**—(Optional) Limit the transmission rate to the specified amount. You can configure this option for all 8 queues of a logical interface (unit) and apply it to shaped or unshaped logical interfaces. If you configure a zero rate-limited transmit rate, all packets belonging to that queue are dropped. On IQE PICs, the **rate-limit** option for the schedulers' transmit rate is implemented as a static policer. Therefore, these schedulers are not aware of congestion and the maximum rate possible on these schedulers is limited by the value specified in the **transmit-rate** statement. Even if there is no congestion, the queue cannot send traffic above the transmit rate due to the static policer.

NOTE: You can apply a transmit rate limit to logical interfaces on Multiservices 100, 400, or 500 PICs. Typically, rate limits are used to prevent a strict-high queue (such as voice) from starving lower priority queues. You can only rate-limit one queue per logical interface. To apply a rate-limit to a Multiservices PIC interface, configure the rate limit in a scheduler and apply the scheduler map to the Multiservices (lsq-) interface at the `[edit class-of-service interfaces]` hierarchy level. For information about configuring other scheduler components, see [“Configuring Schedulers” on page 1579](#).

For more information about scheduler transmission rate, see the following sections:

- [Example: Configuring Scheduler Transmission Rate on page 1593](#)
- [Allocation of Leftover Bandwidth on page 1593](#)

Example: Configuring Scheduler Transmission Rate

Configure the **best-effort** scheduler to use the remainder of the bandwidth on any interface to which it is assigned:

```
class-of-service {
  schedulers {

```

Allocation of Leftover Bandwidth

The allocation of leftover bandwidth is a complex topic. It is difficult to predict and to test, because the behavior of the software varies depending on the traffic mix.

If a queue receives offered loads in excess of the queue's bandwidth allocation, the queue has negative bandwidth credit, and receives a share of any available leftover bandwidth. Negative bandwidth credit means the queue has used up its allocated bandwidth. If a queue's bandwidth credit is positive, meaning it is not receiving offered loads in excess of its bandwidth configuration, then the queue does not receive a share of leftover bandwidth. If the credit is positive, then the queue does not need to use leftover bandwidth, because it can use its own allocation.

This use of leftover bandwidth is the default. If you do not want a queue to use any leftover bandwidth, you must configure it for strict allocation by including the **transmit-rate** statement with the **exact** option at the **[edit class-of-service schedulers scheduler-name]** hierarchy level. With rate control in place, the specified bandwidth is strictly observed. (On Juniper Networks J Series routers, the **exact** option is useful within a given priority, but not between the priorities. For more information, see [“Configuring Schedulers for Priority Scheduling” on page 1594.](#))

On J Series routers, leftover bandwidth is allocated to queues with negative credit in proportion to the configured transmit rate of the queues within a given priority level.

Juniper Networks M Series Multiservice Edge Routers and T Series Core Routers do not distribute leftover bandwidth in proportion to the configured transmit rate of the queues. Instead, the scheduler distributes the leftover bandwidth equally in round-robin fashion to queues that have negative bandwidth credit. All negative-credit queues can take the leftover bandwidth in equal share. This description suggests a simple round-robin distribution process among the queues with negative credits. In actual operation, a queue might change its bandwidth credit status from positive to negative and from negative to positive instantly while the leftover bandwidth is being distributed. Lower-rate queues tend to be allocated a larger share of leftover bandwidth, because their bandwidth credit is more likely to be negative at any given time, if they are overdriven persistently. Also, if there is a large packet size difference, (for example, queue 0 receives 64-byte packets,

whereas queue 1 receives 1500-byte packets), then the actual leftover bandwidth distribution ratio can be skewed substantially, because each round-robin turn allows exactly one packet to be transmitted by a negative-credit queue, regardless of the packet size.

By default, on MX Series routers, the M320 Enhanced Type 4 FPCs, and T4000 routers with Type 5 FPCs and EX Series switches, excess bandwidth is shared in the ratio of the transmit rates. You can adjust this distribution by configuring the **excess-rate** statement at the **[edit class-of-service schedulers scheduler-name]** hierarchy level. You can specify the excess rate sharing by percentage or by proportion.

In summary, J Series routers distribute leftover bandwidth in proportion to the configured rates of the negative-credit queues within a given priority level. M Series and T Series routers distribute leftover bandwidth in equal shares for the queues with the same priority and same negative-credit status. MX Series routers and M320 Enhanced Type 4 FPCs, and EX Series switches, share excess bandwidth in the ratio of the transmit rates, but you can adjust this distribution.

Configuring Schedulers for Priority Scheduling

To configure priority scheduling, include the **priority** statement at the **[edit class-of-service schedulers scheduler-name]** hierarchy level:

```
[edit class-of-service schedulers scheduler-name]  
priority priority-level;
```

The priority level can be **low**, **medium-low**, **medium-high**, **high**, or **strict-high**. The priorities map to numeric priorities in the underlying hardware. In some cases, different priorities behave similarly, because two software priorities behave differently only if they map to two distinct hardware priorities. For more information, see *Platform Support for Priority Scheduling*.

Higher-priority queues transmit packets ahead of lower priority queues as long as the higher-priority forwarding classes retain enough bandwidth credit. When you configure a higher-priority queue with a significant fraction of the transmission bandwidth, the queue might lock out (or *starve*) lower priority traffic.

Strict-high priority queuing works differently on different platforms. For information about strict-high priority queuing on J Series Services Routers, see the J Series router documentation.

The following sections discuss priority scheduling:

- [Example: Configuring Priority Scheduling on page 1595](#)
- [Configuring Strict-High Priority on M Series and T Series Routers on page 1595](#)

Example: Configuring Priority Scheduling

Configure priority scheduling, as shown in the following example:

1. Configure a scheduler, **be-sched**, with **medium-low** priority.

```
[edit class-of-service]
schedulers {
  be-sched {
    priority medium-low;
  }
}
```

2. Configure a scheduler map, **be-map**, that associates **be-sched** with the **best-effort** forwarding class.

```
[edit class-of-service]
scheduler-maps {
  be-map {
    forwarding-class best-effort scheduler be-sched;
  }
}
```

3. Assign **be-map** to a Gigabit Ethernet interface, **ge-0/0/0**.

```
[edit class-of-service]
interfaces {
  ge-0/0/0 {
    scheduler-map be-map;
  }
}
```

Configuring Strict-High Priority on M Series and T Series Routers

On M Series Multiservice Edge Routers and T Series Core Routers, you can configure one queue per interface to have **strict-high** priority, which works the same as **high** priority, but provides unlimited transmission bandwidth. As long as the queue with **strict-high** priority has traffic to send, it receives precedence over all other queues, except queues with **high** priority. Queues with **strict-high** and **high** priority take turns transmitting packets until the **strict-high** queue is empty, the **high** priority queues are empty, or the **high** priority queues run out of bandwidth credit. Only when these conditions are met can lower priority queues send traffic.

When you configure a queue to have **strict-high** priority, you do not need to include the **transmit-rate** statement in the queue configuration at the **[edit class-of-service schedulers scheduler-name]** hierarchy level because the transmission rate of a **strict-high** priority queue is not limited by the WRR configuration. If you do configure a transmission rate on a **strict-high** priority queue, it does not affect the WRR operation. The transmission rate only serves as a placeholder in the output of commands such as the **show interface queue** command.

strict-high priority queues might starve **low** priority queues. The **high** priority allows you to protect traffic classes from being starved by traffic in a **strict-high** queue. For example, a network-control queue might require a small bandwidth allocation (say, 5 percent). You can assign **high** priority to this queue to prevent it from being underserved.

A queue with **strict-high** priority supersedes bandwidth guarantees for queues with lower priority; therefore, we recommend that you use the **strict-high** priority to ensure proper ordering of special traffic, such as voice traffic. You can preserve bandwidth guarantees for queues with lower priority by allocating to the queue with **strict-high** priority only the amount of bandwidth that it generally requires. For example, consider the following allocation of transmission bandwidth:

- Q0 BE—20 percent, low priority
- Q1 EF—30 percent, strict-high priority
- Q2 AF—40 percent, low priority
- Q3 NC—10 percent, low priority

This bandwidth allocation assumes that, in general, the EF forwarding class requires only 30 percent of an interface's transmission bandwidth. However, if short bursts of traffic are received on the EF forwarding class, 100 percent of the bandwidth is given to the EF forwarding class because of the **strict-high** setting.

Configuring Per-Unit Schedulers for Channelized Interfaces

You can configure per-unit scheduling on T1 and DS0 physical interfaces configured on channelized DS3 and STM1 IQ PICs. To enable per-unit scheduling, configure the **per-unit-scheduler** statements at the **[edit interfaces *interface-name*]** hierarchy level.

When per-unit scheduling is enabled on the channelized PICs, you can associate a scheduler map with the physical interface. For more information about configuring scheduler maps, see [“Configuring Scheduler Maps” on page 1613](#).

NOTE: If you configure the **per-unit-scheduler** statement on the physical interface of a 4-port channelized OC-12 IQ PIC and configure 975 logical interfaces or data link connection identifiers (DLCIs), some of the logical interfaces or DLCIs will drop all packets intermittently.

The following example configures per-unit scheduling on a channelized DS3 PIC and an STM1 IQ PIC.

```
[edit interfaces]
ct3-5/3/1 {
  partition 1 interface-type t1;
}
t1-5/3/1:1 {
```

```

per-unit-scheduler; # This enables per-unit scheduling
encapsulation frame-relay;
unit 0 {
    dlci 1;
    family inet {
        address 10.0.0.2/32;
    }
}
}
ct3-5/3/0 {
    partition 1 interface-type ct1;
}
ct1-5/3/0:1 {
    partition 1 timeslots 1 interface-type ds;
}
ds-5/3/0:1:1 {
    per-unit-scheduler; # This enables per-unit scheduling
    encapsulation frame-relay;
    unit 0 {
        dlci 1;
        family inet {
            address 10.0.0.1/32;
        }
    }
}
cau4-3/0/0 {
    partition 1 interface-type cel;
}
cstm1-3/0/0 {
    no-partition 1 interface-type cau4;
}
cel-3/0/0:1 {
    partition 1 timeslots 1 interface-type ds;
}
ds-3/0/0:1:1 {
    per-unit-scheduler; # This enables per-unit scheduling
    encapsulation frame-relay;
    unit 0 {
        dlci 1;
        family inet {
            address 10.1.1.1/32;
        }
    }
}
}

```

}

```

Configuring the Shaping Rate for Physical Interfaces

To configure the shaping rate on the physical interface, either include the **shaping-rate** statement at the **[edit class-of-service interfaces *interface-name*]** hierarchy level or include the **output-traffic-control-profile** statement at the **[edit class-of-service interfaces *interface-name*]** hierarchy level.

You can specify a peak bandwidth rate in bps, either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000). For physical interfaces, the range is from 1000 through 160,000,000,000 bps.

For physical interfaces on T4000 routers with Type 5 FPCs, the shaping rate value for the physical interface must be a minimum of 292 Kbps. The maximum value of **shaping-rate** is limited by the maximum transmission rate of the interface.

The following are two example configurations for applying a shaping rate of 5 Gbps on a T4000 12x10 Gbps physical interface (xe-4/0/0):

Applying a shaping rate at the **[edit class-of-service interfaces *interface-name*] hierarchy:**

```

[edit class-of-service]
interfaces {
  xe-4/0/0 {
    shaping-rate 5g;
  }
}

```

Applying a shaping rate using traffic-control-profiles:

```

[edit class-of-service]
traffic-control-profiles {
  output {
    shaping-rate 5g;
  }
}
interfaces {
  xe-4/0/0 {
    output-traffic-control-profile output;
  }
}

```

To view the results of your configuration, issue the following **show** commands:

- **show class-of-service interface *interface-name***
- **show interfaces *interface-name* extensive**

Oversubscribing Interface Bandwidth

The term *oversubscribing interface bandwidth* means configuring shaping rates (peak information rates [PIRs]) so that their sum exceeds the interface bandwidth.

On Channelized IQ PICs, Gigabit Ethernet IQ PICs, and FRF.15 and FRF.16 link services IQ (LSQ) interfaces on AS PICs, Multiservices PICs, and Multiservices DPCs, you can oversubscribe interface bandwidth. This means that the logical interfaces (and DLCIs within an FRF.15 or FRF.16 bundle) can be oversubscribed when there is leftover bandwidth. In the case of FRF.16 bundle interfaces, the physical interface can be oversubscribed. The oversubscription is capped to the configured PIR. Any unused bandwidth is distributed equally among oversubscribed logical interfaces or DLCIs, or physical interfaces.

For networks that are not likely to experience congestion, oversubscribing interface bandwidth improves network utilization, thereby allowing more customers to be provisioned on a single interface. If the actual data traffic does not exceed the interface bandwidth, oversubscription allows you to sell more bandwidth than the interface can support.

We recommend avoiding oversubscription in networks that are likely to experience congestion. Be cautious not to oversubscribe a service by too much, because this can cause degradation in the performance of the routing platform during congestion. When you configure oversubscription, starvation of some output queues can occur if the actual data traffic exceeds the physical interface bandwidth. You can prevent degradation by using statistical multiplexing to ensure that the actual data traffic does not exceed the interface bandwidth.

NOTE: You cannot oversubscribe interface bandwidth when you configure traffic shaping using the method described in *Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs*.

When configuring oversubscription for FRF.16 bundle interfaces, you can assign traffic control profiles that apply on a physical interface basis. When you apply traffic control profiles to FRF.16 bundles at the *logical* interface level, member link interface bandwidth is underutilized when there is a small proportion of traffic or no traffic at all on an individual DLCI. Support for traffic control features on the FRF.16 bundle physical interface level addresses this limitation.

To configure oversubscription of the interface, perform the following steps:

1. Include the **shaping-rate** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]  
  shaping-rate (percent percentage | rate);
```

NOTE: When configuring oversubscription for FRF.16 bundle interfaces on a physical interface basis, you *must* specify **shaping-rate** as a percentage.

On LSQ interfaces, you can configure the shaping rate as a percentage from 1 through 100.

On IQ and IQ2 interfaces, you can configure the shaping rate as an absolute rate from 1000 through 160,000,000,000 bps.

For all MX Series router and EX Series switch interfaces, the shaping rate can be from 65,535 through 160,000,000,000 bps.

Alternatively, you can configure a shaping rate for a logical interface and oversubscribe the physical interface by including the **shaping-rate** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy level. However, with this configuration approach, you cannot independently control the delay-buffer rate, as described in Step 2.

NOTE: For channelized and Gigabit Ethernet IQ interfaces, the **shaping-rate** and **guaranteed-rate** statements are mutually exclusive. You cannot configure some logical interfaces to use a shaping rate and others to use a guaranteed rate. This means there are no service guarantees when you configure a PIR. For these interfaces, you can configure either a PIR or a committed information rate (CIR), but not both.

This restriction does not apply to Gigabit Ethernet IQ2 PICs or LSQ interfaces on AS PICs. For LSQ and Gigabit Ethernet IQ2 interfaces, you can configure both a PIR and a CIR on an interface. For more information about CIRs, see [“Providing a Guaranteed Minimum Rate” on page 1608](#).

For more information about Gigabit Ethernet IQ2 PICs, see *CoS on Enhanced IQ2 PICs Overview*.

2. Optionally, you can base the delay-buffer calculation on a delay-buffer rate. To do this, include the **delay-buffer-rate** statement at the **[edit class-of-service traffic-control-profiles profile-name]** hierarchy level:

NOTE: When configuring oversubscription for FRF.16 bundle interfaces on a physical interface basis, you *must* specify **delay-buffer-rate** as a percentage.

```
[edit class-of-service traffic-control-profiles profile-name]
  delay-buffer-rate (percent percentage | rate);
```

The delay-buffer rate overrides the shaping rate as the basis for the delay-buffer calculation. In other words, the shaping rate or scaled shaping rate is used for delay-buffer calculations only when the delay-buffer rate is not configured.

For LSQ interfaces, if you do not configure a delay-buffer rate, the guaranteed rate (CIR) is used to assign buffers. If you do not configure a guaranteed rate, the shaping rate (PIR) is used in the undersubscribed case, and the scaled shaping rate is used in the oversubscribed case.

On LSQ interfaces, you can configure the delay-buffer rate as a percentage from 1 through 100.

On IQ and IQ2 interfaces, you can configure the delay-buffer rate as an absolute rate from 1000 through 160,000,000,000 bps.

The actual delay buffer is based on the calculations described in [“Configuring Large Delay Buffers for Slower Interfaces” on page 1581](#) and [“Maximum Delay Buffer for NxDS0 Interfaces” on page 1584](#). For an example showing how the delay-buffer rates are applied, see [“Examples: Oversubscribing Interface Bandwidth” on page 1605](#).

Configuring large buffers on relatively slow-speed links can cause packet aging. To help prevent this problem, the software requires that the sum of the delay-buffer rates be less than or equal to the port speed.

This restriction does not eliminate the possibility of packet aging, so you should be cautious when using the **delay-buffer-rate** statement. Though some amount of extra buffering might be desirable for burst absorption, delay-buffer rates should not far exceed the service rate of the logical interface.

If you configure delay-buffer rates so that the sum exceeds the port speed, the configured delay-buffer rate is not implemented for the last logical interface that you configure. Instead, that logical interface receives a delay-buffer rate of zero, and a warning message is displayed in the CLI. If bandwidth becomes available (because another logical interface is deleted or deactivated, or the port speed is increased), the configured delay-buffer-rate is reevaluated and implemented if possible.

If you do not configure a delay-buffer rate or a guaranteed rate, the logical interface receives a delay-buffer rate in proportion to the shaping rate and the remaining delay-buffer rate available. In other words, the delay-buffer rate for each logical interface with no configured delay-buffer rate is equal to:

$$(\text{remaining delay-buffer rate} * \text{shaping rate}) / (\text{sum of shaping rates})$$

where the remaining delay-buffer rate is equal to:

$$(\text{interface speed}) - (\text{sum of configured delay-buffer rates})$$

3. To assign a scheduler map to the logical interface, include the **scheduler-map** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]  
  scheduler-map map-name;
```

For information about configuring schedulers and scheduler maps, see [“Configuring Schedulers” on page 1579](#) and [“Configuring Scheduler Maps” on page 1613](#).

4. Optionally, you can enable large buffer sizes to be configured. To do this, include the **q-pic-large-buffer** statement at the **[edit chassis fpc *slot-number* pic *pic-number*]** hierarchy level:

```
[edit chassis fpc slot-number pic pic-number]
q-pic-large-buffer;
```

If you do not include this statement, the delay-buffer size is more restricted. We recommend restricted buffers for delay-sensitive traffic, such as voice traffic. For more information, see [“Configuring Large Delay Buffers for Slower Interfaces” on page 1581](#).

- To enable scheduling on logical interfaces, include the **per-unit-scheduler** statement at the **[edit interfaces interface-name]** hierarchy level:

```
[edit interfaces interface-name]
per-unit-scheduler;
```

When you include this statement, the maximum number of VLANs supported is 768 on a single-port Gigabit Ethernet IQ PIC. On a dual-port Gigabit Ethernet IQ PIC, the maximum number is 384.

- To enable scheduling for FRF.16 bundles physical interfaces, include the **no-per-unit-scheduler** statement at the **[edit interfaces interface-name]** hierarchy level:

```
[edit interfaces interface-name]
no-per-unit-scheduler;
```

- To apply the traffic-scheduling profile, include the **output-traffic-control-profile** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
output-traffic-control-profile profile-name;
```

You cannot include the **output-traffic-control-profile** statement in the configuration if any of the following statements are included in the logical interface configuration: **scheduler-map**, **shaping-rate**, **adaptive-shaper**, or **virtual-channel-group** (the last two are valid on Juniper Networks J Series Services Routers only).

[Table 114 on page 1603](#) shows how the bandwidth and delay buffer are allocated in various configurations.

Table 114: Bandwidth and Delay Buffer Allocations by Configuration Scenario

Configuration Scenario	Delay Buffer Allocation
You do not oversubscribe the interface. You do not configure a guaranteed rate. You do not configure a shaping rate. You do not configure a delay-buffer rate.	Logical interface receives the remaining bandwidth and receives a delay buffer in proportion to the remaining bandwidth.
You do not oversubscribe the interface. You do not configure a guaranteed rate. You configure a shaping rate at the [edit class-of-service interfaces interface-name unit logical-unit-number] hierarchy level.	<p>For backward compatibility, the shaped logical interface receives a delay buffer based on the shaping rate. The multiplicative factor depends on whether you include the q-pic-large-buffer statement. For more information, see “Configuring Large Delay Buffers for Slower Interfaces” on page 1581.</p> <p>Unshaped logical interfaces receive the remaining bandwidth and a delay buffer in proportion to the remaining bandwidth.</p>

Table 114: Bandwidth and Delay Buffer Allocations by Configuration Scenario (*continued*)

Configuration Scenario	Delay Buffer Allocation
You oversubscribe the interface. You do not configure a guaranteed rate. You do not configure a shaping rate. You do not configure a delay-buffer rate.	Logical interface receives minimal bandwidth with no guarantees and receives a minimal delay buffer equal to four MTU-sized packets.
You oversubscribe the interface. You configure a shaping rate. You do not configure a guaranteed rate. You do not configure a delay-buffer rate.	<p>Logical interface receives a delay buffer based on the scaled shaping rate:</p> $\text{scaled shaping rate} = (\text{shaping-rate} * [\text{physical interface bandwidth}]) / \text{SUM}(\text{shaping-rates of all logical interfaces on the physical interface})$ <p>The logical interface receives variable bandwidth, depending on how much oversubscription and statistical multiplexing is present. If the amount of oversubscription is low enough that statistical multiplexing does not make all logical interfaces active at the same time and the physical interface bandwidth is not exceeded, the logical interface receives bandwidth equal to the shaping rate. Otherwise, the logical interface receives a smaller amount of bandwidth. In either case, the logical interface bandwidth does not exceed the shaping rate.</p>
You oversubscribe the interface. You configure a shaping rate. You configure a delay-buffer rate.	<p>Logical interface receives a delay buffer based on the delay-buffer rate. For example, on IQ and IQ2 interfaces:</p> <p>delay-buffer-rate <= 10 Mbps: 400-millisecond (ms) delay buffer delay-buffer-rate <= 20 Mbps: 300-ms delay buffer delay-buffer-rate <= 30 Mbps: 200-ms delay buffer delay-buffer-rate <= 40 Mbps: 150-ms delay buffer delay-buffer-rate > 40 Mbps: 100-ms delay buffer</p> <p>On LSQ DLCIs, if total bundle bandwidth < T1 bandwidth:</p> <p>delay-buffer-rate = 1 second</p> <p>On LSQ DLCIs, if total bundle bandwidth >= T1 bandwidth:</p> <p>delay-buffer-rate = 200 ms</p> <p>The multiplicative factor depends on whether you include the q-pic-large-buffer statement. For more information, see "Configuring Large Delay Buffers for Slower Interfaces" on page 1581.</p> <p>The logical interface receives variable bandwidth, depending on how much oversubscription and statistical multiplexing is present. If the amount of oversubscription is low enough that statistical multiplexing does not make all logical interfaces active at the same time and the physical interface bandwidth is not exceeded, the logical interface receives bandwidth equal to the shaping rate. Otherwise, the logical interface receives a smaller amount of bandwidth. In either case, the logical interface bandwidth does not exceed the shaping rate.</p>
You oversubscribe the interface. You do not configure a shaping rate. You configure a guaranteed rate. You configure a delay-buffer rate.	Logical interface receives a delay buffer based on the delay-buffer rate.
You oversubscribe the interface. You do not configure a shaping rate. You do not configure a guaranteed rate. You configure a delay-buffer rate.	This scenario is not allowed. If you configure a delay-buffer rate, the traffic-control profile must also include either a shaping rate or a guaranteed rate.

Table 114: Bandwidth and Delay Buffer Allocations by Configuration Scenario (*continued*)

Configuration Scenario	Delay Buffer Allocation
You oversubscribe the interface. You configure a shaping rate. You configure a guaranteed rate. You do not configure a delay-buffer rate.	<p>Logical interface receives a delay buffer based on the guaranteed rate.</p> <p>This configuration is valid on LSQ interfaces and Gigabit Ethernet IQ2 interfaces only. On channelized interfaces, you cannot configure both a shaping rate (PIR) and a guaranteed rate (CIR).</p>

Verifying Configuration of Bandwidth Oversubscription

To verify your configuration, you can issue this following operational mode commands:

- **show class-of-service interfaces**
- **show class-of-service traffic-control-profile *profile-name***

Examples: Oversubscribing Interface Bandwidth

This section provides two examples: oversubscription of a channelized interface and oversubscription of an LSQ interface.

Oversubscribing a Channelized Interface

Two logical interface units, 0 and 1, are shaped to rates 2 Mbps and 3 Mbps, respectively. The delay-buffer rates are 750 Kbps and 500 Kbps, respectively. The actual delay buffers allocated to each logical interface are 1 second of 750 Kbps and 2 seconds of 500 Kbps, respectively. The 1-second and 2-second values are based on the following calculations:

delay-buffer-rate < [16 x 64 Kbps]): 1 second of delay-buffer-rate
 delay-buffer-rate < [8 x 64 Kbps]): 2 seconds of delay-buffer-rate

For more information about these calculations, see [“Maximum Delay Buffer for NxDSO Interfaces” on page 1584](#).

```
chassis {
  fpc 3 {
    pic 0 {
      q-pic-large-buffer;
    }
  }
}
interfaces {
  t1-3/0/0 {
    per-unit-scheduler;
  }
}
class-of-service {
  traffic-control-profiles {
    tc-profile1 {
      shaping-rate 2m;
      delay-buffer-rate 750k; # 750 Kbps is less than 16 x 64 Kbps
      scheduler-map sched-map1;
    }
    tc-profile2 {
      shaping-rate 3m;
      delay-buffer-rate 500k; # 500 Kbps is less than 8 x 64 Kbps
    }
  }
}
```

```
        scheduler-map sched-map2;
    }
}
interfaces {
    t1-3/0/0 {
        unit 0 {
            output-traffic-control-profile tc-profile1;
        }
        unit 1 {
            output-traffic-control-profile tc-profile2;
        }
    }
}
}
```

**Oversubscribing an
LSQ Interface with
Scheduling Based on
the Logical Interface**

Apply a traffic-control profile to a logical interface representing a DLCI on an FRF.16 bundle:

```
interfaces {
    lsq-1/3/0:0 {
        per-unit-scheduler;
        unit 0 {
            dlci 100;
        }
        unit 1 {
            dlci 200;
        }
    }
}

class-of-service {
    traffic-control-profiles {
        tc_0 {
            shaping-rate percent 100;
            guaranteed-rate percent 60;
            delay-buffer-rate percent 80;
        }
        tc_1 {
            shaping-rate percent 80;
            guaranteed-rate percent 40;
        }
    }
}
interfaces {
    lsq-1/3/0 {
        unit 0 {
            output-traffic-control-profile tc_0;
        }
        unit 1 {
            output-traffic-control-profile tc_1;
        }
    }
}
}
```

Oversubscribing an LSQ Interface with Scheduling Based on the Physical Interface

Apply a traffic-control profile to the physical interface representing an FRF.16 bundle:

```

interfaces {
  lsq-0/2/0:0 {
    no-per-unit-scheduler;
    encapsulation multilink-frame-relay-uni-nni;
    unit 0 {
      dlci 100;
      family inet {
        address 18.18.18.2/24;
      }
    }
  }
}
class-of-service {
  traffic-control-profiles {
    rlsq_tc {
      scheduler-map rlsq;
      shaping-rate percent 60;
      delay-buffer-rate percent 10;
    }
  }
  interfaces {
    lsq-0/2/0:0 {
      output-traffic-control-profile rlsq_tc;
    }
  }
}
scheduler-maps {
  rlsq {
    forwarding-class best-effort scheduler rlsq_scheduler;
    forwarding-class expedited-forwarding scheduler rlsq_scheduler1;
  }
}
schedulers {
  rlsq_scheduler {
    transmit-rate percent 20;
    priority low;
  }
  rlsq_scheduler1 {
    transmit-rate percent 40;
    priority high;
  }
}

```

On an FRF.15 bundle, apply the following configuration:

```
class-of-service {
  traffic-control-profiles {
    rlsq {
      scheduler-map sched_0;
      shaping-rate percent 40;
      delay-buffer-rate percent 50;
    }
  }
  interfaces lsq-2/0/0 {
    unit 0 {
      output-traffic-control-profile rlsq;
    }
  }
}
interfaces lsq-2/0/0 {
  per-unit-scheduler;
  unit 0 {
    encapsulation multilink-frame-relay-end-to-end;
    family inet {
      address 10.1.1.2/32;
    }
  }
}
```

Providing a Guaranteed Minimum Rate

On Gigabit Ethernet IQ PICs, EQ DPCs, Trio MPC/MIC modules, Channelized IQ PICs, and FRF.16 LSQ interfaces on AS PICs, you can configure guaranteed bandwidth, also known as a committed information rate (CIR). This allows you to specify a guaranteed rate for each logical interface. The guaranteed rate is a minimum. If excess physical interface bandwidth is available for use, the logical interface receives more than the guaranteed rate provisioned for the interface.

You cannot provision the sum of the guaranteed rates to be more than the physical interface bandwidth, or the bundle bandwidth for LSQ interfaces. If the sum of the guaranteed rates exceeds the interface or bundle bandwidth, the commit operation does not fail, but the software automatically decreases the rates so that the sum of the guaranteed rates is equal to the available bundle bandwidth.

To configure a guaranteed minimum rate, perform the following steps:

1. Include the **guaranteed-rate** statement at the **[edit class-of-service traffic-control-profile *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]
  guaranteed-rate (percent percentage | rate) <burst-size bytes>;
```

On LSQ interfaces, you can configure the guaranteed rate as a percentage from 1 through 100.

On IQ and IQ2 interfaces, you can configure the guaranteed rate as an absolute rate from 1000 through 160,000,000,000 bps.

NOTE: For channelized and Gigabit Ethernet IQ interfaces, the **shaping-rate** and **guaranteed-rate** statements are mutually exclusive. You cannot configure some logical interfaces to use a shaping rate and others to use a guaranteed rate. This means there are no service guarantees when you configure a PIR. For these interfaces, you can configure either a PIR or a CIR, but not both.

This restriction does not apply to Gigabit Ethernet IQ2 PICs or LSQ interfaces on AS PICs. For LSQ and Gigabit Ethernet IQ2 interfaces, you can configure both a PIR and a CIR on an interface.

For more information about Gigabit Ethernet IQ2 PICs, see *CoS on Enhanced IQ2 PICs Overview*.

2. Optionally, you can base the delay-buffer calculation on a delay-buffer rate. To do this, include the **delay-buffer-rate** statement [edit class-of-service traffic-control-profiles *profile-name*] hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]
  delay-buffer-rate (percent percentage | rate);
```

On LSQ interfaces, you can configure the delay-buffer rate as a percentage from 1 through 100.

On IQ and IQ2 interfaces, you can configure the delay-buffer rate as an absolute rate from 1000 through 160,000,000,000 bps.

The actual delay buffer is based on the calculations described in “[Configuring Large Delay Buffers for Slower Interfaces](#)” on page 1581 and “[Maximum Delay Buffer for NxDSO Interfaces](#)” on page 1584. For an example showing how the delay-buffer rates are applied, see “[Example: Providing a Guaranteed Minimum Rate](#)” on page 1611.

If you do not include the **delay-buffer-rate** statement, the delay-buffer calculation is based on the guaranteed rate, the shaping rate if no guaranteed rate is configured, or the scaled shaping rate if the interface is oversubscribed.

If you do not specify a shaping rate or a guaranteed rate, the logical interface receives a minimal delay-buffer rate and minimal bandwidth equal to four MTU-sized packets.

You can configure a rate for the delay buffer that is higher than the guaranteed rate. This can be useful when the traffic flow might not require much bandwidth in general, but in some cases traffic can be bursty and therefore needs a large buffer.

Configuring large buffers on relatively slow-speed links can cause packet aging. To help prevent this problem, the software requires that the sum of the delay-buffer rates be less than or equal to the port speed. This restriction does not eliminate the possibility of packet aging, so you should be cautious when using the **delay-buffer-rate** statement. Though some amount of extra buffering might be desirable for burst absorption, delay-buffer rates should not far exceed the service rate of the logical interface.

If you configure delay-buffer rates so that the sum exceeds the port speed, the configured delay-buffer rate is not implemented for the last logical interface that you

configure. Instead, that logical interface receives a delay-buffer rate of 0, and a warning message is displayed in the CLI. If bandwidth becomes available (because another logical interface is deleted or deactivated, or the port speed is increased), the configured delay-buffer-rate is reevaluated and implemented if possible.

If the guaranteed rate of a logical interface cannot be implemented, that logical interface receives a delay-buffer rate of 0, even if the configured delay-buffer rate is within the interface speed. If at a later time the guaranteed rate of the logical interface can be met, the configured delay-buffer rate is reevaluated and if the delay-buffer rate is within the remaining bandwidth, it is implemented.

If any logical interface has a configured guaranteed rate, all other logical interfaces on that port that do not have a guaranteed rate configured receive a delay-buffer rate of 0. This is because the absence of a guaranteed rate configuration corresponds to a guaranteed rate of 0 and, consequently, a delay-buffer rate of 0.

3. To assign a scheduler map to the logical interface, include the **scheduler-map** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]  
  scheduler-map map-name;
```

For information about configuring schedulers and scheduler maps, see [“Configuring Schedulers” on page 1579](#) and [“Configuring Scheduler Maps” on page 1613](#).

4. To enable large buffer sizes to be configured, include the **q-pic-large-buffer** statement at the **[edit chassis fpc *slot-number* pic *pic-number*]** hierarchy level:

```
[edit chassis fpc slot-number pic pic-number]  
  q-pic-large-buffer;
```

If you do not include this statement, the delay-buffer size is more restricted. For more information, see [“Configuring Large Delay Buffers for Slower Interfaces” on page 1581](#).

5. To enable scheduling on logical interfaces, include the **per-unit-scheduler** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]  
  per-unit-scheduler;
```

When you include this statement, the maximum number of VLANs supported is 768 on a single-port Gigabit Ethernet IQ PIC. On a dual-port Gigabit Ethernet IQ PIC, the maximum number is 384.

6. To apply the traffic-scheduling profile to the logical interface, include the **output-traffic-control-profile** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]  
  output-traffic-control-profile profile-name;
```

[Table 115 on page 1611](#) shows how the bandwidth and delay buffer are allocated in various configurations.

Table 115: Bandwidth and Delay Buffer Allocations by Configuration Scenario

Configuration Scenario	Delay Buffer Allocation
You do not configure a guaranteed rate. You do not configure a delay-buffer rate.	Logical interface receives minimal bandwidth with no guarantees and receives a minimal delay buffer equal to 4 MTU-sized packets.
You configure a guaranteed rate. You do not configure a delay-buffer rate.	Logical interface receives bandwidth equal to the guaranteed rate and a delay buffer based on the guaranteed rate. The multiplicative factor depends on whether you include the q-pic-large-buffer statement. For more information, see “Configuring Large Delay Buffers for Slower Interfaces” on page 1581 .
You configure a guaranteed rate. You configure a delay-buffer rate.	Logical interface receives bandwidth equal to the guaranteed rate and a delay buffer based on the delay-buffer rate. The multiplicative factor depends on whether you include the q-pic-large-buffer statement. For more information, see “Configuring Large Delay Buffers for Slower Interfaces” on page 1581 .

Verifying Configuration of Guaranteed Minimum Rate

To verify your configuration, you can issue this following operational mode commands:

- **show class-of-service interfaces**
- **show class-of-service traffic-control-profile *profile-name***

Example: Providing a Guaranteed Minimum Rate

Two logical interface units, **0** and **1**, are provisioned with a guaranteed minimum of 750 Kbps and 500 Kbps, respectively. For logical unit **1**, the delay buffer is based on the guaranteed rate setting. For logical unit **0**, a delay-buffer rate of 500 Kbps is specified. The actual delay buffers allocated to each logical interface are 2 seconds of 500 Kbps. The 2-second value is based on the following calculation:

delay-buffer-rate < [8 x 64 Kbps]): 2 seconds of delay-buffer-rate

For more information about this calculation, see [“Maximum Delay Buffer for NxDS0 Interfaces” on page 1584](#).

```
chassis {
  fpc 3 {
    pic 0 {
      q-pic-large-buffer;
    }
  }
}
interfaces {
  t1-3/0/1 {
    per-unit-scheduler;
  }
}
class-of-service {
  traffic-control-profiles {
    tc-profile3 {
      guaranteed-rate 750k;
      scheduler-map sched-map3;
      delay-buffer-rate 500k; # 500 Kbps is less than 8 x 64 Kbps
    }
  }
}
```

```

    }
    tc-profile4 {
        guaranteed-rate 500k; # 500 Kbps is less than 8 x 64 Kbps
        scheduler-map sched-map4;
    }
}
interfaces {
    t1-3/0/1 {
        unit 0 {
            output-traffic-control-profile tc-profile3;
        }
        unit 1 {
            output-traffic-control-profile tc-profile4;
        }
    }
}
}

```

Associating Schedulers with Fabric Priorities

On Juniper Networks M320 Multiservice Edge Routers and T Series Core Routers only, you can associate a scheduler with a class of traffic that has a specific priority while transiting the fabric. Traffic transiting the fabric can have two priority values: **low** or **high**. To associate a scheduler with a fabric priority, include the **priority** and **scheduler** statements at the **[edit class-of-service fabric scheduler-map]** hierarchy level:

```

[edit class-of-service fabric scheduler-map]
priority (high | low) scheduler scheduler-name;

```

NOTE: For a scheduler that you associate with a fabric priority, include only the **drop-profile-map** statement at the **[edit class-of-service schedulers scheduler-name]** hierarchy level. You cannot include the **buffer-size**, **transmit-rate**, and **priority** statements at that hierarchy level.

For information about associating a forwarding class with a fabric priority, see [“Overriding Fabric Priority Queuing” on page 1535](#).

Example: Associating a Scheduler with a Fabric Priority

Associate a scheduler with a class of traffic that has a specific priority while transiting the fabric:

```

[edit class-of-service]
schedulers {
    fab-be-scheduler {
        drop-profile-map loss-priority low protocol any drop-profile fab-profile-1;
        drop-profile-map loss-priority high protocol any drop-profile fab-profile-2;
    }
    fab-ef-scheduler {
        drop-profile-map loss-priority low protocol any drop-profile fab-profile-3;
        drop-profile-map loss-priority high protocol any drop-profile fab-profile-4;
    }
}
drop-profiles {
    fab-profile-1 {

```

```

        fill-level 100 drop-probability 100;
        fill-level 85 drop-probability 50;
    }
    fab-profile-2 {
        fill-level 100 drop-probability 100;
        fill-level 95 drop-probability 50;
    }
    fab-profile-3 {
        fill-level 75 drop-probability 100;
        fill-level 95 drop-probability 50;
    }
    fab-profile-4 {
        fill-level 100 drop-probability 100;
        fill-level 80 drop-probability 50;
    }
}
fabric {
    scheduler-map {
        priority low scheduler fab-be-scheduler;
        priority high scheduler fab-ef-scheduler;
    }
}

```

Configuration Tasks for Scheduler Maps

- [Configuring Scheduler Maps on page 1613](#)
- [Applying Scheduler Maps to Physical Interfaces on page 1613](#)
- [Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs on page 1614](#)
- [Applying Scheduler Maps to Packet Forwarding Component Queues on page 1620](#)

Configuring Scheduler Maps

After defining a scheduler, you can associate it with a specified forwarding class by including it in a *scheduler map*. To do this, include the **scheduler-maps** statement at the **[edit class-of-service]** hierarchy level:

```

[edit class-of-service]
scheduler-maps {
    map-name {
        forwarding-class class-name scheduler scheduler-name;
    }
}

```

Applying Scheduler Maps to Physical Interfaces

After you have defined a scheduler map, as described in “[Configuring Scheduler Maps on page 1613](#)”, you can apply it to an output interface. Include the **scheduler-map** statement at the **[edit class-of-service interfaces interface-name]** hierarchy level:

```

[edit class-of-service interfaces interface-name]
scheduler-map map-name;

```

Interface wildcards are supported. However, scheduler maps using wildcard interfaces are not checked against routing device interfaces at commit time and can result in a configuration that is incompatible with installed hardware. Fully specified interfaces, on

the other hand, check the configuration against the hardware and report errors or warning if the hardware does not support the configuration.

Generally, you can associate schedulers with physical interfaces only. For some IQ interfaces, you can also associate schedulers with the logical interface. For more information, see *Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs*.

NOTE: For original Channelized OC12 PICs, limited CoS functionality is supported. For more information, contact Juniper Networks customer support.

When you apply a scheduler map to a physical interface, or when you modify the configuration of a scheduler map that is already applied to a physical interface, packets already in the output queues of the interface might get dropped. The amount of packet loss is not deterministic and depends on the offered traffic load at the time you apply or modify the scheduler map.

Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs

By default, output scheduling is not enabled on logical interfaces. Logical interfaces without shaping configured share a default scheduler. This scheduler has a committed information rate (CIR) that equals 0. (The CIR is the guaranteed rate.) The default scheduler has a peak information rate (PIR) that equals the physical interface shaping rate.

NOTE: If you apply a shaping rate, you must keep in mind that the transit statistics for physical interfaces are obtained from the packet forwarding engine, but the traffic statistics are supplied by the PIC. Therefore, if shaping is applied to the PIC, the count of packets in the transit statistics fields do not always agree with the counts in the traffic statistics. For example, the IPv6 transit statistics will not necessarily match the traffic statistics on the interface. However, at the logical interface (DLCI) level, both transit and traffic statistics are obtained from the Packet Forwarding Engine and will not show any difference.

Logical interface scheduling (also called *per-unit scheduling*) allows you to enable multiple output queues on a logical interface and associate an output scheduler and shaping rate with the queues. You can configure logical interface scheduling on the following PICs:

- Adaptive Services PIC, on link services IQ (**lsq-**) interfaces
- Channelized E1 IQ PIC
- Channelized OC3 IQ PIC
- Channelized OC12 IQ PIC (Per-unit scheduling is not supported on T1 interfaces configured on this PIC.)
- Channelized STM1 IQ PIC
- Channelized T3 IQ PIC

- E3 IQ PIC
- Gigabit Ethernet IQ PIC
- Gigabit Ethernet IQ2 PIC
- IQE PICs
- Link services PIM (**ls-** interfaces) on J Series routers

For Juniper Networks J Series Services Routers only, you can configure per-unit scheduling for virtual channels. For more information, see the J Series router documentation.

For Channelized and Gigabit Ethernet IQ PICs only, you can configure a shaping rate for a VLAN or DLCI and oversubscribe the physical interface by including the **shaping-rate** statement at the **[edit class-of-service traffic-control-profiles]** hierarchy level. With this configuration approach, you can independently control the delay-buffer rate, as described in [“Oversubscribing Interface Bandwidth” on page 1600](#).

Physical interfaces (for example, **t3-0/0/0**, **t3-0/0/0:0**, and **ge-0/0/0**) support scheduling with any encapsulation type pertinent to that physical interface. For a single port, you cannot apply scheduling to the physical interface if you apply scheduling to one or more of the associated logical interfaces.

For Gigabit Ethernet IQ2 PICs only, you can configure hierarchical traffic shaping, meaning the shaping is performed on both the physical interface and the logical interface. You can also configure input traffic scheduling and shared scheduling. For more information, see *CoS on Enhanced IQ2 PICs Overview*.

Logical interfaces (for example, **t3-0/0/0.0**, **ge-0/0/0.0**, and **t1-0/0/0:0.1**) support scheduling on DLCIs or VLANs only. Furthermore, logical interface scheduling is not supported on PICs that do not have IQ.

NOTE: In the Junos OS implementation, the term *logical interfaces* generally refers to interfaces you configure by including the unit statement at the **[edit interfaces interface-name]** hierarchy level. As such, logical interfaces have the *logical* descriptor at the end of the interface name, as in **ge-0/0/0.1** or **t1-0/0/0:0.1**, where the logical unit number is 1.

Although channelized interfaces are generally thought of as logical or virtual, the Junos OS sees T3, T1, and NxDS0 interfaces within a channelized IQ PIC as physical interfaces. For example, both **t3-0/0/0** and **t3-0/0/0:1** are treated as physical interfaces by the Junos OS. In contrast, **t3-0/0/0.2** and **t3-0/0/0:1.2** are considered logical interfaces because they have the .2 at the end of the interface names.

Within the **[edit class-of-service]** hierarchy level, you cannot use the *.logical* descriptor when you assign properties to logical interfaces. Instead, you must include the unit statement in the configuration. For example:

```
[edit class-of-service]
user@host# set interfaces t3-0/0/0 unit 0 scheduler-map map1
```

Table 116 on page 1616 shows the interfaces that support transmission scheduling.

Table 116: Transmission Scheduling Support by Interfaces Type

Interface Type	PIC Type	Supported	Examples
IQ PICs			
Channelized interfaces configured on IQ PICs	Channelized DS3 IQ	Yes	Example of supported configuration: [edit class-of-service interfaces t1-0/0/0:1] scheduler-map map-1;
Logical interfaces (DLCIs and VLANs only) configured on IQ PICs	Gigabit Ethernet IQ with VLAN tagging enabled	Yes	Example of supported configuration: [edit class-of-service interfaces ge-0/0/0 unit 1] scheduler-map map-1;
	E3 IQ with Frame Relay encapsulation	Yes	Example of supported configuration: [edit class-of-service interfaces e3-0/0/0 unit 1] scheduler-map map-1;
	Channelized OC3 IQ with Frame Relay encapsulation	Yes	Example of supported configuration: [edit class-of-service interfaces t1-1/0/0:1 unit 0] scheduler-map map-1;
	Channelized STM1 IQ with Frame Relay encapsulation	Yes	Example of supported configuration: [edit class-of-service interfaces e1-0/0/0:1 unit 1] scheduler-map map-1;
	Channelized T3 IQ with Frame Relay encapsulation	Yes	Example of supported configuration: [edit class-of-service interfaces t1-0/0/0 unit 1] scheduler-map map-1;
Logical interfaces configured on IQ PICs (interfaces that are not DLCIs or VLANs)	E3 IQ PIC with Cisco HDLC encapsulation	No	Example of unsupported configuration: [edit class-of-service interfaces e3-0/0/0 unit 1] scheduler-map map-1;
Non-IQ PICs			
Physical interfaces	T3	Yes	Example of supported configuration: [edit class-of-service interfaces t3-0/0/0] scheduler-map map-1;
Channelized OC12 PIC	Channelized OC12	Yes	Example of supported configuration: [edit class-of-service interfaces t3-0/0/0:1] scheduler-map map-1;

Table 116: Transmission Scheduling Support by Interfaces Type (*continued*)

Interface Type	PIC Type	Supported	Examples
Channelized interfaces (except the Channelized OC12 PIC)	Channelized STM1	No	Example of unsupported configuration: [edit class-of-service interfaces e1-0/0/0:1] scheduler-map map-1;
Logical interfaces	Fast Ethernet	No	Example of unsupported configuration: [edit class-of-service interfaces fe-0/0/0 unit 1] scheduler-map map-1;
	Gigabit Ethernet	No	Example of unsupported configuration: [edit class-of-service interfaces ge-0/0/0 unit 0] scheduler-map map-1;
	Channelized OC12	No	Example of unsupported configuration: [edit class-of-service interfaces t3-0/0/0:0 unit 2] scheduler-map map-1;

To configure transmission scheduling on logical interfaces, perform the following steps:

1. Enable scheduling on the interface by including the **per-unit-scheduler** statement at the [edit interfaces *interface-name*] hierarchy level:

```
[edit interfaces interface-name]  
per-unit-scheduler;
```

When you include this statement, the maximum number of VLANs supported is 768 on a single-port Gigabit Ethernet IQ PIC. On a dual-port Gigabit Ethernet IQ PIC, the maximum number is 384.

2. Associate a scheduler with the interface by including the **scheduler-map** statement at the [edit class-of-service interfaces *interface-name* unit *logical-unit-number*] hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]  
scheduler-map map-name;
```

3. Configure shaping on the interface by including the **shaping-rate** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]  
  shaping-rate rate;
```

By default, the logical interface bandwidth is the average of unused bandwidth for the number of logical interfaces that require default bandwidth treatment. You can specify a peak bandwidth rate in bps, either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000). The range is from 1000 through 32,000,000,000 bps. For the IQ2 Gigabit Ethernet PIC, the minimum is 80,000 bps, and for the IQ2 10 Gigabit Ethernet PIC, the minimum is 160,000 bps.

For FRF.16 bundles on link services interfaces, only shaping rates based on percentage are supported.

NOTE: If you apply a shaping rate, you must keep in mind that the transit statistics for physical interfaces are obtained from the packet forwarding engine, but the traffic statistics are supplied by the PIC. Therefore, if shaping is applied to the PIC, the count of packets in the transit statistics fields do not always agree with the counts in the traffic statistics. For example, the IPv6 transit statistics will not necessarily match the traffic statistics on the interface. However, at the logical interface (DLCI) level, both transit and traffic statistics are obtained from the Packet Forwarding Engine and will not show any difference.

Example: Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs

Associate the scheduler **sched-map-logical-0** with logical interface **unit 0** on physical interface **t3-1/0/0**, and allocate 10 Mbps of transmission bandwidth to the logical interface.

Associate the scheduler **sched-map-logical-1** with logical interface **unit 1** on physical interface **t3-1/0/0**, and allocate 20 Mbps of transmission bandwidth to the logical interface.

The allocated bandwidth is shared among the individual forwarding classes in the scheduler map. Although these schedulers are configured on a single physical interface, they are independent from each other. Traffic on one logical interface unit does not affect the transmission priority, bandwidth allocation, or drop behavior on the other logical interface unit.

For another example, see the *Junos OS Feature Guides*.

```
[edit interfaces]  
t3-1/0/0:1 {  
  encapsulation frame-relay;  
  per-unit-scheduler;  
}
```

```

[edit class-of-service]
interfaces {
  t3-1/0/0:1 {
    unit 0 {
      scheduler-map sched-map-logical-0;
      shaping-rate 10m;
    }
    unit 1 {

Applying Scheduler Maps to Packet Forwarding Component Queues

On Intelligent Queuing (IQ) and Intelligent Queuing 2 (IQ2) interfaces, the traffic that is fed from the packet forwarding components into the PIC uses low packet loss priority (PLP) by default and is distributed evenly across the four chassis queues (not PIC queues), regardless of the scheduling configuration for each logical interface. This default behavior can cause traffic congestion.

The default chassis scheduler allocates resources for queue 0 through queue 3, with 25 percent of the bandwidth allocated to each queue. When you configure the chassis to use more than four queues, you must configure and apply a custom chassis scheduler to override the default. To apply a custom chassis scheduler, include the **scheduler-map-chassis** statement at the **[edit class-of-service interfaces at-*fpc/pic*/*]** hierarchy level.

To control the aggregated traffic transmitted from the chassis queues into the PIC, you can configure the chassis queues to derive their scheduling configuration from the associated logical interface's. Include the **scheduler-map-chassis derived** statement at the **[edit class-of-service interfaces *type-fpc/pic*/*]** hierarchy level:

```
[edit class-of-service interfaces type-fpc/pic/*]  
scheduler-map-chassis derived;
```

CAUTION: If you include the **scheduler-map-chassis derived** statement in the configuration, packet loss might occur when you subsequently add or remove logical interfaces at the **[edit interfaces *interface-name*]** hierarchy level.

When fragmentation occurs on the egress interface, the first set of packet counters displayed in the output of the **show interfaces queue** command show the post-fragmentation values. The second set of packet counters (under the **Packet Forwarding Engine Chassis Queues** field) show the pre-fragmentation values. For more information about the **show interfaces queue** command, see the *Junos OS Operational Mode Commands*.

You can include both the **scheduler-map** and the **scheduler-map-chassis derived** statements in the same interface configuration. The **scheduler-map** statement controls the scheduler inside the PIC, while the **scheduler-map-chassis derived** statement controls the aggregated traffic transmitted into the entire PIC. For the Gigabit Ethernet IQ PIC, include both statements.

For more information about the **scheduler-map** statement, see [“Applying Scheduler Maps to Physical Interfaces” on page 1613](#). For information about logical interface scheduling configuration, see *Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs*.

Generally, when you include the **scheduler-map-chassis** statement in the configuration, you must use an interface wildcard for the interface name, as in ***type-fpc/pic*/***. The wildcard must use this format—for example, **ge-1/2/***, which means all interfaces on FPC slot 1, PIC slot 2. There is one exception—you can apply the chassis scheduler map to a specific interface on the Gigabit Ethernet IQ PIC only.

According to Junos OS wildcard rules, specific interface configurations override wildcard configurations. For chassis scheduler map configuration, this rule does not apply; instead, specific interface CoS configurations are added to the chassis scheduler map configuration. For more information about how wildcards work with chassis scheduler maps, see [“Examples: Scheduling Packet Forwarding Component Queues” on page 1621](#). For general information about wildcards, see the *Junos OS System Basics Configuration Guide*.

NOTE: The interface applies wildcard configuration only if you do not add any specific configuration. If you add the specific interface configuration, then the interface deletes the applied wildcard configuration and applies the specified configuration.

For more information, see the following sections:

- [Applying Custom Schedulers to Packet Forwarding Component Queues on page 1621](#)
- [Examples: Scheduling Packet Forwarding Component Queues on page 1621](#)

Applying Custom Schedulers to Packet Forwarding Component Queues

Optionally, you can apply a custom scheduler to the chassis queues instead of configuring the chassis queues to automatically derive their scheduling configuration from the logical interfaces on the PIC.

To assign a custom scheduler to the packet forwarding component queues, include the **scheduler-map-chassis** statement at the **[edit class-of-service interfaces type-fpc/pic]** hierarchy level:

```
[edit class-of-service interfaces type-fpc/pic/*]
  scheduler-map-chassis map-name;
```

When you apply a custom scheduler map to packet forwarding component queues, or when you modify the configuration of a custom scheduler map that is already applied to packet forwarding component queues, packets already in the chassis queues might be dropped. The amount of packet loss is not deterministic and depends on the offered traffic load at the time you apply or modify the custom scheduler map.

For information about defining the scheduler map referenced by **map-name**, see [“Configuring Scheduler Maps” on page 1613](#).

Examples: Scheduling Packet Forwarding Component Queues

Applying a Chassis Scheduler Map to a 2-Port IQ PIC

Apply a chassis scheduler map to interfaces **ge-0/1/0** and **ge-0/1/1**.

According to customary wildcard rules, the **ge-0/1/0** configuration overrides the **ge-0/1/*** configuration, implying that the chassis scheduler map **MAP1** is not applied to **ge-0/1/0**. However, the wildcard rule is not obeyed in this case; the chassis scheduler map applies to both interfaces **ge-0/1/0** and **ge-0/1/1**.

```
[edit]
class-of-service {
  interfaces {
    ge-0/1/0 {
```

```
    unit 0 {
      classifiers {
        inet-precedence default;
      }
    }
  }
  ge-0/1/* {
    scheduler-map-chassis derived;
  }
}
```

Not Recommended:
Using a Wildcard for
Gigabit Ethernet IQ
Interfaces When
Applying a Chassis
Scheduler Map

On a Gigabit Ethernet IQ PIC, you can apply the chassis scheduler map at both the specific interface level and the wildcard level. We do not recommend this because the wildcard chassis scheduler map takes precedence, which might not be the desired effect. For example, if you want to apply the chassis scheduler map MAP1 to port 0 and MAP2 to port 1, we do not recommend the following:

```
[edit class-of-service]
interfaces {
  ge-0/1/0 {
    scheduler-map-chassis MAP1;
  }
  ge-0/1/* {
    scheduler-map-chassis MAP2;
  }
}
```

Recommended:
Identifying Gigabit
Ethernet IQ Interfaces
Individually When
Applying a Chassis
Scheduler Map

Instead, we recommend this configuration:

```
[edit class-of-service]
interfaces {
  ge-0/1/0 {
    scheduler-map-chassis MAP1;
  }
  ge-0/1/1 {
    scheduler-map-chassis MAP2;
  }
}
```

Configuring Two T3
Interfaces on a
Channelized DS3 IQ
PIC

```
[edit interfaces]
ct3-3/0/0 {
  no-partition interface-type t3; # use entire port 0 as T3
}
ct3-3/0/1 {
  no-partition interface-type t3; # use entire port 1 as T3
}
t3-3/0/0 {
  unit 0 {
    family inet {
      address 10.0.100.1/30;
    }
  }
}
t3-3/0/1 {
  unit 0 {
```

```

        family inet {
            address 10.0.101.1/30;
        }
    }
}

```

Applying Normal Schedulers to Two T3 Interfaces

Configure a scheduler for the aggregated traffic transmitted into both T3 interfaces.

```

[edit class-of-service]
interfaces {
    t3-3/0/0 {
        scheduler-map sched-qct3-0;
    }
    t3-3/0/1 {
        scheduler-map sched-qct3-1;
    }
}
scheduler-maps {
    sched-qct3-0 {
        forwarding-class best-effort scheduler be-qct3-0;
        forwarding-class expedited-forwarding scheduler ef-qct3-0;
        forwarding-class assured-forwarding scheduler as-qct3-0;
        forwarding-class network-control scheduler nc-qct3-0;
    }
    sched-qct3-1 {
        forwarding-class best-effort scheduler be-qct3-1;
        forwarding-class expedited-forwarding scheduler ef-qct3-1;
        forwarding-class assured-forwarding scheduler as-qct3-1;
        forwarding-class network-control scheduler nc-qct3-1;
    }
    sched-chassis-to-q {
        forwarding-class best-effort scheduler be-chassis;
        forwarding-class expedited-forwarding scheduler ef-chassis;
        forwarding-class assured-forwarding scheduler as-chassis;
        forwarding-class network-control scheduler nc-chassis;
    }
}
schedulers {
    be-qct3-0 {
        transmit-rate percent 40;
    }
    ef-qct3-0 {
        transmit-rate percent 30;
    }
    as-qct3-0 {
        transmit-rate percent 20;
    }
    nc-qct3-0 {
        transmit-rate percent 10;
    }
    ...
}

```

Applying a Chassis Scheduler to Two T3 Interfaces

Bind a scheduler to the aggregated traffic transmitted into the entire PIC. The chassis scheduler controls the traffic from the packet forwarding components feeding the interface **t3-3/0/***.

```
[edit class-of-service]
interfaces {
  t3-3/0/* {
    scheduler-map-chassis derived;
  }
}
```

Not Recommended: Using a Wildcard for Logical Interfaces When Applying a Scheduler

Do not apply a scheduler to a logical interface using a wildcard. For example, if you configure a logical interface (unit) with one parameter, and apply a scheduler map to the interface using a wildcard, the logical interface will not apply the scheduler. The following configuration will commit correctly but will not apply the scheduler map to interface **ge-3/0/0.0**:

```
[edit class-of-service]
interfaces {
  ge-3/0/* {
    unit 0 {
      scheduler-map MY_SCHED_MAP;
    }
  }
  ge-3/0/0 {
    unit 0 {
      shaping-rate 100m;
    }
  }
}
```

Recommended: Identifying Logical Interfaces Individually When Applying a Scheduler

Always apply the scheduler to a logical interface without the wildcard:

```
[edit class-of-service]
interfaces {
  ge-3/0/0 {
    unit 0 {
      scheduler-map MY_SCHED_MAP;
      shaping-rate 100m;
    }
  }
}
```

NOTE: This same wildcard behavior applies to classifiers and rewrites as well as schedulers.

buffer-size (Schedulers)

Syntax	buffer-size (percent <i>percentage</i> remainder temporal <i>microseconds</i>);
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches. Statement introduced in Junos OS Release 12.2 for ACX Series Routers.
Description	Specify buffer size.
	<div>  <p>NOTE: On PTX Series Packet Transport Switches, buffer-size cannot be configured on rate-limited queues.</p> </div>
Default	If you do not include this statement, the default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent, respectively.
Options	<p>percent <i>percentage</i>—Buffer size as a percentage of the total buffer. Range: 0 through 100</p> <p>remainder—Remaining buffer available.</p> <p>temporal <i>microseconds</i>—Buffer size as a temporal value. The queuing algorithm starts dropping packets when it queues more than a computed number of bytes. This maximum is computed by multiplying the logical interface speed by the configured temporal value. Range: The ranges vary by platform. See Table 109 on page 1580.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

delay-buffer-rate

Syntax	delay-buffer-rate (percent <i>percentage</i> <i>rate</i>);
Hierarchy Level	[edit class-of-service traffic-control-profiles <i>profile-name</i>]
Release Information	Statement introduced in Junos OS Release 7.6.
Description	For Gigabit Ethernet IQ, Channelized IQ PICs, and FRF.15 and FRF.16 LSQ interfaces only, base the delay-buffer calculation on a delay-buffer rate.
Default	If you do not include this statement, the delay-buffer calculation is based on the guaranteed rate if one is configured, or the shaping rate if no guaranteed rate is configured. For more information, see Table 114 on page 1603 .
Options	<p>percent<i>percentage</i>—For LSQ interfaces, delay-buffer rate as a percentage of the available interface bandwidth.</p> <p>Range: 1 through 100 percent</p> <p>rate—For IQ and IQ2 interfaces, delay-buffer rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation k (1000), m (1,000,000), or g (1,000,000,000).</p> <p>Range: 1000 through 160,000,000,000 bps</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

excess-priority

Syntax	<code>excess-priority [low medium-low medium-high high none];</code>
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i>]
Release Information	Statement introduced in Junos OS Release 9.3. Option none introduced in Junos OS Release 11.4.
Description	Determine the priority of excess bandwidth traffic on a scheduler.

NOTE: For Link Services IQ (LSQ) PICs or Multiservices PIC (MS-PICs), the **excess-priority** statement is allowed for consistency, but ignored. If an explicit priority is not configured for these interfaces, a default low priority is used. This default priority is also used in the excess region.

Options	<p>low—Excess traffic for this scheduler has low priority.</p> <p>medium-low—Excess traffic for this scheduler has medium-low priority.</p> <p>medium-high—Excess traffic for this scheduler has medium-high priority.</p> <p>high—Excess traffic for this scheduler has high priority.</p> <p>none—System does not demote the priority of guaranteed traffic when the bandwidth exceeds the shaping rate or the guaranteed rate.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

fabric (Class-of-Service)

Syntax	<pre>fabric { scheduler-map { priority (high low) scheduler scheduler-name; } }</pre>
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS 11.4 for EX Series switches.
Description	<p>Define CoS parameters of the switch fabric. For M320 and T Series routers only, associate a scheduler with a fabric priority.</p> <p>On EX Series switches, this statement is supported only on EX8200 standalone switches and EX8200 Virtual Chassis.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• See Associating Schedulers with Fabric Priorities on page 1612.

forwarding-class (Interfaces)

Syntax	<pre>forwarding-class class-name;</pre>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.2 for ACX Series routers.
Description	Associate a forwarding class configuration or default mapping with a specific interface.
Options	<i>class-name</i> —Name of the forwarding class.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Applying Forwarding Classes to Interfaces on page 1531• <i>Configuring Fixed Classification on an ATM IMA Pseudowire</i>• <i>Example: Configuring Fixed Classification on an ATM IMA Pseudowire</i>

guaranteed-rate

Syntax	<code>guaranteed-rate (percent <i>percentage</i> <i>rate</i>) <burst-size <i>bytes</i>>;</code>
Hierarchy Level	[edit class-of-service traffic-control-profiles <i>profile-name</i>]
Release Information	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Option burst-size introduced for Enhanced Queuing (EQ) DPCs in Junos OS Release 9.4.</p> <p>Option burst-size introduced for MPC/MIC modules in Junos OS Release 11.4.</p> <p>Option burst-size introduced for IQ2 and IQ2E interfaces in Junos OS Release 12.3</p>
Description	For Gigabit Ethernet IQ, Channelized IQ PICs, AS PIC FRF.16 LSQ interfaces, and EQ DPCs only, configure a guaranteed minimum rate. You can also configure an optional burst size for a logical interface on EQ DPCs and on IQ2 and IQ2E PICs. This can help to ensure that higher priority services do not starve lower priority services.
Default	If you do not include this statement and you do not include the delay-buffer-rate statement, the logical interface receives a minimal delay-buffer rate and minimal bandwidth equal to 2 MTU-sized packets.
Options	<p>percent <i>percentage</i>—For LSQ interfaces, guaranteed rate as a percentage of the available interface bandwidth.</p> <p>Range: 1 through 100 percent</p> <p><i>rate</i>—For IQ and IQ2 interfaces, guaranteed rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation k (1000), m (1,000,000), or g (1,000,000,000).</p> <p>Range: 1000 through 160,000,000,000 bps</p> <p>burst-size <i>bytes</i>—(Optional) Maximum burst size, in bytes.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

Hierarchy Level [edit class-of-service]

Release Information Statement introduced before Junos OS Release 7.4.
Interface-set level added in Junos OS Release 8.5.

Description Configure interface-specific CoS properties for incoming packets.

NOTE: The dscp-ipv6 and ieee-802.1ad classifier types are not supported on ACX Series routers. For further information about support on ACX Series routers, see *Understanding CoS CLI Configuration Statements on ACX Series Universal Access Routers*.

Options The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

loss-priority (Scheduler Drop Profiles)

Syntax	loss-priority (any high low medium-high medium-low);
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i> drop-profile-map]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches. Statement introduced in Junos OS Release 12.2 for ACX Series Routers.
Description	Specify a loss priority to which to apply a drop profile. The drop profile map sets the drop profile for a specific PLP and protocol type. The inputs for the map are the PLP designation and the protocol type. The output is the drop profile.
Options	any —The drop profile applies to packets with any PLP.

NOTE: On ACX Series Routers, only the **any** option is supported when you configure the **non-tcp** option for **protocol**.

high—The drop profile applies to packets with high PLP.

low—The drop profile applies to packets with low PLP.

medium-high—The drop profile applies to packets with medium-high PLP.

medium-low—The drop profile applies to packets with medium-low PLP.

Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

output-traffic-control-profile

Syntax	<code>output-traffic-control-profile <i>profile-name</i> shared-instance <i>instance-name</i>;</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i>], [edit class-of-service interfaces <i>interface-name</i> interface-set <i>interface-set-name</i>]
Release Information	Statement introduced in Junos OS Release 7.6. interface-set option added for Enhanced Queuing DPCs on MX Series routers in Junos OS Release 8.5. interface-set option added for MPC/MIC interfaces on MX Series routers in Junos OS Release 10.2.
Description	For Channelized IQ PICs, Gigabit Ethernet IQ, Gigabit Ethernet IQ2, and IQ2E PICs, link services IQ (LSQ) interfaces on AS PICs, and Enhanced Queuing DPCs and MPC/MIC interfaces on MX Series routers and on EX Series switches, apply an output traffic scheduling and shaping profile to the logical interface. The shared-instance statement is supported on Gigabit Ethernet IQ2 PICs only.
Options	<i>profile-name</i> —Name of the traffic-control profile to be applied to this interface
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

priority (Schedulers)

Syntax	<code>priority <i>priority-level</i>;</code>
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches. Statement introduced in Junos OS Release 12.2 for ACX Series Routers.
Description	Specify the packet-scheduling priority value.
Options	<p><i>priority-level</i> can be one of the following:</p> <ul style="list-style-type: none"> • low—Scheduler has low priority. • medium-low—Scheduler has medium-low priority. • medium-high—Scheduler has medium-high priority. • high—Scheduler has high priority. Assigning high priority to a queue prevents the queue from being underserved. • strict-high—Scheduler has strictly high priority. Configure a high priority queue with unlimited transmission bandwidth available to it. As long as it has traffic to send, the strict-high priority queue receives precedence over low, medium-low, and medium-high priority queues, but not high priority queues. You can configure strict-high priority on only one queue per interface.
<div>  <p>NOTE: The strict-high priority level is the only priority level supported on ACX Series Routers. However, multiple strict-high priority queues can be configured per interface on ACX Series Routers.</p> </div>	
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Schedulers for Priority Scheduling on page 1594

protocol (Schedulers)

Syntax	protocol (any non-tcp tcp);
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i> drop-profile-map]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches. Statement introduced in Junos OS Release 12.2 for ACX Series Routers.
Description	Specify the protocol type for the specified scheduler.
Options	any —Accept any protocol type. non-tcp —(ACX Series Routers, M Series and T Series (except T4000) routers only) Accept any protocol type other than TCP/IP.

NOTE: On ACX Series Routers, when you configure the **non-tcp** option, only the **any** option is supported for [loss-priority](#).

	tcp —(ACX Series Routers, M Series and T Series (except T4000) routers only) Accept TCP/IP protocol type.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Schedulers on page 1579

scheduler (Fabric Queues)

Syntax	<code>scheduler <i>scheduler-name</i>;</code>
Hierarchy Level	[edit class-of-service fabric scheduler-map <i>priority</i> (high low)]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS 11.4 for EX Series switches.
Description	Define scheduler name. For M320, MX Series, T Series routers and for EX Series switches only, specify a scheduler to associate with a fabric queue. For fabric CoS configuration, schedulers are restricted to transmit rates and drop profiles.
Options	<i>scheduler-name</i> —Name of the scheduler configuration block.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • See Associating Schedulers with Fabric Priorities on page 1612. • <i>Understanding Junos OS CoS Components for EX Series Switches</i>

scheduler (Scheduler Map)

Syntax	<code>scheduler <i>scheduler-name</i>;</code>
Hierarchy Level	[edit class-of-service scheduler-maps <i>map-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.2 for ACX Series Routers.
Description	Associate a scheduler with a scheduler map.
Options	<i>scheduler-name</i> —Name of the scheduler configuration block.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Schedulers on page 1579 • <i>Example: Configuring CoS for a PBB Network</i>

scheduler-map (Fabric Queues)

Syntax	<code>scheduler-map priority (high low) scheduler <i>scheduler-name</i>;</code>
Hierarchy Level	<code>[edit class-of-service fabric]</code>
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS 11.4 for EX Series switches.
Description	<p>Mapping of fabric traffic to packet schedulers. For M320, MX Series, T Series routers, and for EX Series switches only, associate a scheduler with a fabric priority.</p> <p>On EX Series switches, this statement is supported only on EX8200 standalone switches and EX8200 Virtual Chassis.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• See Associating Schedulers with Fabric Priorities on page 1612.• <i>Understanding Junos OS CoS Components for EX Series Switches</i>

scheduler-map (Interfaces and Traffic-Control Profiles)

Syntax	<code>scheduler-map <i>map-name</i>;</code>
Hierarchy Level	<code>[edit class-of-service interfaces <i>interface-name</i>],</code> <code>[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i>],</code> <code>[edit class-of-service traffic-control-profiles]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	<p>For Gigabit Ethernet IQ, Channelized IQ PICs, and FRF.15 and FRF.16 LSQ interfaces only, associate a scheduler map name with an interface or with a traffic-control profile.</p> <p>For channelized OC12 intelligent queuing (IQ), channelized T3 IQ, channelized E1 IQ, and Gigabit Ethernet IQ interfaces only, you can associate a scheduler map name with a logical interface.</p>
Options	<i>map-name</i> —Name of the scheduler map.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Schedulers on page 1579• Oversubscribing Interface Bandwidth on page 1600• output-traffic-control-profile on page 1639

scheduler-map-chassis

Syntax	<code>scheduler-map-chassis (derived <i>map-name</i>);</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-type-fpc/pic/*</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For IQ and IQ2 interfaces, assign a custom scheduler to the packet forwarding component queues that control the aggregated traffic transmitted into the entire PIC.
Default	On Intelligent Queuing (IQ) and Intelligent Queuing 2 (IQ2) interfaces, the traffic that is fed from the packet forwarding components into the PIC uses low packet loss priority (PLP) by default and is distributed evenly across the four chassis queues (not PIC queues), regardless of the scheduling configuration for each logical interface. This default behavior can cause traffic congestion.
Options	<p>derived—Sets the chassis queues to derive their scheduling configuration from the associated logical interface scheduling configuration.</p> <p><i>map-name</i>—Name of the scheduler map configured at the [edit class-of-service scheduler-maps] hierarchy level.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • <i>Applying Scheduler Maps to Packet Forwarding Component Queues</i> • scheduler-map (Fabric Queues) on page 1644

scheduler-maps (For Most Interface Types)

Syntax	<pre>scheduler-maps { map-name { forwarding-class class-name scheduler scheduler-name; } }</pre>
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify a scheduler map name and associate it with the scheduler configuration and forwarding class.
Options	<p>map-name—Name of the scheduler map.</p> <p>The remaining statements are explained separately.</p> <p>See “Configuring Schedulers” on page 1579 and <i>Example: Configuring CoS for a PBB Network</i>.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

schedulers (Class of Service)

Syntax	<pre> schedulers { scheduler-name { adjust-minimum <i>rate</i>; adjust-percent <i>percentage</i>; buffer-size (<i>seconds</i> percent <i>percentage</i> remainder temporal <i>microseconds</i>); drop-profile-map loss-priority (any low medium-low medium-high high) <i>protocol</i> (any non-tcp tcp) drop-profile <i>profile-name</i>; excess-priority [low medium-low medium-high high none]; excess-rate (percent <i>percentage</i> proportion <i>value</i>); priority <i>priority-level</i>; shaping-rate (percent <i>percentage</i> <i>rate</i>); transmit-rate (percent <i>percentage</i> <i>rate</i> remainder) <exact rate-limit>; } } </pre>
Hierarchy Level	[edit class-of-service]
Release Information	<p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 12.1X48 for PTX Series switches.</p>
Description	Specify the scheduler name and parameter values.
Options	<p><i>scheduler-name</i>—Name of the scheduler to be configured.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Schedulers Overview on page 1573 • Default Schedulers Overview on page 1575 • Configuring Schedulers on page 1579 • Configuring a Scheduler • Example: Configuring CoS for a PBB Network

shaping-rate (Applying to an Interface)

Syntax	<code>shaping-rate rate;</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i>], [edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i>]
Release Information	Statement introduced before Junos OS Release 7.4. [edit class-of-service interfaces <i>interface-name</i>] hierarchy level added in Junos OS Release 7.5.
Description	For logical interfaces on which you configure packet scheduling, configure traffic shaping by specifying the amount of bandwidth to be allocated to the logical interface. For physical interfaces on IQ PICs and T4000 routers with Type 5 FPCs, configure traffic shaping based on the rate-limited bandwidth of the total interface bandwidth.

NOTE: The `shaping-rate` statement cannot be applied to a physical interface on J Series routers.

Logical and physical interface traffic shaping rates are mutually exclusive. This means you can include the `shaping-rate` statement at the [edit class-of-service interfaces *interface-name*] hierarchy level or the [edit class-of-service interfaces *interface-name* **unit** *logical-unit-number*] hierarchy level, but not both.

NOTE: For MX Series routers and for EX Series switches, the shaping rate value for the physical interface at the [edit class-of-service interfaces *interface-name*] hierarchy level must be a minimum of 160 Kbps. If the value is less than the sum of the logical interface guaranteed rates, the user is not allowed to apply the shaping rate to a physical interface.

For T4000 routers with Type 5 FPCs, the shaping rate value for the physical interface must be a minimum of 292 Kbps. The maximum value of `shaping-rate` is limited by the maximum transmission rate of the interface.

Alternatively, you can configure a shaping rate for a logical interface and oversubscribe the physical interface by including the `shaping-rate` statement at the [edit class-of-service **traffic-control-profiles**] hierarchy level. With this configuration approach, you can independently control the delay-buffer rate, as described in [“Oversubscribing Interface Bandwidth” on page 1600](#).

For FRF.15 and FRF.16 bundles on link services interfaces, only shaping rates based on percentage are supported.

Default If you do not include this statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level, the default logical interface bandwidth is the average of unused bandwidth for the number of logical interfaces that require default bandwidth treatment. If you do not include this statement at the **[edit class-of-service interfaces *interface-name*]** hierarchy level, the default physical interface bandwidth is the average of unused bandwidth for the number of physical interfaces that require default bandwidth treatment.

Options **rate**—Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: For logical interfaces, 1000 through 32,000,000,000 bps. For physical interfaces, 1000 through 160,000,000,000 bps.

NOTE: For all MX Series and EX series interfaces, the rate can be from 65,535 through 160,000,000,000 bps.

NOTE: For T4000 physical interfaces, the rate can be from 1000 through 160,000,000,000 bps.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

shaping-rate (Oversubscribing an Interface)

Syntax	<code>shaping-rate (percent <i>percentage</i> <i>rate</i>) <burst-size <i>bytes</i>>;</code>
Hierarchy Level	[edit class-of-service traffic-control-profiles <i>profile-name</i>]
Release Information	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Option burst-size introduced for Enhanced Queuing (EQ) DPCs in Junos OS Release 9.4.</p> <p>Option burst-size option introduced for MPC/MIC modules in Junos OS Release 11.4.</p> <p>Option burst-size introduced for IQ2 and IQ2E interfaces in Junos OS Release 12.3.</p>
Description	<p>For Gigabit Ethernet IQ, Channelized IQ PICs, FRF.15 and FRF.16 LSQ interfaces, EQ DPCs, and MPC/MIC modules only, configure a shaping rate for a logical interface. You can also configure an optional burst size for a logical interface on EQ DPCs and on IQ2 and IQ2E PICs. This can help to ensure that higher-priority services do not starve lower-priority services.</p> <p>For physical interfaces on T4000 routers with Type 5 FPCs, configure traffic shaping rate.</p> <p>The sum of the shaping rates for all logical interfaces on the physical interface can exceed the physical interface bandwidth. This practice is known as oversubscription of the peak information rate (PIR).</p>
Default	The default behavior depends on various factors. For more information, see Table 114 on page 1603 .
Options	<p>percent <i>percentage</i>—For LSQ interfaces, shaping rate as a percentage of the available interface bandwidth.</p> <p>Range: 1 through 100 percent</p> <p><i>rate</i>—For IQ and IQ2 interfaces, and T4000 routers with Type 5 FPCs, peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation k (1000), m (1,000,000), or g (1,000,000,000).</p> <p>Range: IQ and IQ2 interfaces—1000 through 160,000,000,000 bps</p> <p>Range: T4000 routers with Type 5 FPCs—the shaping rate value for the physical interface must be a minimum of 292 Kbps. The maximum value of shaping-rate is limited by the maximum transmission rate of the interface.</p> <p>burst-size <i>bytes</i>—(Optional) Maximum burst size, in bytes.</p> <p>Range: 0 through 1,000,000,000</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

traffic-control-profiles

Syntax	<pre> traffic-control-profiles <i>profile-name</i> { adjust-minimum <i>rate</i>; atm-service (cbr rtvbr nrtvbr); delay-buffer-rate (percent <i>percentage</i> <i>rate</i>); peak-rate <i>rate</i>; sustained-rate <i>rate</i>; max-burst-size <i>cells</i>; excess-rate (percent <i>percentage</i> proportion <i>value</i>); excess-rate-high (percent <i>percentage</i> proportion <i>value</i>); excess-rate-low (percent <i>percentage</i> proportion <i>value</i>); guaranteed-rate (percent <i>percentage</i> <i>rate</i>) <burst-size <i>bytes</i>>; overhead-accounting (frame-mode cell-mode) <bytes <i>byte-value</i>>; scheduler-map <i>map-name</i>; shaping-rate (percent <i>percentage</i> <i>rate</i>) <burst-size <i>bytes</i>>; shaping-rate-excess-high <i>rate</i> [burst-size <i>bytes</i>]; shaping-rate-excess-low <i>rate</i> [burst-size <i>bytes</i>]; shaping-rate-priority-high <i>rate</i> [burst-size <i>bytes</i>]; shaping-rate-priority-low <i>rate</i> [burst-size <i>bytes</i>]; shaping-rate-priority-medium <i>rate</i> [burst-size <i>bytes</i>]; } </pre>
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced in Junos OS Release 7.6.
Description	For Gigabit Ethernet IQ, Channelized IQ PICs, FRF.15 and FRF.16 LSQ interfaces, and Enhanced Queuing (EQ) DPCs only, configure traffic shaping and scheduling profiles. For Enhanced EQ PICs and EQ DPCs only, you can include the excess-rate statement.
Options	<p><i>profile-name</i>—Name of the traffic-control profile.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Oversubscribing Interface Bandwidth on page 1600 • Example: Configuring CoS for a PBB Network • output-traffic-control-profile on page 1639

transmit-rate (Schedulers)

Syntax	<code>transmit-rate (rate percent <i>percentage</i> remainder) <exact rate-limit>;</code>
Hierarchy Level	[edit class-of-service schedulers <i>scheduler-name</i>]
Release Information	<p>Statement introduced before Junos OS Release 7.4.</p> <p>rate-limit option introduced in Junos OS Release 8.3. Applied to the Multiservices PICs in Junos OS Release 9.4.</p> <p>Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches.</p> <p>Statement introduced in Junos OS Release 12.2 for ACX Series Routers.</p>
Description	Specify the transmit rate or percentage for a scheduler.
Default	If you do not include this statement, the default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent, respectively.
Options	<p>exact—(Optional) Enforce the exact transmission rate. Under sustained congestion, a rate-controlled queue that goes into negative credit fills up and eventually drops packets. This value should never exceed the rate-controlled amount. For PTX Series Packet Transport Switches, this option is allowed only on the non-strict-high (high, medium-high, medium-low, or low) queues.</p> <p>percent <i>percentage</i>—Percentage of transmission capacity. A percentage of zero drops all packets in the queue.</p> <p>Range: 0 through 100 percent for M, MX, T Series routers and EX Series switches; 1 through 100 percent for PTX Series Packet Transport Switches; 0 through 200 percent for the SONET/SDH OC48/STM16 IQE PIC</p>

NOTE:

- On M Series Multiservice Edge Routers, for interfaces configured on 4-port E1 and 4-port T1 PICs only, you can configure a *percentage* value only from 11 through 100. These two PICs do not support transmission rates less than 11 percent.
 - The configuration of the `transmit-rate percent 0 exact` statement at the [edit class-of-service `schedulers` *scheduler-name*] hierarchy is ineffective on T4000 routers with Type 5 FPC.
 - On Trio MPC/MIC interfaces, when the transmit rate is configured as a percentage and **exact** or **rate-limit** is enabled on a queue, the shaping rate of the parent node is used to compute the transmit rate. If **exact** or **rate-limit** is not configured, the guaranteed rate of the parent node is used to compute the transmit rate.
-

rate—Transmission rate, in bps. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 3200 through 160,000,000,000 bps

NOTE: For all MX Series interfaces, the rate can be from 65,535 through 160,000,000,000 bps.

rate-limit—(Optional) Limit the transmission rate to the rate-controlled amount. In contrast to the **exact** option, the scheduler with the **rate-limit** option shares unused bandwidth above the rate-controlled amount.

NOTE: For PTX Series Packet Transport Switches, this option is allowed only on the strict-high queue. We recommend that you configure rate limit on strict-high queues because the other queues may not meet their guaranteed bandwidths.

NOTE: The configuration of the **rate-limit** statement is supported on T4000 routers only with a Type 5 FPC.

remainder—Use the remaining rate available.

Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

Overview

- [Bandwidth Sharing on page 1666](#)

Bandwidth Sharing

- [Bandwidth Sharing on Nonqueuing Packet Forwarding Engines Overview on page 1666](#)

Bandwidth Sharing on Nonqueuing Packet Forwarding Engines Overview

You can configure bandwidth sharing rate limits, excess rate, and excess priority at the queue level on the following Juniper Networks routers and switches:

- EX Series switches
- M120 Multiservice Edge Router (rate limit and excess priority only; excess rate is not configured by the user)
- M320 router with Enhanced FPCs (rate limit, excess rate, and excess priority)
- MX Series 3D Universal Edge Router with nonqueuing DPCs (rate limit, excess rate, and excess priority)

You configure rate limits when you have a concern that low-latency packets (such as high or strict-high priority packets for voice) might starve low-priority and medium-priority

packets. In Junos OS, the low latency queue is implemented by rate-limiting packets to the transmit bandwidth. The rate-limiting is performed immediately before queuing the packet for transmission. All packets that exceed the rate limit are not queued, but dropped.

By default, if the excess priority is not configured for a queue, the excess priority will be the same as the normal queue priority. If none of the queues have an excess rate configured, then the excess rate will be the same as the transmit rate percentage. If at least one of the queues has an excess rate configured, then the excess rate for the queues that do not have an excess rate configured will be set to zero.

When the physical interface is on queuing hardware such as the IQ, IQ2, or IQE PICs, or MX Series routers queuing DPCs or EX Series switches, these features are dependent on the PIC (or queuing DPC in the case of the MX Series router) configuration.

You cannot configure both rate limits and buffer sizes on these Packet Forwarding Engines.

Four levels of excess priorities are supported: low, medium-low, medium-high, and high.

NOTE: Rate limiting is implemented differently on Enhanced Queuing DPCs and non-queuing Packet Forwarding Engines. On Enhanced Queuing DPCs, rate-limiting is implemented using a single rate two color policer. On non-queuing Packet Forwarding Engines, rate-limiting is achieved by shaping the queue to the transmit rate and keeping the queue delay buffers small to prevent too many packets from being queued once the shaping rate is reached.

Excess Rate and Excess Priority Configuration Examples

To configure the excess rate for nonqueueing Packet Forwarding Engines, include the `excess-rate` statement at the `[edit class-of-service schedulers scheduler-name]` hierarchy level.

To configure the excess priority for nonqueueing Packet Forwarding Engines, include the `excess-priority` statement at the `[edit class-of-service schedulers scheduler-name]` hierarchy level.

The relationship between the configured guaranteed rate, excess rate, guaranteed priority, excess priority, and offered load is not always obvious. The following tables show the expected throughput of a Gigabit Ethernet port with various bandwidth-sharing parameters configured on the queues.

The default behavior of a nonqueueing Gigabit Ethernet interface with multiple priority levels is shown in [Table 117 on page 1669](#). All queues in the table get their guaranteed rate. The excess bandwidth is first offered to the excess high-priority queues. Because these use all available bandwidth, there is no remaining excess bandwidth for the low-priority queues.

Table 117: Current Behavior with Multiple Priority Levels

Queue	Guaranteed (Transmit) Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	high	high	600 Mbps	$200 + 366.67 = 566.67$ Mbps
Q1	10%	high	high	500 Mbps	$100 + 183.33 = 283.33$ Mbps
Q2	10%	low	low	500 Mbps	$100 + 0 = 100$ Mbps
Q3	5%	low	low	500 Mbps	$50 + 0 = 50$ Mbps

The default behavior of a nonqueueing Gigabit Ethernet interface with the same priority levels is shown in [Table 118 on page 1669](#). All queues in the table get their guaranteed rate. Because all queues have the same excess priority, they share the excess bandwidth and each queue gets excess bandwidth in proportion to the transmit rate.

Table 118: Current Behavior with Same Priority Levels

Queue	Guaranteed (Transmit) Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	high	high	500 Mbps	$200 + 244.44 = 444.44$ Mbps
Q1	10%	high	high	500 Mbps	$100 + 122.22 = 222.22$ Mbps
Q2	10%	high	high	500 Mbps	$100 + 122.22 = 222.22$ Mbps
Q3	5%	high	high	500 Mbps	$50 + 61.11 = 111.11$ Mbps

The default behavior of a nonqueuing Gigabit Ethernet interface with the at least one strict-high priority level is shown in [Table 119 on page 1670](#). First the high priority and strict-high are serviced in a weighted round-robin fashion. The high priority queue gets its guaranteed bandwidth and the strict-high queue gets what remains. The high excess priority queue gets all the excess bandwidth.

Table 119: Current Behavior with Strict-High Priority

Queue	Guaranteed (Transmit) Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	strict-high	X	500 Mbps	500 Mbps
Q1	10%	high	high	500 Mbps	100 + 250 = 350 Mbps
Q2	10%	low	low	500 Mbps	100 + 0 = 100 Mbps
Q3	5%	low	low	500 Mbps	50 + 0 = 50 Mbps

The default behavior of a nonqueuing Gigabit Ethernet interface with the at least one strict-high priority level and a higher offered load on Q0 is shown in [Table 120 on page 1670](#). First the high priority and strict-high are serviced in a weighted round-robin fashion. The high priority queue gets its guaranteed bandwidth and the strict-high queue gets what remains. There is no excess bandwidth.

Table 120: Strict-High Priority with Higher Load

Queue	Guaranteed (Transmit) Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	strict-high	X	1 Gbps	900 Mbps
Q1	10%	high	high	500 Mbps	100 + 0 = 100 Mbps
Q2	10%	low	low	500 Mbps	0 + 0 = 0 Mbps
Q3	5%	low	low	500 Mbps	0 + 0 = 0 Mbps

Now consider the behavior of the queues with configured excess rates and excess priorities.

The behavior with multiple priority levels is shown in [Table 121 on page 1671](#). All queues get the guaranteed rate. The excess bandwidth is first offered to the excess high priority queues and these consume all the bandwidth. There is no remaining excess bandwidth for low priority queues.

Table 121: Sharing with Multiple Priority Levels

Queue	Guaranteed (Transmit) Rate	Excess Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	10%	high	high	500 Mbps	$200 + 275 = 475$ Mbps
Q1	10%	20%	high	low	500 Mbps	$100 + 0 = 100$ Mbps
Q2	10%	10%	low	high	500 Mbps	$100 + 275 = 275$ Mbps
Q3	5%	20%	low	low	500 Mbps	$50 + 0 = 50$ Mbps

The behavior with the same (high) priority levels is shown in [Table 122 on page 1671](#). All queues get the guaranteed rate. Because all queues have the same excess priority, they share the excess bandwidth in proportion to their transmit rate.

Table 122: Sharing with the Same Priority Levels

Queue	Guaranteed (Transmit) Rate	Excess Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	10%	high	high	500 Mbps	$200 + 91.67 = 291.67$ Mbps
Q1	10%	20%	high	high	500 Mbps	$100 + 183.33 = 283.33$ Mbps
Q2	10%	10%	high	high	500 Mbps	$100 + 91.67 = 191.67$ Mbps
Q3	5%	20%	high	high	500 Mbps	$50 + 183.33 = 233.33$ Mbps

The behavior with at least one strict-high priority level is shown in [Table 123 on page 1671](#). The high priority and strict-high queues are serviced in a weighted round-robin fashion. The high priority queue gets its guaranteed rate and the strict-high queue gets the rest. The excess high-priority queue get all the excess bandwidth.

Table 123: Sharing with at Least One Strict-High Priority

Queue	Guaranteed (Transmit) Rate	Excess Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	X	strict-high	X	500 Mbps	500 Mbps
Q1	10%	20%	high	low	500 Mbps	$100 + 0 = 100$ Mbps
Q2	10%	10%	low	high	500 Mbps	$100 + 250 = 350$ Mbps
Q3	5%	20%	low	low	500 Mbps	$50 + 0 = 50$ Mbps

The behavior with at least one strict-high priority level and a higher offered load is shown in [Table 124 on page 1672](#). The high priority and strict-high queues are serviced in a weighted round-robin fashion. The high priority queue gets its guaranteed rate and the strict-high queue gets the rest. There is no excess bandwidth.

Table 124: Sharing with at Least One Strict-High Priority and Higher Load

Queue	Guaranteed (Transmit) Rate	Excess Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	X	strict-high	X	900 Mbps	900 Mbps
Q1	10%	20%	high	low	500 Mbps	100 + 0 = 100 Mbps
Q2	10%	10%	low	high	500 Mbps	0 + 0 = 0 Mbps
Q3	5%	20%	low	low	500 Mbps	0 + 0 = 0 Mbps

The behavior with at least one strict-high priority level and a rate limit is shown in [Table 125 on page 1672](#). Queue 0 and Queue 2 are rate limited, so the maximum bandwidth they are offered is the transmit bandwidth and they will not be offered any excess bandwidth. All other queues are offered the guaranteed bandwidth and the excess is shared by the non-rate-limited queues.

Table 125: Sharing with at Least One Strict-High Priority and Rate Limit

Queue	Guaranteed (Transmit) Rate	Rate Limit	Excess Rate	Guaranteed Priority	Excess Priority	Offered Load	Expected Throughput
Q0	20%	Yes	X	strict-high	X	500 Mbps	200 + 0 = 200 Mbps
Q1	10%	No	20%	high	low	500 Mbps	100 + 275 = 375 Mbps
Q2	10%	Yes	10%	low	high	500 Mbps	100 + 0 = 100 Mbps
Q3	5%	No	20%	low	low	500 Mbps	50 + 275 = 325 Mbps

Configuring the Schedulers

The following example configures schedulers, forwarding classes, and a scheduler map for an interface with excess rates and excess priorities.

```
[edit class-of-service schedulers]
scheduler-1 {
  transmit-rate percent 20;
  priority high;
  excess-rate percent 10;
  excess-priority low;
}
```

	<pre> scheduler-2 { transmit-rate percent 10; priority strict-high; } scheduler-3 { transmit-rate percent 10; priority medium-high; excess-rate percent 20; excess-priority high; } scheduler-4 { transmit-rate percent 5; priority medium-high; excess-rate percent 30; excess-priority low; } </pre>
Configuring the Forwarding Classes	<pre> [edit class-of-service] forwarding-classes { class cp_000 queue-num 0; class cp_001 queue-num 1; class cp_010 queue-num 2; class cp_011 queue-num 3; class cp_100 queue-num 4; class cp_101 queue-num 5; class cp_110 queue-num 6; class cp_111 queue-num 7; } </pre>
Configuring the Scheduler Map	<pre> [edit class-of-service scheduler-maps] scheduler-map-1 { forwarding-class cp_000 scheduler scheduler-1; forwarding-class cp_001 scheduler scheduler-2; forwarding-class cp_010 scheduler scheduler-3; forwarding-class cp_011 scheduler scheduler-4; } </pre>
Applying the Scheduler Map to the Interface	<pre> [edit interfaces] ge-1/1/0 { scheduler-map scheduler-map-1; unit 0 { family inet { address 192.168.1.2/32; } } } </pre>

RED Drop Profiles Overview

You can configure two parameters to control congestion at the output stage. The first parameter defines the delay-buffer bandwidth, which provides packet buffer space to absorb burst traffic up to the specified duration of delay. Once the specified delay buffer becomes full, packets with 100 percent drop probability are dropped from the head of the buffer. For more information, see [“Configuring the Scheduler Buffer Size” on page 1579](#).

The second parameter defines the drop probabilities across the range of delay-buffer occupancy, supporting the random early detection (RED) process. When the number of packets queued is greater than the ability of the router or switch to empty a queue, the queue requires a method for determining which packets to drop from the network. To address this, the Junos OS provides the option of enabling RED on individual queues.

Depending on the drop probabilities, RED might drop many packets long before the buffer becomes full, or it might drop only a few packets even if the buffer is almost full.

A *drop profile* is a mechanism of RED that defines parameters that allow packets to be dropped from the network. Drop profiles define the meanings of the loss priorities.

When you configure drop profiles, there are two important values: the queue fullness and the drop probability. The *queue fullness* represents a percentage of the memory used to store packets in relation to the total amount that has been allocated for that specific queue. Similarly, the *drop probability* is a percentage value that correlates to the likelihood that an individual packet is dropped from the network. These two variables are combined in a graph-like format, as shown in [Figure 13 on page 1675](#).

NOTE: You can only specify two fill levels for interpolated drop profiles on the Enhanced Queuing DPC for Juniper Network MX Series Ethernet Services Routers and EX Series switches. For more information about interpolated drop profiles on the Enhanced Queuing DPC for MX Series routers and EX Series switches, see *Configuring WRED on Enhanced Queuing DPCs*.

[Figure 13 on page 1675](#) shows both a segmented and an interpolated graph. Although the formation of these graph lines is different, the application of the profile is the same. When a packet reaches the head of the queue, a random number between 0 and 100 is calculated by the router or switch. This random number is plotted against the drop profile using the current queue fullness of that particular queue. When the random number falls

above the graph line, the packet is transmitted onto the physical media. When the number falls below graph the line, the packet is dropped from the network.

Figure 13: Segmented and Interpolated Drop Profiles

By defining multiple fill levels and drop probabilities, you create a segmented drop profile. The line segments are defined in terms of the following graphical model: in the first quadrant, the x axis represents the fill level, and the y axis represents the drop probability. The initial line segment spans from the origin (0,0) to the point ($\langle l1 \rangle$, $\langle p1 \rangle$); a second line runs from ($\langle l1 \rangle$, $\langle p1 \rangle$) to ($\langle l2 \rangle$, $\langle p2 \rangle$) and so forth, until a final line segment connects (100, 100). The software automatically constructs a drop profile containing 64 fill levels at drop probabilities that approximate the calculated line segments.

NOTE: If you configure the `interpolate` statement, you can specify more than 64 pairs, but the system generates only 64 discrete entries.

You specify drop probabilities in the drop profile section of the class-of-service (CoS) configuration hierarchy and reference them in each scheduler configuration. For each scheduler, you can configure multiple separate drop profiles, one for each combination of loss priority (low, medium-low, medium-high, or high) and protocol.

You can configure a maximum of 32 different drop profiles.

To configure RED drop profiles, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
drop-profiles {
  profile-name {
    fill-level percentage drop-probability percentage;
    interpolate {
      drop-probability [ values ];
      fill-level [ values ];
    }
  }
}
```

Default Drop Profile

By default, if you configure no drop profiles, RED is still in effect and functions as the primary mechanism for managing congestion. In the default RED drop profile, when the fill-level is 0 percent, the drop probability is 0 percent. When the fill-level is 100 percent, the drop probability is 100 percent.

As a backup method for managing congestion, tail dropping takes effect when congestion of small packets occurs. On Juniper Networks M320 Multiservice Edge Routers and T Series Core Routers, the software supports *tail-RED*, which means that when tail dropping occurs, the software uses RED to execute intelligent tail drops. On other routers, the software executes tail drops unconditionally.

Packet Loss Priority Configuration Overview

Loss priority settings help determine which packets are dropped from the network during periods of congestion. The software supports multiple packet loss priority (PLP) designations: **low** and **high**. (In addition, **medium-low** and **medium-high** PLPs are supported when you configure tricolor marking, as discussed in [“Configuring Tricolor Marking” on page 1447](#).) You can set PLP by configuring a behavior aggregate or multifield classifier, as discussed in [“Setting Packet Loss Priority” on page 1337](#) and [“Configuring Multifield Classifiers” on page 1390](#).

NOTE: On T Series routers with different Packet Forwarding Engines (non-Enhanced Scaling and Enhanced Scaling FPCs), you can configure PLP bit copying for ingress and egress unicast and multicast traffic. To configure, include the **copy-plp-all** statement at the [edit class-of-service] hierarchy level.

A drop-profile map examines the loss priority setting of an outgoing packet: **high**, **medium-high**, **medium-low**, **low**, or any.

Obviously, *low*, *medium-low*, *medium-high*, and *high* are relative terms, which by themselves have no meaning. Drop profiles define the meanings of the loss priorities. In the following example, the **low-drop** drop profile defines the meaning of **low** PLP as a 10 percent drop probability when the fill level is 75 percent and a 40 percent drop probability when the fill level is 95 percent. The **high-drop** drop profile defines the meaning of **high** PLP as a 50 percent drop probability when the fill level is 25 percent and a 90 percent drop probability when the fill level is 50 percent.

In this example, the scheduler includes two drop-profile maps, which specify that packets are evaluated by the **low-drop** drop profile if they have a **low** loss priority and are from any protocol. Packets are evaluated by the **high-drop** drop profile if they have a **high** loss priority and are from any protocol.

```
[edit class-of-service]
drop-profiles {
  low-drop {
    interpolate {
      drop-probability [ 10 40];
```

```

        fill-level [ 75 95];
    }
}
high-drop {
    interpolate {
        drop-probability [ 50 90];
        fill-level [ 25 50];
    }
}
}
schedulers {
    best-effort {
        drop-profile-map loss-priority low protocol any drop-profile low-drop;
        drop-profile-map loss-priority high protocol any drop-profile high-drop;
    }
}
}

```

Configuration Tasks

- [Configuring RED Drop Profiles on page 1677](#)
- [Configuring Weighted RED Buffer Occupancy on page 1678](#)

Configuring RED Drop Profiles

You enable RED by applying a drop profile to a scheduler. When RED is operational on an interface, the queue no longer drops packets from the tail of the queue. Rather, packets are dropped after they reach the head of the queue.

To configure a drop profile, include the **drop-profiles** statement at the **[edit class-of-service]** hierarchy level:

```

[edit class-of-service]
drop-profiles {
    profile-name {
        fill-level percentage drop-probability percentage;
        interpolate {
            drop-probability [ values ];
            fill-level [ values ];
        }
    }
}
}

```

In this configuration, include either the **interpolate** statement and its options, or the fill-level and drop-probability **percentage** values. These two alternatives enable you to configure either each drop probability at up to 64 fill-level/drop-probability paired values, or a profile represented as a series of line segments, as discussed in [“RED Drop Profiles Overview” on page 1674](#).

After you configure a drop profile, you must assign the drop profile to a drop-profile map, and assign the drop-profile map to a scheduler, as discussed in [“Configuring Drop Profile Maps for Schedulers” on page 1590](#).

Configuring Weighted RED Buffer Occupancy

By default, RED is performed based on instantaneous buffer occupancy information. However, IQ-PICs can be configured to use *weighted average* buffer occupancy information. This option is configured on a per-PIC basis and applies to the following IQ-PICs:

- Channelized T1/T3
- Channelized E1/E3
- Channelized OC3/STM1
- Channelized OC12

If you configure this feature on an unsupported PIC, you see an error message.

If you configure this feature on a channelized OC12 intelligent queuing (IQ) PIC, the PIC reboots.

When weighted average buffer occupancy is configured, you configure a weight value for averaged buffer occupancy calculations. This weight value is expressed as a negative exponential value of 2 in a fractional expression. For example, a configured weight value of 2 would be expressed as $1/(2^2) = 1/4$. If a configured weight value was configured as 1 (the default), the value would be expressed as $1/(2^1) = 1/2$.

This calculated weight value is applied to the instantaneous buffer occupancy value to determine the new value of the weighted average buffer occupancy. The formula to derive the new weighted average buffer occupancy is:

new average buffer occupancy = weight value * instantaneous buffer occupancy + (1 – weight value) * current average buffer occupancy

For example, if the weight exponent value is configured as 3 (giving a weight value of $1/2^3 = 1/8$), the formula used to determine the new average buffer occupancy based on the instant buffer usage is:

new average buffer occupancy = 1/8 * instantaneous buffer occupancy + (7/8) * current average buffer occupancy

The valid operational range for the weight value on IQ-PICs is 0 through 31. A value of 0 results in the average buffer occupancy being the same as the instantaneous buffer occupancy calculations. Values higher than 31 can be configured, but in these cases the current maximum *operational* value of 31 is used for buffer occupancy calculations.

NOTE: The `show interfaces` command with the `extensive` option displays the *configured* value for the RED buffer occupancy weight exponent. However, in all such cases, the current *operational* maximum value of 31 is used internally.

To configure a Q-PIC for RED weighted average buffer occupancy calculations, include the `red-buffer-occupancy` statement with the `weighted-averaged` option at the `[edit chassis fpc slot-number pic pic-number]` hierarchy level:

```
[edit chassis]
fpc slot-number {
  pic pic-number {
    red-buffer-occupancy {
      weighted-averaged [ instant-usage-weight-exponent exponent-number ];
    }
  }
}
```

Examples

- [Example: Configuring RED Drop Profiles on page 1679](#)
- [Example: Configuring Weighted RED Buffer Occupancy on page 1680](#)

Example: Configuring RED Drop Profiles

Create a segmented configuration and an interpolated configuration that correspond to the graphs in [Figure 14 on page 1679](#). The values defined in the configuration are matched to represent the data points in the graph line. In this example, the drop probability is 25 percent when the queue is 50 percent full. The drop probability increases to 50 percent when the queue is 75 percent full.

Figure 14: Segmented and Interpolated Drop Profiles

Creating a Segmented Configuration

```
class-of-service {
  drop-profiles {
    segmented-style-profile {
```

```

        fill-level 25 drop-probability 25;
        fill-level 50 drop-probability 50;
        fill-level 75 drop-probability 75;
        fill-level 95 drop-probability 100;
    }
}

```

To create the profile's graph line, the software begins at the bottom-left corner, representing a 0 percent fill level and a 0 percent drop probability. This configuration draws a line directly to the right until it reaches the first defined fill level, 25 percent for this configuration. The software then continues the line vertically until the first drop probability is reached. This process is repeated for all of the defined levels and probabilities until the top-right corner of the graph is reached.

Create a smoother graph line by configuring the profile with the **interpolate** statement. This allows the software to automatically generate 64 data points on the graph beginning at (0, 0) and ending at (100, 100). Along the way, the graph line intersects specific data points, which you define as follows:

Creating an Interpolated Configuration

```

class-of-service {
  drop-profiles {
    interpolated-style-profile {
      interpolate {
        fill-level [ 50 75 ];
        drop-probability [ 25 50 ];
      }
    }
  }
}

```

Example: Configuring Weighted RED Buffer Occupancy

Configure the Q-PIC to use a weight value of 1/2 in average buffer occupancy calculations.

```

[edit chassis]
fpc 0 {
  pic 1 {
    red-buffer-occupancy {
      weighted-averaged instant-usage-weight-exponent 1;
    }
  }
}

```

or

```

[edit chassis]
fpc 0 {
  pic 1 {
    red-buffer-occupancy {
      weighted-averaged; # the default value is 1 if not specified
    }
  }
}

```

Configure the Q-PIC to use a weight value of 1/4 in average buffer occupancy calculations.

```
[edit chassis]
fpc 0 {
  pic 1 {
    red-buffer-occupancy {
      weighted-averaged instant-usage-weight-exponent 2;
    }
  }
}
```

- [Classifiers and Rewrite Rules at the Global and Physical Interface Levels Overview on page 1692](#)

Rewriting Packet Header Information Overview

As packets enter or exit a network, edge routers might be required to alter the class-of-service (CoS) settings of the packets. Rewrite rules set the value of the CoS bits within the packet's header. Each rewrite rule reads the current forwarding class and loss priority information associated with the packet, locates the chosen CoS value from a table, and writes this CoS value into the packet header.

In effect, the rewrite rule performs the opposite function of the behavior aggregate (BA) classifier used when the packet enters the routing device. As the packet leaves the routing platform, the final CoS action is generally the application of a rewrite rule.

You configure rewrite rules to alter CoS values in outgoing packets on the outbound interfaces of an edge router to meet the policies of a targeted peer. This allows the downstream routing device in a neighboring network to classify each packet into the appropriate service group.

In addition, you often need to rewrite a given marker (IP precedence, Differentiated Services code point [DSCP], IEEE 802.1p, or MPLS EXP settings) at the inbound interfaces of an edge router to accommodate BA classification by core devices.

Figure 15 on page 1690 shows a flow of packets through four routing devices. Router A rewrites the CoS bits in incoming packet to accommodate the BA classification performed by Routers B and C. Router D alters the CoS bits of the packets before transmitting them to the neighboring network.

Figure 15: Packet Flow Across the Network

To configure CoS rewrite rules, you define the rewrite rule and apply it to an interface. Include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
interfaces {
  interface-name {
    unit logical-unit-number {
      rewrite-rules {
        dscp (rewrite-name | default) protocol protocol-types;
        dscp-ipv6 (rewrite-name | default);
        exp (rewrite-name | default) protocol protocol-types;
        exp-push-push-push default;
        exp-swap-push-push default;
        ieee-802.1 (rewrite-name | default) vlan-tag (outer | outer-and-inner);
        ieee-802.1ad (rewrite-name | default) vlan-tag (outer | outer-and-inner);
        inet-precedence (rewrite-name | default) protocol protocol-types;
      }
    }
  }
}
```

```

    }
  }
}
rewrite-rules {
  (dscp | dscp-ipv6 | exp | frame-relay-de | ieee-802.1 | inet-precedence) rewrite-name {
    import (rewrite-name | default);
    forwarding-class class-name {
      loss-priority level code-point (alias | bits);
    }
  }
}
}

```

Header Bits Preserved, Cleared, and Rewritten

For every incoming packet, the ingress classifier decodes the ingress CoS bits into a forwarding class and packet loss priority (PLP) combination.

The egress CoS information depends on which type of rewrite marker is active, as follows:

- For Multiprotocol Label Switching (MPLS) EXP and IEEE 802.1 rewrite markers, values are derived from the forwarding class and PLP values in rewrite rules. MPLS EXP and IEEE 802.1 markers are not preserved because they are part of the Layer 2 encapsulation.
- For IP precedence and DiffServ code point (DSCP) rewrite markers, the marker alters the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged.

Setting IPv6 DSCP and MPLS EXP Values Independently

On the M120, M320 with Enhanced III FPCs, MX Series Ethernet Services routers, and EX Series switches, you can set the DSCP and MPLS EXP bits independently on IPv6 packets. To enable this feature, include the **protocol mpls** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules dscp-ipv6 rewrite-name]** hierarchy level.

You can set DSCP IPv6 values only at the ingress MPLS node.

The following limitations apply to this feature:

- This feature is supported only on M120, M320 with Enhanced III FPCs, MX Series Ethernet Services routers, and EX Series switches.
- MPLS packets entering another MPLS tunnel at the ingress node may mark only the EXP value if EXP rewrite rules are configured, but not the DSCP value in the IPv6 header.
- This feature does not support MPLS packets generated by the Routing Engine.
- The IP precedence field is not applicable for IPv6, and is not supported.

Related Documentation

- [Configuring DSCP Values for IPv6 Packets Entering the MPLS Tunnel on page 1697](#)

Classifiers and Rewrite Rules at the Global and Physical Interface Levels Overview

On ACX Series Universal Access Routers and EX Series switches, CoS supports classification and rewrite at the global level and physical interface levels.

At a global level, you can define EXP classification.

At a physical interface level, you can define the following features:

- DSCP and inet-precedence classifiers
- DSCP and inet-precedence rewrites
- ieee-802.1 classifiers (inner and outer)
- ieee-802.1 rewrites (outer)

At a logical interface level, you can define the fixed classification and EXP rewrites.

To configure global EXP classifiers, include the **classifiers exp classifier-name** statement at the **[edit class-of-service] system-defaults** hierarchy level.

To configure classifiers or rewrite rules at the physical interface, include either the **classifiers** statement or the **rewrite-rules** statement at the **[edit class-of-service] interfaces interface-name]** hierarchy level.

To display classifiers configured under **system-defaults**, enter the **show class-of-service system-defaults** command.

To display classifiers and rewrite rules bound to physical interfaces, enter the **show class-of-service interfaces interface-name** command.

Configuration Tasks for Applying Rewrite Rules

- [Applying Default Rewrite Rules on page 1693](#)
- [Configuring Rewrite Rules on page 1694](#)
- [Applying Rewrite Rules to Output Logical Interfaces on page 1695](#)
- [Configuring DSCP Values for IPv6 Packets Entering the MPLS Tunnel on page 1697](#)
- [Applying IEEE 802.1p Rewrite Rules to Dual VLAN Tags on page 1699](#)
- [Configuring Classifiers and Rewrite Rules at the Global and Physical Interface Levels on page 1701](#)

Applying Default Rewrite Rules

By default, rewrite rules are not usually applied to interfaces. The exceptions are MPLS interfaces: all MPLS-enabled interfaces use the default EXP rewrite rule, even if not configured. Except for MPLS interfaces, if you want to apply a rewrite rule, you can either design your own rule and apply it to an interface, or you can apply a default rewrite rule. To apply default rewrite rules, include one or more of the following statements at the `[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]` hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
dscp default;
dscp-ipv6 default;
exp default;
ieee-802.1 default vlan-tag (outer | outer-and-inner);
inet-precedence default;
```

Table 126 on page 1693 shows the default rewrite rule mappings. These are based on the default bit definitions of DSCP, DSCP IPv6, EXP, IEEE, and IP CoS values, as shown in “Default CoS Values” on page 1372, and the default forwarding classes shown in *Default Forwarding Classes*.

When the software detects packets whose CoS values match the forwarding class and PLP values in the first two columns in Table 126 on page 1693, the software maps the header bits of those packets to the code-point aliases in the last column in Table 126 on page 1693. The code-point aliases in the last column map to the CoS bits shown in “Default CoS Values” on page 1372.

Table 126: Default Packet Header Rewrite Mappings

Map from Forwarding Class	PLP Value	Map to DSCP/DSCP IPv6/ EXP/IEEE/IP
expedited-forwarding	low	ef
expedited-forwarding	high	ef
assured-forwarding	low	af11
assured-forwarding	high	af12 (DSCP/DSCP IPv6/EXP)
best-effort	low	be
best-effort	high	be
network-control	low	nc1/cs6
network-control	high	nc2/cs7

In the following example, the `ge-1/2/3.0` interface is assigned the default DSCP rewrite rule. One result of this configuration is that each packet exiting the interface with the **expedited-forwarding** forwarding class and the **high** or **low** loss priority has its DSCP bits

rewritten to the DSCP **ef** code-point alias. “[Default CoS Values](#)” on page 1372 shows that this code-point alias maps to the **101110** bits.

Another result of this configuration is that all packets exiting the interface with the **best-effort** forwarding class and the **high** or **low** loss priority have their EXP bits rewritten to the EXP **be** code-point alias. “[Default CoS Values](#)” on page 1372 shows that this code-point alias maps to the **000** bits.

To evaluate all the implications of this example, see “[Default CoS Values](#)” on page 1372 and [Table 126](#) on page 1693.

```
class-of-service {
  interfaces {
    ge-1/2/3 {
      unit 0 {
        rewrite-rules {
          dscp default;
        }
      }
    }
  }
}
```

Configuring Rewrite Rules

You define markers in the rewrite rules section of the CoS configuration hierarchy and reference them in the logical interface configuration. This model supports marking on the DSCP, DSCP IPv6, IP precedence, IEEE 802.1, and MPLS EXP CoS values.

To configure a rewrite-rules mapping and associate it with the appropriate forwarding class and code-point alias or bit set, include the **rewrite-rules** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
rewrite-rules {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | ieee-802.1ad | inet-precedence) rewrite-name {
    import (rewrite-name | default);
    forwarding-class class-name {
      loss-priority level code-point (alias | bits);
    }
  }
}
```

NOTE: The **inet-precedence** statement is not supported on PTX Series Packet Transport Switches.

The rewrite rule sets the code-point aliases and bit patterns for a specific forwarding class and PLP. The inputs for the map are the forwarding class and the PLP. The output of the map is the code-point alias or bit pattern. For more information about how CoS maps work, see “[CoS Inputs and Outputs Overview](#)” on page 1272.

By default, IP precedence rewrite rules alter the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged. This default behavior is not

configurable. The default behavior applies to rules you configure by including the **inet-precedence** statement at the **[edit class-of-service rewrite-rules]** hierarchy level. The default behavior also applies to rewrite rules you configure for MPLS packets with IPv4 payloads. You configure these types of rewrite rules by including the **mpls-inet-both** or **mpls-inet-both-non-vpn** option at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules exp *rewrite-rule-name* protocol]** hierarchy level.

On the M320, T1600, and MX960 routers and EX Series switches, if you configure **vlan-vpls** encapsulation and add an IEEE 802.1 header on a Gigabit Ethernet or 10 Gigabit Ethernet interface to output traffic, but do not apply an IEEE 802.1 rewrite rule, then the default IEEE 802.1 rewrite rule is ignored and the IEEE 802.1p bits are set to match the forwarding class queue.

NOTE: The forwarding class is determined by ingress classification.

Related Documentation

- [Applying Rewrite Rules to Output Logical Interfaces](#)
- [Applying Egress Interface Rewrite Rules to the IEEE 802.1p Field for All Host Outbound Traffic on the Interface on page 1711](#)

Applying Rewrite Rules to Output Logical Interfaces

To assign the rewrite-rules configuration to the output logical interface, include the **rewrite-rules** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
rewrite-rules {
  dscp (rewrite-name | <default>) protocol protocol-types;
  dscp-ipv6 (rewrite-name | <default>) protocol protocol-types
  exp (rewrite-name | <default>) protocol protocol-types;
  exp-push-push-push <default>;
  exp-swap-push-push <default>;
  ieee-802.1 (rewrite-name | <default>) inet-prec vlan-tag (outer | outer-and-inner);
  inet-precedence (rewrite-name | <default>) protocol protocol-types;
}
```

On M120, M320 with an Enhanced III FPC, MX Series routers and T 4000 routers with Type 5 FPCs and EX Series switches, you can combine the **dscp** or **inet-prec** and **exp** options to set the DSCP or IP precedence bits and MPLS EXP bits independently on IP packets entering an MPLS tunnel.

For IQ PICs, you can configure only one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule. If you configure more than one IEEE 802.1 rewrite rule for the IQ PIC, the configuration check fails.

In the following example, the DSCP bits specified in **ss-dscp** are applied to packets entering the MPLS tunnel on **ge-2/1/1**, and the DSCP bits specified in **ss-v6dscp** are applied to IPv6 packets. The EXP bits are set to the bit configuration specified in **ss-exp**:

```
[edit class-of-service interfaces]
ge-2/1/1
  unit 10 {
    rewrite-rules {
      dscp ssf-dscp protocol mpls; # Applies to IPv4 packets entering MPLS tunnel
      dscp-ipv6 ss-v6dscp protocol mpls; # Applies to IPv6 packets entering MPLS tunnel
      exp ss-exp; # Sets label EXP bits independently
    }
  }
}
```

You can use interface wildcards for *interface-name* and *logical-unit-number*. You can also include Layer 2 and Layer 3 rewrite information in the same configuration.

NOTE: On M Series routers only, if you include the `control-word` statement at the `[edit protocols l2circuit neighbor address interface interface-name]` hierarchy level, the software cannot rewrite MPLS EXP bits.

DSCP and DSCP IPv6 rewrite rules are supported on M Series and T Series routers when non-queuing PICs are installed, but are disabled when queuing PICs are installed with the following exceptions:

- On M320 routers, DSCP rewrite is supported on IQ, IQ2, IQE, and IQ2E PICs when used with the Enhanced III FPC.
- On M120 routers, DSCP rewrite is supported on IQ, IQ2, IQE, and IQ2E PICs.

DSCP and DCSP IPv6 rewrite rules are supported on MX Series routers with MPC/MIC interfaces and EX Series switches.

DSCP rewrite rules are not supported on T Series routers when IQ, IQ2, IQE, IQ2E, or PD-5-10XGE-SFPP PICs are installed.

For IQ PICs, you can configure only one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.

On M320 and T Series routers (except for T4000 routers with Type 5 FPCs), for a single interface, you cannot enable a rewrite rule on a subset of forwarding classes. You must assign a rewrite rule to either none of the forwarding classes or all of the forwarding classes. When you assign a rewrite rule to a subset of forwarding classes, the commit does not fail, and the subset of forwarding classes works as expected. However, the forwarding classes to which the rewrite rule is not assigned are rewritten to all zeros.

For example, if you configure a Differentiated Services code point (DSCP) rewrite rule, the bits in the forwarding classes to which you do not assign the rewrite rule are rewritten to 000000; if you configure an IP precedence rewrite rule, the bits in the forwarding classes to which you do not assign the rewrite rule are rewritten to 000.

Configuring DSCP Values for IPv6 Packets Entering the MPLS Tunnel

The following configuration example explains in detail how to set the DSCP and MPLS EXP bits independently on IPv6 packets.

1. Configure the router device (ingress PE router) to classify (behavior aggregate or multifield) the incoming packets to a particular forwarding class.

```
[edit firewall]
family inet6 {
```

```
filter ss-v6filt {
  term ss-vpn {
    from {
      destination-address {
        ::ffff:192.0.2.128/120;
      }
    }
    then {
      loss-priority low;
      forwarding-class ss-fc;
    }
  }
}
```

In the preceding example, the ingress FPC classifies (MF) incoming IPv6 packets destined for address “::ffff:192.0.2.128/120” to forwarding class “ss-fc” and loss priority “low.”

2. Attach the preceding firewall filter to an interface. Because you are matching on inbound traffic, this would be an input filter. This classifies all traffic on the interface “ge-2/1/0” that matches the filter “ss-v6.”

```
[edit interfaces]
ge-2/1/0 {
  hierarchical-scheduler;
  vlan-tagging;
  unit 300 {
    family inet6 {
      filter {
        input ss-v6filt;
      }
      address ::ffff:192.0.2.100/120;
    }
  }
}
```

3. Configure the DSCP–IPv6 rewrite rule for the forwarding class “ss-fc.” This causes the outgoing IPv6 packets belonging to the forwarding class “ss-fc” and loss priority “low” to have their DSCP value rewritten to 100000.

```
[edit class-of-service rewrite-rules]
dscp-ipv6 ss-v6dscp {
  forwarding-class ss-fc {
    loss-priority low code-point 100000;
  }
}
```

4. Configure the EXP rewrite values for the forwarding class “ss-fc.” This rewrite rule stamps an EXP value of 100 on all outgoing MPLS packets assigned to the forwarding class “ss-fc” and loss priority “low.”

```
[edit class-of-service rewrite-rules]
exp ss-exp {
  forwarding-class ss-fc {
    loss-priority low code-point 100;
  }
}
```

```
}
```

5. Apply the preceding rewrite rule to an egress interface. On the egress FPC, all IPv6 packets in the forwarding class “ss-fc” with loss priority “low” are marked with the DSCP value “100000” and an EXP value of “100” before they enter the MPLS tunnel.

```
[edit class-of-service interfaces]
ge-2/1/1 {
  unit 10 {
    rewrite-rules {
      dscp-ipv6 ss-v6dscp protocol mpls;
      exp ss-exp;
    }
  }
}
```

6. To support IPv4 DSCP and MPLS EXP independent rewrite at the same time, you can define and apply an IPv4 DSCP rewrite rule “ss-dscp” to the same interface.

```
[edit class-of-service interfaces]
ge-2/1/1 {
  unit 10 {
    rewrite-rules {
      dscp ss-dscp protocol mpls;
      dscp-ipv6 ss-v6dscp protocol mpls;
      exp ss-exp;
    }
  }
}
```

Applying IEEE 802.1p Rewrite Rules to Dual VLAN Tags

By default, when you apply an IEEE 802.1p rewrite rule to an output logical interface, the software rewrites the IEEE bits in the outer VLAN tag only.

For Gigabit Ethernet IQ2 PICs, 10-port 10-Gigabit OSE PICs, and 10-Gigabit Ethernet IQ2 PICs only, you can rewrite the IEEE bits in both the outer and inner VLAN tags of the tagged Ethernet frames. When you enable class of service (CoS) rewrite for both tags, the same IEEE 802.1p rewrite table is used for the inner and outer VLAN tag.

For IQ PICs, you can only configure one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.

To rewrite both the outer and inner VLAN tags, include the **vlan-tag outer-and-inner** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules *ieee-802.1* (*rewrite-name* | default)]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules
  ieee-802.1 (rewrite-name | default)]
  vlan-tag outer-and-inner;
```

To explicitly specify the default behavior, include the **vlan-tag outer** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules *ieee-802.1* (*rewrite-name* | default)]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules
  ieee-802.1 (rewrite-name | default)]
  vlan-tag outer;
```

For more information about VLAN tags, see the *Junos® OS Network Interfaces*.

On MX routers and EX Series switches, you can perform IEEE 802.1p and DEI rewriting based on forwarding class and PLP at the VPLS ingress PE. You rewrite (mark) the IEEE 802.1p or DEI bits on frames at the VPLS ingress PE based on the value of the forwarding class and PLP established for the traffic. You can rewrite either the outer tag only or the outer and inner tag. When both tags are rewritten, both get the same value. To configure these rewrite rules, include the **ieee-802.1** statement at the **[edit class-of-services routing-instance *routing-instance-name* rewrite-rules]** hierarchy level.

On routing devices with IQ2 or IQ2-E PICs, you can perform IEEE 802.1p and DEI rewriting based on forwarding-class and packet loss priority (PLP) at the VPLS ingress provider edge (PE) router. You rewrite (mark) the IEEE 802.1p or DEI bits on frames at the VPLS ingress PE based on the value of the forwarding-class and PLP established for the traffic. You can rewrite either the outer tag only or both the outer and inner tags. When both tags are rewritten, both get the same value.

NOTE: The 10-port 10-Gigabit OSE PIC does not support DEI rewriting based on forwarding class and PLP at the VPLS ingress PE.

To configure these rewrite rules, include the **ieee-802.1** statement at the **[edit class-of-services routing-instance *routing-instance-name* rewrite-rules]** hierarchy level.

Example: Applying an IEEE 802.1p Rewrite Rule to Dual VLAN Tags

Apply the **ieee8021p-rwrule1** rewrite rule to both inner and outer VLAN tags of Ethernet-tagged frames exiting the **ge-0/0/0.0** interface:

```
class-of-service {
  interfaces {
    ge-0/0/0 {
      unit 0 {
        rewrite-rules {
          ieee-802.1 ieee8021p-rwrule1 vlan-tag outer-and-inner;
        }
      }
    }
  }
}
```

Configuring Classifiers and Rewrite Rules at the Global and Physical Interface Levels

On ACX Series Universal Access Routers and EX Series switches, CoS supports classification and rewrite at the global and physical interface levels.

To configure the global EXP classifier, include the following statements at the **[edit class-of-service] system-defaults** hierarchy level.

```
[edit class-of-service]
{
  system-defaults
  {
    classifiers exp classifier-name
  }
}
```

CoS supports one global system default classifier of the EXP type, as shown in the following example:

```
[edit class-of-service]
{
  system-defaults {
    classifiers {
      exp exp-classf-core;
    }
  }
}
```

To configure classifiers and rewrite rules at the physical interface level, include the following statements at the **[edit class-of-service] interfaces** hierarchy level.

```
[edit class-of-service]
interfaces {
  interface-name
  classifiers dscp classifier-name
  classifiers inet-precedence classifier-name
  classifiers ieee-802.1 [vlan-tag (outer | inner)] classifier-name
  rewrite-rules dscp rewrite-name
  rewrite-rules inet-prec rewrite-name
  rewrite-rules ieee-802.1 rewrite-name
}
```

The following example shows classifiers and rewrite rules configured on physical interfaces:

```
ge-0/1/0 {
  unit 0 {
    rewrite-rules {
      exp custom-exp;
    }
  }
  classifiers {
    dscp dl;
    ieee-802.1 ci;
  }
  rewrite-rules {
```

```
    dscp default;
  }
}
ge-0/1/2 {
  classifiers {
    ieee-802.1 ci;
  }
  rewrite-rules {
    ieee-802.1 ri;
  }
}
ge-0/1/3 {
  unit 0 {
    rewrite-rules {
      exp custom-exp2;
    }
  }
}
ge-0/1/7 {
  classifiers {
    dscp d1;
  }
}
ge-0/1/8 {
  classifiers {
    dscp d1;
  }
}
```

Rewriting MPLS and IPv4 Packet Headers

You can apply a rewrite rule to MPLS and IPv4 packet headers simultaneously. This allows you to initialize MPLS EXP and IP precedence bits at LSP ingress. You can configure different rewrite rules depending on whether the traffic is VPN or non-VPN.

The default MPLS EXP rewrite table contents are shown in [Table 127 on page 1703](#).

Table 127: Default MPLS EXP Rewrite Table

Forwarding Class	Loss Priority	CoS Value
best-effort	low	000
best-effort	high	001
expedited-forwarding	low	010
expedited-forwarding	high	011
assured-forwarding	low	100
assured-forwarding	high	101
network-control	low	110
network-control	high	111

By default, IP precedence rewrite rules alter the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged. This default behavior applies to rewrite rules you configure for MPLS packets with IPv4 payloads.

To override the default MPLS EXP rewrite table and rewrite MPLS and IPv4 packet headers simultaneously, include the **protocol** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp rewrite-rule-name]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp
rewrite-rule-name]
protocol protocol-types;
```

The **protocol** statement defines the types of MPLS packets and packet headers to which the specified rewrite rule is applied. The MPLS packet can be a standard MPLS packet or an MPLS packet with an IPv4 payload. Specify the type of MPLS packet using the following options:

- **mpls**—Applies the rewrite rule to MPLS packets and writes the CoS value to MPLS headers.
- **mpls-inet-both**—Applies the rewrite rule to VPN MPLS packets with IPv4 payloads. On Juniper Networks M120 Multiservice Edge Routers, M320 Multiservice Edge Routers, and T Series Core Routers (except T4000 routers), writes the CoS value to the MPLS and IPv4 headers. On other M Series Multiservice Edge Router routers, causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with **000** code points for the MPLS EXP value, and the configured rewrite code point for IP precedence.
- **mpls-inet-both-non-vpn**—Applies the rewrite rule to non-VPN MPLS packets with IPv4 payloads. On Juniper Networks M120 Multiservice Edge Routers, M320 Multiservice Edge Routers, and T Series Core Routers, writes the CoS value to the MPLS and IPv4 headers. On other M Series Multiservice Edge Routers, causes all ingress MPLS LSP

packets with IPv4 payloads to be initialized with **000** code points for the MPLS EXP value, and the configured rewrite code point for IP precedence.

On M120 routers, M320 routers with Enhanced-III FPCs, MX Series routers, and EX Series switches, you can perform simultaneous DSCP and EXP rewrite by attaching independent DSCP or IPv4 precedence rewrite rules and EXP rewrite rules to the same core interface. Thus, you can rewrite both code points (DSCP and EXP) when the packet is received by the ingress provider edge (PE) router on the MPLS core.

An alternative to overwriting the default with a rewrite-rules mapping is to configure the default packet header rewrite mappings, as discussed in *Applying Default Rewrite Rules*.

By default, IP precedence rewrite rules alter the first three bits on the ToS byte while leaving the last three bits unchanged. This default behavior is not configurable. The default behavior applies to rules you configure by including the **inet-precedence** statement at the **[edit class-of-service rewrite-rules]** hierarchy level. The default behavior also applies to rewrite rules you configure for MPLS packets with IPv4 payloads. You configure these types of rewrite rules by including the **mpls-inet-both** or **mpls-inet-both-non-vpn** option at the **[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp rewrite-rule-name protocol]** hierarchy level.

Example: Rewriting MPLS and IPv4 Packet Headers

On M320 and T Series routers, configure rewrite tables and apply them in various ways to achieve the following results:

- For interface **ge-3/1/0**, the three EXP rewrite tables are applied to packets, depending on the protocol of the payload:
 - IPv4 packets (VPN) that enter the LSPs on interface **ge-3/1/0** are initialized with values from rewrite table **exp-inet-table**. An identical 3-bit value is written into the IP precedence and MPLS EXP bit fields.
 - IPv4 packets (non-VPN) that enter the LSPs on interface **ge-3/1/0** are initialized with values from rewrite table **rule-non-vpn**. An identical 3-bit value is written into the IP precedence and MPLS EXP bit fields.
 - Non-IPv4 packets that enter the LSPs on interface **ge-3/1/0** are initialized with values from rewrite table **rule1**, and written into the MPLS EXP header field only. The statement **exp rule1** has the same result as **exp rule1 protocol mpls**.
- For interface **ge-3/1/0**, IPv4 packets transmitted over a non-LSP layer are initialized with values from IP precedence rewrite table **rule2**.
- For interface **ge-3/1/1**, IPv4 packets that enter the LSPs are initialized with values from EXP rewrite table **exp-inet-table**. An identical 3-bit value is written into the IP precedence and MPLS EXP bit fields.
- For interface **ge-3/1/1**, MPLS packets other than IPv4 Layer 3 types are also initialized with values from table **exp-inet-table**. For VPN MPLS packets with IPv4 payloads, the CoS value is written to MPLS and IPv4 headers. For VPN MPLS packets without IPv4 payloads, the CoS value is written to MPLS headers only.

[edit class-of-service]

```

rewrite-rules {
  exp exp-inet-table {
    forwarding-class best-effort {
      loss-priority low code-point 000;
      loss-priority high code-point 001;
    }
    forwarding-class assured-forwarding {
      loss-priority low code-point 010;
      loss-priority high code-point 011;
    }
    forwarding-class expedited-forwarding {
      loss-priority low code-point 111;
      loss-priority high code-point 110;
    }
    forwarding-class network-control {
      loss-priority low code-point 100;
      loss-priority high code-point 101;
    }
  }
  exp rule1 {
    ...
  }
  inet-precedence rule2 {
    ...
  }
}
exp rule_non_vpn {
  ...
}

interfaces {
  ge-3/1/0 {
    unit 0 {
      rewrite-rules {
        exp rule1;
        inet-precedence rule2;
        exp exp-inet-table protocol mpls-inet-both; # For all VPN traffic.
        exp rule_non_vpn protocol mpls-inet-both-non-vpn; # For all non-VPN
          # traffic.
      }
    }
  }
  ge-3/1/1 {
    unit 0 {
      rewrite-rules {
        exp exp-inet-table protocol [mpls mpls-inet-both];
      }
    }
  }
}

```

Example: Simultaneous DSCP and EXP Rewrite

On M120 routers, M320 routers with Enhanced-III FPCs, MX Series routers, and EX Series switches, configure the simultaneous DSCP and EXP rewrite rules as shown below:

1. Configure CoS.

```
[edit]
user@host# edit class-of-service
```

2. Configure the EXP rewrite rule on the interface.

```
[edit class-of-service]
user@host# set interfaces ge-2/0/3 unit 0 rewrite-rule exp rule1
```

3. Configure the IPv4 rewrite rule on the interface.

```
[edit class-of-service]
user@host# set interfaces ge-2/0/3 unit 0 rewrite-rule inet-precedence rule2
```

4. Configure the IPv4 rewrite rule on the interface and apply it to packets entering the MPLS tunnel.

```
[edit class-of-service]
user@host# set interfaces ge-2/0/3 unit 0 rewrite-rule inet-precedence rule3 protocol
mpls
```

5. Verify the configuration by using the **show interfaces** command.

```
[edit class-of-service]
user@host# show interfaces ge-2/0/3 unit 0
rewrite-rules {
  exp rule1;
  inet-precedence rule2;
  inet-precedence rule3 protocol mpls;
}
```

In the example above, there are two different IPv4 precedence rewrite rules: **rule2** and **rule3**. **rule2** affects the IPv4 to IPv4 traffic and **rule3** affects the IPv4 to MPLS traffic.

Rewriting the EXP Bits of All Three Labels of an Outgoing Packet

In interprovider, carrier-of-carrier, and complex traffic engineering scenarios, it is sometimes necessary to push three labels on the next hop, using a swap-push-push or triple-push operation.

By default, on M Series routers and EX Series switches, the top MPLS EXP label of an outgoing packet is not rewritten when you configure swap-push-push and triple-push operations. On these routing devices, you can rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining the CoS of an incoming MPLS or non-MPLS packet.

When the software performs a swap-push-push operation and no rewriting is configured, the EXP fields of all three labels are the same as in the old label. If there is EXP rewriting configured, the EXP bits of the bottom two labels are overwritten with the table entry. The EXP setting of the top label is retained even with rewriting.

To push three labels on all incoming MPLS packets, include the **exp-swap-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-swap-push-push default;
```

When the software performs a push-push-push operation and if no rewriting is configured, the EXP fields of the bottom two labels are zero. If EXP rewriting is configured, the EXP fields of the bottom two labels are rewritten with the table entry's rewrite value. The EXP field of the top label is inserted with the Qn+PLP value. This Qn reflects the final classification by a multifield classifier if one exists, regardless of whether rewriting is configured.

NOTE: The `exp-push-push-push` and `exp-swap-push-push` configuration on the egress interface does not rewrite the top label's EXP field with the Qn+PLP value on an IQ or IQ2 PIC.

To push three labels on incoming non-MPLS packets, include the `exp-push-push-push default` statement at the `[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]` hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
  exp-push-push-push default;
```

These configurations apply the default MPLS EXP rewrite table, as described in *Rewriting MPLS and IPv4 Packet Headers*. You can configure these operations and override the default MPLS EXP rewrite table with a custom table. For more information about writing and applying a custom rewrite table, see [“Configuring Rewrite Rules” on page 1694](#) and *Applying Rewrite Rules to Output Logical Interfaces*.

NOTE: With a three-label stack, if you do not include the `exp-swap-push-push default` or `exp-push-push-push default` statement in the configuration, the top label's EXP bits are set to zero.

Example: Rewriting the EXP Bits of All Three Labels of an Outgoing Packet

Configure a swap-push-push operation, and override the default rewrite table with a custom table:

```
[edit class-of-service]
forwarding-classes {
  queue 0 be;
  queue 1 ef;
  queue 2 af;
  queue 3 nc;
}
interfaces {
  ge-1/1/3 {
    unit 0 {
      rewrite-rules {
        exp exp_rewrite; # Apply custom rewrite table
        exp-swap-push-push default;
      }
    }
  }
}
```

```
rewrite-rules {  
  exp exp_rew {  
    forwarding-class be {  
      loss-priority low code-point 000;  
      loss-priority high code-point 100;  
    }  
    forwarding-class ef {  
      loss-priority low code-point 001;

  }  
}
```

Rewriting IEEE 802.1p Packet Headers with an MPLS EXP Value

For Ethernet interfaces on Juniper Networks M320 Multiservice Edge Routers, MX Series Ethernet Service Routers, T Series Core Routers, and EX Series switches that have a peer connection to an M Series Multiservice Edge Router, MX Series, T Series router, or EX Series switches, you can rewrite both MPLS EXP and IEEE 802.1p bits to a configured value. This enables you to pass the configured value to the Layer 2 VLAN path. For IQ PICs, you can only configure one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.

To rewrite both the MPLS EXP and IEEE 802.1p bits, you must include EXP and IEEE 802.1p rewrite rules in the interface configuration. To configure EXP and IEEE 802.1p rewrite rules, include the **rewrite-rules** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy level, specifying the **exp** and **ieee-802.1** options:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]  
rewrite-rules {  
  exp rewrite-rule-name;  
  ieee-802.1 default;  
}
```

When you combine these two rewrite rules, only the EXP rewrite table is used for rewriting packet headers. If you do not configure a VLAN on the interface, only the EXP rewriting is in effect. If you do not configure an LSP on the interface or if the MPLS EXP rewrite rule mapping is removed, the IEEE 802.1p default rewrite rules mapping takes effect.

NOTE: You can also combine other rewrite rules. IP, DSCP, DSCP IPv6, and MPLS EXP are associated with Layer 3 packet headers, and IEEE 802.1p is associated with Layer 2 packet headers.

For IQ PICs, you can only configure one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.

If you combine IEEE 802.1p with IP rewrite rules, the Layer 3 packets and Layer 2 headers are rewritten with the IP rewrite rule.

If you combine IEEE 802.1p with DSCP or DSCP IPv6 rewrite rules, three bits of the Layer 2 header and six bits of the Layer 3 packet header are rewritten with the DSCP or DSCP IPv6 rewrite rule.

The following example shows how to configure an EXP rewrite rule and apply it to both MPLS EXP and IEEE 802.1p bits:

```
[edit class-of-service]
rewrite-rules {
  exp exp-ieee-table {
    forwarding-class best-effort {
      loss-priority low code-point 000;
      loss-priority high code-point 001;
    }
    forwarding-class assured-forwarding {
      loss-priority low code-point 010;
      loss-priority high code-point 011;
    }
    forwarding-class expedited-forwarding {
      loss-priority low code-point 111;
      loss-priority high code-point 110;
    }
    forwarding-class network-control {
      loss-priority low code-point 100;
      loss-priority high code-point 101;
    }
  }
}
interfaces {
  ge-3/1/0 {
    unit 0 {
      rewrite-rules {
        exp exp-ieee-table;
        ieee-802.1 default;
      }
    }
  }
}
```

Configuring the IEEE 802.1p Field for CoS Host Outbound Traffic

This topic provides a summary of the configuration for setting the IEEE 802.1p field in the Ethernet frame header for host outbound traffic (control plane traffic). You can set a global value for the priority code point that applies to all host outbound traffic. Additionally, or alternatively, you can specify that rewrite rules are applied to all host outbound traffic on egress logical interfaces. These are rules that have been previously configured to set the IEEE 802.1p field for data traffic on those interfaces.

Configuration of 802.1p bits is supported only on the following hardware and software components:

- EX Series switches
- MX Series 3D Universal Edge Routers
- Enhanced Queuing DPCs
- MPCs
- Junos OS Release 12.3 or later

To configure the IEEE 802.1p field settings:

1. (Optional) Specify a global default value for the IEEE 802.1p field for all host outbound traffic.

See [“Configuring a Global Default IEEE 802.1p Value for All Host Outbound Traffic” on page 1710](#).

2. (Optional) Specify that the IEEE 802.1p rewrite rules for the egress logical interfaces are applied to all host outbound traffic on those interfaces.

See [“Applying Egress Interface Rewrite Rules to the IEEE 802.1p Field for All Host Outbound Traffic on the Interface” on page 1711](#).

Related Documentation

Configuring a Global Default IEEE 802.1p Value for All Host Outbound Traffic

This topic describes how to configure a global default value for the IEEE 802.1p field for all host outbound traffic on MX Series routers and EX Series switches.

To configure a global default value for the IEEE 802.1p field:

- Specify the value.

```
[edit class-of-service host-outbound-traffic ieee-802.1]
user@host# set default value
```

For example, specify that a value of 010 is applied to all host outbound traffic:

```
[edit class-of-service host-outbound-traffic ieee-802.1]
user@host# set default 010
```

- [Rewriting Packet Header Information Overview on page 1690](#)

Applying Egress Interface Rewrite Rules to the IEEE 802.1p Field for All Host Outbound Traffic on the Interface

This topic describes how to apply rewrite rules for egress logical interfaces to the IEEE 802.1p field for all host outbound traffic on those interfaces on MX Series routers and EX Series switches.

This task requires separately configured rewrite rules that map packet loss priority information to the code point value in the 802.1p field for data traffic on egress logical interfaces. See *Rewriting Packet Header Information Overview* in the *Junos OS Class of Service Configuration Guide*.

To configure the rewrite rules:

1. Configure the CoS rewrite rules to map the forwarding class to the desired value for the 802.1p field.

See [“Configuring Rewrite Rules” on page 1694](#).

2. Associate the rewrite rules to the desired egress logical interfaces.

See *Applying Rewrite Rules to Output Logical Interfaces*.

3. (Optional) Configure the forwarding class for host outbound traffic. Do not configure this forwarding class if you want to use the default forwarding class assignment (input classification).

See [“Overriding the Input Classification” on page 1560](#).

To configure the rewrite rules to apply to the host outbound traffic IEEE 802.1p field:

- Configure the rewrite rules.

```
[edit class-of-service host-outbound-traffic ieee-802.1]
user@host# set rewrite-rules
```

```
[edit class-of-service]
rewrite-rules {
  ieee-802.1 rewrite_foo {
    forwarding-class network-control {
      loss-priority low code-point 101;
    }
  }
}
interfaces {
  ge-1/0/0 {
    unit 100 {
      rewrite-rules {
        ieee-802.1 rewrite_foo vlan-tag outer-and-inner;
      }
    }
  }
}
```

```

}
host-outbound-traffic {
    forwarding-class network-control;
}
host-outbound-traffic {
    ieee-802.1 {
        rewrite-rules;
    }
}

```

Setting Ingress DSCP Bits for Multicast Traffic over Layer 3 VPNs

By default, the DSCP bits on outer IP headers arriving at an ingress PE router using generic routing encapsulation (GRE) are not set for multicast traffic sent over an Layer 3 virtual private network (VPN) provider network. However, you can configure a type-of-service (ToS) rewrite rule so the router sets the DSCP bits of GRE packets to be consistent with the service provider's overall core network CoS policy. The bits are set at the core-facing interface of the ingress provider edge (PE) router. For more information about rewriting IP header bits, see [“Rewriting Packet Header Information Overview” on page 1690](#).

This section describes this configuration from a CoS perspective. The examples are not complete multicast or VPN configurations. For more information about multicast, see the *Multicast Protocols Configuration Guide*. For more information about Layer 3 VPNs, see the *Junos OS VPNs Configuration Guide*.

To configure the rewrite rules on the core-facing interface of the ingress PE, include the **rewrite-rules** statement at the **[edit class-of-service]** hierarchy level. You apply the rule to the proper ingress interface at the **[edit class-of-service interfaces]** hierarchy level to complete the configuration. This ingress DSCP rewrite is independent of classifiers placed on ingress traffic arriving on the customer-facing interface of the PE router.

The rewrite rules are applied to all unicast packets and multicast groups. You cannot configure different rewrite rules for different multicast groups. The use of DSCPv6 bits is not supported because IPv6 multicast is not supported. You can configure another rewrite rule for the EXP bits on MPLS CE-CE unicast traffic.

This example defines a rewrite rule called **dscp-rule** that establishes a value of **000000** for best-effort traffic. The rule is applied to the outgoing, core-facing PE interface **ge-2/3/0**.

```

[edit class-of-service]
rewrite-rules {
    dscp dscp-rule {
        forwarding-class best-effort {
            loss-priority low code-point 000000;
        }
    }
}

```

```

[edit class-of-service interfaces]

```

```

ge-2/3/0 {
  unit 0 {
    rewrite-rules {
      dscp dscp-rule;
    }
  }
}

```

Example

- [Example: Per-Node Rewriting of EXP Bits on page 1713](#)

Example: Per-Node Rewriting of EXP Bits

To configure a custom table to rewrite the EXP bits, also known as CoS bits, on a particular node, the classifier table and the rewrite table must specify exactly the same CoS values.

In addition, the least significant bit of the CoS value itself must represent the PLP value. For example, CoS value **000** must be associated with PLP **low**, **001** must be associated with PLP **high**, and so forth.

This example configures a custom table to rewrite the EXP bits on a particular node:

```

[edit class-of-service]
classifiers {
  exp exp-class {
    forwarding-class be {
      loss-priority low code-points 000;
      loss-priority high code-points 001;
    }
    forwarding-class af {
      loss-priority low code-points 010;
      loss-priority high code-points 011;
    }
    forwarding-class ef {
      loss-priority low code-points 100;
      loss-priority high code-points 101;
    }
    forwarding-class nc {
      loss-priority low code-points 110;
      loss-priority high code-points 111;
    }
  }
}
rewrite-rules {
  exp exp-rw {
    forwarding-class be {
      loss-priority low code-point 000;
      loss-priority high code-point 001;
    }
    forwarding-class af {
      loss-priority low code-point 010;
      loss-priority high code-point 011;
    }
    forwarding-class ef {
      loss-priority low code-point 100;

```

```
        loss-priority high code-point 101;
    }
    forwarding-class nc {
        loss-priority low code-point 110;
        loss-priority high code-point 111;
    }
}
}
```

exp

Syntax	<code>exp (rewrite-name default) protocol protocol-types;</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS Release 12.2. for ACX series
Description	Apply an MPLS experimental (EXP) rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules exp] hierarchy level.</p> <p>default—The default mapping.</p> <p>By default, IP precedence rewrite rules alter the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged. This default behavior applies to rewrite rules you configure for MPLS packets with IPv4 payloads. You configure these types of rewrite rules by including the mpls-inet-both or mpls-inet-both-non-vpn option at the [edit class-of-service interfaces <i>interface</i> <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules exp <i>rewrite-rule-name</i> protocol] hierarchy level. The IP precedence rewrite rules explanation does not apply to ACX Series Universal Access routers.</p> <p>On interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series Ethernet Services Routers and EX Series switches, we highly recommend that you configure the default option when you configure a behavior aggregate (BA) classifier that does not include a specific rewrite rule for MPLS packets. Doing so ensures that MPLS exp value is rewritten according to the BA classifier rules configured for forwarding or packet loss priority. This does not apply to ACX Series Universal Access routers.</p> <p>The remaining statement is explained separately.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

exp-push-push-push

Syntax	exp-push-push-push default;
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For M Series routers and EX Series switches, rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining CoS of an incoming non-MPLS packet.
Options	default —Apply the default MPLS EXP rewrite table.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • <i>Rewriting the EXP Bits of All Three Labels of an Outgoing Packet</i> • dscp (Rewrite Rules) on page 1382 • dscp-ipv6 (Class-of-Service) on page 1357 • exp on page 1358 • exp-swap-push-push on page 1724 • ieee-802.1 (Rewrite Rules on Logical Interface) on page 1360 • ieee-802.1ad on page 1362 • inet-precedence on page 1364 • rewrite-rules (Definition) on page 1481

exp-swap-push-push

Syntax	exp-swap-push-push default;
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For M Series routers and EX Series switches, rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining CoS of an incoming MPLS packet.
Options	default —Apply the default MPLS EXP rewrite table.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

forwarding-class (BA Classifiers)

Syntax	<code>forwarding-class <i>class-name</i> { <code>loss-priority level</code> <code>code-points</code> [<i>aliases</i>] [<i>bit-patterns</i>]; }</code>
Hierarchy Level	[edit class-of-service classifiers <i>type classifier-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Define forwarding class name and option values.
Options	<p><i>class-name</i>—Name of the forwarding class.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Defining Classifiers on page 1330 • <i>Example: Configuring CoS for a PBB Network</i>

frame-relay-de (Defining Loss Priority Maps)

Syntax	<pre>frame-relay-de <i>name</i> { loss-priority <i>level</i> <i>code-points</i> [<i>alias</i> <i>bits</i>]; }</pre>
Hierarchy Level	[edit class-of-service loss-priority-maps]
Release Information	Statement introduced in Junos OS Release 11.4.
Description	Define a Frame Relay discard eligibility (DE) bit loss priority map.
Options	<p><i>name</i>—Name of the loss priority map.</p> <p><i>loss-priority level</i>—Level of the loss priority to be applied based on the specified CoS values. The loss priority level can be one of the following:</p> <ul style="list-style-type: none">• high—Packet has high loss priority.• low—Packet has low loss priority.• medium-high—Packet has medium-high loss priority.• medium-low—Packet has medium-low loss priority. <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

host-outbound-traffic

Syntax	<pre> host-outbound-traffic { forwarding-class class-name; dscp-code-point value; ieee-802.1 { default value; rewrite-rules; } } </pre>
Hierarchy Level	[edit class-of-service]
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Statement introduced before Junos OS 11.4 for EX Series switches.</p>
Description	<p>Allow queue selection for all traffic generated by the Routing Engine (host). The selected queue must be configured properly. The configuration of specific DSCP code point bits for the ToS field of the generated packets is also allowed. Transit packets are not affected; only packets originating on the Routing Engine are affected. By default, the forwarding class (queue) and DSCP bits are set according to those given in <i>Default Routing Engine Protocol Queue Assignments</i>. This feature is not available on J Series routers.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

ieee-802.1 (Rewrite Rules on Logical Interface)

Syntax	ieee-802.1 (<i>rewrite-name</i> default) vlan-tag (outer outer-and-inner);
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4. vlan-tag statement introduced in Junos OS Release 8.1.
Description	Apply an IEEE-802.1 rewrite rule. For IQ PICs, you can only configure one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.
Options	rewrite-name —Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules ieee-802.1] hierarchy level. default —The default mapping.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Rewrite Rules on page 1694• <i>Example: Configuring CoS for a PBB Network</i>• dscp (Rewrite Rules) on page 1382• dscp-ipv6 (Class-of-Service) on page 1357• exp on page 1358• exp-push-push-push on page 1723• exp-swap-push-push on page 1724• ieee-802.1ad on page 1362• inet-precedence on page 1364• rewrite-rules (Definition) on page 1481

ieee-802.1 (Host Outbound Traffic)

Syntax	<pre>ieee-802.1 { default <i>value</i>; rewrite-rules; }</pre>
Hierarchy Level	[edit class-of-service host-outbound-traffic]
Release Information	Statement introduced in Junos OS Release 12.3.
Description	<p>Apply the IEEE 802.1p rewrite rules associated with the egress logical interface to the IEEE 802.1p PCP field for all host outbound traffic on that interface.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

ieee-802.1 (Rewrite Rules on Physical Interface)

Syntax	<pre>ieee-802.1 (<i>rewrite-name</i> default) ;</pre>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i>] rewrite-rules
Release Information	Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Access routers.
Description	Apply an IEEE-802.1 rewrite rule.
Options	<p><i>rewrite-name</i>—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules ieee-802.1] hierarchy level.</p> <p>default—The default mapping.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

ieee-802.1ad

Syntax	ieee-802.1ad (<i>rewrite-name</i> default) vlan-tag (outer outer-and-inner);
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced in Junos OS Release 9.2.
Description	Apply a IEEE-802.1ad rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules ieee-802.1ad] hierarchy level.</p> <p>default—The default rewrite bit mapping.</p> <p>vlan-tag—The rewrite rule is applied to the outer or outer-and-inner VLAN tag.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Configuring Rewrite Rules on page 1694• <i>Example: Configuring CoS for a PBB Network</i>• dscp (Rewrite Rules) on page 1382• dscp-ipv6 (Class-of-Service) on page 1357• exp on page 1358• exp-push-push-push on page 1723• exp-swap-push-push on page 1724• ieee-802.1 (Rewrite Rules on Logical Interface) on page 1360• inet-precedence on page 1364• rewrite-rules (Definition) on page 1481

import (Rewrite Rules)

Syntax	<code>import (rewrite-name default);</code>
Hierarchy Level	<code>[edit class-of-service rewrite-rules type rewrite-name]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify a default or previously defined rewrite-rules mapping to import.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the <code>[edit class-of-service rewrite-rules]</code> hierarchy level.</p> <p>default—The default rewrite-rules mapping.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Configuring Rewrite Rules on page 1694

inet-precedence

Syntax	<code>inet-precedence (rewrite-name default);</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Apply a IPv4 precedence rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules inet-precedence] hierarchy level.</p> <p>default—The default mapping. By default, IP precedence rewrite rules alter the first three bits on the type of service (ToS) byte while leaving the last three bits unchanged.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Configuring Rewrite Rules on page 1694• dscp (Rewrite Rules) on page 1382• dscp-ipv6 (Class-of-Service) on page 1357• exp on page 1358• exp-push-push-push on page 1723• exp-swap-push-push on page 1724• ieee-802.1 (Rewrite Rules on Logical Interface) on page 1360• ieee-802.1ad on page 1362• rewrite-rules (Definition) on page 1481

inet-precedence (Rewrite Rules on Physical Interface)

Syntax	<code>inet-precedence (<i>rewrite-name</i> default);</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> rewrite-rules]
Release Information	Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Access routers.
Description	Apply a IPv4 precedence rewrite rule.
Options	<p><i>rewrite-name</i>—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules inet-precedence] hierarchy level.</p> <p>default—The default mapping. By default, IP precedence rewrite rules alter the first three bits on the type of service (ToS) byte while leaving the last three bits unchanged.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

interfaces

```

Hierarchy Level [edit class-of-service]

Release Information Statement introduced before Junos OS Release 7.4.
Interface-set level added in Junos OS Release 8.5.

Description Configure interface-specific CoS properties for incoming packets.

NOTE: The dscp-ipv6 and ieee-802.1ad classifier types are not supported on ACX Series routers. For further information about support on ACX Series routers, see *Understanding CoS CLI Configuration Statements on ACX Series Universal Access Routers*.

Options The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

loss-priority (BA Classifiers)

Syntax	loss-priority <i>level</i> ;
Hierarchy Level	[edit class-of-service classifiers <i>type classifier-name</i> forwarding-class <i>class-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify packet loss priority value for a specific set of code-point aliases and bit patterns.
Options	<i>level</i> can be one of the following: <ul style="list-style-type: none">• high—Packet has high loss priority.• medium-high—Packet has medium-high loss priority.• medium-low—Packet has medium-low loss priority.• low—Packet has low loss priority.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Overview of BA Classifier Types on page 1321• Example: Configuring CoS for a PBB Network• Configuring Tricolor Marking on page 1447

loss-priority-maps

Syntax	<pre> loss-priority-maps { frame-relay-de <i>rewrite-name</i> { loss-priority <i>level</i> { <i>code-points</i> [<i>aliases</i>] [<i>bit-patterns</i>]; } } } </pre>
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced in JUNOS Release 11.4.
Description	Map the loss priority of incoming packets based on the CoS values.
Options	<p>frame-relay-de <i>rewrite-name</i>—Name of the Frame Relay DE bit loss priority map.</p> <p>loss-priority <i>level</i>—The loss priority level can be one of the following:</p> <ul style="list-style-type: none"> • high—Packet has high loss priority. • low—Packet has low loss priority. • medium-high—Packet has medium-high loss priority. • medium-low—Packet has medium-low loss priority. <p>The remaining statements are explained separately.</p>

vlan-tag

Syntax	vlan-tag (outer outer-and-inner);
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules ieee-802.1 (<i>rewrite-name</i> default)]
Release Information	Statement introduced in Junos OS Release 8.1.
Description	For Gigabit Ethernet IQ2 PICs only, apply this IEEE-802.1 rewrite rule to the outer or outer and inner VLAN tags.
Default	If you do not include this statement, the rewrite rule applies to the outer VLAN tag only.
Options	outer —Apply the rewrite rule to the outer VLAN tag only. outer-and-inner —Apply the rewrite rule to both the outer and inner VLAN tags.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

Overview

- [Routing Engine Protocol Queue Assignments on page 1745](#)

Routing Engine Protocol Queue Assignments

- [Default Routing Engine Protocol Queue Assignments on page 1745](#)
- [Changing the Routing Engine Outbound Traffic Defaults on page 1747](#)

Default Routing Engine Protocol Queue Assignments

[Table 128 on page 1746](#) lists (in alphabetical order) how Routing Engine-sourced traffic is mapped to output queues. The following caveats apply to [Table 128 on page 1746](#):

- For all packets sent to queue 3 over a VLAN-tagged interface, the software sets the 802.1p bit to 110.
- For IPv4 and IPv6 packets, the software copies the IP type-of-service (ToS) value into the 802.1p field independently of which queue the packets are sent out.
- For MPLS packets, the software copies the EXP bits into the 802.1p field.

Table 128: Routing Engine Protocol Queue Assignments

Routing Engine Protocol	Queue Assignment
Adaptive Services PIC	TCP tickle (keepalive packets for idle session generated with stateful firewall to probe idle TCP sessions) are sent from queue 0.
Bidirectional Forwarding Detection (BFD) Protocol	Queue 3
Border Gateway Protocol (BGP)	Queue 0
BGP TCP Retransmission	Queue 3
Cisco High-Level Data Link Control (HDLC)	Queue 3
Distance Vector Multicast Routing Protocol (DVMRP)	Queue 3
Frame Relay Local Management Interface (LMI)	Queue 3
Frame Relay Asynchronization permanent virtual circuit (PVC)/data link connection identifier (DLCI) status messages	Queue 3
FTP	Queue 0
Intermediate System-to-Intermediate System (IS-IS) Open Systems Interconnection (OSI)	Queue 3
Internet Group Management Protocol (IGMP) query	Queue 3
IGMP Report	Queue 0
IP version 6 (IPv6) Neighbor Solicitation	Queue 3
IPv6 Neighbor Advertisement	Queue 3
IPv6 Router Advertisement	Queue 0
Label Distribution Protocol (LDP) User Datagram Protocol (UDP) hello	Queue 3
LDP keepalive and Session data	Queue 0
LDP TCP Retransmission	Queue 3
Link Aggregation Control Protocol (LACP)	Queue 3

Table 128: Routing Engine Protocol Queue Assignments (*continued*)

Routing Engine Protocol	Queue Assignment
Link Services (LS) PIC	If link fragmentation and interleaving (LFI) is enabled, all routing protocol packets larger than 128 bytes are transmitted from queue 0. This ensures that VoIP traffic is not affected. Fragmentation is supported on queue 0 only.
Multicast listener discovery (MLD)	Queue 0
Multicast Source Discovery Protocol (MSDP)	Queue 0
MSDP TCP Retransmission	Queue 3
Multilink Frame Relay Link Integrity Protocol (LIP)	Queue 3
Open Shortest Path First (OSPF) protocol data unit (PDU)	Queue 3
Protocol Independent Multicast (PIM)	Queue 3
Real-time performance monitoring (RPM) probe packets	Queue 3
Resource Reservation Protocol (RSVP)	Queue 3
Routing Information Protocol (RIP)	Queue 3
Simple Network Management Protocol (SNMP)	Queue 0
SSH	Queue 0
Telnet	Queue 0
Virtual Router Redundancy Protocol (VRRP)	Queue 3
xnm-clear-text	Queue 0
xnm-ssl	Queue 0

Changing the Routing Engine Outbound Traffic Defaults

You can modify the default queue assignment (forwarding class) and DSCP bits used in the ToS field of packets generated by the Routing Engine. By default, the forwarding class (queue) and packet loss priority (PLP) bits are set according to the values given in [“Default DSCP and DSCP IPv6 Classifier” on page 1326](#).

TCP-related packets, such as BGP or LDP, use queue 3 (network control) for retransmitted traffic. Changing the defaults for Routing Engine-sourced traffic does not affect transit

or incoming traffic. The changes apply to all packets relating to Layer 3 and Layer 2 protocols, but not MPLS EXP bits or IEEE 802.1p bits. This feature applies to all application-level traffic such as FTP or ping operations as well.

This feature is not available on Juniper Networks J Series Services Routers.

The queue selected is global to the routing device. That is, the traffic is placed in the selected queue on all egress interfaces. In the case of a restricted interface, the Routing Engine-sourced traffic flows through the restricted queue.

The queue selected must be properly configured on all interfaces. For more information about configuring queues and forwarding classes, see [“Overview of Forwarding Classes” on page 1526](#).

To change the default queue and DSCP bits for Routing Engine-sourced traffic, include the **host-outbound-traffic** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
host-outbound-traffic {
  forwarding-class class-name;
  dscp-code-point value;
}
```

The following example places all Routing Engine-sourced traffic into queue 3 (network control) with a DSCP code point value of 101010:

```
[edit class-of-service]
host-outbound-traffic {
  forwarding-class network-control;
  dscp-code-point 101010;
}
```

exp

Syntax	exp (<i>rewrite-name</i> default) protocol <i>protocol-types</i> ;
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS Release 12.2. for ACX series
Description	Apply an MPLS experimental (EXP) rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules exp] hierarchy level.</p> <p>default—The default mapping.</p> <p>By default, IP precedence rewrite rules alter the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged. This default behavior applies to rewrite rules you configure for MPLS packets with IPv4 payloads. You configure these types of rewrite rules by including the mpls-inet-both or mpls-inet-both-non-vpn option at the [edit class-of-service interfaces <i>interface</i> <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules exp <i>rewrite-rule-name</i> protocol] hierarchy level. The IP precedence rewrite rules explanation does not apply to ACX Series Universal Access routers.</p> <p>On interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series Ethernet Services Routers and EX Series switches, we highly recommend that you configure the default option when you configure a behavior aggregate (BA) classifier that does not include a specific rewrite rule for MPLS packets. Doing so ensures that MPLS exp value is rewritten according to the BA classifier rules configured for forwarding or packet loss priority. This does not apply to ACX Series Universal Access routers.</p> <p>The remaining statement is explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

host-outbound-traffic

Syntax host-outbound-traffic {
 forwarding-class *class-name*;
 dscp-code-point *value*;
 ieee-802.1 {
 default *value*;
 rewrite-rules;
 }
 }

Hierarchy Level [edit class-of-service]

Release Information Statement introduced in Junos OS Release 8.4.
 Statement introduced before Junos OS 11.4 for EX Series switches.

Description Allow queue selection for all traffic generated by the Routing Engine (host). The selected queue must be configured properly. The configuration of specific DSCP code point bits for the ToS field of the generated packets is also allowed. Transit packets are not affected; only packets originating on the Routing Engine are affected. By default, the forwarding class (queue) and DSCP bits are set according to those given in *Default Routing Engine Protocol Queue Assignments*. This feature is not available on J Series routers.

The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
 interface-control—To add this statement to the configuration.

Hierarchy Level [edit class-of-service [interfaces](#)]

Release Information Statement introduced in Junos OS Release 8.4.

Description On the MX Series routers and EX Series switches, you can apply classifiers or rewrite rules to an integrated bridging and routing (IRB) interface. All types of classifiers and rewrite rules are allowed. These classifiers and rewrite rules are independent of others configured on the MX Series router and on EX Series switches.

The statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

CoS for Tunnels Overview

For Adaptive Services, Link Services, and Tunnel PICs installed on Juniper Networks M Series Multiservice Edge Routers and T Series Core Routers with enhanced Flexible PIC Concentrators (FPCs), class-of-service (CoS) information is preserved inside generic routing encapsulation (GRE) and IP-IP tunnels.

For the ES PIC installed on M Series and T Series routers with enhanced FPCs, class-of-service information is preserved inside IP Security (IPsec) tunnels. For IPsec tunnels, you do not need to configure CoS, because the ES PIC copies the type-of-service (ToS) byte from the inner IP header to the GRE or IP-IP header.

For IPsec tunnels, the IP header type-of-service (ToS) bits are copied to the outer IPsec header at encryption side of the tunnel. You can rewrite the outer ToS bits in the IPsec

header using a rewrite rule. On the decryption side of the IPsec tunnel, the ToS bits in the IPsec header are not written back to the original IP header field. You can still apply a firewall filter to the ToS bits to apply a packet action on egress. For more information about ToS bits and the Multiservices PICs, see *Multiservices PIC ToS Translation*. For more information about IPsec and Multiservices PICs, see the *Junos Services Interfaces Configuration Release 11.2*.

To configure CoS for tunnels, include the following statements at the **[edit class-of-service]** and **[edit interfaces]** hierarchy level:

```
[edit class-of-service]
interfaces {
  interface-name {
    unit logical-unit-number {
      rewrite-rules {
        dscp (rewrite-name | default);
        dscp-ipv6 (rewrite-name | default);
        exp (rewrite-name | default) protocol protocol-types;
        exp-push-push-push default;
        exp-swap-push-push default;
        ieee-802.1 (rewrite-name | default);
        inet-precedence (rewrite-name | default);
      }
    }
  }
}
rewrite-rules {
  (dscp | dscp-ipv6 | exp | ieee-802.1 | inet-precedence) rewrite-name {
    import (rewrite-name | default);
    forwarding-class class-name {
      loss-priority level code-point (alias | bits);
    }
  }
}
[edit interfaces]
gre-interface-name {
  unit logical-unit-number;
  copy-tos-to-outer-ip-header;
}
```

- [Configuration Statements on page 1770](#)

Configuration Task

- [Configuring CoS for Tunnels on page 1766](#)

Configuring CoS for Tunnels

To configure CoS for GRE and IP-IP tunnels, perform the following configuration tasks:

1. To configure the tunnel, include the **tunnel** statement at the **[edit interfaces ip-fpc/pic/port unit logical-unit-number]** or **[edit interfaces gr-fpc/pic/port unit logical-unit-number]** hierarchy level.
2. To rewrite traffic on the outbound interface, include the **rewrite-rules** statement at the **[edit class-of-service]** and **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy levels. For GRE and IP-IP tunnels, you can configure IP precedence and DSCP rewrite rules.
3. To classify traffic on the inbound interface, you can configure a behavior aggregate (BA) classifier or firewall filter. Include the **loss-priority** and **forwarding-class** statements at the **[edit firewall filter filter-name term term-name then]** hierarchy level, or the **classifiers** statement at the **[edit class-of-service]** hierarchy level.
4. For a GRE tunnel, the default is to set the ToS bits in the outer IP header to all 0s. To copy the ToS bits from the inner IP header to the outer, include the **copy-tos-to-outer-ip-header** statement at the **[edit interfaces gr-fpc/pic/port unit logical-unit-number]** hierarchy level. (This inner-to-outer ToS bits copying is already the default behavior for IP-IP tunnels.)

Examples

- [Example: Configuring CoS for Tunnels on page 1767](#)
- [Example: Configuring a GRE Tunnel to Copy ToS Bits to the Outer IP Header on page 1770](#)

Example: Configuring CoS for Tunnels

In [Figure 16 on page 1767](#), Router A acts as a tunnel ingress device. The link between interfaces **ge-1/0/0** in Router A and **ge-1/3/0** in Router B is the GRE or IP-IP tunnel. Router A monitors the traffic received from interface **ge-1/3/0**. By way of interface **ge-1/0/0**, Router C generates traffic to Router B.

Figure 16: CoS with a Tunnel Configuration

```
Router A [edit interfaces]
ge-1/0/0 {
  unit 0 {
    family inet {
      address 10.80.0.2/24;
    }
  }
}

        }
    }
}

```

```
Router C    [edit interfaces]
            ge-1/0/0 {
              unit 0 {
                family inet {
                  address 10.90.0.1/24;
                }
              }
            }

            [edit routing-options]
            static {
              route 1.1.1.1/32 next-hop 10.90.0.2;
              route 2.2.2.2/32 next-hop 10.90.0.2;
            }
```

Example: Configuring a GRE Tunnel to Copy ToS Bits to the Outer IP Header

Unlike IP-IP tunnels, GRE tunnels do not copy the ToS bits to the outer IP header by default. To copy the inner ToS bits to the outer IP header (which is required for some tunneled routing protocols) on packets sent by the Routing Engine, include the **copy-tos-to-outer-ip-header** statement at the logical unit hierarchy level of a GRE interface. This example copies the inner ToS bits to the outer IP header on a GRE tunnel:

```
[edit interfaces]
gr-0/0/0 {
  unit 0 {
    copy-tos-to-outer-ip-header;
    family inet;
  }
}
```

code-point

Syntax	<code>code-point [<i>aliases</i>] [<i>bit-patterns</i>];</code>
Hierarchy Level	[edit class-of-service rewrite-rules type <i>rewrite-name</i> forwarding-class <i>class-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify one or more code-point aliases or bit sets for association with a forwarding class.
Options	<i>aliases</i> —Name of each alias. <i>bit-patterns</i> —Value of the code-point bits, in decimal form.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	• Configuring Rewrite Rules on page 1694

dscp (Rewrite Rules)

Syntax	<code>dscp (rewrite-name default);</code>
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For IPv4 traffic, apply a Differentiated Services (DiffServ) code point (DSCP) rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules dscp] hierarchy level.</p> <p>default—The default mapping.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

exp

Syntax	<code>exp (rewrite-name default) protocol protocol-types;</code>
Hierarchy Level	<code>[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]</code>
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced before Junos OS Release 12.2. for ACX series
Description	Apply an MPLS experimental (EXP) rewrite rule.
Options	<p>rewrite-name—Name of a rewrite-rules mapping configured at the <code>[edit class-of-service rewrite-rules exp]</code> hierarchy level.</p> <p>default—The default mapping.</p> <p>By default, IP precedence rewrite rules alter the first three bits on the type-of-service (ToS) byte while leaving the last three bits unchanged. This default behavior applies to rewrite rules you configure for MPLS packets with IPv4 payloads. You configure these types of rewrite rules by including the mpls-inet-both or mpls-inet-both-non-vpn option at the <code>[edit class-of-service interfaces interface interface-name unit logical-unit-number rewrite-rules exp rewrite-rule-name protocol]</code> hierarchy level. The IP precedence rewrite rules explanation does not apply to ACX Series Universal Access routers.</p> <p>On interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series Ethernet Services Routers and EX Series switches, we highly recommend that you configure the default option when you configure a behavior aggregate (BA) classifier that does not include a specific rewrite rule for MPLS packets. Doing so ensures that MPLS exp value is rewritten according to the BA classifier rules configured for forwarding or packet loss priority. This does not apply to ACX Series Universal Access routers.</p> <p>The remaining statement is explained separately.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

exp-push-push-push

Syntax	exp-push-push-push default;
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For M Series routers and EX Series switches, rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining CoS of an incoming non-MPLS packet.
Options	default —Apply the default MPLS EXP rewrite table.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Rewriting the EXP Bits of All Three Labels of an Outgoing Packet</i>• dscp (Rewrite Rules) on page 1382• dscp-ipv6 (Class-of-Service) on page 1357• exp on page 1358• exp-swap-push-push on page 1724• ieee-802.1 (Rewrite Rules on Logical Interface) on page 1360• ieee-802.1ad on page 1362• inet-precedence on page 1364• rewrite-rules (Definition) on page 1481

exp-swap-push-push

Syntax	exp-swap-push-push default;
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For M Series routers and EX Series switches, rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining CoS of an incoming MPLS packet.
Options	default —Apply the default MPLS EXP rewrite table.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

forwarding-class (BA Classifiers)

Syntax	<code>forwarding-class <i>class-name</i> { <code>loss-priority level code-points</code> [<i>aliases</i>] [<i>bit-patterns</i>]; }</code>
Hierarchy Level	[edit class-of-service classifiers <i>type classifier-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Define forwarding class name and option values.
Options	<i>class-name</i> —Name of the forwarding class. The remaining statements are explained separately.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Defining Classifiers on page 1330• <i>Example: Configuring CoS for a PBB Network</i>

ieee-802.1 (Rewrite Rules on Logical Interface)

Syntax	<code>ieee-802.1</code> (<i>rewrite-name</i> default) vlan-tag (outer outer-and-inner);
Hierarchy Level	[edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i> rewrite-rules]
Release Information	Statement introduced before Junos OS Release 7.4. vlan-tag statement introduced in Junos OS Release 8.1.
Description	Apply an IEEE-802.1 rewrite rule. For IQ PICs, you can only configure one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.
Options	rewrite-name —Name of a rewrite-rules mapping configured at the [edit class-of-service rewrite-rules ieee-802.1] hierarchy level. default —The default mapping.
Required Privilege Level	interface —To view this statement in the configuration. interface-control —To add this statement to the configuration.

}
}

```

Hierarchy Level [edit class-of-service]

Release Information Statement introduced before Junos OS Release 7.4.
Interface-set level added in Junos OS Release 8.5.

Description Configure interface-specific CoS properties for incoming packets.

NOTE: The dscp-ipv6 and ieee-802.1ad classifier types are not supported on ACX Series routers. For further information about support on ACX Series routers, see *Understanding CoS CLI Configuration Statements on ACX Series Universal Access Routers*.

Options The remaining statements are explained separately.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

copy-tos-to-outer-ip-header

Syntax	copy-tos-to-outer-ip-header;
Hierarchy Level	[edit interfaces at- <i>fpc/pic/port</i> unit <i>logical-unit-number</i>], [edit logical-systems <i>logical-system-name</i> interfaces at- <i>fpc/pic/port</i> unit <i>logical-unit-number</i>]
Release Information	Statement introduced in Junos OS Release 8.2.
Description	For GRE tunnel interfaces only, enables the inner IP header's ToS bits to be copied to the outer IP packet header.
Default	If you omit this statement, the ToS bits in the outer IP header are set to 0.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring a GRE Tunnel to Copy ToS Bits to the Outer IP Header on page 1770

Overview

- Rate Limiting on page 1803

Rate Limiting

- Configuring the Junos OS ICMPv4 Rate Limit for ICMPv4 Routing Engine Messages on page 1803
- Configuring the Junos OS ICMPv6 Rate Limit for ICMPv6 Routing Engine Messages on page 1803

Configuring the Junos OS ICMPv4 Rate Limit for ICMPv4 Routing Engine Messages

To limit the rate at which ICMPv4 messages can be generated by the Routing Engine and sent to the Routing Engine, include the **icmpv4-rate-limit** statement at the **[edit system internet-options]** hierarchy level:

icmpv4-rate-limit bucket-size *bucket-size* packet-rate *packet-rate*;

The bucket size is the number of seconds in the rate-limiting bucket. The packet rate is the rate-limiting packets earned per second. Specify a **bucket-size** from 0 through 4294967295 seconds. The default value is 5 seconds. Specify a **packet-rate** from 0 through 4,294,967,295. The default value is 1000.

Layer 2 VLANs Overview

You can configure one or more VLANs to perform Layer 2 bridging. The Layer 2 bridging functions include integrated routing and bridging (IRB) for support for Layer 2 bridging and Layer 3 IP routing on the same interface, and virtual switches that isolate a LAN segment with its spanning-tree protocol instance and separate its VLAN ID space.

A VLAN is a set of logical ports that share the same flooding or broadcast characteristics and span one or more ports of multiple devices.

You can configure one or more VLANs to perform Layer 2 bridging. Thus, MX Series routers or EX Series switches can function as Layer 2 switches, each with multiple bridging, or broadcast, domains that participate in the same Layer 2 network. You can also configure Layer 3 routing support for a VLAN. Integrated routing and bridging (IRB) provides support for Layer 2 bridging and Layer 3 IP routing on the same interface. IRB enables you to route

packets to another routed interface or to another VLAN that has a Layer 3 protocol configured.

You can also group one or more VLANs within a single instance, or virtual switch. Multiple virtual switches, each of which operates independently of other virtual switches on the device, are supported. Virtual switches isolate a LAN segment with its spanning-tree protocol instance and separate its VLAN ID space. Thus, each virtual switch can participate in a different Layer 2 network.

VLANs provide support for a Layer 2 trunk port. A Layer 2 trunk interface enables you to configure a single logical interface to represent multiple VLANs on a physical interface. You can configure a set of VLANs and VLAN identifiers that are automatically associated with one or more Layer 2 trunk interfaces. Packets received on a trunk interface are forwarded within a VLAN that has the same VLAN identifier. A Layer 2 trunk interface also supports IRB within a VLAN. In addition, you can configure Layer 2 learning and forwarding properties that apply to the entire set of VLANs.

You can configure VPLS ports in a virtual switch instead of a dedicated routing instance of type **vpls** so that the logical interfaces of the Layer 2 VLANs in the virtual switch can handle VPLS routing instance traffic. Packets received on a Layer 2 trunk interface are forwarded within a VLAN that has the same VLAN identifier.

Layer 2 Learning and Forwarding Overview

You can configure Layer 2 MAC address and VLAN learning and forwarding properties in support of Layer 2 bridging. Unicast media access control (MAC) addresses are learned to avoid flooding the packets to all the ports in a VLAN. A source MAC entry is created in its source and destination MAC tables for each MAC address learned from packets received on ports that belong to the VLAN.

By default, Layer 2 address learning is enabled. You can disable MAC learning for a device or for a specific VLAN or logical interfaces. You can also configure the following Layer 2 forwarding properties:

- Timeout interval for MAC entries
- MAC accounting
- A limit to the number of MAC addresses learned from the logical interfaces

For more information about how to configure VLANs and virtual switches, see [“Configuring a VLAN” on page 1829](#) and [“Configuring a Layer 2 Virtual Switch” on page 1847](#).

Layer 2 Learning and Forwarding for VLANs Overview

When you configure a VLAN, Layer 2 address learning is enabled by default. The VLAN learns unicast media access control (MAC) addresses to avoid flooding the packets to all the ports in the VLAN. Each VLAN creates a source MAC entry in its source and destination MAC tables for each source MAC address learned from packets received on the ports that belong to the VLAN.

NOTE: Traffic is not flooded back onto the interface on which it was received. However, because this “split horizon” occurs at a late stage, the packet statistics displayed by commands such as `show interfaces queue` will include flood traffic.

You can optionally disable MAC learning either for the entire device or for a specific VLAN or logical interface. You can also configure the following Layer 2 learning and forwarding properties:

- Static MAC entries for logical interfaces only
- Limit to the number of MAC addresses learned from a specific logical interface or from all the logical interfaces in a VLAN
- Size of the MAC address table for the VLAN
- MAC accounting for a VLAN

Layer 2 Learning and Forwarding for VLANs Acting as a Switch for a Layer 2 Trunk Port

Layer 2 learning is enabled by default. A set of VLANs, configured to function as a switch with a Layer 2 trunk port, learns unicast media access control (MAC) addresses to avoid flooding packets to the trunk port.

NOTE: Traffic is not flooded back onto the interface on which it was received. However, because this “split horizon” occurs at a late stage, the packet statistics displayed by commands such as `show interfaces queue` will include flood traffic.

You can optionally disable Layer 2 learning for the entire set of VLANs as well as modify the following Layer 2 learning and forwarding properties:

- Limit the number of MAC addresses learned from the Layer 2 trunk port associated with the set of VLANs
- Modify the size of the MAC address table for the set of VLANs
- Enable MAC accounting for the set of VLANs

Guidelines for Configuring VLAN Identifiers for VLANs and VPLS Routing Instances

For a VLAN that is performing Layer 2 switching only, you do not have to specify a VLAN identifier.

For a VLAN that is performing Layer 3 IP routing, you must specify either a VLAN identifier or dual VLAN identifier tags.

For a VPLS routing instance, you must specify either a VLAN identifier or dual VLAN identifier tags.

MVRP

- [Understanding Multiple VLAN Registration Protocol \(MVRP\) on page 1824](#)

Understanding Multiple VLAN Registration Protocol (MVRP)

You can configure Multiple VLAN Registration Protocol (MVRP) on Juniper Networks MX Series routers and EX Series switches. The primary purpose of MVRP is to manage dynamic VLAN registration in switching networks. In managing dynamic VLAN registration, MVRP also prunes VLAN information.

MVRP is an Layer 2 application protocol of the Multiple Registration Protocol (MRP) and is defined in the IEEE 802.1ak standard. MRP and MVRP were designed by IEEE to perform the same functions as Generic Attribute Registration Protocol (GARP) and GARP VLAN Registration Protocol (GVRP) while overcoming some GARP and GVRP limitations, in particular limitations involving bandwidth usage and convergence time in large networks with large numbers of VLANs.

MVRP was created by IEEE as a replacement application for GVRP. MVRP and GVRP cannot be run concurrently to share VLAN information in a switching network.

This topic describes:

- [How MVRP Works on page 1824](#)
- [Basics of MVRP on page 1825](#)
- [MVRP Registration Modes on page 1825](#)
- [MRP Timers on page 1825](#)
- [MRP VLAN Messages on page 1826](#)
- [MVRP Limitations on page 1826](#)

How MVRP Works

The VLAN registration information sent by MVRP protocol data units (PDUs) includes the current VLANs membership—that is, which routers are members of which VLANs—and which router interfaces are in which VLAN. MVRP shares all information in the PDU with all routers participating in MVRP in the switching network.

MVRP stays synchronized using these PDUs. The routers in the network participating in MVRP receive these PDUs during state changes and update their MVRP states accordingly. MVRP timers dictate when PDUs can be sent and when routers receiving MVRP PDUs can update their MVRP information.

VLAN information is distributed as part of the MVRP message exchange process and can be used to dynamically create VLANs, which are VLANs created on one switch and propagated to other routers as part of the MVRP message exchange process. Dynamic VLAN creation using MVRP is enabled by default but can be disabled.

As part of ensuring that VLAN membership information is current, MVRP removes routers and interfaces from the VLAN information when they become unavailable. Pruning VLAN information has these benefits:

- Limits the network VLAN configuration to active participants only, reducing network overhead.
- Targets the scope of broadcast, unknown unicast, and multicast (BUM) traffic to interested devices only.

Basics of MVRP

MVRP is disabled by default. You can configure MVRP router interfaces to participate in MVRP for the switching network. MVRP can only be enabled on trunk interfaces, and dynamic VLAN configuration through MVRP is enabled by default when MVRP is enabled.

MVRP Registration Modes

The MVRP registration mode defines whether an interface does or does not participate in MVRP.

The following MVRP registration modes are configurable:

- forbidden—The interface does not register or declare VLANs (except statically configured VLANs).
- normal—The interface accepts MVRP messages and participates in MVRP. This is the default registration mode setting.
- restricted—The interface—The interface ignores all MVRP JOIN messages received for VLANs that are not statically configured on the interface.

MRP Timers

MVRP registration and updates are controlled by timers that are part of the MRP protocol. These timers are set on a per-interface basis and define when MVRP PDUs can be sent and when MVRP information can be updated on a switch.

The following timers are used to control the operation of MVRP:

- Join timer—Controls the interval for the next MVRP PDU transmit opportunity.
- Leave timer—Controls the period of time that an interface on the switch waits in the Leave state before changing to the unregistered state.
- LeaveAll timer—Controls the frequency with which the interface generates LeaveAll messages.

BEST PRACTICE: Maintain default timer settings unless there is a compelling reason to change the settings. Modifying timers to inappropriate values might cause an imbalance in the operation of MVRP.

MRP VLAN Messages

MVRP uses MRP messages to register and declare MVRP states for a switch and to inform the switching network that a switch is leaving MVRP. These messages are communicated as part of the PDU to communicate the state of a particular switch interface on the switching network to the other switches in the network.

The following messages are communicated for MVRP:

- Empty—VLAN information is not being declared and is not registered.
- In—VLAN information is not being declared but is registered.
- JoinEmpty—VLAN information is being declared but not registered.
- JoinIn—VLAN information is being declared and is registered.
- Leave—VLAN information that was previously registered is being withdrawn.
- LeaveAll—All registrations will be de-registered. Participants that want to participate in MVRP will need to re-register.
- New—VLAN information is new and possibly not previously registered.

MVRP Limitations

The following limitations apply when configuring MVRP:

- MVRP works with Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP), but not with VLAN Spanning Tree Protocol (VSTP).
- MVRP is allowed only on single tagged trunk ports.
- MVRP is not allowed if a physical interface has more than one logical interface.
- MVRP is only allowed if a logical has one trunk interface (unit 0).

Proxy ARP

- [Restricted and Unrestricted Proxy ARP Overview on page 1827](#)

Restricted and Unrestricted Proxy ARP Overview

By default, the Junos OS responds to an Address Resolution Protocol (ARP) request only if the destination address of the ARP request is local to the incoming interface.

For Ethernet Interfaces, you can configure the router or switches to proxy-reply to the ARP requests using the restricted or unrestricted proxy ARP configuration.

You might want to configure restricted or unrestricted proxy ARP for routers that act as provider edge (PE) devices in Ethernet Layer 2 LAN switching domains.

NOTE: From Junos OS Release 10.0 onward, Junos OS does not respond to proxy ARP requests with the default route 0.0.0.0. This behavior is in compliance with RFC 1027.

Restricted Proxy ARP

Restricted proxy ARP enables the router or switch to respond to the ARP requests in which the physical networks of the source and target are not the same and the router or switch has an active route to the target address in the ARP request. The router does not reply if the target address is on the same subnet and the same interface as the ARP requestor.

Unrestricted Proxy ARP

Unrestricted proxy ARP enables the router or switch to respond to any ARP request, on condition that the router has an active route to the destination address of the ARP request. The route is not limited to the incoming interface of the request, nor is it required to be a direct route.

WARNING: If you configure unrestricted proxy ARP, the proxy router replies to ARP requests for the target IP address on the same interface as the incoming ARP request. This behavior is appropriate for cable modem termination system (CMTS) environments, but might cause Layer 2 reachability problems if you enable unrestricted proxy ARP in other environments.

When an IP client broadcasts the ARP request across the Ethernet wire, the end node with the correct IP address responds to the ARP request and provides the correct MAC address. If the unrestricted proxy ARP feature is enabled, the router response is redundant and might fool the IP client into determining that the destination MAC address within its own subnet is the same as the address of the router.

NOTE: While the destination address can be remote, the source address of the ARP request must be on the same subnet as the interface upon which the ARP request is received. For security reasons, this rule applies to both unrestricted and restricted proxy ARP.

Topology Considerations for Unrestricted Proxy ARP

In most situations, you should not configure the router or switch to perform unrestricted proxy ARP. Do so only for special situations, such as when cable modems are used.

[Figure 17 on page 1828](#) and [Figure 18 on page 1828](#) show examples of situations in which you might want to configure unrestricted proxy ARP.

In [Figure 17 on page 1828](#), the edge device is not running any IP protocols. In this case, you configure the core router to perform unrestricted proxy ARP. The edge device is the client of the proxy.

In [Figure 18 on page 1828](#), the Broadband Remote Access Server (B-RAS) routers are not running any IP protocols. In this case, you configure unrestricted proxy ARP on the B-RAS interfaces. This allows the core device to behave as though it is directly connected to the end users.

Configuring a VLAN

A VLAN must include a set of logical interfaces that participate in Layer 2 learning and forwarding. You can optionally configure a VLAN identifier and a Layer 3 interface for the VLAN to also support Layer 3 IP routing.

To enable a VLAN, include the following statements:

```
[edit]
vans {
  vlan-name {
    domain-type bridge;
    interface interface-name;
    l3-interface interface-name;
```

```
    vlan-id (none | all | number);
    vlan-id-list [ vlan-id-numbers ];
    vlan-tags outer number inner number);
  }
}
```

You cannot use the slash (/) character in VLAN names. If you do, the configuration does not commit and an error is generated.

For the **vlan-id** statement, you can specify either a valid VLAN identifier or the **none** or **all** options.

To include one or more logical interfaces in the VLAN, specify an **interface-name** for an Ethernet interface you configured at the **[edit interfaces]** hierarchy level.

NOTE: A maximum of 4096 active logical interfaces are supported for a VLAN or on each mesh group in a virtual private LAN service (VPLS) instance configured for Layer 2 bridging.

By default, each VLAN maintains a Layer 2 forwarding database that contains media access control (MAC) addresses learned from packets received on the ports that belong to the VLAN. You can modify Layer 2 forwarding properties, for example, disabling MAC learning for the entire system or a VLAN, adding static MAC addresses for specific logical interfaces, and limiting the number of MAC addresses learned by the entire system, the VLAN, or a logical interface.

You can also configure spanning tree protocols to prevent forwarding loops.

Configuring VLAN Identifiers for VLANs and VPLS Routing Instances

You can configure VLAN identifiers for a VLAN or a VPLS routing instance in the following ways:

- By using either the **vlan-id** statement or the **vlan-tags** statement to configure a normalizing VLAN identifier. This topic describes how normalizing VLAN identifiers are processed and translated in a VLAN or a VPLS routing instance.
- By using the **input-vlan-map** and the **output-vlan-map** statements at the **[edit interfaces interface-name unit logic-unit-number]** or **[edit logical-systems logical-system-name interfaces interface-name unit logic-unit-number]** hierarchy level to configure VLAN mapping.

The **vlan-id** and **vlan-tags** statements are used to specify the normalizing VLAN identifier under the VLAN or VPLS routing instance. The normalizing VLAN identifier is used to perform the following functions:

- Translate, or normalize, the VLAN tags of packets received into a learn VLAN identifier.
- Create multiple learning domains that each contain a learn VLAN identifier. A learning domain is a MAC address database to which MAC addresses are added based on the learn VLAN identifier.

NOTE: You cannot configure VLAN mapping using the `input-vlan-map` and `output-vlan-map` statements if you configure a normalizing VLAN identifier for a VLAN or VPLS routing instance using the `vlan-id` or `vlan-tags` statements.

To configure a VLAN identifier for a VLAN, include either the `vlan-id` or the `vlan-tags` statement at the `[edit interfaces interface-name unit logic-unit-number]` or `[edit logical-systems logical-system-name interfaces interface-name unit logic-unit-number]` hierarchy level, and then include that logical interface in the VLAN configuration.

For a VPLS routing instance, include either the `vlan-id` or `vlan-tags` statement at the `[edit interfaces interface-name unit logic-unit-number]` or `[edit logical-systems logical-system-name interfaces interface-name unit logic-unit-number]` hierarchy level, and then include that logical interface in the VPLS routing instance configuration.

NOTE: For a single VLAN or VPLS routing instance, you can include either the `vlan-id` or the `vlan-tags` statement, but not both. If you do not configure a `vlan-id`, `vlan-tags`, or `vlan-id-list` [`vlan-id-numbers`] for the VLAN or the VPLS routing instance, the Layer 2 packets received are forwarded to the outbound Layer 2 interface without having the VLAN tag modified unless an `output-vlan-map` is configured on the Layer 2 interface. This results in a frame being forwarded to a Layer 2 interface with a VLAN tag that is different from what is configured for the Layer 2 interface. Note that a frame received from the Layer 2 interface is still required to match the VLAN tag(s) specified in the interface configuration. The invalid configuration may cause a Layer 2 loop to occur.

The VLAN tags associated with the inbound logical interface are compared with the normalizing VLAN identifier. If the tags are different, they are rewritten as described in [Table 129 on page 1834](#). The source MAC address of a received packet is learned based on the normalizing VLAN identifier.

NOTE: You do not have to specify a VLAN identifier for a VLAN that is performing Layer 2 switching only. To support Layer 3 IP routing, you must specify either a VLAN identifier or a pair of VLAN tags. However, you cannot specify the same VLAN identifier for more than one VLAN within a routing instance. Each VLAN must have a unique VLAN identifier.

If the VLAN tags associated with the outbound logical interface and the normalizing VLAN identifier are different, the normalizing VLAN identifier is rewritten to match the VLAN tags of the outbound logical interface, as described in [Table 130 on page 1835](#).

For the packets sent over the VPLS routing instance to be tagged by the normalizing VLAN identifier, include one of the following configuration statements:

- **vlan-id *number*** to tag all packets that are sent over the VPLS virtual tunnel (VT) interfaces with the VLAN identifier.
- **vlan-tags outer *number* inner *number*** to tag all packets sent over the VPLS VT interfaces with dual outer and inner VLAN tags.

Use the **vlan-id none** statement to have the VLAN tags removed from packets associated with an inbound logical interface when those packets are sent over VPLS VT interfaces. Note that those packets might still be sent with other customer VLAN tags.

The **vlan-id all** statement enables you to configure bridging for several VLANs with a minimum amount of configuration. Configuring this statement creates a learning domain for:

- Each inner VLAN, or learn VLAN, identifier of a logical interface configured with two VLAN tags
- Each VLAN, or learn VLAN, identifier of a logical interface configured with one VLAN tag

We recommend that you do not use customer VLAN IDs in a VPLS routing instance because customer VLAN IDs are used for learning only.

You should use the service VLAN ID in a VPLS routing instance, as in the following configuration:

```
[edit]
interface ge-1/1/1 {
  vlan-tagging;
  unit 1 {
    vlan-id s1; /* Service vlan */
    encapsulation vlan-vpls;
    input-vlan-map pop; /* Pop the service vlan on input */
    output-vlan-map push; /* Push the service vlan on output */
  }
}
interface ge-1/1/2 {
  encapsulation ethernet-vpls;
  unit 0;
}
routing-instances {
  V1 {
    instance-type vpls;
    vlan-id all;
    interface ge-1/1/1.1;
    interface ge-1/1/2.0;
  }
}
```

NOTE: If you configure the `vlan-id all` statement in a VPLS routing instance, we recommend using the `input-vlan-map pop` and `output-vlan-map push` statements on the logical interface to pop the service VLAN ID on input and push the service VLAN ID on output and in this way, limit the impact of double-tagged frames on scaling. You cannot use the native `vlan-id` statement when the `vlan-id all` statement is included in the configuration.

The `vlan-id-list [vlan-id-numbers]` statement enables you to configure bridging for multiple VLANs on a trunk interface. Configuring this statement creates a learning domain for:

- Each VLAN listed: `vlan-id-list [100 200 300]`
- Each VLAN in a range: `vlan-id-list [100-200]`
- Each VLAN in a list and range combination: `vlan-id-list [50, 100-200, 300]`

The following steps outline the process for bridging a packet received over a Layer 2 logical interface when you specify a normalizing VLAN identifier using either the `vlan-id number` or `vlan-tags` statement for a VLAN or a VPLS routing instance:

1. When a packet is received on a physical port, it is accepted only if the VLAN identifier of the packet matches the VLAN identifier of one of the logical interfaces configured on that port.
2. The VLAN tags of the received packet are then compared with the normalizing VLAN identifier. If the VLAN tags of the packet are different from the normalizing VLAN identifier, the VLAN tags are rewritten as described in [Table 129 on page 1834](#).
3. If the source MAC address of the received packet is not present in the source MAC table, it is learned based on the normalizing VLAN identifier.
4. The packet is then forwarded toward one or more outbound Layer 2 logical interfaces based on the destination MAC address. A packet with a known unicast destination MAC address is forwarded only to one outbound logical interface. For each outbound Layer 2 logical interface, the normalizing VLAN identifier configured for the VLAN or VPLS routing instance is compared with the VLAN tags configured on that logical interface. If the VLAN tags associated with an outbound logical interface do not match the normalizing VLAN identifier configured for the VLAN or VPLS routing instance, the VLAN tags are rewritten as described in [Table 130 on page 1835](#).

The tables below show how VLAN tags are applied for traffic sent to and from the VLAN, depending on how the `vlan-id` and `vlan-tags` statements are configured for the VLAN and on how identifiers are configured for the logical interfaces in a VLAN or VPLS routing instance. Depending on your configuration, the following rewrite operations are performed on VLAN tags:

- **pop**—Remove a VLAN tag from the top of the VLAN tag stack.
- **pop-pop**—Remove both the outer and inner VLAN tags of the frame.
- **pop-swap**—Remove the outer VLAN tag of the frame and replace the inner VLAN tag of the frame.

- **swap**—Replace the VLAN tag of the frame.
- **push**—Add a new VLAN tag to the top of the VLAN stack.
- **push-push**—Push two VLAN tags in front of the frame.
- **swap-push**—Replace the VLAN tag of the frame and add a new VLAN tag to the top of the VLAN stack.
- **swap-swap**—Replace both the outer and inner VLAN tags of the frame.

Table 129 on page 1834 shows specific examples of how the VLAN tags for packets sent to the VLAN are processed and translated, depending on your configuration. “—” means that the statement is not supported for the specified logical interface VLAN identifier. “No operation” means that the VLAN tags of the received packet are not translated for the specified input logical interface.

Table 129: Statement Usage and Input Rewrite Operations for VLAN Identifiers for a VLAN

VLAN Identifier of Logical Interface	VLAN Configurations for a VLAN			
	vlan-id none	vlan-id 200	vlan-id all	vlan tags outer 100 inner 300
none	No operation	push 200	—	push 100, push 300
200	pop 200	No operation	No operation	swap 200 to 300, push 100
1000	pop 1000	swap 1000 to 200	No operation	swap 1000 to 300, push 100
vlan-tags outer 2000 inner 300	pop 2000, pop 300	pop 2000, swap 300 to 200	pop 2000	swap 2000 to 100
vlan-tags outer 100 inner 400	pop 100, pop 400	pop 100, swap 400 to 200	pop 100	swap 400 to 300
vlan-id-range 10-100	—	—	No operation	—
vlan-tags outer 200 inner-range 10-100	—	—	pop 200	—

Table 130 on page 1835 shows specific examples of how the VLAN tags for packets sent from the VLAN are processed and translated, depending on your configuration. “—” means that the statement is not supported for the specified logical interface VLAN identifier. “No operation” means that the VLAN tags of the outbound packet are not translated for the specified output logical interface.

Table 130: Statement Usage and Output Rewrite Operations for VLAN Identifiers for a VLAN

VLAN Identifier of Logical Interface	VLAN Configurations for a VLAN			
	vlan-id none	vlan-id 200	vlan-id all	vlan tags outer 100 inner 300
none	no operation	pop 200	–	pop 100, pop 300
200	push 200	No operation	No operation	pop 100, swap 300 to 200
1000	push 1000	swap 200 to 1000	No operation	pop 100, swap 300 to 1000
vlan-tags outer 2000 inner 300	push 2000, push 300	swap 200 to 300, push 2000	push 2000	swap 100 to 2000
vlan-tags outer 100 inner 400	push 100, push 400	swap 200 to 400, push 100	push 100	swap 300 to 400
vlan-id-range 10-100	–	–	No operation	–
vlan-tags outer 200 inner-range 10-100	–	–	push 200	–

Configuring Integrated Routing and Bridging for VLANs

Integrated routing and bridging (IRB) provides simultaneous support for Layer 2 bridging and Layer 3 routing on the same interface. IRB enables you to route packets to another routed interface or to another VLAN that has an IRB interface configured. You configure a logical routing interface by specifying **irb** as an interface name at the **[edit interfaces]** hierarchy level and including that interface in the VLAN.

NOTE: You can include only one Layer 3 interface in a VLAN.

To configure a VLAN with IRB support, include the following statements:

```
[edit]
vlands {
  vlan-name {
    domain-type bridge;
    interface interface-name;
    l3-interface interface-name;
    vlan-id (none | number);
    vlan-tags outer number inner number;
  }
}
```

For each VLAN that you configure, specify a **vlan-name**. You must also specify the value **bridge** for the **domain-type** statement.

For the **vlan-id** statement, you can specify either a valid VLAN identifier or the **none** option.

NOTE: If you configure a Layer 3 interface to support IRB in a VLAN, you cannot use the **all** option for the **vlan-id** statement.

The **vlan-tags** statement enables you to specify a pair of VLAN identifiers; an **outer** tag and an **inner** tag.

NOTE: For a single VLAN, you can include either the **vlan-id** statement or the **vlan-tags** statement, but not both.

To include one or more logical interfaces in the VLAN, specify the **interface-name** for each Ethernet interface to include that you configured at the **[edit interfaces]** hierarchy level.

NOTE: A maximum of 4096 active logical interfaces are supported for a VLAN or on each mesh group in a VPLS routing instance configured for Layer 2 bridging.

To associate a Layer 3 interface with a VLAN, include the **l3-interface interface-name** statement and specify an **interface-name** you configured at the **[edit interfaces irb]** hierarchy level. You can configure only one Layer 3 interface for each VLAN.

IRB interfaces are supported for multicast snooping.

In multihomed VPLS configurations, you can configure VPLS to keep a VPLS connection up if only an IRB interface is available by configuring the **irb** option for the **connectivity-type** statement at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level. The **connectivity-type** statement has the **ce** and **irb** options. The **ce** option is the default and specifies that a CE interface is required to maintain the VPLS connection. By default, if only an IRB interface is available, the VPLS connection is brought down.

NOTE: When you configure IRB interfaces in more than one logical system on a device, all of the IRB logical interfaces share the same MAC address.

Configuring a Set of VLANs to Act as a Switch for a Layer 2 Trunk Port

You can configure a set of VLANs that are associated with a Layer 2 trunk port. The set of VLANs function as a switch. Packets received on a trunk interface are forwarded within a VLAN that has the same VLAN identifier. A trunk interface also provides support for IRB, which provides support for Layer 2 bridging and Layer 3 IP routing on the same interface.

To configure a Layer 2 trunk port and set of VLANs, include the following statements:

[edit interfaces]

```

interface-name {
  unit number {
    family ethernet-switching {
      interface-mode access;
      vlan-members (vlan-name | vlan-tag);
    }
  }
}
interface-name {
  native-vlan-id number;
  unit number {
    family ethernet-switching {
      interface-mode trunk;
      vlan-members (vlan-name | vlan-tag);
    }
  }
}
[edit vlans ]
vlan-name {
  vlan-id number;
  vlan-id-list [ vlan-id-numbers ];
  ....
}

```

You must configure a VLAN and VLAN identifier for each VLAN associated with the trunk interface. You can configure one or more trunk or access interfaces at the **[edit interfaces]** hierarchy level. An access interface enables you to accept packets with no VLAN identifier.

Disabling MAC Learning for a VLAN or Logical Interface

You can disable MAC learning for all logical interfaces in a specified VLAN, or for a specific logical interface in a VLAN. Disabling dynamic MAC learning prevents the specified interfaces from learning source MAC addresses.

To disable MAC learning for all logical interfaces in a VLAN in a virtual switch, include the **no-mac-learning** statement at the **[edit vlans vlan-name switch-options]** hierarchy level:

```

[edit]
vlans {
  vlan-name {
    domain-type bridge;
    interface interface-name;
    switch-options {
      no-mac-learning;
    }
  }
}

```

To disable MAC learning for a specific logical interface in a VLAN, include the **no-mac-learning** statement at the **[edit vlans vlan-name switch-options interface interface-name]** hierarchy level.

```

[edit]
vlans {
  vlan-name {
    domain-type bridge;
    interface interface-name;
  }
}

```

```
switch-options {  
  interface interface-name {  
    no-mac-learning;  
  }  
}
```

NOTE: When you disable MAC learning, source MAC addresses are not dynamically learned, and any packets sent to these source addresses are flooded into the VLAN.

NOTE: When you gather interfaces into a VLAN, the `no-mac-learn-enable` statement at the `[edit interfaces interface-name ether-options ethernet-switch-profile]` hierarchy level is not supported. You must use the `no-mac-learning` statement at the `[edit vlans vlan-name switch-options interface interface-name]` hierarchy level to disable MAC learning on an interface in a VLAN.

NOTE: When MAC learning is disabled for a VPLS routing instance, traffic is not load balanced and only one of the equal-cost next hops is used.

Disabling MAC Learning for a Set of VLANs

You can disable MAC learning for a set of VLANs. Disabling dynamic MAC learning prevents the Layer 2 trunk port associated with the set of VLANs from learning source and destination MAC addresses. When you disable MAC learning, source MAC addresses are not dynamically learned, and any packets sent to these source addresses are flooded into the switch.

To disable MAC learning for a set of VLANs, include the **no-mac-learning** statement at the `[edit switch-options]` hierarchy level:

```
[edit switch-options]  
no-mac-learning;
```

Enabling MAC Accounting

By default, MAC accounting is disabled. You can enable packet accounting either for a router or switch as a whole or for a specific VLAN. After you enable packet accounting, the Junos OS maintains packet counters for each MAC address learned.

To enable MAC accounting, include the **global-mac-statistics** statement at the `[edit protocols l2-learning]` hierarchy level:

```
[edit protocols l2-learning]  
global-mac-statistics;
```

Enabling MAC Accounting for a VLAN

By default, MAC accounting is disabled. You can enable packet counting for a VLAN. When you enable packet accounting, the Junos OS maintains packet counters for each MAC address learned on the interfaces in the VLAN.

To enable MAC accounting for a VLAN, include the **mac-statistics** statement at the **[edit vlans *vlan-name* switch-options]** hierarchy level:

```
[edit vlans vlan-name switch-options]
mac-statistics;
```

Enabling MAC Accounting for a Set of VLANs

By default, MAC accounting is disabled. You can enable packet counting for a set of VLANs. After you enable packet accounting, the Junos OS maintains packet counters for each MAC address learned on the trunk port associated with the set of VLANs.

To enable MAC accounting for a set of VLANs, include the **mac-statistics** statement at the **[edit switch-options]** hierarchy level:

```
[edit switch-options on page 430]
mac-statistics;
```

Configuring Inner and Outer TPIDs and VLAN IDs

For some rewrite operations, you must configure the inner or outer TPID values and inner or outer VLAN ID values. These values can be applied to either the input VLAN map or the output VLAN map.

On Ethernet IQ, IQ2, and IQ2-E interfaces; on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces; and on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, to configure the inner TPID, include the **inner-tag-protocol-id** statement:

```
inner-tag-protocol-id tpid;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**
- **[edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]**

For the inner VLAN ID, include the **inner-vlan-id** statement. For the outer TPID, include the **tag-protocol-id** statement. For the outer VLAN ID, include the **vlan-id** statement:

```
input-vlan-map {
  (pop | pop-pop | pop-swap | push | push-push | swap | swap-push | swap-swap);
  inner-tag-protocol-id tpid;
  inner-vlan-id number;
  tag-protocol-id tpid;
```

```

    vlan-id number;
  }
  output-vlan-map {
    (pop | pop-pop | pop-swap | push | push-push | swap | swap-push | swap-swap);
    inner-tag-protocol-id tpid;
    inner-vlan-id number;
    tag-protocol-id tpid;
    vlan-id number;
  }

```

For aggregated Ethernet interfaces using Gigabit Ethernet IQ interfaces, include the **tag-protocol-id** statement for the outer TPID. For the outer VLAN ID, include the **vlan-id** statement:

```

input-vlan-map {
  (pop | push | swap);
  tag-protocol-id tpid;
  vlan-id number;
}
output-vlan-map {
  (pop | push | swap);
  tag-protocol-id tpid;
  vlan-id number;
}

```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

The VLAN IDs you define in the input VLAN maps are stacked on top of the VLAN ID bound to the logical interface. For more information about binding a VLAN ID to the logical interface, see *802.1Q VLANs Overview*.

All TPIDs you include in input and output VLAN maps must be among those you specify at the [edit interfaces *interface-name* ether-options ethernet-switch-profile tag-protocol-id [*tpids*]] hierarchy level.

Table 131 on page 1840 and Table 132 on page 1841 specify when these statements are required. Table 131 on page 1840 indicates valid statement combinations for rewrite operations for the input VLAN map. “No” means the statement must not be included in the input VLAN map for the rewrite operation. “Optional” means the statement may be optionally specified for the rewrite operation in the input VLAN map. “Any” means that you must include the **vlan-id** statement, **tag-protocol-id** statement, **inner-vlan-id** statement, or **inner-tag-protocol-id** statement.

Table 131: Rewrite Operations and Statement Usage for Input VLAN Maps

Rewrite Operation	Input VLAN Map Statements			
	vlan-id	tag-protocol-id	inner-vlan-id	inner-tag-protocol-id
push	Optional	Optional	No	No

Table 131: Rewrite Operations and Statement Usage for Input VLAN Maps (*continued*)

	Input VLAN Map Statements			
pop	No	No	No	No
swap	Any	Any	No	No
push-push	Optional	Optional	Optional	optional
swap-push	Optional	Optional	Any	Any
swap-swap	Optional	Optional	Any	Any
pop-swap	No	No	Any	Any
pop-pop	No	No	No	No

Table 132 on page 1841 indicates valid statement combinations for rewrite operations for the output VLAN map. “No” means the statement must not be included in the output VLAN map for the rewrite operation. “Optional” means the statement may be optionally specified for the rewrite operation in the output VLAN map.

Table 132: Rewrite Operations and Statement Usage for Output VLAN Maps

	Output VLAN Map Statements			
Rewrite Operation	vlan-id	tag-protocol-id	inner-vlan-id	inner-tag-protocol-id
push	No	Optional	No	No
pop	No	No	No	No
swap	No	Optional	No	No
push-push	No	Optional	No	Optional
swap-push	No	Optional	No	Optional
swap-swap	No	Optional	No	Optional
pop-swap	No	No	No	Optional
pop-pop	No	No	No	No

The following examples use Table 131 on page 1840 and Table 132 on page 1841 and show how the **pop-swap** operation can be configured in an input VLAN map and an output VLAN map:

Input VLAN Map with inner-vlan-id Statement, Output VLAN Map with Optional inner-tag-protocol-id Statement	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>] <code>input-vlan-map { pop-swap; inner-vlan-id <i>number</i>; }</code> <code>output-vlan-map { pop-swap; inner-tag-protocol-id <i>tpid</i>; }</code>
--	---

Input VLAN Map with inner-tag-protocol-id Statement, Output VLAN Map with Optional inner-tag-protocol-id Statement	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>] <code>input-vlan-map { pop-swap; inner-tag-protocol-id <i>tpid</i>; }</code> <code>output-vlan-map { pop-swap; inner-tag-protocol-id <i>tpid</i>; }</code>
--	---

Input VLAN Map with inner-tag-protocol-id and inner-vlan-id Statements	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>] <code>input-vlan-map { pop-swap; inner-vlan-id <i>number</i>; inner-tag-protocol-id <i>tpid</i>; }</code>
---	---

Stacking a VLAN Tag

To stack a VLAN tag on all tagged frames entering or exiting the interface, include the **push**, **vlan-id**, and **tag-protocol-id** statements in the input VLAN map or the output VLAN map:

```
input-vlan-map input-vlan-map {
  push;
  vlan-id number;
  tag-protocol-id tpid;
}
output-vlan-map {
  push;
  tag-protocol-id tpid;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

The VLAN IDs you define in the input VLAN maps are stacked on top of the VLAN ID bound to the logical interface.

All TPIDs you include in input and output VLAN maps must be among those you specify at the [edit interfaces *interface-name* ether-options ethernet-switch-profile tag-protocol-id [*tpids*]] hierarchy level.

Configuring the Size of the MAC Address Table

You can modify the size of the MAC address table for each VLAN. The default table size is 5120 addresses. The minimum you can configure is 16 addresses, and the maximum is 1,048,575 addresses.

If the MAC table limit is reached, new addresses can no longer be added to the table. Unused MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added.

To modify the size of the MAC table, include the **mac-table-size** *limit* statement at the [edit vlans *vlan-name* switch-options] hierarchy level:

```
[edit]
vlans {
  vlan-name {
    domain-type bridge;
    switch-options {
      mac-table-size limit {
        packet-action drop;
```

```

    }
  }
}

```

Related Documentation

- [Configuring Static MAC Addresses for Logical Interfaces in a Bridge Domain](#)
- [Limiting MAC Addresses Learned from an Interface in a Bridge Domain](#)
- [Enabling MAC Accounting for a Bridge Domain](#)

Configuring Static MAC Addresses for Logical Interfaces in a VLAN

You can manually add static MAC entries for the logical interfaces in a VLAN. You can specify one or more static MAC addresses for each logical interface.

To add a static MAC address for a logical interface in a VLAN, include the **static-mac mac-address** statement at the **[edit vlans vlan-name switch-options interface interface-name]** hierarchy level.

```

[edit]
vlans {
  vlan-name {
    domain-type bridge;
    switch-options {
      interface interface-name {
        static-mac mac-address {
          <vlan-id number>;
        }
      }
    }
  }
}

```

You can optionally specify a VLAN identifier for the static MAC address by using the **vlan-id** statement. To specify a VLAN identifier for a static MAC address, you must use the **all** option when configuring a VLAN identifier for the VLAN.

NOTE: If a static MAC address you configure for a logical interface appears on a different logical interface, packets sent to that interface are dropped.

Related Documentation

- [Configuring the Size of the MAC Address Table on page 1843](#)
- [Enabling MAC Accounting for a VLAN on page 1839](#)

Disabling Layer 2 Learning and Forwarding

Disabling dynamic MAC learning on an MX Series router or an EX Series switch prevents all the logical interfaces on the router from learning source and destination MAC addresses.

To disable MAC learning for an MX Series router or an EX Series switch, include the **global-no-mac-learning** statement at the **[edit protocols l2-learning]** hierarchy level:

```
[edit protocols l2-learning]
global-no-mac-learning;
```

For information about how to configure a virtual switch, see *Configuring a Layer 2 Virtual Switch*.

Configuring Multiple VLAN Registration Protocol (MVRP)

Multiple VLAN Registration Protocol (MVRP) is used to manage dynamic VLAN registration in Carrier Ethernet network. You can use MVRP on MX Series routers or on EX Series switches.

For information about using MVRP on EX Series switches, see *Example: Configuring Automatic VLAN Administration Using MVRP on EX Series Switches*.

MVRP is disabled by default on MX Series routers and EX Series switches.

To enable MVRP or set MVRP options, follow these instructions:

- [Enabling MVRP on page 1845](#)
- [Disabling MVRP on page 1846](#)
- [Changing the Registration Mode to Disable Dynamic VLANs on page 1846](#)
- [Configuring Timer Values on page 1846](#)
- [Configuring the Multicast MAC address for MVRP on page 1847](#)
- [Configuring an MVRP Interface as a Point-to-Point Interface on page 1847](#)
- [Configuring MVRP Tracing Options on page 1847](#)

Enabling MVRP

MVRP can only be enabled on trunk interfaces.

To enable MVRP on a specific trunk interface (here, interface **ge-3/0/5**):

```
[edit protocols mvrp]
user@host# set interfaces ge-3/0/5
```

Disabling MVRP

MVRP is disabled by default. You only need to perform this procedure if you have previously enabled MVRP.

To disable MVRP on all trunk interfaces, use one of the following:

```
[edit protocols mvrp]
user@host# deactivate protocols mvrp
user@host# delete protocols mvrp
```

Changing the Registration Mode to Disable Dynamic VLANs

When the registration mode for an interface is set to **normal** (the default), dynamic VLANs are created on interfaces participating in MVRP. The dynamic VLANs created on one router device are then propagated by means of MVRP to other router devices in a topology.

However, Dynamic VLAN creation through MVRP can be disabled for all trunk interfaces on a router device or for individual trunk interfaces.

For information about disabling dynamic VLAN creation on an interface so that the interface does not register and does not participate in MVRP, see *Controlling the Management State of a VLAN in MVRP Configurations (CLI Procedure)*.

Configuring Timer Values

The timers in MVRP define the amount of time an interface waits to join or leave MVRP or to send or process the MVRP information for the router or switch after receiving an MVRP PDU:

- The join timer controls the amount of time the router waits to accept a registration request.
- The leave timer controls the period of time that the router waits in the Leave state before changing to the unregistered state.
- The leaveall timer controls the frequency with which the LeaveAll messages are communicated.

The default MVRP timer values are 200 ms for the join timer, 1000 ms for the leave timer, and 10000 ms for the leaveall timer.

BEST PRACTICE: Maintain default timer settings unless there is a compelling reason to change the settings. Modifying timers to inappropriate values might cause an imbalance in the operation of MVRP.

To set the join timer for a specific interface:

```
[edit protocols mvrp]
user@host# set interfaces ge-3/0/5 join-timer 300
```

To set the leave timer for a specific interface:

```
[edit protocols mvrp]
```

```
user@host# set interfaces ge-3/0/5 leave-timer 1200
```

To set the leaveall timer for a specific interface:

```
[edit protocols mvrp]
user@host# set interface ge-3/0/5 leaveall-timer 12000
```

Configuring the Multicast MAC address for MVRP

MVRP uses the customer MVRP multicast MAC address when MVRP is enabled. However, you can configure MVRP to instead use the provider MVRP multicast MAC address.

To configure MVRP to use the provider MVRP multicast MAC address:

```
[edit protocols mvrp]
user@host# set bpdu-destination-mac-address provider-bridge-group;
```

Configuring an MVRP Interface as a Point-to-Point Interface

Specify that a configured interface is connected point-to-point. If specified, a point-to-point subset of the MRP state machine provides a simpler and more efficient method to accelerate convergence on the network.

To specify that an MVRP interface is point-to-point (here, interface **ge-3/0/5**):

```
[edit protocols mvrp]
user@host# set interfaces ge-3/0/5 point-to-point;
```

Configuring MVRP Tracing Options

Set MVRP protocol-level tracing options.

To specify MVRP protocol tracing (here, the file is **/var/log/mvrp-log**, size is **2m**, number of files is **28**, the option **world-readable** indicates the log can be read by user, and MVRP is flagging **events**):

```
[edit protocols mvrp]
user@host# edit protocols mvrp traceoptions file /var/log/mvrp-log size 2m files 28
world-readable flag events
```

Configuring a Layer 2 Virtual Switch

A Layer 2 virtual switch, which isolates a LAN segment with its spanning-tree protocol instance and separates its VLAN ID space, filters and forwards traffic only at the data link layer. Each VLAN consists of a set of logical ports that participate in Layer 2 learning and forwarding. A virtual switch represents a Layer 2 network.

Two main types of interfaces are used in virtual switch hierarchies:

- Layer 2 logical interface—This type of interface uses the VLAN-ID as a virtual circuit identifier and the scope of the VLAN-ID is local to the interface port. This type of interface is often used in service-provider-centric applications.
- Access or trunk interface—This type of interface uses a VLAN-ID with global significance. The access or trunk interface is implicitly associated with VLANs based on VLAN membership. Access or trunk interfaces are typically used in enterprise-centric applications.

NOTE: The difference between access interfaces and trunk interfaces is that access interfaces can be part of one VLAN only and the interface is normally attached to an end-user device (packets are implicitly associated with the configured VLAN). In contrast, trunk interfaces multiplex traffic from multiple VLANs and usually interconnect switches.

To configure a Layer 2 virtual switch, include the following statements:

```
[edit]
routing-instances {
  routing-instance-name (
    instance-type virtual-switch;
    vlans vlan-name{
      vlan-id (all | none | number);
      [...configure optional VLAN parameters]
    }
  }
}
```

To enable a virtual switch, you must specify **virtual-switch** as the **instance-type**.

The VLANs that are specified with the **vlan-id** statement are included in the virtual switch.

You can configure other optional VLAN parameters in the virtual switch.

Related Documentation

- [Configuring a Layer 2 Virtual Switch with a Layer 2 Trunk Port on page 1848](#)

Configuring a Layer 2 Virtual Switch with a Layer 2 Trunk Port

You can associate one or more Layer 2 trunk interfaces with a virtual switch.

A virtual switch configured with a Layer 2 trunk port also supports IRB within a VLAN. IRB provides simultaneous support for Layer 2 bridging and Layer 3 IP routing on the same interface. Only an interface configured with the **interface-mode (access | trunk)** statement can be associated with a virtual switch. An access interface enables you to accept packets with no VLAN identifier.

In addition, you can configure Layer 2 learning and forwarding properties for the virtual switch.

To configure a virtual switch with a Layer 2 trunk interface, include the following statements:

```
[edit]
routing-instances {
  routing-instance-name {
    instance-type virtual-switch;
    interface interface-name;
    vlans name {
      vlan-id (all | none | number);
      [...configure optional VLAN parameters]
    }
  }
}
```

Related Documentation

- [Configuring a Layer 2 Virtual Switch on page 1847](#)

Configuring VLAN Encapsulation

To configure encapsulation on an interface, enter the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]
encapsulation type;
```

The following list contains important notes regarding encapsulation:

- Ethernet interfaces in VLAN mode can have multiple logical interfaces. In CCC and VPLS modes, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512 through 4094 are reserved for CCC or VPLS VLANs. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for CCC or VPLS VLANs.
- For encapsulation type **flexible-ethernet-services**, all VLAN IDs are valid.
- For some encapsulation types, including flexible Ethernet services, Ethernet VLAN CCC, and VLAN VPLS, you can also configure the encapsulation type that is used inside the VLAN circuit itself. To do this, include the **encapsulation** statement:

```
encapsulation (vlan-ccc | vlan-tcc | vlan-vpls);
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**
- You cannot configure a logical interface with VLAN CCC or VLAN VPLS encapsulation unless you also configure the physical device with the same encapsulation or with flexible Ethernet services encapsulation. In general, the logical interface must have a VLAN ID of 512 or higher; if the VLAN ID is 511 or lower, it will be subject to the normal destination filter lookups in addition to source address filtering. However if you configure flexible Ethernet services encapsulation, this VLAN ID restriction is removed.

In general, you configure an interface's encapsulation at the **[edit interfaces *interface-name*]** hierarchy level.

Example: Configuring VLAN Encapsulation on a Gigabit Ethernet Interface

Configure VLAN CCC encapsulation on a Gigabit Ethernet interface:

```
interfaces ge-2/1/0 {  
  vlan-tagging;  
  encapsulation vlan-ccc;  
  unit 0 {  
    encapsulation vlan-ccc;  
    vlan-id 600;  
  }  
}
```

Example: Configuring VLAN Encapsulation on an Aggregated Ethernet Interface

Configure VLAN CCC encapsulation on an aggregated Gigabit Ethernet interface:

```
interfaces ae0 {  
  vlan-tagging;  
  encapsulation vlan-vpls;  
  unit 0 {  
    vlan-id 100;  
  }  
}
```

Configuring Restricted and Unrestricted Proxy ARP

To configure restricted or unrestricted proxy ARP, include the **proxy-arp** statement:

proxy-arp (restricted |unrestricted);

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

To return to the default—that is, to disable restricted or unrestricted proxy ARP—delete the **proxy-arp** statement from the configuration:

```
[edit]  
user@host# delete interfaces interface-name unit logical-unit-number proxy-arp
```

You can track the number of restricted or unrestricted proxy ARP requests processed by the router or switch by issuing the **show system statistics arp** operational mode command.

NOTE: When proxy ARP is enabled as default or unrestricted, the router or switch responds to any ARP request as long as the device has an active route to the target address of the ARP request. This gratuitous ARP behavior can result in an error when the receiving interface and target response interface are the same and the end device (for example, a client) performs a duplicate address check. To prevent this error, configure the router or switch interface with the `no-gratuitous-arp-reply` statement. See *Configuring Gratuitous ARP* for information about how to disable responses to gratuitous ARP requests.

Rewriting a VLAN Tag and Adding a New Tag

On Ethernet IQ, IQ2 and IQ2-E interfaces, on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, and on Gigabit Ethernet and 10-Gigabit Ethernet interfaces on EX Series switches, to replace the outer VLAN tag of the incoming frame with a user-specified VLAN tag value, include the **swap-push** statement in the input VLAN map or output VLAN map:

swap-push

A user-specified outer VLAN tag is pushed in front. The outer tag becomes an inner tag in the final frame.

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* **input-vlan-map**]
- [edit interfaces *interface-name* unit *logical-unit-number* **output-vlan-map**]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* **input-vlan-map**]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* **output-vlan-map**]

See *Configuring Inner and Outer TPIDs and VLAN IDs* and *Configuring Inner and Outer TPIDs and VLAN IDs* for information about configuring inner and outer VLAN ID values and inner and outer TPID values required for VLAN maps.

Configuring VLAN Translation with a VLAN ID List

In many cases, the VLAN identifiers on the frames of an interface's packets are not correct. VLAN translation, or VLAN rewrite, allows you to configure bidirectional VLAN identifier translation with a list on frames arriving on and leaving from a logical interface. This lets you use unique VLAN identifiers internally and maintain legacy VLAN identifiers on logical interfaces.

To perform VLAN translation on the packets on a trunk interface, insert the **vlan-rewrite** statement at the **[edit interfaces *interface-name* unit *unit-number*]** hierarchy level. You must also include the **interface-mode trunk** statement within the **[edit interfaces *interface-name* unit *unit-number* family ethernet-switching]** hierarchy because VLAN translation is only supported on trunk interfaces. The reverse translation takes place on traffic exiting the interface. In other words, if VLAN 200 is translated to 500 on traffic entering the interface, VLAN 500 is translated to VLAN 200 on traffic leaving the interface.

The following example translates incoming trunk packets from VLAN identifier 200 to 500 and 201 to 501 (other valid VLAN identifiers are not affected):

```
[edit interfaces ge-1/0/1]
unit 0 {
  ... # Other logical interface statements
  family ethernet-switching {
    interface-mode trunk # Translation is only for trunks
    inner-vlan-id-list [ 100 500–600 ];
    vlan-rewrite {
      translate 200 500;
      translate 201 501;
    }
    ... # Other ethernet-switching statements
  }
}
```

NOTE: This example also translates frame VLANs from 500 to 200 and 501 to 201 on egress.

Configuring a Logical Interface for Access Mode

Enterprise network administrators can configure a single logical interface to accept untagged packets and forward the packets within a specified VLAN. A logical interface configured to accept untagged packets is called an *access interface* or *access port*.

`interface-mode access;`

You can include this statement at the following hierarchy levels:

- `[edit interfaces interface-name unit logical-unit-number family ethernet-switching]`
- `[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number family ethernet-switching]`

When an untagged or tagged packet is received on an access interface, the packet is accepted, the VLAN ID is added to the packet, and the packet is forwarded within the VLAN that is configured with the matching VLAN ID.

The following example configures a logical interface as an access port with a VLAN ID of 20 on routers and switches that support the enhanced Layer 2 software:

```
[edit interfaces ge-1/2/0]
unit 1 {
  family ethernet-switching {
    interface-mode access;
    vlan members 20;
  }
}
```

[Layer 2 Routing Instances Configuration Hierarchy](#)

Use the **vpls** routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN.

To configure routing instances for Layer 2 networks, include the following statements:

```
routing-instances {
  routing-instance-name {
    access {
      address-assignment {
        ... same statements as in the address-assignment subhierarchy in [edit access]
        Hierarchy Level ...
      }
      address-protection;
      description text;
      egress-protection {
        context-identifier context-id;
      }
      forwarding-options {
        ...forwarding-options...
      }
      instance-role role;
      instance-type type;
      interface interface-name;
      l2-domain-id-for-l3 id;
      l2vpn-id community;
      layer3-domain-identifier identifier;
      multicast-snooping-options {
        ... same statements as in [edit multicast-snooping-options] Hierarchy Level EXCEPT
        FOR ...
      }
    }
  }
}
```

```

            interface interface-name {
                interface-mac-limit limit {
                    packet-action drop;
                }
            }
            mac-statistics;
            mac-table-size limit {
                packet-action drop;
            }
            no-mac-learning;
            static-mac mac-address;
        }
    }
}
}
```

With the exception of the **instance-type virtual-switch** statement (which configures a virtual-switch routing instance), you can include the statements at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

The **instance-type virtual-switch** statement is not supported at the **[edit logical-systems *logical-system-name*]** hierarchy level.

bpdu-destination-mac-address

Syntax	bpdu-destination-mac-address provider-bridge-group;
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols mvrp], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type), [edit protocols mvrp], [edit routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type)
Release Information	Statement introduced in Junos OS Release 10.1 for MX Series routers.
Description	For Multiple VLAN Registration Protocol (MVRP) configurations, specifies the multicast address for MVRP. If configured, the provider MVRP multicast MAC address is used; otherwise, the Junos OS uses the customer MVRP multicast MAC address.
Default	By default, the provider MVRP multicast MAC address is used (if configured). Otherwise, the customer MVRP MAC address is used.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Automatic VLAN Administration Using MVRP • Configuring Multiple VLAN Registration Protocol (MVRP) on page 1845 • Verifying That MVRP Is Working Correctly on page 1937 • Understanding Multiple VLAN Registration Protocol (MVRP) on page 1824

bridge-priority

Syntax	<code>bridge-priority <i>priority</i>;</code>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> protocols (<i>mstp</i> <i>rstp</i>)],</p> <p>[edit logical-systems <i>logical-system-name</i> protocols <i>mstp msti msti-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> protocols <i>vstp vlan vlan-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (<i>mstp</i> <i>rstp</i>)],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols <i>mstp msti msti-id</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols <i>vstp vlan vlan-id</i>],</p> <p>[edit protocols (<i>mstp</i> <i>rstp</i>)],</p> <p>[edit protocols <i>mstp msti msti-id</i>],</p> <p>[edit protocols <i>vstp vlan vlan-id</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols (<i>mstp</i> <i>rstp</i>)],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols <i>mstp msti msti-id</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols <i>vstp vlan vlan-id</i>]</p>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p>
Description	Determine which bridge is elected as the root bridge. If two bridges have the same path cost to the root bridge, the bridge priority determines which bridge becomes the designated bridge for a LAN segment.
Options	<p><i>priority</i>—The bridge priority can be set only in increments of 4096.</p> <p>Range: 0 through 61,440</p> <p>Default: 32,768</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

encapsulation (Physical Interface)

Syntax	encapsulation (atm-ccc-cell-relay atm-pvc cisco-hdlc cisco-hdlc-ccc cisco-hdlc-tcc ethernet-bridge ethernet-ccc ethernet-over-atm ethernet-tcc ethernet-vpls ethernet-vpls-fr ether-vpls-over-atm-llc ethernet-vpls-ppp extended-frame-relay-ccc extended-frame-relay-ether-type-tcc extended-frame-relay-tcc extended-vlan-bridge extended-vlan-ccc extended-vlan-tcc extended-vlan-vpls flexible-ethernet-services flexible-frame-relay frame-relay frame-relay-ccc frame-relay-ether-type frame-relay-ether-type-tcc frame-relay-port-ccc frame-relay-tcc generic-services multilink-frame-relay-uni-nni ppp ppp-ccc ppp-tcc vlan-ccc vlan-vci-ccc vlan-vpls);
Hierarchy Level	[edit interfaces <i>interface-name</i>], [edit interfaces rlsq <i>number:number</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 11.1 for EX Series switches. Statement introduced in Junos OS Release 12.1 for PTX Series Packet Transport Switches (flexible-ethernet-services, ethernet-ccc, and ethernet-tcc options only).
Description	Specify the physical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.
Default	ppp—Use serial PPP encapsulation.
Options	<p>atm-ccc-cell-relay—Use ATM cell-relay encapsulation.</p> <p>atm-pvc—Use ATM PVC encapsulation.</p> <p>cisco-hdlc—Use Cisco-compatible High-Level Data Link Control (HDLC) framing.</p> <p>cisco-hdlc-ccc—Use Cisco-compatible HDLC framing on CCC circuits.</p> <p>cisco-hdlc-tcc—Use Cisco-compatible HDLC framing on TCC circuits for connecting different media.</p> <p>ethernet-bridge—Use Ethernet bridge encapsulation on Ethernet interfaces that have bridging enabled and that must accept all packets.</p> <p>ethernet-ccc—Use Ethernet CCC encapsulation on Ethernet interfaces that must accept packets carrying standard Tag Protocol ID (TPID) values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, CCC is not supported.</p> <p>ethernet-over-atm—For interfaces that carry IPv4 traffic, use Ethernet over ATM encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces. As defined in RFC 2684, <i>Multiprotocol Encapsulation over ATM Adaptation Layer 5</i>, this encapsulation type allows ATM interfaces to connect to devices that support only bridge protocol data units (BPDUs). Junos OS does not completely support bridging, but accepts BPDU packets as a default gateway. If you use the router as an edge device, then the router acts as a default gateway. It accepts Ethernet LLC/SNAP frames with IP or ARP in the payload, and drops the rest. For packets destined to the Ethernet LAN, a route lookup is done using the destination</p>

IP address. If the route lookup yields a full address match, the packet is encapsulated with an LLC/SNAP and MAC header, and the packet is forwarded to the ATM interface.

ethernet-tcc—For interfaces that carry IPv4 traffic, use Ethernet TCC encapsulation on interfaces that must accept packets carrying standard TPID values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC is not supported.

ethernet-vpls—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard TPID values. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

ethernet-vpls-fr—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

ethernet-vpls-ppp—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer layer 2 PPP connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use it to forward the packet into a given VPLS instance.

ether-vpls-over-atm-llc—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

extended-frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to CCC.

extended-frame-relay-ether-type-tcc—Use extended Frame Relay ether type TCC for Cisco-compatible Frame Relay for DLCIs 1 through 1022. This encapsulation type is used for circuits with different media on either side of the connection.

extended-frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits to connect different media. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to TCC.

extended-vlan-bridge—Use extended VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

extended-vlan-ccc—Use extended VLAN encapsulation on CCC circuits with Gigabit Ethernet and 4-port Fast Ethernet interfaces that must accept packets carrying 802.1Q values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, extended VLAN CCC is not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC is not supported.

extended-vlan-tcc—For interfaces that carry IPv4 traffic, use extended VLAN encapsulation on TCC circuits with Gigabit Ethernet interfaces on which you want to use 802.1Q tagging. For 4-port Gigabit Ethernet PICs, extended VLAN TCC is not supported.

extended-vlan-vpls—Use extended VLAN VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

flexible-ethernet-services—For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. Aggregated Ethernet bundles can use this encapsulation type. This encapsulation type allows you to configure any combination of route, TCC, CCC, Layer 2 virtual private networks (VPNs), and VPLS encapsulations on a single physical port. If you configure flexible Ethernet services encapsulation on the physical interface, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.

flexible-frame-relay—For IQ interfaces only, use flexible Frame Relay encapsulation when you want to configure multiple per-unit Frame Relay encapsulations. This encapsulation type allows you to configure any combination of TCC, CCC, and standard Frame Relay encapsulations on a single physical port. Also, each logical interface can have any DLCI value from 1 through 1022.

frame-relay—Use Frame Relay encapsulation.

frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits.

frame-relay-ether-type—Use Frame Relay ether type encapsulation for compatibility with the Cisco Frame Relay.

frame-relay-ether-type-tcc—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media.

frame-relay-port-ccc—Use Frame Relay port CCC encapsulation to transparently carry all the DLCIs between two customer edge (CE) routers without explicitly configuring each DLCI on the two provider edge (PE) routers with Frame Relay transport. When you use this encapsulation type, you can configure the **ccc** family only.

frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits to connect different media.

generic-services—Use generic services encapsulation for services with a hierarchical scheduler.

multilink-frame-relay-uni-nni—Use MLFR UNI NNI encapsulation. This encapsulation is used on link services, voice services interfaces functioning as FRF.16 bundles, and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

ppp—Use serial PPP encapsulation.

ppp-ccc—Use serial PPP encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

ppp-tcc—Use serial PPP encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

vlan-ccc—Use Ethernet VLAN encapsulation on CCC circuits.

vlan-vci-ccc—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only. All logical interfaces configured on the Ethernet interface must also have the encapsulation type set to **vlan-vci-ccc**.

vlan-vpls—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.

Required Privilege Level	interface —To view this statement in the configuration. interface-control —To add this statement to the configuration.

Release Information	Statement introduced before Junos OS Release 7.4. Option max-sessions-vs-a-ignore introduced in Junos OS Release 11.4.
Description	Configure protocol family information for the logical interface.

NOTE: Not all subordinate stanzas are available to every protocol family.

Options *family*—Protocol family:

- **any**—Protocol-independent family used for Layer 2 packet filtering

NOTE: This option is not supported on T4000 Type 5 FPCs.

- **ethernet-switching**—(M Series and T Series routers only) Configure only when the physical interface is configured with **ethernet-bridge** type encapsulation or when the logical interface is configured with **vlan-bridge** type encapsulation
- **ccc**—Circuit cross-connect protocol suite
- **inet**—Internet Protocol version 4 suite
- **inet6**—Internet Protocol version 6 suite
- **iso**—International Organization for Standardization Open Systems Interconnection (ISO OSI) protocol suite
- **mlfr-end-to-end**—Multilink Frame Relay FRF.15
- **mlfr-uni-nni**—Multilink Frame Relay FRF.16
- **multilink-ppp**—Multilink Point-to-Point Protocol
- **mpls**—Multiprotocol Label Switching (MPLS)
- **pppoe**—Point-to-Point Protocol over Ethernet
- **tcc**—Translational cross-connect protocol suite
- **tnp**—Trivial Network Protocol
- **vpls**—(M Series and T Series routers only) Virtual private LAN service

The remaining statements are explained separately.

Required Privilege Level *interface*—To view this statement in the configuration.

fast-aps-switch

Syntax	fast-aps-switch;
Hierarchy Level	[edit interfaces <i>interface-name</i> sonet-options aps]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	(M320 routers with Channelized OC3/STM1 Circuit Emulation PIC with SFP only and EX Series switches) Reduce the Automatic Protection Switching (APS) switchover time in Layer 2 circuits.
	<div>  <p>NOTE:</p> <ul style="list-style-type: none"> Configuring this statement reduces the APS switchover time only when the Layer 2 circuit encapsulation type for the interface receiving traffic from a Layer 2 circuit neighbor is SAToP. When the fast-aps-switch statement is configured in revertive APS mode, you must configure an appropriate value for revert time to achieve reduction in APS switchover time. To prevent the logical interfaces in the data path from being shut down, configure appropriate hold-time values on all the interfaces in the data path that support TDM. The fast-aps-switch statement cannot be configured when the APS annex-b option is configured. The interfaces that have the fast-aps-switch statement configured cannot be used in virtual private LAN service (VPLS) environments. </div>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> <i>Reducing APS Switchover Time in Layer 2 Circuits</i>

global-mac-limit

Syntax	<code>global-mac-limit <i>limit</i> { <code>packet-action</code> drop; }</code>
Hierarchy Level	[edit protocols l2-learning]
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6.
Description	(MX Series routers and EX Series switches only) Limit the number of media access control (MAC) addresses learned from the logical interfaces on the router.
Default	393,215 MAC addresses
Options	<i>limit</i> —Number of MAC addresses that can be learned systemwide. Range: 20 through 1,048,575 The remaining statement is explained separately in the “Summary of Bridge Domain Configuration Statements” chapter.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

interface

Syntax	<code>interface <i>interface-name</i>;</code>
Hierarchy Level	[edit bridge-domains <i>bridge-domain-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i>], [edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i>], [edit vlans on page 445 <i>vlan-name</i>]
Release Information	Statement introduced in Junos OS Release 8.4. Support for top-level configuration for the virtual-switch type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or a bridge domain configured within a virtual switch. Support for logical systems added in Junos OS Release 9.6. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	(MX Series routers and EX Series switches only) Specify the logical interfaces to include in the bridge domain, VLAN, VPLS instance, or virtual switch.
Options	<i>interface-name</i> —Name of a logical interface. For more information about how to configure logical interfaces, see the <i>Junos® OS Network Interfaces</i> .
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Configuring a Bridge Domain</i>• Configuring a VLAN on page 1829• <i>Configuring a Layer 2 Virtual Switch</i>• Configuring a Layer 2 Virtual Switch on page 1847

interface (MVRP)

Syntax	<pre>interface (all <i>interface-name</i>) { join-timer <i>milliseconds</i>; leave-timer <i>milliseconds</i>; leaveall-timer <i>milliseconds</i>; point-to-point; registration (forbidden normal restricted); }</pre>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> protocols mvrp],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type),</p> <p>[edit protocols mvrp],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type)</p>
Release Information	Statement introduced in Junos OS Release 10.1 for MX Series routers.
Description	Specify interfaces on which to configure Multiple VLAN Registration Protocol (MVRP).
Default	By default, MVRP is disabled.
Options	<p>all—All interfaces on the router or switch.</p> <p><i>interface-name</i>—Names of interface to be configured for MVRP.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Automatic VLAN Administration Using MVRP • Configuring Multiple VLAN Registration Protocol (MVRP) on page 1845 • Verifying That MVRP Is Working Correctly on page 1937 • Understanding Multiple VLAN Registration Protocol (MVRP) on page 1824

interface (Spanning Tree)

Syntax	<pre>interface <i>interface-name</i> { bpdv-timeout-action { alarm; block; } cost <i>cost</i>; edge; mode (p2p shared); no-root-port; priority <i>interface-priority</i>; }</pre>
Hierarchy Level	<pre>[edit logical-systems <i>logical-system-name</i> protocols (<i>mstp</i> <i>rstp</i> <i>vstp</i>)], [edit logical-systems <i>logical-system-name</i> protocols <i>vstp</i> vlan <i>vlan-id</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols (<i>mstp</i> <i>rstp</i> <i>vstp</i>)], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols <i>vstp</i> vlan <i>vlan-id</i>], [edit protocols (<i>mstp</i> <i>rstp</i> <i>vstp</i>)], [edit protocols <i>vstp</i> vlan <i>vlan-id</i>], [edit routing-instances <i>routing-instance-name</i> protocols (<i>mstp</i> <i>rstp</i> <i>vstp</i>)], [edit routing-instances <i>routing-instance-name</i> protocols <i>vstp</i> vlan <i>vlan-id</i>]</pre>
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6.
Description	Configure the interface to participate in the RSTP or MSTP instance.
Options	<i>interface-name</i> —Name of a Gigabit Ethernet or 10-Gigabit Ethernet interface. The remaining statements are explained separately.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Spanning-Tree Instance Interface on page 5042

interface-mac-limit

Syntax	<pre>interface-mac-limit <i>limit</i> { packet-action drop; }</pre>
Hierarchy Level	<pre>[edit bridge-domains <i>bridge-domain-name</i> bridge-options], [edit bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>], [edit logical-systems <i>logical-system-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options], [edit logical-systems <i>logical-system-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> switch-options], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> switch-options interface <i>interface-name</i>], [edit logical-systems <i>logical-system-name</i> switch-options], [edit logical-systems <i>logical-system-name</i> switch-options interface <i>interface-name</i>], [edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options], [edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>], [edit routing-instances <i>routing-instance-name</i> switch-options], [edit routing-instances <i>routing-instance-name</i> switch-options interface <i>interface-name</i>], [edit switch-options], [edit switch-options on page 430], [edit switch-options interface <i>interface-name</i>], [edit switch-options on page 430 interface <i>interface-name</i>], [edit vlans on page 445 <i>vlan-name</i> switch-options], [edit vlans on page 445 <i>vlan-name</i> switch-options interface <i>interface-name</i>]</pre>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Support for the switch-options statement added in Junos OS Release 9.2.</p> <p>Support for top-level configuration for the virtual-switch type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or a bridge domain configured within a virtual switch.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p> <p>[edit switch-options], [edit switch-options interface <i>interface-name</i>], [edit vlans <i>vlan-name</i> switch-options], and [edit vlans <i>vlan-name</i> switch-options interface <i>interface-name</i>] hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	<p>(MX Series routers or EX Series switches only) Configure a limit to the number of MAC addresses that can be learned from a bridge domain, VLAN, virtual switch, or set of bridge domains or VLANs.</p>
Default	1024 MAC addresses for each logical interface.

Options *limit*—Maximum number of MAC addresses learned from an interface.

Range: 1 through 131,071 MAC addresses per interface

The remaining statement is explained separately.

Required Privilege routing—To view this statement in the configuration.

Level routing-control—To add this statement to the configuration.

interface-mode

Syntax	interface-mode (access trunk);
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family bridge], [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family ethernet-switching] [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family bridge]
Release Information	Statement introduced in Junos OS Release 9.2. Statement introduced in Junos Release 12.3R2 for EX Series switches.
Description	Determines whether the logical interface accepts or discards packets based on VLAN tags. Specify the trunk option to accept packets with a VLAN ID that matches the list of VLAN IDs specified in the vlan-id-list statement, then forward the packet within the bridge domain or VLAN configured with the matching VLAN ID. Specify the access option to accept packets with no VLAN ID, then forward the packet within the bridge domain or VLAN configured with the VLAN ID that matches the VLAN ID specified in the vlan-id statement.
<div style="display: flex; align-items: center;">  <div> <p>NOTE: On MX Series routers, if you want IGMP snooping to be functional for a bridge domain, then you should not configure interface-mode and irb for that bridge. Such a configuration commit succeeds, but IGMP snooping is not functional, and a message informing the same is displayed. For more information, see <i>Configuring a Trunk Interface on a Bridge Network</i>.</p> </div> </div>	
Options	<p>access—Configure a logical interface to accept untagged packets. Specify the VLAN to which this interface belongs using the vlan-id statement.</p> <p>trunk—Configure a single logical interface to accept packets tagged with any VLAN ID specified with the vlan-id-list statement.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • <i>Configuring a Logical Interface for Access Mode</i> • <i>Configuring a Logical Interface for Trunk Mode</i>

interfaces

Syntax	<code>interfaces { ... }</code>
Hierarchy Level	[edit]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Configure interfaces on the router or switch.
Default	The management and internal Ethernet interfaces are automatically configured. You must configure all other interfaces.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Physical Interface Configuration Statements Overview</i>• <i>Configuring Aggregated Ethernet Link Protection</i>

isid

Syntax	<code>isid isid-number vlan-id-list [vlan-ids];</code>
Hierarchy Level	[edit routing-instances <i>routing-instance-name</i> service-groups <i>service-group-name</i> pbb-service-options]
Release Information	Statement introduced in JUNOS Release 10.0.
Description	For IEEE 802.1ah provider backbone bridge (PBB) configurations, configure the service identifier (I-SID) for the customer routing instance (I-component) service group.
Options	<i>isid</i> —Service identifier. Enter an I-SID in the range from 256 through 16777214 . <i>vlan-id-list [vlan-ids]</i> —List of service VLANs (S-VLANs).
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Example: Configuring E-LINE and E-LAN Services for a PBB Network</i>

isis-list

Syntax	isis-list all-service-groups;
Hierarchy Level	[edit interfaces <i>pseudo-logical-interface-name</i> unit <i>logical-unit-number</i> family bridge]
Release Information	Statement introduced in JUNOS Release 10.0.
Description	For IEEE 802.1ah provider backbone bridge (PBB) configurations, map all service identifiers (I-SIDs) specified for the service groups.
Options	all-service-groups —Map all service identifiers (I-SIDs) for the specified service groups.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Example: Configuring E-LINE and E-LAN Services for a PBB Network</i>

join-timer (MVRP)

Syntax	<code>join-timer <i>milliseconds</i>;</code>
Hierarchy Level	<code>[edit logical-systems <i>logical-system-name</i> protocols <i>mvrp</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols</code> <code> <i>mvrp</i> interface (all <i>interface-name</i>)] (for virtual switch instance type),</code> <code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols</code> <code> <i>mvrp</i>] (for virtual switch instance type),</code> <code>[edit logical-systems <i>logical-system-name</i> protocols <i>mvrp</i> interface (all <i>interface-name</i>)],</code> <code>[edit protocols <i>mvrp</i> interface (all <i>interface-name</i>)],</code> <code>[edit routing-instances <i>routing-instance-name</i> protocols <i>mvrp</i>] (for virtual switch instance</code> <code> type),</code> <code>[edit routing-instances <i>routing-instance-name</i> protocols <i>mvrp</i> interface (all <i>interface-name</i>)]</code> <code> (for virtual switch instance type)</code>
Release Information	Statement introduced in Junos OS Release 10.1 for MX Series routers.
Description	For Multiple VLAN Registration Protocol (MVRP), configure the maximum interval interfaces must wait before sending MVRP protocol data units (PDUs).
Default	200 milliseconds
Options	<i>milliseconds</i> —Interval that the interface must wait before sending MVRP PDUs. Maintain default timer settings unless there is a compelling reason to change the settings. Modifying timers to inappropriate values might cause an imbalance in the operation of MVRP.
Required Privilege Level	<code>routing</code> —To view this statement in the configuration. <code>routing-control</code> —To add this statement to the configuration.

l2-learning

Syntax	l2-learning { global-mac-limit <i>limit</i> ; global-mac-statistics; global-mac-table-aging-time <i>seconds</i> ; global-no-mac-learning; }
Hierarchy Level	[edit protocols]
Release Information	Statement introduced in Junos OS Release 8.4.
Description	(MX Series routers and EX Series switches only) Configure Layer 2 address learning and forwarding properties globally. The statements are explained separately.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • <i>Layer 2 Learning and Forwarding Overview</i>

l3-interface

Syntax	l3-interface <i>interface-name-logical-unit-number</i> ;
Hierarchy Level	[edit interfaces <i>ge-chassis/slot/port</i> unit <i>logical-unit-number</i> family ethernet-switching] [edit vlans <i>vlan-name</i>]
Release Information	Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series. [edit vlans <i>vlan-name</i>] hierarchy level introduced in Junos OS Release 12.3R2 for EX Series switches and MX Series routers.
Description	Associate a Layer 3 interface with the VLAN. Configure Layer 3 interfaces on trunk ports to allow the interface to transfer traffic between multiple VLANs. Within a VLAN, traffic is bridged, while across VLANs, traffic is routed.
Default	No Layer 3 (routing) interface is associated with the VLAN.
Options	<i>interface-name-logical-unit-number</i> —Name of a logical interface.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

leaveall-timer (MVRP)

Syntax	<code>leaveall-timer <i>milliseconds</i>;</code>
Hierarchy Level	<p>[edit logical-systems <i>logical-system-name</i> protocols mvrp],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvrp interface (all <i>interface-name</i>)] (for virtual switch instance type),</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type),</p> <p>[edit logical-systems <i>logical-system-name</i> protocols mvrp interface (all <i>interface-name</i>)],</p> <p>[edit protocols mvrp interface (all <i>interface-name</i>)],</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type),</p> <p>[edit routing-instances <i>routing-instance-name</i> protocols mvrp interface (all <i>interface-name</i>)] (for virtual switch instance type)</p>
Release Information	Statement introduced in Junos OS Release 10.1 for MX Series routers.
Description	For Multiple VLAN Registration Protocol (MVRP), configure the interval at which the LeaveAll state operates on the interface.
Default	10000 milliseconds
Options	<i>milliseconds</i> —Interval between the sending of Leave All messages. Maintain default timer settings unless there is a compelling reason to change the settings. Modifying timers to inappropriate values might cause an imbalance in the operation of MVRP.
Required Privilege Level	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>

Release Information Statement introduced in Junos OS Release 10.1 for MX Series routers.

Description For Layer 2 networks, configure Multiple VLAN Registration Protocol (MVRP) to dynamically share VLAN information and dynamically configure needed VLANs. Maintaining VLAN configurations based on active VLANs reduces the amount of traffic traveling in the network, saving network resources. MVRP is configured on trunk interfaces.

The remaining statements are explained separately.

Default MVRP is disabled by default.

Required Privilege Level routing—To view this statement in the configuration.
 routing-control—To add this statement to the configuration.

native-vlan-id

Syntax	<code>native-vlan-id <i>number</i>;</code>
Hierarchy Level	[edit interfaces <i>ge-fpc/pic/port</i>] [edit interfaces <i>interface-name</i>]
Release Information	Statement introduced in Junos OS Release 8.3. Statement introduced in Junos OS Release 12.2 for ACX Series Universal Access Routers. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	<p>For 1-, 4-, and 8-port Gigabit Ethernet IQ2 and IQ2-E PICs, for 1-port 10-Gigabit Ethernet IQ2 and IQ2-E PICs configured for 802.1Q flexible VLAN tagging, for all Ethernet interfaces on MX Series routers, and for aggregated Ethernet interfaces on IQ2 and IQ2-E PICs or MX Series DPCs, configure mixed tagging support for untagged packets on a port. When the native-vlan-id statement is included with the <i>flexible-vlan-tagging</i> statement, untagged packets are accepted on the same mixed VLAN-tagged port.</p> <p>The logical interface on which untagged packets are received must be configured with the same native VLAN ID as that configured on the physical interface. To configure the logical interface, include the vlan-id statement (matching the native-vlan-id statement on the physical interface) at the [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>] hierarchy level.</p> <p>When the native-vlan-id statement is included with the interface-mode the statement, untagged packets are accepted and forwarded within the bridge domain that is configured with the matching VLAN ID.</p>
	<div>  <p>NOTE: As per 12.3 Ethernet Interfaces Configuration Guide, native-vlan-id enables the tagged interface to accept untagged frames. However, when native-vlan-id is configured, VLAN ID is popped in egress as long as the VID in the outgoing frame matches the native-vlan-id.</p> </div>
Options	<p>number—VLAN ID number.</p> <p>Range: (ACX Series routers and EX Series switches) 0 through 4094.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

no-mac-learning

Syntax	no-mac-learning;
Hierarchy Level	<p>[edit bridge-domains <i>bridge-domain-name</i> bridge-options],</p> <p>[edit logical-systems <i>logical-system-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options],</p> <p>[edit logical-systems <i>logical-system-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>],</p> <p>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> switch-options],</p> <p>[edit logical-systems <i>logical-system-name</i> switch-options],</p> <p>[edit bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options],</p> <p>[edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i> bridge-options interface <i>interface-name</i>],</p> <p>[edit routing-instances <i>routing-instance-name</i> switch-options],</p> <p>[edit switch-options],</p> <p>[edit switch-options on page 430],</p> <p>[edit switch-options on page 430 interface <i>interface-name</i>],</p> <p>[edit vlans on page 445 <i>vlan-name</i> switch-options],</p> <p>[edit vlans on page 445 <i>vlan-name</i> switch-options interface <i>interface-name</i>]</p>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Support for the switch-options statement added in Junos OS Release 9.2.</p> <p>Support for top-level configuration for the virtual-switch type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or bridge domain configured within a virtual switch.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p> <p>[edit switch-options], [edit switch-options interface <i>interface-name</i>], [edit vlans <i>vlan-name</i> switch-options], and [edit vlans <i>vlan-name</i> switch-options interface <i>interface-name</i>] hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	(MX Series routers and EX Series switches only) Disable MAC learning for a virtual switch, for a bridge domain or VLAN, for a specific logical interface in a bridge domain or VLAN, or for a set of bridge domains or VLANs associated with a Layer 2 trunk port.
	<div>  <p>NOTE: When MAC learning is disabled for a VPLS routing instance, traffic is not load balanced and only one of the equal-cost next hops is used.</p> </div>
Default	MAC learning is enabled. Use no-mac-learning to disable MAC learning.

Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Layer 2 Learning and Forwarding for Bridge Domains Overview • Layer 2 Learning and Forwarding for VLANs Overview on page 1822 • Layer 2 Learning and Forwarding for Bridge Domains Functioning as Switches with Layer 2 Trunk Ports • Layer 2 Learning and Forwarding for VLANs Acting as a Switch for a Layer 2 Trunk Port on page 1823

output-vlan-map (Gigabit Ethernet IQ, 10-Gigabit Ethernet SFPP, and 10-Gigabit Ethernet SFP)

Syntax	<pre>output-vlan-map { (pop pop-pop pop-swap push push-push swap swap-push swap-swap); inner-tag-protocol-id <i>tpid</i>; inner-vlan-id <i>number</i>; tag-protocol-id <i>tpid</i>; vlan-id <i>number</i>; }</pre>
Hierarchy Level	<pre>[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i>]</pre>
Release Information	Statement introduced before Junos OS Release 7.4. pop-pop , pop-swap , push-push , swap-push , and swap-swap statements added in Junos OS Release 8.1.
Description	<p>For Gigabit Ethernet IQ and 10-Port 10-Gigabit Ethernet SFPP interfaces only, define the rewrite operation to be applied to outgoing frames on this logical interface.</p> <p>The statements are explained separately.</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

Release Information Statement introduced in Junos OS Release 8.4.
 Support for the **switch-options** statement added in Junos OS Release 9.2.
 Support for top-level configuration for the **virtual-switch** type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or a bridge domain configured within a virtual switch.
 Support for logical systems added in Junos OS Release 9.6.
 [edit switch-options interface *interface-name* **interface-mac-limit** *limit*], [edit switch-options **interface-mac-limit** *limit*], [edit switch-options **mac-table-size** *limit*], [edit vlans *vlan-name* switch-options interface *interface-name* **interface-mac-limit** *limit*], [edit vlans *vlan-name* switch-options **interface-mac-limit** *limit*], and [edit vlans *vlan-name* switch-options **mac-table-size** *limit*] hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series switches.

Description	(MX Series routers and EX Series switches only) Specify that packets for new source MAC addresses be dropped after the MAC address limit is reached. If this statement is not configured, then packets for new source MAC addresses are forwarded by default.
Default	Disabled. The default is for packets for new source MAC addresses to be forwarded after the MAC address limit is reached.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Layer 2 Learning and Forwarding for Bridge Domains Overview</i>• Layer 2 Learning and Forwarding for VLANs Overview on page 1822• <i>Layer 2 Learning and Forwarding for Bridge Domains Functioning as Switches with Layer 2 Trunk Ports</i>• Layer 2 Learning and Forwarding for VLANs Acting as a Switch for a Layer 2 Trunk Port on page 1823

point-to-point (MVRP)

Syntax	point-to-point;
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols mvrp interface (all <i>interface-name</i>)], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvrp interface (all <i>interface-name</i>)] (for virtual switch instance type), [edit protocols mvrp interface (all <i>interface-name</i>)], [edit routing-instances <i>routing-instance-name</i> protocols mvrp interface (all <i>interface-name</i>)] (for virtual switch instance type)
Release Information	Statement introduced in Junos OS Release 10.1 for MX Series routers. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	(Optional) For Multiple VLAN Registration Protocol (MVRP) configurations, configure an interface to be recognized as a point-to-point connection. If specified, a point-to-point subset of the MRP state machine is used to provide a simpler and more efficient method to accelerate convergence on the network. Point-to-point must be enabled after enabling MVRP for the interface to be recognized as a point-to-point connection.
Default	MVRP is disabled by default. point-to-point is disabled by default.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring Automatic VLAN Administration Using MVRP• Configuring Multiple VLAN Registration Protocol (MVRP) on page 1845• Verifying That MVRP Is Working Correctly on page 1937• Understanding Multiple VLAN Registration Protocol (MVRP) on page 1824• join-timer on page 1902• leaveall-timer on page 1904• leave-timer on page 1905• registration on page 1921

pop

Syntax	pop;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> input-vlan-map], [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> input-vlan-map], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Specify the VLAN rewrite operation to remove a VLAN tag from the top of the VLAN tag stack. The outer VLAN tag of the frame is removed. On MX series routers, this statement can be used on Gigabit Ethernet IQ and 10-Gigabit Ethernet IQ2 and IQ2-E interfaces, 10-Gigabit Ethernet LAN/WAN PIC, and aggregated Ethernet interfaces using Gigabit Ethernet IQ interfaces.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • <i>Removing a VLAN Tag</i>

pop-pop

Syntax	pop-pop;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> input-vlan-map], [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> input-vlan-map], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map]
Release Information	Statement introduced in Junos OS Release 8.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	<p>Specify the VLAN rewrite operation to remove both the outer and inner VLAN tags of the frame.</p> <p>On MX Series routers, you can use this statement on Gigabit Ethernet IQ, IQ2 and IQ2-E interfaces, 10-Gigabit Ethernet LAN/WAN PIC, and for aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs.,</p>
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Removing the Outer and Inner VLAN Tags</i>

pop-swap

Syntax	pop-swap;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> input-vlan-map], [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> input-vlan-map], [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map]
Release Information	Statement introduced in Junos OS Release 8.1. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Specify the VLAN rewrite operation to remove the outer VLAN tag of the frame, and replace the inner VLAN tag of the frame with a user-specified VLAN tag value. The inner tag becomes the outer tag in the final frame. On MX Series routers, you can use this statement for Gigabit Ethernet IQ, IQ2, and IQ2-E interfaces, 10-Gigabit Ethernet LAN/WAN PIC, and for aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

Release Information	<p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	<p>For Gigabit Ethernet IQ and 10-Gigabit Ethernet IQ2 and IQ2-E interfaces only, configure the outer TPID value. All TPIDs you include in input and output VLAN maps must be among those you specify at the [edit interfaces <i>interface-name</i> gigether-options ethernet-switch-profile tag-protocol-id [<i>tpids</i>]] hierarchy level.</p> <p>For 10-Gigabit Ethernet LAN/WAN PIC interfaces on T Series routers, value the default TPID value (0x8100) is supported.</p>
Default	If the tag-protocol-id statement is not configured, the TPID value is 0x8100.
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> Configuring Inner and Outer TPIDs and VLAN IDs

traceoptions (MVRP)

Syntax	<pre>traceoptions { file <i>name</i> <size <i>size</i>> <files <i>number</i>> <(world-readable no-world-readable)>; flag <i>flag</i> <flag-modifier> <disable>; }</pre>
Hierarchy Level	[edit logical-systems <i>logical-system-name</i> protocols mvrp], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type), [edit protocols mvrp], [edit routing-instances <i>routing-instance-name</i> protocols mvrp] (for virtual switch instance type)
Release Information	Statement introduced in Junos OS Release 10.1 for MX Series routers.
Description	For Multiple VLAN Registration Protocol (MVRP), configure tracing options.
Default	Traceoptions is disabled.
Options	<p>disable —(Optional) Disable the tracing operation. One use of this option is to disable a single operation when you have defined a broad group of tracing operations, such as all.</p> <p>file <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. To include the file statement, you must specify a filename. Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. We recommend that you place MVRP tracing output in the file <code>/var/log/mvrp-log</code>.</p> <p>files <i>number</i>—(Optional) Maximum number of trace files, in the range from 2 through 1000. The default is 1 trace file. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the size option.</p> <p>flag <i>flag</i>—Specify which tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none">• all—Enable all trace options flags.• error—Trace all failure conditions.• events—Trace process state change and cleanup events.• pdu—Trace RAPS PDU reception and transmission.• socket—Trace socket activity.• state-machine—Trace information about the state machine.• timers—Trace protocol timers.

no-world-readable—(Optional) Prevent any user from reading the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB) or megabytes (MB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file.0***. When the ***trace-file*** again reaches its maximum size, ***trace-file.0*** is renamed ***trace-file.1*** and ***trace-file*** is renamed ***trace-file.0***. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten. The file size range is from 10240 through 4294967295. The default file size is 1MB.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level	routing—To view this statement in the configuration.
	routing-control—To add this statement to the configuration.

vlan-id (Bridge Domain or VLAN)

Syntax	<code>vlan-id (all none <i>number</i>);</code>
Hierarchy Level	<code>[edit bridge-domains <i>bridge-domain-name</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> bridge-domains <i>bridge-domain-name</i>],</code> <code>[edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i></code> <code>bridge-domains <i>bridge-domain-name</i>],</code> <code>[edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i>]</code> <code>[edit vlans <i>vlan-name</i>]</code>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Support for Layer 2 trunk ports added in Junos OS Release 9.2.</p> <p>Support for SRX 3400, SRX 3600, SRX 5600, and SRX 5800 devices added in Junos OS Release 9.6.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p> <p>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Specify a VLAN identifier (VID) to include in the packets sent to and from the bridge domain or VLAN, or a VPLS routing instance.

NOTE: When configuring a VLAN identifier for provider backbone bridge (PBB) routing instances, dual-tagged VIDs and the none option are not permitted.

Options *number*—A valid VLAN identifier. If you configure multiple bridge domains or VLANs with a valid VLAN identifier, you must specify a unique VLAN identifier for each. However, you can use the same VLAN identifier for bridge domains or VLANs that belong to different virtual switches. Use this option to send single tagged frames with the specified VLAN identifier over VPLS VT interfaces.

NOTE: If you specify a VLAN identifier, you cannot also use the all option. They are mutually exclusive.

all—Specify that the bridge domain or VLAN spans all the VLAN identifiers configured on the member logical interfaces.

NOTE: You cannot specify the all option if you include a routing interface in the bridge domain or VLAN.

none—Specify to enable shared VLAN learning or to send untagged frames over VPLS VT interfaces.

NOTE: Multichassis link aggregation (MC-LAG) does not support the none option with the vlan-id statement with bridge domains or VLANs.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

vlan-rewrite

Syntax	vlan-rewrite translate (200 500 201 501)
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>number</i> family bridge interface-mode trunk] [edit interfaces <i>interface-name</i> unit <i>number</i> family ethernet-switching interface-mode trunk]
Release Information	Statement introduced in Junos OS Release 9.4. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Translates an incoming VLAN to a bridge-domain VLAN, corresponding counter translation at egress. Supports translation of VLAN 200 to VLAN 500 and VLAN 201 to VLAN 501. Other valid VLANs pass through without translation.
Options	translate 200 500 —Translates incoming packets with VLAN 200 to 500. translate 201 501 —Translates incoming packets with VLAN 201 to 501. translate 202 502 —Translates incoming packets with VLAN 202 to 502.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Rewriting a VLAN Tag and Adding a New Tag on page 1851

vlan-tags

Syntax	<code>vlan-tags outer <i>number</i> inner <i>number</i>;</code>
Hierarchy Level	[edit bridge-domains <i>bridge-domain-name</i>], [edit logical-systems <i>logical-system-name</i> bridge-domains <i>bridge-domain-name</i>], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i>], [edit routing-instances <i>routing-instance-name</i> bridge-domains <i>bridge-domain-name</i>] [edit vlans on page 445 <i>vlan-name</i>]
Release Information	Statement introduced in Junos OS Release 8.4. Support for logical systems added in Junos OS Release 9.6. Statement introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	Specify dual VLAN identifier tags for a bridge domain, VLAN, or VPLS routing instance.
Options	outer <i>number</i> —A valid VLAN identifier. inner <i>number</i> —A valid VLAN identifier.
Required Privilege Level	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.

Routine Monitoring

- [Verifying That MVRP Is Working Correctly on page 1937](#)

Verifying That MVRP Is Working Correctly

Purpose	After configuring your MX Series router or EX Series switch to participate in Multiple VLAN Registration Protocol (MVRP), verify that the configuration is properly set and that MVRP messages are being sent and received on your switch.
Action	1. Confirm that the router is declaring Virtual LANs (VLANs).

Show that MVRP is enabled:

```
user@host> show mvrp
MVRP configuration for routing instance 'default-switch'
MVRP dynamic VLAN creation : Enabled
MVRP BPDU MAC address      : Customer bridge group (01-80-C2-00-00-21)
MVRP timers (ms)
  Interface   Join   Leave  LeaveAll
  ge-11/3/0   200   800    10000
```

Show the MVRP applicant state:

```
user@host> show mvrp applicant-state
MVRP applicant state for routing instance 'default-switch'
(V0) Very anxious observer, (VP) Very anxious passive, (VA) Very anxious new,
(AN) Anxious new, (AA) Anxious active, (QA) Quiet active, (LA) Leaving active,
(AO) Anxious observer, (QO) Quiet observer, (LO) Leaving observer,
(AP) Anxious passive, (QP) Quiet passive
```

VLAN Id	Interface	State
100	ge-11/3/0	Declaring (QA)
200	ge-11/3/0	Declaring (QA)
300	ge-11/3/0	Declaring (QA)

2. Confirm that VLANs are registered on interfaces.

List VLANs in the registered state:

```
user@host> show mvrp registration-state
MVRP registration state for routing instance 'default-switch'
```

VLAN Id	Interface	Registrar State	Forced State	Managed State	STP State
100	ge-11/3/0	Registered	Registered	Normal	Forwarding
200	ge-11/3/0	Registered	Registered	Normal	Forwarding
300	ge-11/3/0	Empty	Empty	Normal	Forwarding

3. Display a list of VLANs created dynamically.

List dynamic VLAN membership:

```
user@host> show mvrp dynamic-vlan-memberships
MVRP dynamic vlans for routing instance 'default-switch'
(s) static vlan, (f) fixed registration
```

VLAN Id	Interfaces
100	ge-3/3/0 ge-3/0/5
200	ge-3/3/0 ge-3/0/5

Meaning The output of `show mvrp applicant-state` shows that trunk interface `ge-11/3/0` is declaring (sending out) interest in the VLAN IDs `100`, `200`, and `300` and MVRP is operating properly.

The output of `show mvrp registrant-state` shows the registrar state for VLANs `100` and `200` as **Registered**, indicating that these VLANs are receiving traffic from a customer site. VLAN `300` is in an **Empty** state and is not receiving traffic from a customer site.

The output of the **show mvrp dynamic-vlan-membership** shows that VLANs 100 and 200 are created dynamically (here, on an MX Series router operating as an aggregation switch between MX Series routers operating as edge switches). VLANs created statically are marked with an (s) (which is not indicated in this output).

show ethernet-switching interface

Syntax	show ethernet-switching interface <brief detail extensive> <interface-name>
Release Information	Command introduced in Junos OS Release 12.3R2. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	(MX Series routers and EX Series switches only) Display Layer 2 learning information for all the interfaces.
Options	none —Display Ethernet-switching information for all interfaces. brief detail extensive —(Optional) Display the specified level of output. interface-name —(Optional) Display Ethernet-switching information for the specified interface.
Required Privilege Level	view
List of Sample Output	show ethernet-switching interface ae10.0 on page 1945
Output Fields	Table 133 on page 1944 describes the output fields for the show ethernet-switching interface command. Output fields are listed in the approximate order in which they appear.

Table 133: show ethernet-switching interface Output Fields

Field Name	Field Description
Logical interface	Name of the logical interface.
VLAN members	VLANs associated with this interface.
Tag	VLAN ID.
MAC limit	Number of MAC addresses that can be associated with the interface.
STP state	Spanning tree protocol (STP) state.
Logical interface flags	Status of Layer 2 learning properties for each interface: <ul style="list-style-type: none"> • DL—MAC learning is disabled. • LH—MAC interface limit has been reached.. • AD—Packets are dropped after the MAC interface limit is reached. • DN—The MAC interface is down.
Tagging	Tagging state of the VLAN.

Sample Output

show ethernet-switching interface ae10.0

```

user@host> show ethernet-switching interface ae10.0

show ethernet-switching statistics

Syntax	show ethernet-switching statistics <instance <i>instance-name</i>> <logical-system <i>logical-system-name</i>> <vlan-name <i>vlan-name</i>>
Release Information	Command introduced in Junos OS Release 12.3R2. Command introduced in Junos OS Release 12.3R2 for EX Series switches.
Description	(MX Series routers and EX Series switches only) Display Ethernet-switching statistics.
Options	none —Display Ethernet-switching statistics for all VLANs in all routing instances. instance <i>instance-name</i> —(Optional) Display statistics for the specified routing instance. logical-system <i>logical-system-name</i> —(Optional) Display Ethernet-switching statistics information for the specified logical system. vlan-name <i>vlan-name</i> —(Optional) Display statistics for the specified VLAN.
Required Privilege Level	view
List of Sample Output	show ethernet-switching statistics on page 1946

show ethernet-switching table

Syntax	<pre>show ethernet-switching table <brief count detail extensive> <address> <instance <i>instance-name</i>> <interface <i>interface-name</i>> <interface <i>interface-name</i>> isid <i>isid</i> <address> <vlan-id (all-vlan <i>vlan-id</i>)> <vlan-name (all <i>vlan-name</i>)></pre>
Release Information	<p>Command introduced in Junos OS Release 12.3R2.</p> <p>Command introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	(MX Series routers and EX Series switches only) Display Layer 2 MAC address information.
Options	<p>none—Display all learned Layer 2 MAC address information.</p> <p>brief count detail extensive—(Optional) Display the specified level of output.</p> <p>address—(Optional) Display the specified learned Layer 2 MAC address information.</p> <p>instance <i>instance-name</i>—(Optional) Display learned Layer 2 MAC addresses for the specified routing instance.</p> <p>interface <i>interface-name</i>—(Optional) Display learned Layer 2 MAC addresses for the specified interface.</p> <p>isid <i>isid</i>—(Optional) Display learned Layer 2 MAC addresses for the specified ISID.</p> <p>logical-system <i>logical-system-name</i>—(Optional) Display Ethernet-switching statistics information for the specified logical system.</p> <p>vlan-id (all-vlan <i>vlan-id</i>)—(Optional) Display learned Layer 2 MAC addresses for all VLANs or for the specified VLAN.</p> <p>vlan-name (all <i>vlan-name</i>)—(Optional) Display learned Layer 2 MAC addresses for all VLANs or for the specified VLAN.</p>
Additional Information	When Layer 2 protocol tunneling is enabled, the tunneling MAC address 01:00:0c:cd:cd:d0 is installed in the MAC table. When the Cisco Discovery Protocol (CDP), Spanning Tree Protocol (STP), or VLAN Trunk Protocol (VTP) is configured for Layer 2 protocol tunneling on an interface, the corresponding protocol MAC address is installed in the MAC table.

[show ethernet-switching table extensive on page 1954](#)

Output Fields [Table 134 on page 1950](#) describes the output fields for the **show ethernet-switching table** command. Output fields are listed in the approximate order in which they appear.

Table 134: show ethernet-switching table Output fields

Field Name	Field Description
Routing instance	Name of the routing instance.
VLAN name	Name of the VLAN.
MAC address	MAC address or addresses learned on a logical interface.
MAC flags	Status of MAC address learning properties for each interface: <ul style="list-style-type: none"> • S—Static MAC address is configured. • D—Dynamic MAC address is configured. • L—Locally learned MAC address is configured. • SE—MAC accounting is enabled. • NM—Non-configured MAC. • R—Locally learned MAC address is configured.
Logical interface	Name of the logical interface.
MAC count	Number of MAC addresses learned on the specific routing instance or interface.
Learning interface	Name of the logical interface on which the MAC address was learned.
Learning VLAN	VLAN ID of the routing instance or VLAN in which the MAC address was learned.
Layer 2 flags	Debugging flags signifying that the MAC address is present in various lists.
Epoch	Spanning-tree-protocol epoch number identifying when the MAC address was learned. Used for debugging.
Sequence number	Sequence number assigned to this MAC address. Used for debugging.
Learning mask	Mask of the Packet Forwarding Engines where this MAC address was learned. Used for debugging.
IPC generation	Creation time of the logical interface when this MAC address was learned. Used for debugging.

Sample Output**show ethernet-switching table**

```
user@host> show ethernet-switching table
```

Output Fields	See Table 135 on page 1957 for the output fields for the show interfaces (10-Gigabit Ethernet) command.

Table 135: show interfaces Gigabit Ethernet Output Fields

Field Name	Field Description	Level of Output
Physical Interface		
Physical interface	Name of the physical interface.	All levels
Enabled	State of the interface. Possible values are described in the “Enabled Field” section under “Common Output Fields Description” on page 2376 .	All levels
Interface index	Index number of the physical interface, which reflects its initialization sequence.	detail extensive none
SNMP ifIndex	SNMP index number for the physical interface.	detail extensive none
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Link-level type	Encapsulation being used on the physical interface.	All levels
MTU	Maximum transmission unit size on the physical interface.	All levels
Speed	Speed at which the interface is running.	All levels
Loopback	Loopback status: Enabled or Disabled . If loopback is enabled, type of loopback: Local or Remote .	All levels
Source filtering	Source filtering status: Enabled or Disabled .	All levels
LAN-PHY mode	10-Gigabit Ethernet interface operating in Local Area Network Physical Layer Device (LAN PHY) mode. LAN PHY allows 10-Gigabit Ethernet wide area links to use existing Ethernet applications.	All levels
WAN-PHY mode	10-Gigabit Ethernet interface operating in Wide Area Network Physical Layer Device (WAN PHY) mode. WAN PHY allows 10-Gigabit Ethernet wide area links to use fiber-optic cables and other devices intended for SONET/SDH.	All levels
Unidirectional	Unidirectional link mode status for 10-Gigabit Ethernet interface: Enabled or Disabled for parent interface; Rx-only or Tx-only for child interfaces.	All levels
Flow control	Flow control status: Enabled or Disabled .	All levels
Auto-negotiation	(Gigabit Ethernet interfaces) Autonegotiation status: Enabled or Disabled .	All levels
Remote-fault	(Gigabit Ethernet interfaces) Remote fault status: <ul style="list-style-type: none"> • Online—Autonegotiation is manually configured as online. • Offline—Autonegotiation is manually configured as offline. 	All levels
Device flags	Information about the physical device. Possible values are described in the “Device Flags” section under “Common Output Fields Description” on page 2376 .	All levels
Interface flags	Information about the interface. Possible values are described in the “Interface Flags” section under “Common Output Fields Description” on page 2376 .	All levels

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Link flags	Information about the link. Possible values are described in the “Links Flags” section under “ Common Output Fields Description ” on page 2376.	All levels
Wavelength	(10-Gigabit Ethernet dense wavelength-division multiplexing [DWDM] interfaces) Displays the configured wavelength, in nanometers (nm).	All levels
Frequency	(10-Gigabit Ethernet DWDM interfaces only) Displays the frequency associated with the configured wavelength, in terahertz (THz).	All levels
CoS queues	Number of CoS queues configured.	detail extensive none
Schedulers	(Gigabit Ethernet intelligent queuing 2 (IQ2) interfaces only) Number of CoS schedulers configured.	extensive
Hold-times	Current interface hold-time up and hold-time down, in milliseconds.	detail extensive
Current address	Configured MAC address.	detail extensive none
Hardware address	Hardware MAC address.	detail extensive none
Last flapped	Date, time, and how long ago the interface went from down to up. The format is Last flapped: year-month-day hour:minute:second:timezone (hour:minute:second ago) . For example, Last flapped: 2002-04-26 10:52:40 PDT (04:33:20 ago) .	detail extensive none
Input Rate	Input rate in bits per second (bps) and packets per second (pps). The value in this field also includes the Layer 2 overhead bytes for ingress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level.	None specified
Output Rate	Output rate in bps and pps. The value in this field also includes the Layer 2 overhead bytes for egress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level.	None specified
Statistics last cleared	Time when the statistics for the interface were last set to zero.	detail extensive
Egress accounting overhead	Layer 2 overhead in bytes that is accounted in the interface statistics for egress traffic.	detail extensive
Ingress accounting overhead	Layer 2 overhead in bytes that is accounted in the interface statistics for ingress traffic.	detail extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Traffic statistics	<p>Number and rate of bytes and packets received and transmitted on the physical interface.</p> <ul style="list-style-type: none"> • Input bytes—Number of bytes received on the interface. The value in this field also includes the Layer 2 overhead bytes for ingress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level. • Output bytes—Number of bytes transmitted on the interface. The value in this field also includes the Layer 2 overhead bytes for egress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level. • Input packets—Number of packets received on the interface. • Output packets—Number of packets transmitted on the interface. <p>Gigabit Ethernet and 10-Gigabit Ethernet IQ PICs count the overhead and CRC bytes.</p> <p>For Gigabit Ethernet IQ PICs, the input byte counts vary by interface type. For more information, see Table 135 on page 1957.</p>	detail extensive
Input errors	<p>Input errors on the interface. The following paragraphs explain the counters whose meaning might not be obvious:</p> <ul style="list-style-type: none"> • Errors—Sum of the incoming frame aborts and FCS errors. • Drops—Number of packets dropped by the input queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism. • Framing errors—Number of packets received with an invalid frame checksum (FCS). • Runts—Number of frames received that are smaller than the runt threshold. • Policed discards—Number of frames that the incoming packet match code discarded because they were not recognized or not of interest. Usually, this field reports protocols that the Junos OS does not handle. • L3 incompletes—Number of incoming packets discarded because they failed Layer 3 (usually IPv4) sanity checks of the header. For example, a frame with less than 20 bytes of available IP header is discarded. L3 incomplete errors can be ignored by configuring the ignore-l3-incompletes statement. • L2 channel errors—Number of times the software did not find a valid logical interface for an incoming frame. • L2 mismatch timeouts—Number of malformed or short packets that caused the incoming packet handler to discard the frame as unreadable. • FIFO errors—Number of FIFO errors in the receive direction that are reported by the ASIC on the PIC. If this value is ever nonzero, the PIC is probably malfunctioning. • Resource errors—Sum of transmit drops. 	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Output errors	<p>Output errors on the interface. The following paragraphs explain the counters whose meaning might not be obvious:</p> <ul style="list-style-type: none"> • Carrier transitions—Number of times the interface has gone from down to up. This number does not normally increment quickly, increasing only when the cable is unplugged, the far-end system is powered down and then up, or another problem occurs. If the number of carrier transitions increments quickly (perhaps once every 10 seconds), the cable, the far-end system, or the PIC or PIM is malfunctioning. • Errors—Sum of the outgoing frame aborts and FCS errors. • Drops—Number of packets dropped by the output queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism. • Collisions—Number of Ethernet collisions. The Gigabit Ethernet PIC supports only full-duplex operation, so for Gigabit Ethernet PICs, this number should always remain 0. If it is nonzero, there is a software bug. • Aged packets—Number of packets that remained in shared packet SDRAM so long that the system automatically purged them. The value in this field should never increment. If it does, it is most likely a software bug or possibly malfunctioning hardware. • FIFO errors—Number of FIFO errors in the send direction as reported by the ASIC on the PIC. If this value is ever nonzero, the PIC is probably malfunctioning. • HS link CRC errors—Number of errors on the high-speed links between the ASICs responsible for handling the router interfaces. • MTU errors—Number of packets whose size exceeded the MTU of the interface. • Resource errors—Sum of transmit drops. 	extensive
Egress queues	Total number of egress queues supported on the specified interface.	detail extensive
Queue counters (Egress)	<p>CoS queue number and its associated user-configured forwarding class name.</p> <ul style="list-style-type: none"> • Queued packets—Number of queued packets. • Transmitted packets—Number of transmitted packets. • Dropped packets—Number of packets dropped by the ASIC's RED mechanism. 	detail extensive
Ingress queues	Total number of ingress queues supported on the specified interface. Displayed on IQ2 interfaces.	extensive
Queue counters (Ingress)	<p>CoS queue number and its associated user-configured forwarding class name. Displayed on IQ2 interfaces.</p> <ul style="list-style-type: none"> • Queued packets—Number of queued packets. • Transmitted packets—Number of transmitted packets. • Dropped packets—Number of packets dropped by the ASIC's RED mechanism. 	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Active alarms and Active defects	<p>Ethernet-specific defects that can prevent the interface from passing packets. When a defect persists for a certain amount of time, it is promoted to an alarm. Based on the routing device configuration, an alarm can ring the red or yellow alarm bell on the routing device, or turn on the red or yellow alarm LED on the craft interface. These fields can contain the value None or Link.</p> <ul style="list-style-type: none"> • None—There are no active defects or alarms. • Link—Interface has lost its link state, which usually means that the cable is unplugged, the far-end system has been turned off, or the PIC is malfunctioning. 	detail extensive none
OTN alarms	Active OTN alarms identified on the interface.	detail extensive
OTN defects	OTN defects received on the interface.	detail extensive
OTN FEC Mode	<p>The FECmode configured on the interface.</p> <ul style="list-style-type: none"> • efec—Enhanced forward error correction (EFEC) is configured to detect and correct bit errors. • gfec—G.709 Forward error correction (GFEC) mode is configured to detect and correct bit errors. • none—FEC mode is not configured. 	detail extensive
OTN Rate	<p>OTN mode.</p> <ul style="list-style-type: none"> • fixed-stuff-bytes—Fixed stuff bytes 11.0957 Gbps. • no-fixed-stuff-bytes—No fixed stuff bytes 11.0491 Gbps. • pass-through—Enable OTN passthrough mode. • no-pass-through—Do not enable OTN passthrough mode. 	detail extensive
OTN Line Loopback	Status of the line loopback, if configured for the DWDM OTN PIC. Its value can be: enabled or disabled .	detail extensive
OTN FEC statistics	<p>The forward error correction (FEC) counters for the DWDM OTN PIC.</p> <ul style="list-style-type: none"> • Corrected Errors—The count of corrected errors in the last second. • Corrected Error Ratio—The corrected error ratio in the last 25 seconds. For example, 1e-7 is 1 error per 10 million bits. 	detail extensive
OTN FEC alarms	<p>OTN FEC excessive or degraded error alarms triggered on the interface.</p> <ul style="list-style-type: none"> • FEC Degrade—OTU FEC Degrade defect. • FEC Excessive—OTU FEC Excessive Error defect. 	detail extensive
OTN OC	<p>OTN OC defects triggered on the interface.</p> <ul style="list-style-type: none"> • LOS—OC Loss of Signal defect. • LOF—OC Loss of Frame defect. • LOM—OC Loss of Multiframe defect. • Wavelength Lock—OC Wavelength Lock defect. 	detail extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
OTN OTU	OTN OTU defects detected on the interface <ul style="list-style-type: none"> • AIS—OTN AIS alarm. • BDI—OTN OTU BDI alarm. • IAE—OTN OTU IAE alarm. • TTIM—OTN OTU TTIM alarm. • SF—OTN ODU bit error rate fault alarm. • SD—OTN ODU bit error rate defect alarm. • TCA-ES—OTN ODU ES threshold alarm. • TCA-SES—OTN ODU SES threshold alarm. • TCA-UAS—OTN ODU UAS threshold alarm. • TCA-BBE—OTN ODU BBE threshold alarm. • BIP—OTN ODU BIP threshold alarm. • BBE—OTN OTU BBE threshold alarm. • ES—OTN OTU ES threshold alarm. • SES—OTN OTU SES threshold alarm. • UAS—OTN OTU UAS threshold alarm. 	detail extensive
Received DAPI	Destination Access Port Interface (DAPI) from which the packets were received.	detail extensive
Received SAPI	Source Access Port Interface (SAPI) from which the packets were received.	detail extensive
Transmitted DAPI	Destination Access Port Interface (DAPI) to which the packets were transmitted.	detail extensive
Transmitted SAPI	Source Access Port Interface (SAPI) to which the packets were transmitted.	detail extensive
PCS statistics	(10-Gigabit Ethernet interfaces) Displays Physical Coding Sublayer (PCS) fault conditions from the WAN PHY or the LAN PHY device. <ul style="list-style-type: none"> • Bit errors—High bit error rate. Indicates the number of bit errors when the PCS receiver is operating in normal mode. • Errored blocks—Loss of block lock. The number of errored blocks when PCS receiver is operating in normal mode. 	detail extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
MAC statistics	<p>Receive and Transmit statistics reported by the PIC's MAC subsystem, including the following:</p> <ul style="list-style-type: none"> • Total octets and total packets—Total number of octets and packets. For Gigabit Ethernet IQ PICs, the received octets count varies by interface type. For more information, see Table 136 on page 1971 • Unicast packets, Broadcast packets, and Multicast packets—Number of unicast, broadcast, and multicast packets. • CRC/Align errors—Total number of packets received that had a length (excluding framing bits, but including FCS octets) of between 64 and 1518 octets, inclusive, and had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). • FIFO error—Number of FIFO errors that are reported by the ASIC on the PIC. If this value is ever nonzero, the PIC or a cable is probably malfunctioning. • MAC control frames—Number of MAC control frames. • MAC pause frames—Number of MAC control frames with pause operational code. • Oversized frames—Number of frames that exceed 1518 octets. • Jabber frames—Number of frames that were longer than 1518 octets (excluding framing bits, but including FCS octets), and had either an FCS error or an alignment error. This definition of jabber is different from the definition in IEEE-802.3 section 8.2.1.5 (10BASE5) and section 10.3.1.4 (10BASE2). These documents define jabber as the condition in which any packet exceeds 20 ms. The allowed range to detect jabber is from 20 ms to 150 ms. • Fragment frames—Total number of packets that were less than 64 octets in length (excluding framing bits, but including FCS octets), and had either an FCS error or an alignment error. Fragment frames normally increment because both runts (which are normal occurrences caused by collisions) and noise hits are counted. • VLAN tagged frames—Number of frames that are VLAN tagged. The system uses the TPID of 0x8100 in the frame to determine whether a frame is tagged or not. • Code violations—Number of times an event caused the PHY to indicate "Data reception error" or "invalid data symbol error." 	extensive
OTN Received Overhead Bytes	APS/PCC0: 0x02, APS/PCC1: 0x11, APS/PCC2: 0x47, APS/PCC3: 0x58 Payload Type: 0x08	extensive
OTN Transmitted Overhead Bytes	APS/PCC0: 0x00, APS/PCC1: 0x00, APS/PCC2: 0x00, APS/PCC3: 0x00 Payload Type: 0x08	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Filter statistics	<p>Receive and Transmit statistics reported by the PIC's MAC address filter subsystem. The filtering is done by the content-addressable memory (CAM) on the PIC. The filter examines a packet's source and destination MAC addresses to determine whether the packet should enter the system or be rejected.</p> <ul style="list-style-type: none"> • Input packet count—Number of packets received from the MAC hardware that the filter processed. • Input packet rejects—Number of packets that the filter rejected because of either the source MAC address or the destination MAC address. • Input DA rejects—Number of packets that the filter rejected because the destination MAC address of the packet is not on the accept list. It is normal for this value to increment. When it increments very quickly and no traffic is entering the routing device from the far-end system, either there is a bad ARP entry on the far-end system, or multicast routing is not on and the far-end system is sending many multicast packets to the local routing device (which the routing device is rejecting). • Input SA rejects—Number of packets that the filter rejected because the source MAC address of the packet is not on the accept list. The value in this field should increment only if source MAC address filtering has been enabled. If filtering is enabled, if the value increments quickly, and if the system is not receiving traffic that it should from the far-end system, it means that the user-configured source MAC addresses for this interface are incorrect. • Output packet count—Number of packets that the filter has given to the MAC hardware. • Output packet pad count—Number of packets the filter padded to the minimum Ethernet size (60 bytes) before giving the packet to the MAC hardware. Usually, padding is done only on small ARP packets, but some very small IP packets can also require padding. If this value increments rapidly, either the system is trying to find an ARP entry for a far-end system that does not exist or it is misconfigured. • Output packet error count—Number of packets with an indicated error that the filter was given to transmit. These packets are usually aged packets or are the result of a bandwidth problem on the FPC hardware. On a normal system, the value of this field should not increment. • CAM destination filters, CAM source filters—Number of entries in the CAM dedicated to destination and source MAC address filters. There can only be up to 64 source entries. If source filtering is disabled, which is the default, the values for these fields should be 0. 	extensive
PMA PHY	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) SONET error information:</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. Any state other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • PHY Lock—Phase-locked loop • PHY Light—Loss of optical signal 	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
WIS section	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) SONET error information:</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. Any state other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • BIP-B1—Bit interleaved parity for SONET section overhead • SEF—Severely errored framing • LOL—Loss of light • LOF—Loss of frame • ES-S—Errored seconds (section) • SES-S—Severely errored seconds (section) • SEFS-S—Severely errored framing seconds (section) 	extensive
WIS line	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) Active alarms and defects, plus counts of specific SONET errors with detailed information.</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. State other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • BIP-B2—Bit interleaved parity for SONET line overhead • REI-L—Remote error indication (near-end line) • RDI-L—Remote defect indication (near-end line) • AIS-L—Alarm indication signal (near-end line) • BERR-SF—Bit error rate fault (signal failure) • BERR-SD—Bit error rate defect (signal degradation) • ES-L—Errored seconds (near-end line) • SES-L—Severely errored seconds (near-end line) • UAS-L—Unavailable seconds (near-end line) • ES-LFE—Errored seconds (far-end line) • SES-LFE—Severely errored seconds (far-end line) • UAS-LFE—Unavailable seconds (far-end line) 	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
WIS path	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) Active alarms and defects, plus counts of specific SONET errors with detailed information.</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. Any state other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • BIP-B3—Bit interleaved parity for SONET section overhead • REI-P—Remote error indication • LOP-P—Loss of pointer (path) • AIS-P—Path alarm indication signal • RDI-P—Path remote defect indication • UNEQ-P—Path unequipped • PLM-P—Path payload label mismatch • ES-P—Errored seconds (near-end STS path) • SES-P—Severely errored seconds (near-end STS path) • UAS-P—Unavailable seconds (near-end STS path) • SES-PFE—Severely errored seconds (far-end STS path) • UAS-PFE—Unavailable seconds (far-end STS path) 	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Autonegotiation information	<p>Information about link autonegotiation.</p> <ul style="list-style-type: none"> • Negotiation status: <ul style="list-style-type: none"> • Incomplete—Ethernet interface has the speed or link mode configured. • No autonegotiation—Remote Ethernet interface has the speed or link mode configured, or does not perform autonegotiation. • Complete—Ethernet interface is connected to a device that performs autonegotiation and the autonegotiation process is successful. • Link partner status—OK when Ethernet interface is connected to a device that performs autonegotiation and the autonegotiation process is successful. • Link partner: <ul style="list-style-type: none"> • Link mode—Depending on the capability of the attached Ethernet device, either Full-duplex or Half-duplex. • Flow control—Types of flow control supported by the remote Ethernet device. For Fast Ethernet interfaces, the type is None. For Gigabit Ethernet interfaces, types are Symmetric (link partner supports PAUSE on receive and transmit), Asymmetric (link partner supports PAUSE on transmit), and Symmetric/Asymmetric (link partner supports both PAUSE on receive and transmit or only PAUSE receive). • Remote fault—Remote fault information from the link partner—Failure indicates a receive link error. OK indicates that the link partner is receiving. Negotiation error indicates a negotiation error. Offline indicates that the link partner is going offline. • Local resolution—Information from the link partner: <ul style="list-style-type: none"> • Flow control—Types of flow control supported by the remote Ethernet device. For Gigabit Ethernet interfaces, types are Symmetric (link partner supports PAUSE on receive and transmit), Asymmetric (link partner supports PAUSE on transmit), and Symmetric/Asymmetric (link partner supports both PAUSE on receive and transmit or only PAUSE receive). • Remote fault—Remote fault information. Link OK (no error detected on receive), Offline (local interface is offline), and Link Failure (link error detected on receive). 	extensive
Received path trace, Transmitted path trace	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) SONET/SDH interfaces allow path trace bytes to be sent inband across the SONET/SDH link. Juniper Networks and other router manufacturers use these bytes to help diagnose misconfigurations and network errors by setting the transmitted path trace message so that it contains the system hostname and name of the physical interface. The received path trace value is the message received from the routing device at the other end of the fiber. The transmitted path trace value is the message that this routing device transmits.</p>	extensive
Packet Forwarding Engine configuration	<p>Information about the configuration of the Packet Forwarding Engine:</p> <ul style="list-style-type: none"> • Destination slot—FPC slot number. 	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
CoS information	Information about the CoS queue for the physical interface. <ul style="list-style-type: none"> • CoS transmit queue—Queue number and its associated user-configured forwarding class name. • Bandwidth %—Percentage of bandwidth allocated to the queue. • Bandwidth bps—Bandwidth allocated to the queue (in bps). • Buffer %—Percentage of buffer space allocated to the queue. • Buffer usec—Amount of buffer space allocated to the queue, in microseconds. This value is nonzero only if the buffer size is configured in terms of time. • Priority—Queue priority: low or high. • Limit—Displayed if rate limiting is configured for the queue. Possible values are none and exact. If exact is configured, the queue transmits only up to the configured bandwidth, even if excess bandwidth is available. If none is configured, the queue transmits beyond the configured bandwidth if bandwidth is available. 	extensive
Logical Interface		
Logical interface	Name of the logical interface.	All levels
Index	Index number of the logical interface, which reflects its initialization sequence.	detail extensive none
SNMP ifIndex	SNMP interface index number for the logical interface.	detail extensive none
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Flags	Information about the logical interface. Possible values are described in the "Logical Interface Flags" section under "Common Output Fields Description" on page 2376 .	All levels

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
VLAN-Tag	<p>Rewrite profile applied to incoming or outgoing frames on the outer (Out) VLAN tag or for both the outer and inner (In) VLAN tags.</p> <ul style="list-style-type: none"> • push—An outer VLAN tag is pushed in front of the existing VLAN tag. • pop—The outer VLAN tag of the incoming frame is removed. • swap—The outer VLAN tag of the incoming frame is overwritten with the user specified VLAN tag information. • push—An outer VLAN tag is pushed in front of the existing VLAN tag. • push-push—Two VLAN tags are pushed in from the incoming frame. • swap-push—The outer VLAN tag of the incoming frame is replaced by a user-specified VLAN tag value. A user-specified outer VLAN tag is pushed in front. The outer tag becomes an inner tag in the final frame. • swap-swap—Both the inner and the outer VLAN tags of the incoming frame are replaced by the user specified VLAN tag value. • pop-swap—The outer VLAN tag of the incoming frame is removed, and the inner VLAN tag of the incoming frame is replaced by the user-specified VLAN tag value. The inner tag becomes the outer tag in the final frame. • pop-pop—Both the outer and inner VLAN tags of the incoming frame are removed. 	brief detail extensive none
Demux:	<p>IP demultiplexing (demux) value that appears if this interface is used as the demux underlying interface. The output is one of the following:</p> <ul style="list-style-type: none"> • Source Family Inet • Destination Family Inet 	detail extensive none
Encapsulation	Encapsulation on the logical interface.	All levels
Protocol	Protocol family. Possible values are described in the “Protocol Field” section under “ Common Output Fields Description ” on page 2376.	detail extensive none
MTU	Maximum transmission unit size on the logical interface.	detail extensive none
Maximum labels	Maximum number of MPLS labels configured for the MPLS protocol family on the logical interface.	detail extensive none
Traffic statistics	<p>Number and rate of bytes and packets received and transmitted on the specified interface set.</p> <ul style="list-style-type: none"> • Input bytes, Output bytes—Number of bytes received and transmitted on the interface set. The value in this field also includes the Layer 2 overhead bytes for ingress or egress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level. • Input packets, Output packets—Number of packets received and transmitted on the interface set. 	detail extensive
IPv6 transit statistics	Number of IPv6 transit bytes and packets received and transmitted on the logical interface if IPv6 statistics tracking is enabled.	extensive
Local statistics	Number and rate of bytes and packets destined to the routing device.	extensive

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Transit statistics	Number and rate of bytes and packets transiting the switch. NOTE: For Gigabit Ethernet intelligent queuing 2 (IQ2) interfaces, the logical interface egress statistics might not accurately reflect the traffic on the wire when output shaping is applied. Traffic management output shaping might drop packets after they are tallied by the Output bytes and Output packets interface counters. However, correct values display for both of these egress statistics when per-unit scheduling is enabled for the Gigabit Ethernet IQ2 physical interface, or when a single logical interface is actively using a shared scheduler.	extensive
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Route Table	Route table in which the logical interface address is located. For example, 0 refers to the routing table inet.0.	detail extensive none
Flags	Information about protocol family flags. Possible values are described in the “Family Flags” section under “ Common Output Fields Description ” on page 2376.	detail extensive
Donor interface	(Unnumbered Ethernet) Interface from which an unnumbered Ethernet interface borrows an IPv4 address.	detail extensive none
Preferred source address	(Unnumbered Ethernet) Secondary IPv4 address of the donor loopback interface that acts as the preferred source address for the unnumbered Ethernet interface.	detail extensive none
Input Filters	Names of any input filters applied to this interface. If you specify a precedence value for any filter in a dynamic profile, filter precedence values appear in parenthesis next to all interfaces.	detail extensive
Output Filters	Names of any output filters applied to this interface. If you specify a precedence value for any filter in a dynamic profile, filter precedence values appear in parenthesis next to all interfaces.	detail extensive
Mac-Validate Failures	Number of MAC address validation failures for packets and bytes. This field is displayed when MAC address validation is enabled for the logical interface.	detail extensive none
Addresses, Flags	Information about the address flags. Possible values are described in the “Addresses Flags” section under “ Common Output Fields Description ” on page 2376.	detail extensive none
<i>protocol-family</i>	Protocol family configured on the logical interface. If the protocol is inet , the IP address of the interface is also displayed.	brief
Flags	Information about address flag (possible values are described in the “Addresses Flags” section under “ Common Output Fields Description ” on page 2376.	detail extensive none
Destination	IP address of the remote side of the connection.	detail extensive none
Local	IP address of the logical interface.	detail extensive none
Broadcast	Broadcast address of the logical interlace.	detail extensive none

Table 135: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive

For Gigabit Ethernet IQ PICs, traffic and MAC statistics output varies. [Table 136 on page 1971](#) describes the traffic and MAC statistics for two sample interfaces, each of which is sending traffic in packets of 500 bytes (including 478 bytes for the Layer 3 packet, 18 bytes for the Layer 2 VLAN traffic header, and 4 bytes for cyclic redundancy check [CRC] information). In [Table 136 on page 1971](#), the **ge-0/3/0** interface is the inbound physical interface, and the **ge-0/0/0** interface is the outbound physical interface. On both interfaces, traffic is carried on logical unit .50 (VLAN 50).

Table 136: Gigabit Ethernet IQ PIC Traffic and MAC Statistics by Interface Type

Interface Type	Sample Command	Byte and Octet Counts Include	Comments
Inbound physical interface	show interfaces ge-0/3/0 extensive	Traffic statistics: Input bytes: 496 bytes per packet, representing the Layer 2 packet MAC statistics: Received octets: 500 bytes per packet, representing the Layer 2 packet + 4 bytes	The additional 4 bytes are for the CRC.
Inbound logical interface	show interfaces ge-0/3/0.50 extensive	Traffic statistics: Input bytes: 478 bytes per packet, representing the Layer 3 packet	
Outbound physical interface	show interfaces ge-0/0/0 extensive	Traffic statistics: Input bytes: 490 bytes per packet, representing the Layer 3 packet + 12 bytes MAC statistics: Received octets: 478 bytes per packet, representing the Layer 3 packet	For input bytes, the additional 12 bytes includes 6 bytes for the destination MAC address + 4 bytes for VLAN + 2 bytes for the Ethernet type.
Outbound logical interface	show interfaces ge-0/0/0.50 extensive	Traffic statistics: Input bytes: 478 bytes per packet, representing the Layer 3 packet

show interfaces (Gigabit Ethernet)

Syntax	<pre>show interfaces <i>ge-fpc/pic/port</i> <brief detail extensive terse> <descriptions> <media> <snmp-index <i>snmp-index</i>> <statistics></pre>
Release Information	Command introduced before Junos OS Release 7.4.
Description	(M Series, T Series, and MX Series routers and EX Series switches only) Display status information about the specified Gigabit Ethernet interface.
Options	<p><i>ge-fpc/pic/port</i>—Display standard information about the specified Gigabit Ethernet interface.</p> <p>brief detail extensive terse—(Optional) Display the specified level of output.</p> <p>descriptions—(Optional) Display interface description strings.</p> <p>media—(Optional) Display media-specific information about network interfaces.</p> <p>snmp-index <i>snmp-index</i>—(Optional) Display information for the specified SNMP index of the interface.</p> <p>statistics—(Optional) Display static interface statistics.</p>
Additional Information	In a logical system, this command displays information only about the logical interfaces and not about the physical interfaces.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> <i>Verifying and Managing Agent Circuit Identifier-Based Dynamic VLAN Configuration</i>
List of Sample Output	<p>show interfaces (Gigabit Ethernet) on page 1996</p> <p>show interfaces (Gigabit Ethernet on MX Series Routers) on page 1996</p> <p>show interfaces extensive (Gigabit Ethernet on MX Series Routers showing interface transmit statistics configuration) on page 1997</p> <p>show interfaces brief (Gigabit Ethernet) on page 1997</p> <p>show interfaces detail (Gigabit Ethernet) on page 1998</p> <p>show interfaces extensive (Gigabit Ethernet IQ2) on page 1999</p> <p>show interfaces (Gigabit Ethernet Unnumbered Interface) on page 2002</p> <p>show interfaces (ACI Interface Set Configured) on page 2002</p>
Output Fields	<p>Table 137 on page 1982 describes the output fields for the show interfaces (Gigabit Ethernet) command. Output fields are listed in the approximate order in which they appear. For Gigabit Ethernet IQ and IQE PICs, the traffic and MAC statistics vary by interface type. For more information, see Table 138 on page 1995.</p>

Table 137: show interfaces Gigabit Ethernet Output Fields

Field Name	Field Description	Level of Output
Physical Interface		
Physical interface	Name of the physical interface.	All levels
Enabled	State of the interface. Possible values are described in the “Enabled Field” section under “Common Output Fields Description” on page 2376 .	All levels
Interface index	Index number of the physical interface, which reflects its initialization sequence.	detail extensive none
SNMP ifIndex	SNMP index number for the physical interface.	detail extensive none
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Link-level type	Encapsulation being used on the physical interface.	All levels
MTU	Maximum transmission unit size on the physical interface.	All levels
Speed	Speed at which the interface is running.	All levels
Loopback	Loopback status: Enabled or Disabled . If loopback is enabled, type of loopback: Local or Remote .	All levels
Source filtering	Source filtering status: Enabled or Disabled .	All levels
LAN-PHY mode	10-Gigabit Ethernet interface operating in Local Area Network Physical Layer Device (LAN PHY) mode. LAN PHY allows 10-Gigabit Ethernet wide area links to use existing Ethernet applications.	All levels
WAN-PHY mode	10-Gigabit Ethernet interface operating in Wide Area Network Physical Layer Device (WAN PHY) mode. WAN PHY allows 10-Gigabit Ethernet wide area links to use fiber-optic cables and other devices intended for SONET/SDH.	All levels
Unidirectional	Unidirectional link mode status for 10-Gigabit Ethernet interface: Enabled or Disabled for parent interface; Rx-only or Tx-only for child interfaces.	All levels
Flow control	Flow control status: Enabled or Disabled .	All levels
Auto-negotiation	(Gigabit Ethernet interfaces) Autonegotiation status: Enabled or Disabled .	All levels
Remote-fault	(Gigabit Ethernet interfaces) Remote fault status: <ul style="list-style-type: none"> Online—Autonegotiation is manually configured as online. Offline—Autonegotiation is manually configured as offline. 	All levels
Device flags	Information about the physical device. Possible values are described in the “Device Flags” section under “Common Output Fields Description” on page 2376 .	All levels
Interface flags	Information about the interface. Possible values are described in the “Interface Flags” section under “Common Output Fields Description” on page 2376 .	All levels

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Link flags	Information about the link. Possible values are described in the “Links Flags” section under “ Common Output Fields Description ” on page 2376.	All levels
Wavelength	(10-Gigabit Ethernet dense wavelength-division multiplexing [DWDM] interfaces) Displays the configured wavelength, in nanometers (nm).	All levels
Frequency	(10-Gigabit Ethernet DWDM interfaces only) Displays the frequency associated with the configured wavelength, in terahertz (THz).	All levels
CoS queues	Number of CoS queues configured.	detail extensive none
Schedulers	(Gigabit Ethernet intelligent queuing 2 [IQ2] interfaces only) Number of CoS schedulers configured.	extensive
Hold-times	Current interface hold-time up and hold-time down, in milliseconds (ms).	detail extensive
Current address	Configured MAC address.	detail extensive none
Hardware address	Hardware MAC address.	detail extensive none
Last flapped	Date, time, and how long ago the interface went from down to up. The format is Last flapped: year-month-day hour:minute:second:timezone (hour:minute:second ago) . For example, Last flapped: 2002-04-26 10:52:40 PDT (04:33:20 ago) .	detail extensive none
Input Rate	Input rate in bits per second (bps) and packets per second (pps).	None
Output Rate	Output rate in bps and pps.	None
Statistics last cleared	Time when the statistics for the interface were last set to zero.	detail extensive
Egress accounting overhead	Layer 2 overhead in bytes that is accounted in the interface statistics for egress traffic.	detail extensive
Ingress accounting overhead	Layer 2 overhead in bytes that is accounted in the interface statistics for ingress traffic.	detail extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Traffic statistics	<p>Number and rate of bytes and packets received and transmitted on the physical interface.</p> <ul style="list-style-type: none"> • Input bytes—Number of bytes received on the interface. The value in this field also includes the Layer 2 overhead bytes for ingress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level. • Output bytes—Number of bytes transmitted on the interface. The value in this field also includes the Layer 2 overhead bytes for egress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level. • Input packets—Number of packets received on the interface. • Output packets—Number of packets transmitted on the interface. <p>Gigabit Ethernet and 10-Gigabit Ethernet IQ PICs count the overhead and CRC bytes.</p> <p>For Gigabit Ethernet IQ PICs, the input byte counts vary by interface type. For more information, see Table 31 under the show interfaces (10-Gigabit Ethernet) command.</p>	detail extensive
Input errors	<p>Input errors on the interface. The following paragraphs explain the counters whose meaning might not be obvious:</p> <ul style="list-style-type: none"> • Errors—Sum of the incoming frame aborts and FCS errors. • Drops—Number of packets dropped by the input queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism. • Framing errors—Number of packets received with an invalid frame checksum (FCS). • Runts—Number of frames received that are smaller than the runt threshold. • Policed discards—Number of frames that the incoming packet match code discarded because they were not recognized or not of interest. Usually, this field reports protocols that Junos OS does not handle. • L3 incompletes—Number of incoming packets discarded because they failed Layer 3 (usually IPv4) sanity checks of the header. For example, a frame with less than 20 bytes of available IP header is discarded. L3 incomplete errors can be ignored by configuring the ignore-l3-incompletes statement. • L2 channel errors—Number of times the software did not find a valid logical interface for an incoming frame. • L2 mismatch timeouts—Number of malformed or short packets that caused the incoming packet handler to discard the frame as unreadable. • FIFO errors—Number of FIFO errors in the receive direction that are reported by the ASIC on the PIC. If this value is ever nonzero, the PIC is probably malfunctioning. • Resource errors—Sum of transmit drops. 	extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Output errors	<p>Output errors on the interface. The following paragraphs explain the counters whose meaning might not be obvious:</p> <ul style="list-style-type: none"> • Carrier transitions—Number of times the interface has gone from down to up. This number does not normally increment quickly, increasing only when the cable is unplugged, the far-end system is powered down and then up, or another problem occurs. If the number of carrier transitions increments quickly (perhaps once every 10 seconds), the cable, the far-end system, or the PIC or PIM is malfunctioning. • Errors—Sum of the outgoing frame aborts and FCS errors. • Drops—Number of packets dropped by the output queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism. • Collisions—Number of Ethernet collisions. The Gigabit Ethernet PIC supports only full-duplex operation, so for Gigabit Ethernet PICs, this number should always remain 0. If it is nonzero, there is a software bug. • Aged packets—Number of packets that remained in shared packet SDRAM so long that the system automatically purged them. The value in this field should never increment. If it does, it is most likely a software bug or possibly malfunctioning hardware. • FIFO errors—Number of FIFO errors in the send direction as reported by the ASIC on the PIC. If this value is ever nonzero, the PIC is probably malfunctioning. • HS link CRC errors—Number of errors on the high-speed links between the ASICs responsible for handling the router interfaces. • MTU errors—Number of packets whose size exceeded the MTU of the interface. • Resource errors—Sum of transmit drops. 	extensive
Egress queues	Total number of egress queues supported on the specified interface.	detail extensive
Queue counters (Egress)	<p>CoS queue number and its associated user-configured forwarding class name.</p> <ul style="list-style-type: none"> • Queued packets—Number of queued packets. • Transmitted packets—Number of transmitted packets. • Dropped packets—Number of packets dropped by the ASIC's RED mechanism. 	detail extensive
Ingress queues	Total number of ingress queues supported on the specified interface. Displayed on IQ2 interfaces.	extensive
Queue counters (Ingress)	<p>CoS queue number and its associated user-configured forwarding class name. Displayed on IQ2 interfaces.</p> <ul style="list-style-type: none"> • Queued packets—Number of queued packets. • Transmitted packets—Number of transmitted packets. • Dropped packets—Number of packets dropped by the ASIC's RED mechanism. 	extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Active alarms and Active defects	<p>Ethernet-specific defects that can prevent the interface from passing packets. When a defect persists for a certain amount of time, it is promoted to an alarm. Based on the router configuration, an alarm can ring the red or yellow alarm bell on the router, or turn on the red or yellow alarm LED on the craft interface. These fields can contain the value None or Link.</p> <ul style="list-style-type: none"> • None—There are no active defects or alarms. • Link—Interface has lost its link state, which usually means that the cable is unplugged, the far-end system has been turned off, or the PIC is malfunctioning. 	detail extensive none
Interface transmit statistics	<p>(On MX Series devices) Status of the interface-transmit-statistics configuration: Enabled or Disabled.</p> <ul style="list-style-type: none"> • Enabled—When the interface-transmit-statistics statement is included in the configuration. If this is configured, the interface statistics show the actual transmitted load on the interface. • Disabled—When the interface-transmit-statistics statement is not included in the configuration. If this is not configured, the interface statistics show the offered load on the interface. 	detail extensive
OTN FEC statistics	<p>The forward error correction (FEC) counters provide the following statistics:</p> <ul style="list-style-type: none"> • Corrected Errors—The count of corrected errors in the last second. • Corrected Error Ratio—The corrected error ratio in the last 25 seconds. For example, 1e-7 is 1 error per 10 million bits. 	detail extensive
PCS statistics	<p>(10-Gigabit Ethernet interfaces) Displays Physical Coding Sublayer (PCS) fault conditions from the WAN PHY or the LAN PHY device.</p> <ul style="list-style-type: none"> • Bit errors—High bit error rate. Indicates the number of bit errors when the PCS receiver is operating in normal mode. • Errored blocks—Loss of block lock. The number of errored blocks when the PCS receiver is operating in normal mode. 	detail extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
MAC statistics	<p>Receive and Transmit statistics reported by the PIC's MAC subsystem, including the following:</p> <ul style="list-style-type: none"> • Total octets and total packets—Total number of octets and packets. For Gigabit Ethernet IQ PICs, the received octets count varies by interface type. For more information, see Table 31 under the show interfaces (10-Gigabit Ethernet) command. • Unicast packets, Broadcast packets, and Multicast packets—Number of unicast, broadcast, and multicast packets. • CRC/Align errors—Total number of packets received that had a length (excluding framing bits, but including FCS octets) of between 64 and 1518 octets, inclusive, and had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). • FIFO error—Number of FIFO errors that are reported by the ASIC on the PIC. If this value is ever nonzero, the PIC or a cable is probably malfunctioning. • MAC control frames—Number of MAC control frames. • MAC pause frames—Number of MAC control frames with pause operational code. • Oversized frames—There are two possible conditions regarding the number of oversized frames: <ul style="list-style-type: none"> • Packet length exceeds 1518 octets, or • Packet length exceeds MRU • Jabber frames—Number of frames that were longer than 1518 octets (excluding framing bits, but including FCS octets), and had either an FCS error or an alignment error. This definition of jabber is different from the definition in IEEE-802.3 section 8.2.1.5 (10BASE5) and section 10.3.1.4 (10BASE2). These documents define jabber as the condition in which any packet exceeds 20 ms. The allowed range to detect jabber is from 20 ms to 150 ms. • Fragment frames—Total number of packets that were less than 64 octets in length (excluding framing bits, but including FCS octets) and had either an FCS error or an alignment error. Fragment frames normally increment because both runts (which are normal occurrences caused by collisions) and noise hits are counted. • VLAN tagged frames—Number of frames that are VLAN tagged. The system uses the TPID of 0x8100 in the frame to determine whether a frame is tagged or not. <p>NOTE: The 20-port Gigabit Ethernet MIC (MIC-3D-20GE-SFP) does not have hardware counters for VLAN frames. Therefore, the VLAN tagged frames field displays 0 when the show interfaces command is executed on a 20-port Gigabit Ethernet MIC. In other words, the number of VLAN tagged frames cannot be determined for the 20-port Gigabit Ethernet MIC.</p> <ul style="list-style-type: none"> • Code violations—Number of times an event caused the PHY to indicate "Data reception error" or "invalid data symbol error." 	extensive
OTN Received Overhead Bytes	APS/PCC0: 0x02, APS/PCC1: 0x11, APS/PCC2: 0x47, APS/PCC3: 0x58 Payload Type: 0x08	extensive
OTN Transmitted Overhead Bytes	APS/PCC0: 0x00, APS/PCC1: 0x00, APS/PCC2: 0x00, APS/PCC3: 0x00 Payload Type: 0x08	extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Filter statistics	<p>Receive and Transmit statistics reported by the PIC's MAC address filter subsystem. The filtering is done by the content-addressable memory (CAM) on the PIC. The filter examines a packet's source and destination MAC addresses to determine whether the packet should enter the system or be rejected.</p> <ul style="list-style-type: none"> • Input packet count—Number of packets received from the MAC hardware that the filter processed. • Input packet rejects—Number of packets that the filter rejected because of either the source MAC address or the destination MAC address. • Input DA rejects—Number of packets that the filter rejected because the destination MAC address of the packet is not on the accept list. It is normal for this value to increment. When it increments very quickly and no traffic is entering the router from the far-end system, either there is a bad ARP entry on the far-end system, or multicast routing is not on and the far-end system is sending many multicast packets to the local router (which the router is rejecting). • Input SA rejects—Number of packets that the filter rejected because the source MAC address of the packet is not on the accept list. The value in this field should increment only if source MAC address filtering has been enabled. If filtering is enabled, if the value increments quickly, and if the system is not receiving traffic that it should from the far-end system, it means that the user-configured source MAC addresses for this interface are incorrect. • Output packet count—Number of packets that the filter has given to the MAC hardware. • Output packet pad count—Number of packets the filter padded to the minimum Ethernet size (60 bytes) before giving the packet to the MAC hardware. Usually, padding is done only on small ARP packets, but some very small IP packets can also require padding. If this value increments rapidly, either the system is trying to find an ARP entry for a far-end system that does not exist or it is misconfigured. • Output packet error count—Number of packets with an indicated error that the filter was given to transmit. These packets are usually aged packets or are the result of a bandwidth problem on the FPC hardware. On a normal system, the value of this field should not increment. • CAM destination filters, CAM source filters—Number of entries in the CAM dedicated to destination and source MAC address filters. There can only be up to 64 source entries. If source filtering is disabled, which is the default, the values for these fields should be 0. 	extensive
PMA PHY	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) SONET error information:</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. Any state other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • PHY Lock—Phase-locked loop • PHY Light—Loss of optical signal 	extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
WIS section	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) SONET error information:</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. Any state other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • BIP-B1—Bit interleaved parity for SONET section overhead • SEF—Severely errored framing • LOL—Loss of light • LOF—Loss of frame • ES-S—Errored seconds (section) • SES-S—Severely errored seconds (section) • SEFS-S—Severely errored framing seconds (section) 	extensive
WIS line	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) Active alarms and defects, plus counts of specific SONET errors with detailed information:</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. Any state other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • BIP-B2—Bit interleaved parity for SONET line overhead • REI-L—Remote error indication (near-end line) • RDI-L—Remote defect indication (near-end line) • AIS-L—Alarm indication signal (near-end line) • BERR-SF—Bit error rate fault (signal failure) • BERR-SD—Bit error rate defect (signal degradation) • ES-L—Errored seconds (near-end line) • SES-L—Severely errored seconds (near-end line) • UAS-L—Unavailable seconds (near-end line) • ES-LFE—Errored seconds (far-end line) • SES-LFE—Severely errored seconds (far-end line) • UAS-LFE—Unavailable seconds (far-end line) 	extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
WIS path	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) Active alarms and defects, plus counts of specific SONET errors with detailed information:</p> <ul style="list-style-type: none"> • Seconds—Number of seconds the defect has been active. • Count—Number of times that the defect has gone from inactive to active. • State—State of the error. Any state other than OK indicates a problem. <p>Subfields are:</p> <ul style="list-style-type: none"> • BIP-B3—Bit interleaved parity for SONET section overhead • REI-P—Remote error indication • LOP-P—Loss of pointer (path) • AIS-P—Path alarm indication signal • RDI-P—Path remote defect indication • UNEQ-P—Path unequipped • PLM-P—Path payload (signal) label mismatch • ES-P—Errored seconds (near-end STS path) • SES-P—Severely errored seconds (near-end STS path) • UAS-P—Unavailable seconds (near-end STS path) • SES-PFE—Severely errored seconds (far-end STS path) • UAS-PFE—Unavailable seconds (far-end STS path) 	extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Autonegotiation information	<p>Information about link autonegotiation.</p> <ul style="list-style-type: none"> • Negotiation status: <ul style="list-style-type: none"> • Incomplete—Ethernet interface has the speed or link mode configured. • No autonegotiation—Remote Ethernet interface has the speed or link mode configured, or does not perform autonegotiation. • Complete—Ethernet interface is connected to a device that performs autonegotiation and the autonegotiation process is successful. • Link partner status—OK when Ethernet interface is connected to a device that performs autonegotiation and the autonegotiation process is successful. • Link partner—Information from the remote Ethernet device: <ul style="list-style-type: none"> • Link mode—Depending on the capability of the link partner, either Full-duplex or Half-duplex. • Flow control—Types of flow control supported by the link partner. For Gigabit Ethernet interfaces, types are Symmetric (link partner supports PAUSE on receive and transmit), Asymmetric (link partner supports PAUSE on transmit), Symmetric/Asymmetric (link partner supports PAUSE on receive and transmit or only PAUSE on transmit), and None (link partner does not support flow control). • Remote fault—Remote fault information from the link partner—Failure indicates a receive link error. OK indicates that the link partner is receiving. Negotiation error indicates a negotiation error. Offline indicates that the link partner is going offline. • Local resolution—Information from the local Ethernet device: <ul style="list-style-type: none"> • Flow control—Types of flow control supported by the local device. For Gigabit Ethernet interfaces, advertised capabilities are Symmetric/Asymmetric (local device supports PAUSE on receive and transmit or only PAUSE on receive) and None (local device does not support flow control). Depending on the result of the negotiation with the link partner, local resolution flow control type will display Symmetric (local device supports PAUSE on receive and transmit), Asymmetric (local device supports PAUSE on receive), and None (local device does not support flow control). • Remote fault—Remote fault information. Link OK (no error detected on receive), Offline (local interface is offline), and Link Failure (link error detected on receive). 	extensive
Received path trace, Transmitted path trace	<p>(10-Gigabit Ethernet interfaces, WAN PHY mode) SONET/SDH interfaces allow path trace bytes to be sent inband across the SONET/SDH link. Juniper Networks and other router manufacturers use these bytes to help diagnose misconfigurations and network errors by setting the transmitted path trace message so that it contains the system hostname and name of the physical interface. The received path trace value is the message received from the router at the other end of the fiber. The transmitted path trace value is the message that this router transmits.</p>	extensive
Packet Forwarding Engine configuration	<p>Information about the configuration of the Packet Forwarding Engine:</p> <ul style="list-style-type: none"> • Destination slot—FPC slot number. 	extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
CoS information	Information about the CoS queue for the physical interface. <ul style="list-style-type: none"> • CoS transmit queue—Queue number and its associated user-configured forwarding class name. • Bandwidth %—Percentage of bandwidth allocated to the queue. • Bandwidth bps—Bandwidth allocated to the queue (in bps). • Buffer %—Percentage of buffer space allocated to the queue. • Buffer usec—Amount of buffer space allocated to the queue, in microseconds. This value is nonzero only if the buffer size is configured in terms of time. • Priority—Queue priority: low or high. • Limit—Displayed if rate limiting is configured for the queue. Possible values are none and exact. If exact is configured, the queue transmits only up to the configured bandwidth, even if excess bandwidth is available. If none is configured, the queue transmits beyond the configured bandwidth if bandwidth is available. 	extensive
Logical Interface		
Logical interface	Name of the logical interface.	All levels
Index	Index number of the logical interface, which reflects its initialization sequence.	detail extensive none
SNMP ifIndex	SNMP interface index number for the logical interface.	detail extensive none
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Flags	Information about the logical interface. Possible values are described in the "Logical Interface Flags" section under " Common Output Fields Description " on page 2376.	All levels

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
VLAN-Tag	<p>Rewrite profile applied to incoming or outgoing frames on the outer (Out) VLAN tag or for both the outer and inner (In) VLAN tags.</p> <ul style="list-style-type: none"> • push—An outer VLAN tag is pushed in front of the existing VLAN tag. • pop—The outer VLAN tag of the incoming frame is removed. • swap—The outer VLAN tag of the incoming frame is overwritten with the user-specified VLAN tag information. • push—An outer VLAN tag is pushed in front of the existing VLAN tag. • push-push—Two VLAN tags are pushed in from the incoming frame. • swap-push—The outer VLAN tag of the incoming frame is replaced by a user-specified VLAN tag value. A user-specified outer VLAN tag is pushed in front. The outer tag becomes an inner tag in the final frame. • swap-swap—Both the inner and the outer VLAN tags of the incoming frame are replaced by the user-specified VLAN tag value. • pop-swap—The outer VLAN tag of the incoming frame is removed, and the inner VLAN tag of the incoming frame is replaced by the user-specified VLAN tag value. The inner tag becomes the outer tag in the final frame. • pop-pop—Both the outer and inner VLAN tags of the incoming frame are removed. 	brief detail extensive none
Demux	<p>IP demultiplexing (demux) value that appears if this interface is used as the demux underlying interface. The output is one of the following:</p> <ul style="list-style-type: none"> • Source Family Inet • Destination Family Inet 	detail extensive none
Encapsulation	Encapsulation on the logical interface.	All levels
ACI VLAN: Dynamic Profile	Name of the dynamic profile that defines the agent circuit identifier (ACI) interface set. If configured, the ACI interface set enables the underlying Ethernet interface to create dynamic VLAN subscriber interfaces based on ACI information.	brief detail extensive none
Protocol	Protocol family. Possible values are described in the “Protocol Field” section under “ Common Output Fields Description ” on page 2376.	detail extensive none
MTU	Maximum transmission unit size on the logical interface.	detail extensive none
Dynamic Profile	(MX Series routers with Trio MPCs only) Name of the dynamic profile that was used to create this interface configured with a Point-to-Point Protocol over Ethernet (PPPoE) family.	detail extensive none
Service Name Table	(MX Series routers with Trio MPCs only) Name of the service name table for the interface configured with a PPPoE family.	detail extensive none
Max Sessions	(MX Series routers with Trio MPCs only) Maximum number of PPPoE logical interfaces that can be activated on the underlying interface.	detail extensive none

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Duplicate Protection	(MX Series routers with Trio MPCs only) State of PPPoE duplicate protection: On or Off . When duplicate protection is configured for the underlying interface, a dynamic PPPoE logical interface cannot be activated when an existing active logical interface is present for the same PPPoE client.	detail extensive none
Maximum labels	Maximum number of MPLS labels configured for the MPLS protocol family on the logical interface.	detail extensive none
Traffic statistics	<p>Number and rate of bytes and packets received and transmitted on the specified interface set.</p> <ul style="list-style-type: none"> • Input bytes, Output bytes—Number of bytes received and transmitted on the interface set. The value in this field also includes the Layer 2 overhead bytes for ingress or egress traffic on Ethernet interfaces if you enable accounting of Layer 2 overhead at the PIC level or the logical interface level. • Input packets, Output packets—Number of packets received and transmitted on the interface set. 	detail extensive
IPv6 transit statistics	Number of IPv6 transit bytes and packets received and transmitted on the logical interface if IPv6 statistics tracking is enabled.	extensive
Local statistics	Number and rate of bytes and packets destined to the router.	extensive
Transit statistics	<p>Number and rate of bytes and packets transiting the switch.</p> <p>NOTE: For Gigabit Ethernet intelligent queuing 2 (IQ2) interfaces, the logical interface egress statistics might not accurately reflect the traffic on the wire when output shaping is applied. Traffic management output shaping might drop packets after they are tallied by the Output bytes and Output packets interface counters. However, correct values display for both of these egress statistics when per-unit scheduling is enabled for the Gigabit Ethernet IQ2 physical interface, or when a single logical interface is actively using a shared scheduler.</p>	extensive
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Route Table	Route table in which the logical interface address is located. For example, 0 refers to the routing table inet.0.	detail extensive none
Flags	Information about protocol family flags. Possible values are described in the "Family Flags" section under " Common Output Fields Description " on page 2376.	detail extensive
Donor interface	(Unnumbered Ethernet) Interface from which an unnumbered Ethernet interface borrows an IPv4 address.	detail extensive none
Preferred source address	(Unnumbered Ethernet) Secondary IPv4 address of the donor loopback interface that acts as the preferred source address for the unnumbered Ethernet interface.	detail extensive none
Input Filters	Names of any input filters applied to this interface. If you specify a precedence value for any filter in a dynamic profile, filter precedence values appear in parentheses next to all interfaces.	detail extensive

Table 137: show interfaces Gigabit Ethernet Output Fields (*continued*)

Field Name	Field Description	Level of Output
Output Filters	Names of any output filters applied to this interface. If you specify a precedence value for any filter in a dynamic profile, filter precedence values appear in parentheses next to all interfaces.	detail extensive
Mac-Validate Failures	Number of MAC address validation failures for packets and bytes. This field is displayed when MAC address validation is enabled for the logical interface.	detail extensive none
Addresses, Flags	Information about the address flags. Possible values are described in the “Addresses Flags” section under “Common Output Fields Description” on page 2376 .	detail extensive none
protocol-family	Protocol family configured on the logical interface. If the protocol is inet , the IP address of the interface is also displayed.	brief
Flags	Information about the address flag. Possible values are described in the “Addresses Flags” section under “Common Output Fields Description” on page 2376 .	detail extensive none
Destination	IP address of the remote side of the connection.	detail extensive none
Local	IP address of the logical interface.	detail extensive none
Broadcast	Broadcast address of the logical interface.	detail extensive none
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive

Table 138: Gigabit Ethernet IQ PIC Traffic and MAC Statistics by Interface Type

Interface Type	Sample Command	Byte and Octet Counts Include	Comments
Inbound physical interface	show interfaces ge-0/3/0 extensive	<p>Traffic statistics:</p> <p>Input bytes: 496 bytes per packet, representing the Layer 2 packet</p> <p>MAC statistics:</p> <p>Received octets: 500 bytes per packet, representing the Layer 2 packet + 4 bytes</p>	The additional 4 bytes are for the CRC.
Inbound logical interface	show interfaces ge-0/3/0.50 extensive	<p>Traffic statistics:</p> <p>Input bytes: 478 bytes per packet, representing the Layer 3 packet</p>	

Table 138: Gigabit Ethernet IQ PIC Traffic and MAC Statistics by Interface Type (*continued*)

Interface Type	Sample Command	Byte and Octet Counts Include	Comments
Outbound physical interface	show interfaces ge-0/0/0 extensive	Traffic statistics: Input bytes: 490 bytes per packet, representing the Layer 3 packet + 12 bytes MAC statistics: Received octets: 478 bytes per packet, representing the Layer 3 packet	For input bytes, the additional 12 bytes include 6 bytes for the destination MAC address plus 4 bytes for VLAN plus 2 bytes for the Ethernet type.
Outbound logical interface	show interfaces ge-0/0/0.50 extensive	Traffic statistics: Input bytes: 478 bytes per packet, representing the Layer 3 packet

```

NOTE: For Gigabit Ethernet intelligent queuing 2 (IQ2) interfaces, the logical interface egress statistics displayed in the **show interfaces** command output might not accurately reflect the traffic on the wire when output shaping is applied. Traffic management output shaping might drop packets after they are tallied by the interface counters. For detailed information, see the description of the logical interface **Transit statistics** fields in [Table 137 on page 1982](#).

show interfaces irb

Syntax	<pre>show interfaces irb <brief detail extensive terse> <descriptions> <media> <routing-instance <i>instance-name</i>> <snmp-index <i>snmp-index</i>> <statistics></pre>
Release Information	<p>Command introduced in Junos OS Release 12.3R2.</p> <p>Command introduced in Junos OS Release 12.3R2 for EX Series switches.</p>
Description	Display integrated routing and bridging interfaces information.
Options	<p>brief detail extensive terse—(Optional) Display the specified level of output.</p> <p>descriptions—(Optional) Display interface description strings.</p> <p>media—(Optional) Display media-specific information about network interfaces.</p> <p>routing-instance <i>instance-name</i>—(Optional) Display information for the interface with the specified SNMP index.</p> <p>snmp-index <i>snmp-index</i>—(Optional) Display information for the interface with the specified SNMP index.</p> <p>statistics—(Optional) Display static interface statistics.</p>
Additional Information	Integrated routing and bridging (IRB) provides simultaneous support for Layer 2 bridging and Layer 3 IP routing on the same interface. IRB enables you to route local packets to another routed interface or to another VLAN that has a Layer 3 protocol configured.
Required Privilege Level	view
List of Sample Output	<p>show interfaces irb extensive on page 2008</p> <p>show interfaces irb snmp-index on page 2009</p>
Output Fields	Table 139 on page 2004 lists the output fields for the show interfaces irb command. Output fields are listed in the approximate order in which they appear.

Table 139: show interfaces irb Output Fields

Field Name	Field Description	Level of Output
Physical Interface		
Physical interface	Name of the physical interface.	All levels
Enabled	State of the physical interface. Possible values are described in the “Enabled Field” section under “Common Output Fields Description” on page 2376 .	All levels

Table 139: show interfaces irb Output Fields (*continued*)

Field Name	Field Description	Level of Output
Proto	Protocol configured on the interface.	terse
Interface index	Physical interface index number, which reflects its initialization sequence.	detail extensive none
SNMP ifIndex	SNMP index number for the physical interface.	detail extensive none
Type	Physical interface type.	detail extensive none
Link-level type	Encapsulation being used on the physical interface.	detail extensive brief none
MTU	MTU size on the physical interface.	detail extensive brief none
Clocking	Reference clock source: Internal or External . Always unspecified on IRB interfaces.	detail extensive brief
Speed	Speed at which the interface is running. Always unspecified on IRB interfaces.	detail extensive brief
Device flags	Information about the physical device. Possible values are described in the "Device Flags" section under " Common Output Fields Description " on page 2376.	detail extensive brief none
Interface flags	Information about the interface. Possible values are described in the "Interface Flags" section under " Common Output Fields Description " on page 2376.	detail extensive brief none
Link type	Physical interface link type: full duplex or half duplex .	detail extensive none
Link flags	Information about the link. Possible values are described in the "Links Flags" section under " Common Output Fields Description " on page 2376.	detail extensive none
Physical Info	Physical interface information.	All levels
Hold-times	Current interface hold-time up and hold-time down, in milliseconds.	detail extensive
Current address	Configured MAC address.	detail extensive none
Hardware address	MAC address of the hardware.	detail extensive none
Alternate link address	Backup address of the link.	detail extensive
Last flapped	Date, time, and how long ago the interface went from down to up. The format is Last flapped: year-month-day hours:minutes:seconds timezone (hours:minutes:seconds ago) . For example, Last flapped: 2002-04-26 10:52:40 PDT (04:33:20 ago) .	detail extensive none
Statistics last cleared	Time when the statistics for the interface were last set to zero.	detail extensive

Table 139: show interfaces irb Output Fields (*continued*)

Field Name	Field Description	Level of Output
Traffic statistics	<p>Number and rate of bytes and packets received and transmitted on the physical interface.</p> <ul style="list-style-type: none"> • Input bytes—Number of bytes received on the interface. • Output bytes—Number of bytes transmitted on the interface. • Input packets—Number of packets received on the interface • Output packets—Number of packets transmitted on the interface. 	detail extensive
IPv6 transit statistics	<p>Number of IPv6 transit bytes and packets received and transmitted on the physical interface if IPv6 statistics tracking is enabled.</p> <ul style="list-style-type: none"> • Input bytes—Number of bytes received on the interface. • Output bytes—Number of bytes transmitted on the interface. • Input packets—Number of packets received on the interface. • Output packets—Number of packets transmitted on the interface. 	detail extensive
Input errors	<p>Input errors on the interface. The following paragraphs explain the counters whose meaning might not be obvious:</p> <ul style="list-style-type: none"> • Errors—Sum of the incoming frame aborts and FCS errors. • Drops—Number of packets dropped by the input queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism. • Framing errors—Number of packets received with an invalid frame checksum (FCS). • Runts—Number of frames received that are smaller than the runt threshold. • Giants—Number of frames received that are larger than the giant threshold. • Policed discards—Number of frames that the incoming packet match code discarded because they were not recognized or not of interest. Usually, this field reports protocols that the Junos OS does not handle. • Resource errors—Sum of transmit drops. 	detail extensive
Output errors	<p>Output errors on the interface. The following paragraphs explain the counters whose meaning might not be obvious:</p> <ul style="list-style-type: none"> • Carrier transitions—Number of times the interface has gone from down to up. This number does not normally increment quickly, increasing only when the cable is unplugged, the far-end system is powered down and up, or another problem occurs. If the number of carrier transitions increments quickly (perhaps once every 10 seconds), the cable, the far-end system, or the DPC is malfunctioning. • Errors—Sum of the outgoing frame aborts and FCS errors. • Drops—Number of packets dropped by the output queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism. • MTU errors—Number of packets whose size exceeded the MTU of the interface. • Resource errors—Sum of transmit drops. 	detail extensive

Logical Interface

Table 139: show interfaces irb Output Fields (*continued*)

Field Name	Field Description	Level of Output
Logical interface	Name of the logical interface.	All levels
Index	Index number of the logical interface (which reflects its initialization sequence).	detail extensive none
SNMP ifIndex	SNMP interface index number of the logical interface.	detail extensive none
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Flags	Information about the logical interface. Possible values are described in the "Logical Interface Flags" section under "Common Output Fields Description" on page 2376 .	detail extensive
Encapsulation	Encapsulation on the logical interface.	detail extensive
Bandwidth	Speed at which the interface is running.	detail extensive
Routing Instance	Routing instance IRB is configured under.	detail extensive
Bridging Domain	Bridging domain IRB is participating in.	detail extensive
Traffic statistics	Number and rate of bytes and packets received and transmitted on the logical interface. <ul style="list-style-type: none"> • Input bytes—Number of bytes received on the interface. • Output bytes—Number of bytes transmitted on the interface. • Input packets—Number of packets received on the interface • Output packets—Number of packets transmitted on the interface. 	detail extensive
IPv6 transit statistics	Number of IPv6 transit bytes and packets received and transmitted on the logical interface if IPv6 statistics tracking is enabled. <ul style="list-style-type: none"> • Input bytes—Number of bytes received on the interface. • Output bytes—Number of bytes transmitted on the interface. • Input packets—Number of packets received on the interface. • Output packets—Number of packets transmitted on the interface. 	detail extensive
Local statistics	Statistics for traffic received from and transmitted to the Routing Engine.	detail extensive
Transit statistics	Statistics for traffic transiting the router.	detail extensive
Protocol	Protocol family configured on the local interface. Possible values are described in the "Protocol Field" section under "Common Output Fields Description" on page 2376 .	detail extensive
MTU	Maximum transmission unit size on the logical interface.	detail extensive

Table 139: show interfaces irb Output Fields (*continued*)

Field Name	Field Description	Level of Output
Maximum labels	Maximum number of MPLS labels configured for the MPLS protocol family on the logical interface.	detail extensive none
Generation	Unique number for use by Juniper Networks technical support only.	detail extensive
Route table	Routing table in which the logical interface address is located. For example, 0 refers to the routing table inet.0.	detail extensive
Addresses, Flags	Information about address flags. Possible values are described in the “Addresses Flags” section under “Common Output Fields Description” on page 2376 .	detail extensive
Policer	The policer that is to be evaluated when packets are received or transmitted on the interface.	detail extensive
Flags	Information about the logical interface. Possible values are described in the “Logical Interface Flags” section under “Common Output Fields Description” on page 2376 .	detail extensive

show interfaces queue

Syntax	<pre>show interfaces queue <aggregate remaining-traffic> <both-ingress-egress> <egress> <forwarding-class forwarding-class> <ingress> <interface-name interface-name> <l2-statistics> <remaining-traffic></pre>
Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>both-ingress-egress, egress, and ingress options introduced in Junos OS Release 7.6.</p> <p>Command introduced in Junos OS Release 11.1 for the QFX Series.</p> <p>l2-statistics option introduced in Junos OS Release 12.1.</p>
Description	Display class-of-service (CoS) queue information for physical interfaces.
Options	<p>none—Show detailed CoS queue statistics for all physical interfaces.</p> <p>aggregate—(Optional) Display the aggregated queuing statistics of all logical interfaces that have traffic-control profiles configured. (Not on the QFX Series.)</p> <p>both-ingress-egress—(Optional) On Gigabit Ethernet Intelligent Queuing 2 (IQ2) PICs, display both ingress and egress queue statistics. (Not on the QFX Series.)</p> <p>egress—(Optional) Display egress queue statistics.</p> <p>forwarding-class forwarding-class—(Optional) Forwarding class name for this queue. Shows detailed CoS statistics for the queue associated with the specified forwarding class.</p> <p>ingress—(Optional) On Gigabit Ethernet IQ2 PICs, display ingress queue statistics. (Not on the QFX Series.)</p> <p>interface-name interface-name—(Optional) Show detailed CoS queue statistics for the specified interface.</p> <p>l2-statistics—(optional) Display layer 2 statistics for MLPPP, FRF.15, and FRF.16 bundles</p>

Overhead for Layer 2 Statistics

Transmitted packets and transmitted byte counts are displayed for the layer 2 level with the addition of encapsulation overheads applied for fragmentation, as shown in [Table 140 on page 2012](#). Others counters, such as packets and bytes queued (input) and drop counters, are displayed at the layer 3 level. In the case of link fragmentation and interleaving (LFI) for which not fragmentation is applied, corresponding layer 2 overheads are added, as shown in [Table 140 on page 2012](#).

Table 140: Layer 2 Overhead, Transmitted Packets/Bytes

Protocol	Fragmentation		LFI
	First fragmentation	Second to n fragmentations	
	Bytes	Bytes	
MLPPP (Long)	13	12	8
MLPPP (short)	11	10	8
MLFR (FRF15)	12	10	8
MFR (FRF16)	10	8	-
MCMLPPP(Long)	13	12	-
MCMLPPP(Short)	11	10	-

Layer 2 Statistics - Fragmentation Overhead Calculation

MLPPP/MC-MLPPP Overhead details:

=====

Fragment 1:

```

Outer PPP header           : 4 bytes
Long or short sequence MLPPP header : 4 bytes or 2 bytes
Inner PPP header           : 1 byte
HDLC flag and FCS bytes    : 4 bytes

```

Fragments 2 .. n :

```

Outer PPP header           : 4 bytes
Long or short sequence MLPPP header : 4 bytes or 2 bytes
HDLC flag and FCS bytes    : 4 bytes

```

MLFR (FRF15) Overhead details:

=====

Fragment 1:

```

Framereelay header        : 2 bytes
Control,NLPID             : 2 bytes
Fragmentaion header       : 2 bytes
Inner proto               : 2 bytes
HDLC flag and FCS         : 4 bytes

```

Fragments 2 ...n :

```

Framereelay header        : 2 bytes
Control,NLPID             : 2 bytes
Fragmentaion header       : 2 bytes
HDLC flag and FCS         : 4 bytes

```

MFR (FRF16) Overhead details:

=====

```

Fragment 1:
  Fragmentation header : 2 bytes
  Framereelay header   : 2 bytes
  Inner proto          : 2 bytes
  HDLC flag and FCS    : 4 bytes

Fragments 2 ...n :
  Fragmentation header : 2 bytes
  Framereelay header   : 2 bytes
  HDLC flag and FCS    : 4 bytes

```

Overhead with LFI

```

MLPPP(Long & short sequence):
=====
  Outer PPP header : 4 bytes
  HDLC flag and FCS : 4 bytes

MLFR (FRF15):
=====
  Framereelay header : 2 bytes
  Control,NLPID      : 2 bytes
  HDLC flag and FCS  : 4 bytes

```

The following examples show overhead for different cases:

- A 1000-byte packet is sent to a mlppp bundle without any fragmentation. At the layer 2 level, bytes transmitted is 1013 in 1 packet. This overhead is for MLPPP long sequence encap.
- A 1000-byte packet is sent to a mlppp bundle with a fragment threshold of 250byte. At the layer 2 level, bytes transmitted is 1061 bytes in 5 packets.
- A 1000-byte LFI packet is sent to an mlppp bundle. At the layer 2 level, bytes transmitted is 1008 in 1 packet.

remaining-traffic—(Optional) Display the queuing statistics of all logical interfaces that do not have traffic-control profiles configured. (Not on the QFX Series.)

Additional Information On M Series routers (except for the M320 and M120 routers), this command is valid only for a PIC installed on an enhanced Flexible PIC Concentrator (FPC).

Queue statistics for aggregated interfaces are supported on the M Series and T Series routers only. Statistics for an aggregated interface are the summation of the queue statistics of the child links of that aggregated interface. You can view the statistics for a child interface by using the **show interfaces statistics** command for that child interface.

When you configure tricolor marking on a 10-port 1-Gigabit Ethernet PIC, for queues 6 and 7 only, the output does not display the number of queued bytes and packets, or the number of bytes and packets dropped because of RED. If you do not configure tricolor marking on the interface, these statistics are available for all queues.

For the 4-port Channelized OC12 IQE PIC and 1-port Channelized OC48 IQE PIC, the **Packet Forwarding Engine Chassis Queues** field represents traffic bound for a particular

physical interface on the PIC. For all other PICs, the **Packet Forwarding Engine Chassis Queues** field represents the total traffic bound for the PIC.

For Gigabit Ethernet IQ2 PICs, the **show interfaces queue** command output does not display the number of tail-dropped packets. This limitation does not apply to Packet Forwarding Engine chassis queues.

When fragmentation occurs on the egress interface, the first set of packet counters shows the postfragmentation values. The second set of packet counters (under the **Packet Forwarding Engine Chassis Queues** field) shows the prefragmentation values.

The behavior of the **egress** queues for the **Routing Engine-Generated Traffic** is not same as the configured queue for MLPPP and MFR configurations.

For information about how to configure CoS, see the *Junos® OS Network Interfaces*. For related CoS operational mode commands, see the *Junos OS Operational Mode Commands*.

- [show interfaces queue \(Channelized OC12 IQE Type 3 PIC in SONET Mode\) on page 2035](#)
- [show interfaces queue \(QFX Series\) on page 2045](#)
- [show interfaces queue l2-statistics \(lsq interface\) on page 2046](#)

Output Fields [Table 141 on page 2014](#) lists the output fields for the **show interfaces queue** command. Output fields are listed in the approximate order in which they appear.

Table 141: show interfaces queue Output Fields

Field Name	Field Description
Physical interface	Name of the physical interface.
Enabled	State of the interface. Possible values are described in the “Enabled Field” section under “ Common Output Fields Description ” on page 2376.
Interface index	Physical interface's index number, which reflects its initialization sequence.
SNMP ifIndex	SNMP index number for the interface.
Forwarding classes supported	Total number of forwarding classes supported on the specified interface.

Table 141: show interfaces queue Output Fields (*continued*)

Field Name	Field Description
Forwarding classes in use	Total number of forwarding classes in use on the specified interface.
Ingress queues supported	On Gigabit Ethernet IQ2 PICs only, total number of ingress queues supported on the specified interface.
Ingress queues in use	On Gigabit Ethernet IQ2 PICs only, total number of ingress queues in use on the specified interface.
Output queues supported	Total number of output queues supported on the specified interface.
Output queues in use	Total number of output queues in use on the specified interface.
Egress queues supported	Total number of egress queues supported on the specified interface.
Egress queues in use	Total number of egress queues in use on the specified interface.
Queue	Queue number.
Queue counters (Ingress)	<p>CoS queue number and its associated user-configured forwarding class name. Displayed on IQ2 interfaces.</p> <ul style="list-style-type: none"> • Queued packets—Number of queued packets. • Transmitted packets—Number of transmitted packets. • Dropped packets—Number of packets dropped by the ASIC's RED mechanism.
Burst size	(Logical interfaces on IQ PICs only) Maximum number of bytes up to which the logical interface can burst. The burst size is based on the shaping rate applied to the interface.
Forwarding classes	Forwarding class name.
Queued Packets	<p>Number of packets queued to this queue.</p> <p>NOTE: For Gigabit Ethernet IQ2 interfaces, the Queued Packets count is calculated by the Junos OS interpreting one frame buffer as one packet. If the queued packets are very large or very small, the calculation might not be completely accurate for transit traffic. The count is completely accurate for traffic terminated on the router.</p>
Queued Bytes	<p>Number of bytes queued to this queue. The byte counts vary by PIC type. For more information, see Table 142 on page 2017.</p>
Transmitted Packets	<p>Number of packets transmitted by this queue. When fragmentation occurs on the egress interface, the first set of packet counters shows the postfragmentation values. The second set of packet counters (displayed under the Packet Forwarding Engine Chassis Queues field) shows the prefragmentation values.</p> <p>NOTE: For layer 2 statistics, see “Overhead for Layer 2 Statistics” on page 2011</p>

Table 141: show interfaces queue Output Fields (*continued*)

Field Name	Field Description
Transmitted Bytes	<p>Number of bytes transmitted by this queue. The byte counts vary by PIC type. For more information, see Table 142 on page 2017.</p> <p>NOTE: On MX Series routers, this number can be inaccurate when you issue the command for a physical interface repeatedly and in quick succession, because the statistics for the child nodes are collected infrequently. Wait ten seconds between successive iterations to avoid this situation.</p> <p>NOTE: For layer 2 statistics, see “Overhead for Layer 2 Statistics” on page 2011</p>
Tail-dropped packets	Number of packets dropped because of tail drop.
RED-dropped packets	<p>Number of packets dropped because of random early detection (RED).</p> <ul style="list-style-type: none"> • (M Series and T Series routers only) On M320 and M120 routers and the T Series routers, the total number of dropped packets is displayed. On all other M Series routers, the output classifies dropped packets into the following categories: <ul style="list-style-type: none"> • Low, non-TCP—Number of low-loss priority non-TCP packets dropped because of RED. • Low, TCP—Number of low-loss priority TCP packets dropped because of RED. • High, non-TCP—Number of high-loss priority non-TCP packets dropped because of RED. • High, TCP—Number of high-loss priority TCP packets dropped because of RED. • (J Series routers and MX Series routers with enhanced DPCs, and T Series routers with enhanced FPCs only) The output classifies dropped packets into the following categories: <ul style="list-style-type: none"> • Low—Number of low-loss priority packets dropped because of RED. • Medium-low—Number of medium-low loss priority packets dropped because of RED. • Medium-high—Number of medium-high loss priority packets dropped because of RED. • High—Number of high-loss priority packets dropped because of RED.
RED-dropped bytes	<p>Number of bytes dropped because of RED. The byte counts vary by PIC type. For more information, see Table 142 on page 2017.</p> <ul style="list-style-type: none"> • (M Series and T Series routers only) On M320 and M120 routers and the T Series routers, only the total number of dropped bytes is displayed. On all other M Series routers, the output classifies dropped bytes into the following categories: <ul style="list-style-type: none"> • Low, non-TCP—Number of low-loss priority non-TCP bytes dropped because of RED. • Low, TCP—Number of low-loss priority TCP bytes dropped because of RED. • High, non-TCP—Number of high-loss priority non-TCP bytes dropped because of RED. • High, TCP—Number of high-loss priority TCP bytes dropped because of RED. • (J Series routers only) The output classifies dropped bytes into the following categories: <ul style="list-style-type: none"> • Low—Number of low-loss priority bytes dropped because of RED. • Medium-low—Number of medium-low loss priority bytes dropped because of RED. • Medium-high—Number of medium-high loss priority bytes dropped because of RED. • High—Number of high-loss priority bytes dropped because of RED.

Byte counts vary by PIC type. [Table 142 on page 2017](#) shows how the byte counts on the outbound interfaces vary depending on the PIC type. [Table 142 on page 2017](#) is based on the assumption that outbound interfaces are sending IP traffic with 478 bytes per packet.

Table 142: Byte Count by PIC Type

PIC Type	Output Level	Byte Count Includes	Comments
Gigabit Ethernet IQ and IQE PICs	Interface	<p>Queued: 490 bytes per packet, representing 478 bytes of Layer 3 packet + 12 bytes</p> <p>Transmitted: 490 bytes per packet, representing 478 bytes of Layer 3 packet + 12 bytes</p> <p>RED dropped: 496 bytes per packet representing 478 bytes of Layer 3 packet + 18 bytes</p>	<p>The 12 additional bytes include 6 bytes for the destination MAC address + 4 bytes for the VLAN + 2 bytes for the Ethernet type.</p> <p>For RED dropped, 6 bytes are added for the source MAC address.</p>
	Packet forwarding component	<p>Queued: 478 bytes per packet, representing 478 bytes of Layer 3 packet</p> <p>Transmitted: 478 bytes per packet, representing 478 bytes of Layer 3 packet</p>	—
Non-IQ PIC	Interface	<p>T Series, TX Series, T1600, and MX Series routers:</p> <ul style="list-style-type: none"> • Queued: 478 bytes of Layer 3 packet. • Transmitted: 478 bytes of Layer 3 packet. <p>T4000 routers with Type 5 FPCs :</p> <ul style="list-style-type: none"> • Queued: 478 bytes of Layer 3 packet + the full Layer 2 overhead including 4 bytes CRC + the full Layer 1 overhead 8 bytes preamble + 12 bytes Inter frame Gap. • Transmitted: 478 bytes of Layer 3 packet + the full Layer 2 overhead including 4 bytes CRC + the full Layer 1 overhead 8 bytes preamble + 12 bytes Interframe Gap. <p>M Series routers:</p> <ul style="list-style-type: none"> • Queued: 478 bytes of Layer 3 packet. • Transmitted: 478 bytes of Layer 3 packet + the full Layer 2 overhead. <p>PTX Series Packet Transport Switches:</p> <ul style="list-style-type: none"> • Queued: 478 bytes of Layer 3 packet + the full Layer 2 overhead including 4 bytes FCS + the full Layer 1 overhead of the MAC header DA + SA + EtherType (non-VLAN). • Transmitted: 478 bytes of Layer 3 packet + the full Layer 2 overhead including 4 bytes CRC + the full Layer 1 overhead of the MAC header DA + SA + EtherType (non-VLAN). • RED dropped: 478 bytes of Layer 3 packet + 22 bytes special header. To the TQ, this packet has 4 bytes more than queued or transmitted. 	<p>The Layer 2 overhead is 14 bytes for non-VLAN traffic and 18 bytes for VLAN traffic.</p>

Table 142: Byte Count by PIC Type (*continued*)

PIC Type	Output Level	Byte Count Includes	Comments
IQ and IQE PICs with a SONET/SDH interface	Interface	<p>Queued: 482 bytes per packet, representing 478 bytes of Layer 3 packet + 4 bytes</p> <p>Transmitted: 482 bytes per packet, representing 478 bytes of Layer 3 packet + 4 bytes</p> <p>RED dropped: 482 bytes per packet, representing 478 bytes of Layer 3 packet + 4 bytes</p>	The additional 4 bytes are for the Layer 2 Point-to-Point Protocol (PPP) header.
	Packet forwarding component	<p>Queued: 478 bytes per packet, representing 478 bytes of Layer 3 packet</p> <p>Transmitted: 486 bytes per packet, representing 478 bytes of Layer 3 packet + 8 bytes</p>	For transmitted packets, the additional 8 bytes includes 4 bytes for the PPP header and 4 bytes for a cookie.
Non-IQ PIC with a SONET/SDH interface	Interface	<p>T Series, TX Series, T1600, and MX Series routers:</p> <ul style="list-style-type: none"> Queued: 478 bytes of Layer 3 packet. Transmitted: 478 bytes of Layer 3 packet. <p>M Series routers:</p> <ul style="list-style-type: none"> Queued: 478 bytes of Layer 3 packet. Transmitted: 483 bytes per packet, representing 478 bytes of Layer 3 packet + 5 bytes RED dropped: 478 bytes per packet, representing 478 bytes of Layer 3 packet 	For transmitted packets, the additional 5 bytes includes 4 bytes for the PPP header and 1 byte for the packet loss priority (PLP).
Interfaces configured with Frame Relay Encapsulation	Interface	The default Frame Relay overhead is 7 bytes. If you configure the Frame Check Sequence (FCS) to 4 bytes, then the overhead increases to 10 bytes.	
1-port 10-Gigabit Ethernet IQ2 and IQ2-E PICs	Interface	<p>Queued: 478 bytes of Layer 3 packet + the full Layer 2 overhead including CRC.</p> <p>Transmitted: 478 bytes of Layer 3 packet + the full Layer 2 overhead including CRC.</p>	The Layer 2 overhead is 18 bytes for non-VLAN traffic and 22 bytes for VLAN traffic.
4-port 1G IQ2 and IQ2-E PICs	Packet forwarding component	Queued: 478 bytes of Layer 3 packet.	—
8-port 1G IQ2 and IQ2-E PICs		Transmitted: 478 bytes of Layer 3 packet.	

Sample Output

show interfaces queue (Aggregated Ethernet on a T320 Router)

The following example shows that the aggregated Ethernet interface, **ae1**, has traffic on queues **af1** and **af12**:

```

user@host> show interfaces queue ae1
Physical interface: ae1, Enabled, Physical link is Up
Interface index: 158, SNMP ifIndex: 33 Forwarding classes: 8 supported, 8 in use
Output queues: 8 supported, 8 in use
Queue: 0, Forwarding classes: be
  Queued:
    Packets      :           5           0 pps
    Bytes        :          242           0 bps
  Transmitted:
    Packets      :           5           0 pps
    Bytes        :          242           0 bps

show mvrp

Syntax	show mvrp
Release Information	Command introduced in Junos OS Release 10.1.
Description	For MX Series routers and EX Series switches, display Multiple VLAN Registration Protocol (MVRP) configuration information.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • show mvrp applicant-state on page 2049 • show mvrp dynamic-vlan-memberships on page 2051 • show mvrp interface on page 2052 • show mvrp registration-state on page 2053 • show mvrp statistics on page 2055
List of Sample Output	show mvrp on page 2047
Output Fields	Table 143 on page 2047 lists the output fields for the show mvrp command. Output fields are listed in the approximate order in which they appear.

Table 143: show mvrp Output Fields

Field Name	Field Description
MVRP dynamic VLAN creation	Displays whether global MVRP dynamic Virtual LAN (VLAN) creation is Enabled or Disabled .
MVRP BPDU MAC address	Displays the multicast media access control (MAC) address for MVRP. If configured, the provider MVRP multicast MAC address is used; otherwise, the customer MVRP multicast MAC address is used.
MVRP timers (ms)	Displays MVRP timer information: <ul style="list-style-type: none"> • Interface—The interface on which MVRP is configured. • Join—The maximum number of milliseconds the interfaces must wait before sending VLAN advertisements. • Leave—The number of milliseconds an interface must wait after receiving a Leave message to remove the interface from the VLAN specified in the message. • LeaveAll—The interval at which LeaveAll messages are sent on interfaces. LeaveAll messages maintain current MVRP VLAN membership information in the network.

Sample Output

show mvrp

```
user@host> show mvrp
```

```
MVRP configuration for routing instance 'default-switch'
MVRP dynamic VLAN creation : Enabled
MVRP BPDU MAC address      : Customer bridge group (01-80-C2-00-00-21)
MVRP timers (ms)

show mvrp applicant-state

Syntax	show mvrp applicant-state
Release Information	Command introduced in Junos OS Release 10.1.
Description	For MX Series routers and EX Series switches, display Multiple VLAN Registration Protocol (MVRP) applicant state information.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • show mvrp on page 2047 • show mvrp interface on page 2052 • show mvrp registration-state on page 2053 • show mvrp statistics on page 2055
List of Sample Output	show mvrp applicant-state on page 2050
Output Fields	Table 144 on page 2049 lists the output fields for the show mvrp applicant-state command. Output fields are listed in the approximate order in which they appear.

Table 144: show mvrp applicant-state Output Fields

Field Name	Field Description
VLAN Id	Displays the Virtual LAN (VLAN) ID number.
Interface	Displays the interface number associated with the VLAN ID.
State	Displays one of the following MVRP registrar states: <ul style="list-style-type: none"> • VO—Very anxious observer. • VP—Very anxious passive. • VA—Very anxious new. • AN—Anxious new. • AA—Anxious active. • QA—Quiet active. • LA—Leaving active. • AO—Anxious observer. • QO—Quiet observer. • LO—Leaving observer. • AP—Anxious passive. • QA—Quiet passive.

Sample Output

show mvrp applicant-state

```
user@host> show mvrp applicant-state
MVRP applicant state for routing instance 'default-switch'
(V0) Very anxious observer, (VP) Very anxious passive, (VA) Very anxious new,
(AN) Anxious new, (AA) Anxious active, (QA) Quiet active, (LA) Leaving active,
(A0) Anxious observer, (Q0) Quiet observer, (L0) Leaving observer,
(AP) Anxious passive, (QP) Quiet passive
```

VLAN Id	Interface	State
100	ge-11/3/0	Declaring (QA)
200	ge-11/3/0	Declaring (QA)
300	ge-11/3/0	Declaring (QA)

show mvrp dynamic-vlan-memberships

Syntax	show mvrp dynamic-vlan-memberships
Release Information	Command introduced in Junos OS Release 10.1.
Description	For MX Series routers and EX Series switches, display all Virtual LANs (VLANs) that have been created dynamically using Multiple VLAN Registration Protocol (MVRP) on the router or switch.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none"> • show mvrp on page 2047 • show mvrp applicant-state on page 2049 • show mvrp interface on page 2052 • show mvrp registration-state on page 2053 • show mvrp statistics on page 2055
List of Sample Output	show mvrp dynamic-vlan-memberships on page 2051
Output Fields	Table 145 on page 2051 lists the output fields for the show mvrp dynamic-vlan-memberships command. Output fields are listed in the approximate order in which they appear.

Table 145: show mvrp dynamic-vlan-memberships Output Fields

Field Name	Field Description
VLAN Id	The VLAN ID of the dynamically created VLAN.
Interfaces	The interface or interfaces that are bound to the dynamically created VLAN.

Sample Output

show mvrp dynamic-vlan-memberships

```

user@host> show mvrp dynamic-vlan-memberships
MVRP dynamic vlans for routing instance 'default-switch'
(s) static vlan, (f) fixed registration

VLAN Id      Interfaces
  100 (s)    ge-11/3/0
  200 (s)    ge-11/3/0
  300 (s)

```

show mvrp interface

Syntax	show mvrp interface
Release Information	Command introduced in Junos OS Release 10.1.
Description	For MX Series routers and EX Series switches, display Multiple VLAN Registration Protocol (MVRP) interface-specific information.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • show mvrp on page 2047 • show mvrp applicant-state on page 2049 • show mvrp dynamic-vlan-memberships on page 2051 • show mvrp registration-state on page 2053 • show mvrp statistics on page 2055
List of Sample Output	show mvrp interface on page 2052
Output Fields	Table 146 on page 2052 lists the output fields for the show mvrp interface command. Output fields are listed in the approximate order in which they appear.

Table 146: show mvrp interface Output Fields

Field Name	Field Description
Interface	Interface on which MVRP is configured.
Status	Status of the MVRP: Enabled or Disabled .
Registration Mode	Registration for the interface: Fixed , Forbidden , or Normal .
Applicant Mode	Applicant mode.

Sample Output

show mvrp interface

```

user@host> show mvrp interface
MVRP interface information for routing instance 'default-switch'

Interface      Status      Registration Mode      Applicant
Mode
ge-11/2/8      Enabled     Normal                 Normal
ge-11/0/9      Enabled     Normal                 Normal
ge-11/3/0      Enabled     Normal                 Normal

```

show mvrp registration-state

Syntax	show mvrp registration-state
Release Information	Command introduced in Junos OS Release 10.1.
Description	For MX Series routers and EX Series switches, display Multiple VLAN Registration Protocol (MVRP) registration state information.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • show mvrp on page 2047 • show mvrp dynamic-vlan-memberships on page 2051 • show mvrp interface on page 2052 • show mvrp statistics on page 2055
List of Sample Output	show mvrp registration-state on page 2053
Output Fields	Table 147 on page 2053 lists the output fields for the show mvrp registration-state command. Output fields are listed in the approximate order in which they appear.

Table 147: show mvrp registration-state Output Fields

Field Name	Field Description
VLAN Id	Displays the Virtual LAN (VLAN) ID number.
Interface	Displays the interface number associated with the VLAN ID.
Registrar State	Displays whether the registrar state is Registered or Empty .
Forced State	Displays whether the forced state is Registered or Empty .
Managed State	Displays one of the following states: <ul style="list-style-type: none"> • Fixed—VLANs always stay in a registered state and are declared as such on all other forwarding ports. • Normal—VLANs participate in the MVRP protocol and honor incoming join requests normally. • Forbidden—VLANs ignore the incoming join requests and always stay in an unregistered state.
STP State	Displays whether the Spanning Tree Protocol (STP) is Blocking or Forwarding .

Sample Output

show mvrp registration-state

```
user@host> show mvrp registration-state
MVRP registration state for routing instance 'default-switch'
```

VLAN Id	Interface	Registrar State	Forced State	Managed State	STP State
100	ge-11/2/8	Empty	Registered	Fixed	Forwarding
	ge-11/0/9	Empty	Empty	Normal	Forwarding
	ge-11/3/0	Registered	Registered	Normal	Forwarding
101	ge-11/2/8	Empty	Registered	Fixed	Forwarding
	ge-11/0/9	Empty	Empty	Normal	Forwarding
	ge-11/3/0	Registered	Registered	Normal	Forwarding

show mvrp statistics

Syntax	show mvrp statistics
Release Information	Command introduced in Junos OS Release 10.1.
Description	For MX Series routers and EX Series switches, display Multiple VLAN Registration Protocol (MVRP) statistics in the form of Multiple Registration Protocol data unit (MRPDU) messages.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • show mvrp on page 2047 • show mvrp applicant-state on page 2049 • show mvrp dynamic-vlan-memberships on page 2051 • show mvrp interface on page 2052 • show mvrp registration-state on page 2053

traceroute ethernet

Syntax	traceroute ethernet (<i>mac-address</i> <i>mep-id</i>) maintenance-association <i>ma-name</i> maintenance-domain <i>md-name</i> ttl <i>value</i> <wait seconds>
Release Information	Command introduced in Junos OS Release 9.0. mep-id option introduced in Junos OS Release 9.1.
Description	Triggers the linktrace protocol to trace the route between two maintenance points. The result of the traceroute protocol is stored in the path database. To display the path database, use the show oam ethernet connectivity-fault-management path-database command. Before using the traceroute command, you can verify the remote MEP's MAC address using the show oam ethernet connectivity-fault-management path-database command.
Options	mac-address —Destination unicast MAC address of the remote maintenance point. mep-id —MEP identifier of the remote maintenance point. The range of values is 1 through 8191. maintenance-association <i>ma-name</i> —Specifies an existing maintenance association from the set of configured maintenance associations. maintenance-domain <i>md-name</i> —Specifies an existing maintenance domain from the set of configured maintenance domains. ttl value —Number of hops to use in the linktrace request. The range is 1 to 255 hops. The default is 4. wait seconds —(Optional) Maximum time to wait for a response to the traceroute request. The range is 1 to 255 seconds. The default is 5.
Required Privilege Level	network
List of Sample Output	traceroute ethernet on page 2060
Output Fields	Table 149 on page 2059 lists the output fields for the traceroute ethernet command. Output fields are listed in the approximate order in which they appear.

Table 149: traceroute ethernet Output Fields

Field Name	Field Description
Linktrace to	MAC address of the destination maintenance point.
Interface	Local interface used to send the linktrace message (LTM).

Table 149: traceroute ethernet Output Fields (*continued*)

Field Name	Field Description
Maintenance Domain	Maintenance domain specified in the traceroute command.
Level	Maintenance domain level configured.
Maintenance Association	Maintenance association specified in the traceroute command.
Local Mep	The local maintenance end point identifier.
Transaction Identifier	4-byte identifier maintained by the MEP. Each LTM uses a transaction identifier. The transaction identifier is maintained globally across all Maintenance Domains. Use the transaction identifier to match an incoming linktrace response (LTR), with a previously sent LTM.
Hop	Sequential hop count of the linktrace path.
TTL	Number of hops remaining in the linktrace message. The time to live (TTL) is decremented at each hop.
Source MAC address	MAC address of the 802.1ag maintenance point that is sending the linktrace message.
Next-hop MAC address	MAC address of the 802.1ag node that is the next hop in the LTM path.

Sample Output

traceroute ethernet

```

user@host> traceroute ethernet maintenance-domain md1 maintenance-association ma1

Graceful Routing Engine Switchover Concepts

Graceful Routing Engine switchover (GRES) feature in Junos OS enables a routing platform with redundant Routing Engines to continue forwarding packets, even if one Routing Engine fails. Graceful Routing Engine switchover preserves interface and kernel information. Traffic is not interrupted. However, graceful Routing Engine switchover does not preserve the control plane. Neighboring routers detect that the router has experienced a restart and react to the event in a manner prescribed by individual routing protocol specifications. To preserve routing during a switchover, graceful Routing Engine switchover

must be combined with either graceful restart protocol extensions or nonstop active routing. Any updates to the master Routing Engine are replicated to the backup Routing Engine as soon as they occur. If the kernel on the master Routing Engine stops operating, the master Routing Engine experiences a hardware failure, or the administrator initiates a manual switchover, mastership switches to the backup Routing Engine.

NOTE: To quickly restore or to preserve routing protocol state information during a switchover, graceful Routing Engine switchover must be combined with either graceful restart or nonstop active routing (NSR), respectively. For more information about graceful restart, see [“Graceful Restart Concepts” on page 2085](#). For more information about nonstop active routing, see [“Nonstop Active Routing Concepts” on page 2072](#).

If the backup Routing Engine does not receive a keepalive from the master Routing Engine after 2 seconds (4 seconds on M20 routers), it determines that the master Routing Engine has failed and takes mastership. The Packet Forwarding Engine seamlessly disconnects from the old master Routing Engine and reconnects to the new master Routing Engine. The Packet Forwarding Engine does not reboot, and traffic is not interrupted. The new master Routing Engine and the Packet Forwarding Engine then become synchronized. If the new master Routing Engine detects that the Packet Forwarding Engine state is not up to date, it resends state update messages.

NOTE: Successive Routing Engine switchover events must be a minimum of 240 seconds (4 minutes) apart after both Routing Engines have come up.

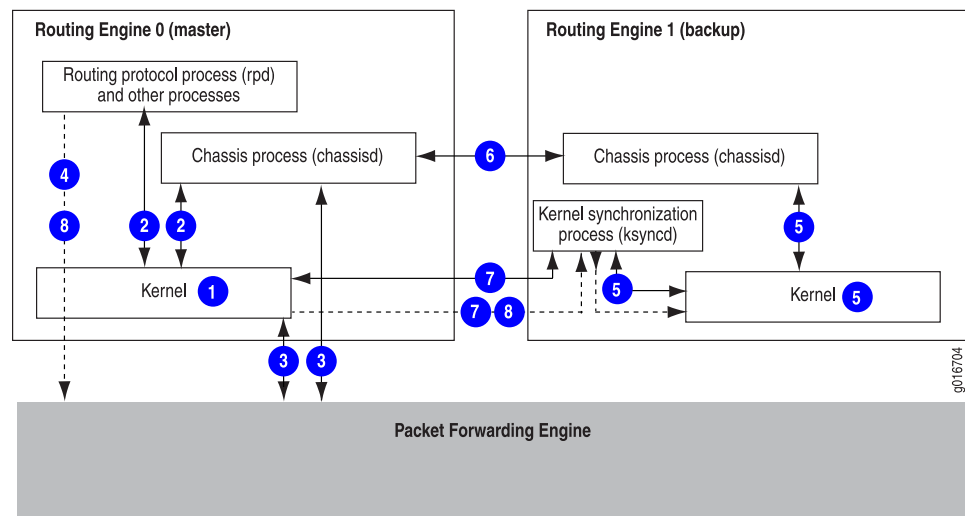

If the router displays a warning message similar to “Standby Routing Engine is not ready for graceful switchover. Packet Forwarding Engines that are not ready for graceful switchover might be reset,” do not attempt switchover. If you choose to proceed with switchover, only the Packet Forwarding Engines that were not ready for graceful switchover are reset. None of the FPCs should spontaneously restart. We recommend that you wait until the warning no longer appears and then proceed with the switchover.

NOTE: We do not recommend performing a commit operation on the backup Routing Engine when graceful Routing Engine switchover is enabled on the router.

[Figure 19 on page 2063](#) shows the system architecture of graceful Routing Engine switchover and the process a routing platform follows to prepare for a switchover.

Figure 19: Preparing for a Graceful Routing Engine Switchover

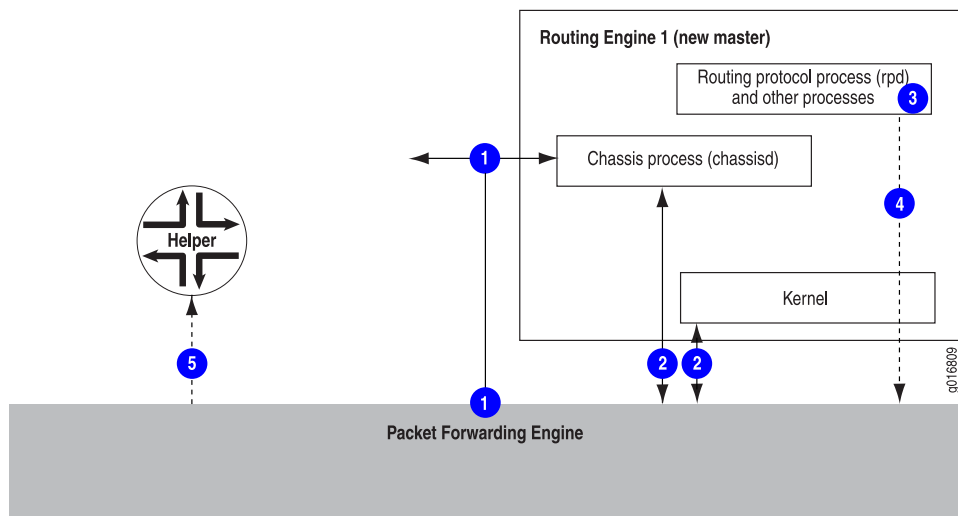

The switchover preparation process for graceful Routing Engine switchover follows these steps:

1. The master Routing Engine starts.
2. The routing platform processes (such as the chassis process [chassisd]) start.
3. The Packet Forwarding Engine starts and connects to the master Routing Engine.
4. All state information is updated in the system.
5. The backup Routing Engine starts.
6. The system determines whether graceful Routing Engine switchover has been enabled.
7. The kernel synchronization process (ksyncd) synchronizes the backup Routing Engine with the master Routing Engine.
8. After ksyncd completes the synchronization, all state information and the forwarding table are updated.

Figure 20 on page 2064 shows the effects of a switchover on the routing platform.

Figure 20: Graceful Routing Engine Switchover Process

When a switchover occurs, the switchover process follows these steps:

1. When keepalives from the master Routing Engine are lost, the system switches over gracefully to the backup Routing Engine.
2. The Packet Forwarding Engine connects to the backup Routing Engine, which becomes the new master.
3. Routing platform processes that are not part of graceful Routing Engine switchover (such as the routing protocol process [rpd]) restart.
4. State information learned from the point of the switchover is updated in the system.
5. If configured, graceful restart protocol extensions collect and restore routing information from neighboring peer *helper* routers.

NOTE: On T Series and M320 routers, the Switch Interface Boards (SIBs) are taken offline and restarted one by one during a graceful Routing Engine switchover. This is done to provide the SPMB that manages the SIB enough time to populate state information for its associated SIB. However, on a fully-populated chassis where all FPCs are sending traffic at full line rate, there might be momentary packet loss during the switchover.

Effects of a Routing Engine Switchover

Table 150 on page 2065 describes the effects of a Routing Engine switchover when no high availability features are enabled and when graceful Routing Engine switchover, graceful restart, and nonstop active routing features are enabled.

Table 150: Effects of a Routing Engine Switchover

Feature	Benefits	Considerations
Dual Routing Engines only (no features enabled)	When the switchover to the new master Routing Engine is complete, routing convergence takes place and traffic is resumed.	All physical interfaces are taken offline, Packet Forwarding Engines restart, the standby Routing Engine restarts the routing protocol process (rpd), and all hardware and interfaces are discovered by the new master Routing Engine. The switchover takes several minutes and all of the router's adjacencies are aware of the physical (interface alarms) and routing (topology) change.
Graceful Routing Engine switchover enabled	During the switchover, interface and kernel information is preserved. The switchover is faster because the Packet Forwarding Engines are not restarted.	The new master Routing Engine restarts the routing protocol process (rpd). All hardware and interfaces are acquired by a process that is similar to a warm restart. All adjacencies are aware of the router's change in state.
Graceful Routing Engine switchover and nonstop active routing enabled	Traffic is not interrupted during the switchover. Interface, kernel, and routing protocol information is preserved.	Unsupported protocols must be refreshed using the normal recovery mechanisms inherent in each protocol.
Graceful Routing Engine switchover and graceful restart enabled	Traffic is not interrupted during the switchover. Interface and kernel information is preserved. Graceful restart protocol extensions quickly collect and restore routing information from the neighboring routers.	Neighbors are required to support graceful restart and a wait interval is required. The routing protocol process (rpd) restarts. For certain protocols, a significant change in the network can cause graceful restart to stop.

- [Understanding High Availability Features on Juniper Networks Routers](#)
- [Graceful Routing Engine Switchover System Requirements on page 2065](#)
- [Configuring Graceful Routing Engine Switchover on page 2117](#)
- [Requirements for Routers with a Backup Router Configuration on page 2068](#)

Graceful Routing Engine Switchover System Requirements

Graceful Routing Engine switchover is supported on all routing platforms that contain dual Routing Engines. All Routing Engines configured for graceful Routing Engine switchover must run the same Junos OS Release. Hardware and software support for graceful Routing Engine switchover is described in the following sections:

- [Graceful Routing Engine Switchover Platform Support on page 2066](#)
- [Graceful Routing Engine Switchover Feature Support on page 2066](#)
- [Graceful Routing Engine Switchover DPC Support on page 2067](#)
- [Graceful Routing Engine Switchover and Subscriber Access on page 2068](#)
- [Graceful Routing Engine Switchover PIC Support on page 2068](#)

Graceful Routing Engine Switchover Platform Support

To enable graceful Routing Engine switchover, your system must meet these minimum requirements:

- M20 and M40e routers—Junos OS Release 5.7 or later
- M10i router—Junos OS Release 6.1 or later
- M320 router—Junos OS Release 6.2 or later
- T320 router, T640 router, and TX Matrix router—Junos OS Release 7.0 or later
- M120 router—Junos OS Release 8.2 or later
- MX960 router—Junos OS Release 8.3 or later
- MX480 router—Junos OS Release 8.4 or later (8.4R2 recommended)
- MX240 router—Junos OS Release 9.0 or later
- T1600 router—Junos OS Release 8.5 or later
- T4000 router—Junos OS Release 12.1R2 or later
- TX Matrix Plus router—Junos OS Release 9.6 or later

For more information about support for graceful Routing Engine switchover, see the sections that follow.

Graceful Routing Engine Switchover Feature Support

Graceful Routing Engine switchover supports most Junos OS features in Release 5.7 and later. Particular Junos OS features require specific versions of Junos OS. See [Table 151 on page 2066](#).

Table 151: Graceful Routing Engine Switchover Feature Support

Application	Junos OS Release
Aggregated Ethernet interfaces with Link Aggregation Control Protocol (LACP) and aggregated SONET interfaces	6.2
Asynchronous Transfer Mode (ATM) virtual circuits (VCs)	6.2
Logical systems	6.3
NOTE: In Junos OS Release 9.3 and later, the logical router feature is renamed to logical system.	
Multicast	6.4 (7.0 for TX Matrix router)
Multilink Point-to-Point Protocol (MLPPP) and Multilink Frame Relay (MLFR)	7.0

Table 151: Graceful Routing Engine Switchover Feature Support (*continued*)

Application	Junos OS Release
Automatic Protection Switching (APS)—The current active interface (either the designated working or the designated protect interface) remains the active interface during a Routing Engine switchover.	7.4
Point-to-multipoint Multiprotocol Label Switching MPLS LSPs (transit only)	7.4
Compressed Real-Time Transport Protocol (CRTP)	7.6
Virtual private LAN service (VPLS)	8.2
Ethernet Operation, Administration, and Management (OAM) as defined by IEEE 802.3ah	8.5
Extended DHCP relay agent	8.5
Ethernet OAM as defined by IEEE 802.1ag	9.0
Packet Gateway Control Protocol (PGCP) process (pgcpd) on Multiservices 500 PICs on T640 routers.	9.0
Subscriber access	9.4
Layer 2 Circuit and LDP-based VPLS pseudowire redundant configuration	9.6

The following constraints apply to graceful Routing Engine switchover feature support:

- When graceful Routing Engine switchover and aggregated Ethernet interfaces are configured in the same system, the aggregated Ethernet interfaces must not be configured for fast-polling LACP. When fast polling is configured, the LACP polls time out at the remote end during the Routing Engine mastership switchover. When LACP polling times out, the aggregated link and interface are disabled. The Routing Engine mastership change is fast enough that standard and slow LACP polling do not time out during the procedure. However, note that this restriction does not apply to MX Series Routers that are running Junos OS Release 9.4 or later and have distributed periodic packet management (PPM) enabled—which is the default configuration—on them. In such cases, you can configure graceful Routing Engine switchover and have aggregated Ethernet interfaces configured for fast-polling LACP on the same device.
- VRRP changes mastership when a Routing Engine switchover occurs, even when graceful Routing Engine switchover is configured.

Graceful Routing Engine Switchover DPC Support

Graceful Routing Engine switchover supports all Dense Port Concentrators (DPCs) on the MX Series 3D Universal Edge Routers running the appropriate version of Junos OS. For more information about DPCs, see the *MX Series DPC Guide*.

Graceful Routing Engine Switchover and Subscriber Access

Graceful Routing Engine switchover currently supports most of the features directly associated with dynamic DHCP and dynamic PPPoE subscriber access. Graceful Routing Engine switchover also supports the unified in-service software upgrade (ISSU) for the DHCP access model and the PPPoE access model used by subscriber access.

Graceful Routing Engine Switchover PIC Support

Graceful Routing Engine switchover is supported on most PICs, except for the services PICs listed in this section. The PIC must be on a supported routing platform running the appropriate version of Junos OS. For information about FPC types, FPC/PIC compatibility, and the initial Junos OS Release in which an FPC supported a particular PIC, see the PIC guide for your router platform.

The following constraints apply to graceful Routing Engine switchover support for services PICs:

- You can include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level on a router with Adaptive Services, Multiservices, and Tunnel Services PICs configured on it and successfully commit the configuration. However, all services on these PICs—except the Layer 2 service packages and extension-provider and SDK applications on Multiservices PICs—are reset during a switchover.
- Graceful Routing Engine switchover is not supported on any Monitoring Services PICs or Multilink Services PICs. If you include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level on a router with either of these PIC types configured on it and issue the **commit** command, the commit fails.
- Graceful Routing Engine switchover is not supported on Multiservices 400 PICs configured for monitoring services applications. If you include the **graceful-switchover** statement, the commit fails.

NOTE: When an unsupported PIC is online, you cannot enable graceful Routing Engine switchover. If graceful Routing Engine switchover is already enabled, an unsupported PIC cannot come online.

Requirements for Routers with a Backup Router Configuration

If your Routing Engine configuration includes a **backup-router** statement or an **inet6-backup-router** statement, you can also use the **destination** statement to specify a subnet address or multiple subnet addresses for the backup router. Include destination subnets for the backup Routing Engine at the **[edit system (backup-router]**

inet6-backup-router) address] hierarchy level. This requirement also applies to any T640 router connected to a TX Matrix router that includes a **backup-router** or **inet6-backup-router** statement.

NOTE: If you have a backup router configuration in which multiple static routes point to a gateway from the management Ethernet interface, you must configure prefixes that are more specific than the static routes or include the **retain** flag at the **[edit routing-options static route]** hierarchy level.

For example, if you configure the static route 172.16.0.0/12 from the management Ethernet interface for management purposes, you must specify the backup router configuration as follows:

```
backup-router 172.29.201.62 destination [172.16.0.0/13 172.16.128.0/13]
```

Nonstop Bridging Concepts

Nonstop bridging uses the same infrastructure as graceful Routing Engine switchover (GRES) to preserve interface and kernel information. However, nonstop bridging also saves Layer 2 Control Protocol (L2CP) information by running the Layer 2 Control Protocol process (l2cpd) on the backup Routing Engine.

NOTE: To use nonstop bridging, you must first enable graceful Routing Engine switchover on your routing platform. For more information about graceful Routing Engine switchover, see [“Understanding Graceful Routing Engine Switchover in the Junos OS” on page 2061](#).

Figure 21 on page 2070 shows the system architecture of nonstop bridging and the process a routing platform follows to prepare for a switchover.

Figure 21: Nonstop Bridging Switchover Preparation Process

The switchover preparation process for nonstop bridging follows these steps:

1. The master Routing Engine starts.
2. The routing platform processes on the master Routing Engine (such as the chassis process [chassisd] and the Layer 2 Control Protocol process [l2cpd]) start.
3. The Packet Forwarding Engine starts and connects to the master Routing Engine.
4. All state information is updated in the system.
5. The backup Routing Engine starts, including the chassis process (chassisd) and the Layer 2 Control Protocol process (l2cpd).
6. The system determines whether graceful Routing Engine switchover and nonstop bridging have been enabled.
7. The kernel synchronization process (ksyncd) synchronizes the backup Routing Engine with the master Routing Engine.
8. For supported protocols, state information is updated directly between the l2cpds on the master and backup Routing Engines.

Figure 22 on page 2071 shows the effects of a switchover on the routing platform.

Figure 22: Nonstop Bridging During a Switchover

The switchover process follows these steps:

1. When keepalives from the master Routing Engine are lost, the system switches over gracefully to the backup Routing Engine.
2. The Packet Forwarding Engine connects to the backup Routing Engine, which becomes the new master. Because the Layer 2 Control Protocol process (l2cpd) and chassis process (chassisd) are already running, these processes do not need to restart.
3. State information learned from the point of the switchover is updated in the system. Forwarding and bridging are continued during the switchover, resulting in minimal packet loss.

Nonstop Bridging System Requirements

This topic contains the following sections:

- [Platform Support on page 2071](#)
- [Protocol Support on page 2072](#)

Platform Support

Nonstop bridging is supported on MX Series 3D Universal Edge Routers. Your system must be running Junos OS Release 8.4 or later.

Nonstop bridging is supported on EX Series Ethernet Switch with redundant Routing Engines.

For a list of the EX Series switches and Layer 2 protocols that support nonstop bridging, see [“EX Series Switch Software Features Overview” on page 63](#).

NOTE: All Routing Engines configured for nonstop bridging must be running the same Junos OS release.

Protocol Support

Nonstop bridging is supported for the following Layer 2 control protocols:

- Spanning Tree Protocol (STP)
- Rapid Spanning Tree Protocol (RSTP)
- Multiple Spanning Tree Protocol (MSTP)

Nonstop Active Routing (NSR)

- [Nonstop Active Routing Concepts on page 2072](#)
- [Nonstop Active Routing System Requirements on page 2075](#)

Nonstop Active Routing Concepts

Nonstop active routing (NSR) uses the same infrastructure as graceful Routing Engine switchover (GRES) to preserve interface and kernel information. However, nonstop active routing also saves routing protocol information by running the routing protocol process (rpd) on the backup Routing Engine. By saving this additional information, nonstop active routing is self-contained and does not rely on helper routers to assist the routing platform in restoring routing protocol information. Nonstop active routing is advantageous in networks where neighbor routers do not support graceful restart protocol extensions. As a result of this enhanced functionality, nonstop active routing is a natural replacement for graceful restart.

NOTE: To use nonstop active routing, you must first enable graceful Routing Engine switchover on your routing platform. For more information about graceful Routing Engine switchover, see [“Understanding Graceful Routing Engine Switchover in the Junos OS” on page 2061](#).

Figure 23 on page 2073 shows the system architecture of nonstop active routing and the process a routing platform follows to prepare for a switchover.

Figure 23: Nonstop Active Routing Switchover Preparation Process

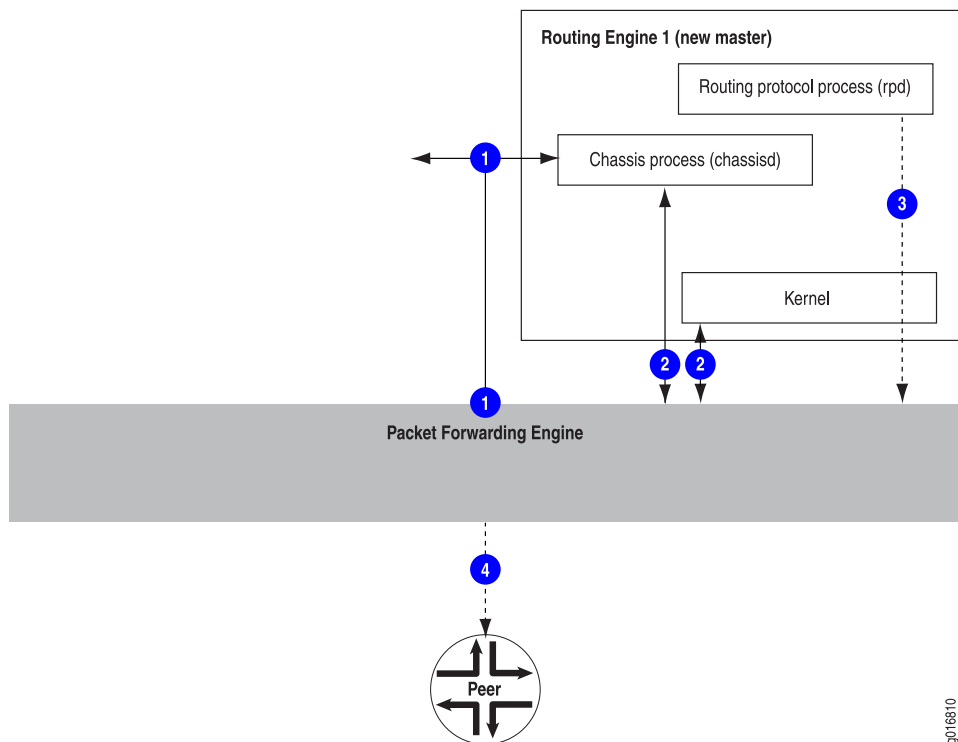

The switchover preparation process for nonstop active routing follows these steps:

1. The master Routing Engine starts.
2. The routing platform processes on the master Routing Engine (such as the chassis process [chassisd] and the routing protocol process [rpd]) start.
3. The Packet Forwarding Engine starts and connects to the master Routing Engine.
4. All state information is updated in the system.
5. The backup Routing Engine starts, including the chassis process (chassisd) and the routing protocol process (rpd).
6. The system determines whether graceful Routing Engine switchover and nonstop active routing have been enabled.
7. The kernel synchronization process (ksyncd) synchronizes the backup Routing Engine with the master Routing Engine.
8. For supported protocols, state information is updated directly between the routing protocol processes on the master and backup Routing Engines.

Figure 24 on page 2074 shows the effects of a switchover on the routing platform.

Figure 24: Nonstop Active Routing During a Switchover

The switchover process follows these steps:

1. When keepalives from the master Routing Engine are lost, the system switches over gracefully to the backup Routing Engine.
2. The Packet Forwarding Engine connects to the backup Routing Engine, which becomes the new master. Because the routing protocol process (rpd) and chassis process (chassisd) are already running, these processes do not need to restart.
3. State information learned from the point of the switchover is updated in the system. Forwarding and routing are continued during the switchover, resulting in minimal packet loss.
4. Peer routers continue to interact with the routing platform as if no change had occurred. Routing adjacencies and session state relying on underlying routing information are preserved and not reset.

Nonstop Active Routing Platform Support

[Table 152 on page 2075](#) lists the platforms that support nonstop active routing (NSR).

Table 152: Nonstop Active Routing Platform Support

Platform	Junos OS Release
M10i router	8.4 or later
M20 router	8.4 or later
M40e router	8.4 or later
M120 router	9.0 or later
M320 router	8.4 or later
MX Series routers	9.0 or later
PTX Series Packet Transport switches	12.1R4 or later
<p>NOTE:</p> <p>Nonstop active routing (NSR) switchover on PTX series is supported only for the following MPLS and VPN protocols and applications using chained composite next hops:</p> <ul style="list-style-type: none"> • Labeled BGP • Layer 2 VPNs excluding Layer 2 interworking (Layer 2 stitching) • Layer 3 VPNs • LDP • RSVP 	
T320 router, T640 router, and TX Matrix router	8.4 or later
T1600 router	8.5 or later

Table 152: Nonstop Active Routing Platform Support (*continued*)

Platform	Junos OS Release
TX Plus Matrix router	10.0 or later

NOTE: All Routing Engines configured for nonstop active routing must be running the same Junos OS release.

Nonstop Active Routing Protocol and Feature Support

Table 153 on page 2076 lists the protocols that are supported by nonstop active routing.

Table 153: Nonstop Active Routing Protocol and Feature Support

Protocol	Junos OS Release
Aggregated Ethernet interfaces with Link Aggregation Control Protocol (LACP)	9.4 or later
Bidirectional Forwarding Detection (BFD)	8.5 or later
For more information, see “Nonstop Active Routing BFD Support” on page 2078.	
BGP	8.4 or later
For more information, see “Nonstop Active Routing BGP Support” on page 2079.	
Labeled BGP (PTX Series Packet Transport Switches only)	12.1R4 or later
IS-IS	8.4 or later
LDP	8.4 or later
LDP-based virtual private LAN service (VPLS)	9.3 or later
LDP OAM (operation, administration, and management) features	9.6 or later
LDP (PTX Series Packet Transport Switches only)	12.1R4 or later

Nonstop active routing support for LDP includes:

- LDP unicast transit LSPs
- LDP egress LSPs for labeled internal BGP (IBGP) and external BGP (EBGP)
- LDP over RSVP transit LSPs
- LDP transit LSPs with indexed next hops
- LDP transit LSPs with unequal cost load balancing

NOTE: Nonstop active routing is not supported for LDP Point-to-Multipoint LSPs and LDP ingress LSPs.

Table 153: Nonstop Active Routing Protocol and Feature Support (*continued*)

Protocol	Junos OS Release
Layer 2 circuits	(on LDP-based VPLS) 9.2 or later (on RSVP-TE LSP) 11.1 or later
Layer 2 VPNs	9.1 or later
Layer 2 VPNs (PTX Series Packet Transport Switches only)	12.1R4 or later
NOTE: Nonstop active routing is not supported for Layer 2 interworking (Layer 2 stitching).	
Layer 3 VPNs (see the first Note after this table for restrictions)	9.2 or later
Layer 3 VPNs (PTX Series Packet Transport Switches only)	12.1R4 or later
Multicast Source Discovery Protocol (MSDP)	12.1 or later
For more information, see “Nonstop Active Routing MSDP Support” on page 2083 .	
OSPF/OSPFv3	8.4 or later
Protocol Independent Multicast (PIM)	(for IPv4) 9.3 or later
For more information, see “Nonstop Active Routing PIM Support” on page 2080 .	(for IPv6) 10.4 or later
RIP and RIP next generation (RIPng)	9.0 or later
RSVP (PTX Series Packet Transport Switches only)	12.1R4 or later
Nonstop active routing support for RSVP includes:	
<ul style="list-style-type: none"> Point-to-Multipoint LSPs <ul style="list-style-type: none"> RSVP Point-to-Multipoint ingress, transit, and egress LSPs using existing non-chained next hop. RSVP Point-to-Multipoint transit LSPs using composite next hops for Point-to-Multipoint label routes. Point-to-Point LSPs <ul style="list-style-type: none"> RSVP Point-to-Point ingress, transit, and egress LSPs using non-chained next hops. RSVP Point-to-Point transit LSPs using chained composite next hops. 	
RSVP-TE LSP	9.5 or later
For more information, see “Nonstop Active Routing Support for RSVP-TE LSPs” on page 2083 .	

Table 153: Nonstop Active Routing Protocol and Feature Support (*continued*)

Protocol	Junos OS Release
VPLS	(LDP-based) 9.1 or later (RSVP-TE-based) 11.2 or later

NOTE: Layer 3 VPN support does not include dynamic GRE tunnels, multicast VPNs, or BGP flow routes.

NOTE: If you configure a protocol that is not supported by nonstop active routing, the protocol operates as usual. When a switchover occurs, the state information for the unsupported protocol is not preserved and must be refreshed using the normal recovery mechanisms inherent in the protocol.

NOTE: On routers that have logical systems configured on them, only the master logical system supports nonstop active routing.

Nonstop Active Routing BFD Support

Nonstop active routing supports the Bidirectional Forwarding Detection (BFD) protocol, which uses the topology discovered by routing protocols to monitor neighbors. The BFD protocol is a simple hello mechanism that detects failures in a network. Because BFD is streamlined to be efficient at fast liveness detection, when it is used in conjunction with routing protocols, routing recovery times are improved. With nonstop active routing enabled, BFD session states are not restarted when a Routing Engine switchover occurs.

NOTE: BFD session states are saved only for clients using aggregate or static routes or for BGP, IS-IS, OSPF/OSPFv3, or PIM.

When a BFD session is distributed to the Packet Forwarding Engine, BFD packets continue to be sent during a Routing Engine switchover. If nondistributed BFD sessions are to be kept alive during a switchover, you must ensure that the session failure detection time is greater than the Routing Engine switchover time. The following BFD sessions are not distributed to the Packet Forwarding Engine: multihop sessions, tunnel-encapsulated sessions, and sessions over integrated routing and bridging (IRB) interfaces.

NOTE: BFD is an intensive protocol that consumes system resources. Specifying a minimum interval for BFD less than 100 ms for Routing Engine-based sessions and 10 ms for distributed BFD sessions can cause undesired BFD flapping. The minimum-interval configuration statement is a BFD liveness detection parameter.

Depending on your network environment, these additional recommendations might apply:

- For large-scale network deployments with a large number of BFD sessions, specify a minimum interval of 300 ms for Routing Engine-based sessions, and 100 ms for distributed BFD sessions.
- For very large-scale network deployments with a large number of BFD sessions, contact Juniper Networks customer support for more information.
- For BFD sessions to remain up during a Routing Engine switchover event when nonstop active routing is configured, specify a minimum interval of 2500 ms for Routing Engine-based sessions. For distributed BFD sessions with nonstop active routing configured, the minimum interval recommendations are unchanged and depend only on your network deployment.

Nonstop Active Routing BGP Support

Nonstop active routing BGP support is subject to the following conditions:

- You must include the **path-selection external-router-ID** statement at the **[edit protocols bgp]** hierarchy level to ensure consistent path selection between the master and backup Routing Engines during and after the nonstop active routing switchover.
- If the BGP peer in the master Routing Engine has negotiated address-family capabilities that are not supported for nonstop active routing, then the corresponding BGP neighbor state on the backup Routing Engine shows as idle. On switchover, the BGP session is reestablished from the new master Routing Engine.

Only the following address families are supported for nonstop active routing.

NOTE: Address families are supported only on the main instance of BGP. Only unicast is supported on VRF instances.

- inet unicast
- inet labeled-unicast
- inet multicast
- inet6 labeled-unicast
- inet6 multicast
- inet6 unicast

- route-target
 - l2vpn signaling
 - inet6-vpn unicast
 - inet-vpn unicast
 - inet-mdt
 - iso-vpn
- BGP route dampening does not work on the backup Routing Engine when nonstop active routing is enabled.

Nonstop Active Routing Layer 2 Circuit and VPLS Support

Nonstop active routing supports Layer 2 circuit and VPLS on both LDP-based and RSVP-TE-based networks. Nonstop active routing support enables the backup Routing Engine to track the label advertised by Layer 2 circuit and VPLS on the primary Routing Engine, and to use the same label after the Routing Engine switchover.

in Junos OS Release 9.6 and later, nonstop active routing support is extended to the Layer 2 circuit and LDP-based VPLS pseudowire redundant configurations.

Nonstop Active Routing PIM Support

Nonstop active routing supports Protocol Independent Multicast (PIM) with stateful replication on backup Routing Engines. State information replicated on the backup Routing Engine includes information about neighbor relationships, join and prune events, rendezvous point (RP) sets, synchronization between routes and next hops, multicast session states, and the forwarding state between the two Routing Engines.

NOTE: Nonstop active routing for PIM is supported for IPv4 on Junos OS Release 9.3 and later, and for IPv6 on Junos OS Release 10.4 and later. Starting with Release 11.1, Junos OS also supports nonstop active routing for PIM on devices that have both IPv4 and IPv6 configured on them.

To configure nonstop active routing for PIM, include the same statements in the configuration as for other protocols: the **nonstop-routing** statement at the **[edit routing-options]** hierarchy level and the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level. To trace PIM nonstop active routing events, include the **flag nsr-synchronization** statement at the **[edit protocols pim traceoptions]** hierarchy level.

NOTE: The **clear pim join**, **clear pim register**, and **clear pim statistics** operational mode commands are not supported on the backup Routing Engine when nonstop active routing is enabled.

Nonstop active routing support varies for different PIM features. The features fall into the following three categories: supported features, unsupported features, and incompatible features.

Supported features:

- Auto-RP

NOTE: Nonstop active routing PIM support on IPv6 does not support auto-RP because IPv6 does not support auto-RP.

- Bootstrap router (BSR)
- Static RPs
- Embedded RP on non-RP IPv6 routers
- Local RP

NOTE: RP set information synchronization is supported for local RP and BSR (on IPv4 and IPv6), autoRP (on IPv4), and embedded RP (on IPv6).

- BFD
- Dense mode
- Sparse mode
- Source-specific multicast (SSM)
- Draft Rosen multicast VPNs (MVPNs)
- Anycast RP (anycast RP set information synchronization and anycast RP register state synchronization on IPv4 and IPv6 configurations)
- Flow maps
- Unified ISSU
- Policy features such as neighbor policy, bootstrap router export and import policies, scope policy, flow maps, and reverse path forwarding (RPF) check policies
- Upstream assert synchronization
- PIM join load balancing

Starting with Release 12.2, Junos OS extends the nonstop active routing PIM support to draft Rosen MVPNs. Nonstop active routing PIM support for draft Rosen MVPNs enables nonstop active routing-enabled devices to preserve draft Rosen MPVN-related information—such as default and data multicast distribution tree (MDT) states—across switchovers. In releases earlier than 12.2, nonstop active routing PIM configuration was incompatible with draft Rosen MPVN configuration.

The backup Routing Engine sets up the default MDT based on the configuration and the information it receives from the master Routing Engine, and keeps updating the default MDT state information.

However, for data MDTs, the backup Routing Engine relies on the master Routing Engine to provide updates when data MDTs are created, updated, or deleted. The backup Routing

Engine neither monitors data MDT flow rates nor triggers a data MDT switchover based on variations in flow rates. Similarly, the backup Routing Engine does not maintain the data MDT delay timer or timeout timer. It does not send MDT join TLV packets for the data MDTs until it takes over as the master Routing Engine. After the switchover, the new master Routing Engine starts sending MDT join TLV packets for each data MDT, and also resets the data MDT timers. Note that the expiration time for the timers might vary from the original values on the previous master Routing Engine.

Starting with Release 12.3, Junos OS extends the Protocol Independent Multicast (PIM) nonstop active routing support to IGMP-only interfaces.

In Junos OS releases earlier than 12.3, the PIM joins created on IGMP-only interfaces were not replicated on the backup Routing Engine. Thus, the corresponding multicast routes were marked as pruned (meaning discarded) on the backup Routing Engine. Because of this limitation, after a switchover, the new master Routing Engine had to wait for the IGMP module to come up and start receiving reports to create PIM joins and to install multicast routes. This caused traffic loss until the multicast joins and routes were reinstated.

However, in Junos OS Release 12.3 and later, the multicast joins on the IGMP-only interfaces are mapped to PIM states, and these states are replicated on the backup Routing Engine. If the corresponding PIM states are available on the backup, the multicast routes are marked as forwarding on the backup Routing Engine. This enables uninterrupted traffic flow after a switchover. This enhancement covers IGMPv2, IGMPv3, MLDv1, and MLDv2 reports and leaves.

Unsupported features: You can configure the following PIM features on a router along with nonstop active routing, but they function as if nonstop active routing is not enabled. In other words, during Routing Engine switchover and other outages, their state information is not preserved, and traffic loss is to be expected.

- Internet Group Management Protocol (IGMP) exclude mode
- IGMP snooping

Incompatible features: Nonstop active routing does not support the following features, and you cannot configure them on a router enabled for PIM nonstop active routing. The commit operation fails if the configuration includes both nonstop active routing and one or more of these features:

- Next-generation MVPNs with PIM provider tunnels

Junos OS provides a configuration statement that disables nonstop active routing for PIM only, so that you can activate incompatible PIM features and continue to use nonstop active routing for the other protocols on the router. Before activating an incompatible PIM feature, include the **nonstop-routing disable** statement at the **[edit protocols pim]** hierarchy level. Note that in this case, nonstop active routing is disabled for all PIM features, not just incompatible features.

Nonstop Active Routing MSDP Support

Starting with Release 12.1, Junos OS extends nonstop active routing support to the Multicast Source Discovery Protocol (MSDP).

Nonstop active routing support for MSDP preserves the following MSDP-related information across the switchover:

- MSDP configuration and peer information
- MSDP peer socket information
- Source-active and related information

However, note that the following restrictions or limitations apply to nonstop active routing MSDP support:

- Because the backup Routing Engine learns the active source information by processing the source-active messages from the network, synchronizing of source active information between the master and backup Routing Engines might take up to 60 seconds. So, no planned switchover is allowed within 60 seconds of the initial replication of the sockets.
- Similarly, Junos OS does not support two planned switchovers within 240 seconds of each other.

Junos OS enables you to trace MSDP nonstop active routing events by including the **flag nsr-synchronization** statement at the **[edit protocols msdp traceoptions]** hierarchy level.

Nonstop Active Routing Support for RSVP-TE LSPs

Junos OS extends nonstop active routing support to label-switching routers (LSRs) and Layer 2 Circuits that are part of an RSVP-TE LSP. Nonstop active routing support on LSRs ensures that the master to backup Routing Engine switchover on an LSR remains transparent to the network neighbors and that the LSP information remains unaltered during and after the switchover.

You can use the **show rsvp version** command to view the nonstop active routing mode and state on an LSR. Similarly, you can use the **show mpls lsp** and **show rsvp session** commands on the standby Routing Engine to view the state recreated on the standby Routing Engine.

The Junos OS nonstop active routing feature is also supported on RSVP point-to-multipoint LSPs. Nonstop active routing support for RSVP point-to-multipoint egress and transit LSPs was added in Junos OS Release 11.4, and for ingress LSPs in Release 12.1. During the switchover, the LSP comes up on the backup Routing Engine that shares and synchronizes the state information with the master Routing Engine before and after the switchover. Nonstop active routing support for point-to-multipoint transit and egress LSPs ensures that the switchover remains transparent to the network neighbors, and preserves the LSP information across the switchover.

However, Junos OS nonstop active routing support for RSVP point-to-multipoint LSPs does not include support for dynamically created point-to-multipoint LSPs, such as VPLS and next-generation MVPNs.

The **show rsvp session detail** command enables you to check the point-to-multipoint LSP remerge state information (**P2MP LSP re-merge**; possible values are **head**, **member**, and **none**).

However, Junos OS does not support nonstop active routing for the following features:

- Generalized Multiprotocol Label Switching (GMPLS) and LSP hierarchy
- Interdomain or loose-hop expansion LSPs
- BFD liveness detection

Nonstop active routing support for RSVP-TE LSPs is subject to the following limitations and restrictions:

- Detour LSPs are not maintained across a switchover and so, detour LSPs might fail to come back online after the switchover.
- Control plane statistics corresponding to the **show rsvp statistics** and **show rsvp interface detail | extensive** commands are not maintained across Routing Engine switchovers.
- Statistics from the backup Routing Engine are not reported for **show mpls lsp statistics** and **monitor mpls label-switched-path** commands. However, if a switchover occurs, the backup Routing Engine, after taking over as the master, starts reporting statistics. Note that the **clear statistics** command issued on the old master Routing Engine does not have any effect on the new master Routing Engine, which reports statistics, including any uncleared statistics.
- State timeouts might take additional time during nonstop active routing switchover. For example, if a switchover occurs after a neighbor has missed sending two hello messages to the master, the new master Routing Engine waits for another three hello periods before timing out the neighbor.
- On the RSVP ingress router, if you configure auto-bandwidth functionality, the bandwidth adjustment timers are set in the new master after the switchover. This causes a one-time increase in the length of time required for the bandwidth adjustment after the switchover occurs.
- RSVP ingress LSPs that have BFD liveness detection enabled on them do not come up on the backup Routing Engine during the switchover. Such BFD-enabled LSPs have to be reestablished after the switchover.
- Backup LSPs —LSPs that are established between the point of local repair (PLR) and the merge point after a node or link failure—are not preserved during a Routing Engine switchover.
- When nonstop active routing is enabled, graceful restart is not supported. However, graceful restart helper mode is supported.

Graceful Restart Concepts

With routing protocols, any service interruption requires that an affected router recalculate adjacencies with neighboring routers, restore routing table entries, and update other protocol-specific information. An unprotected restart of a router can result in forwarding delays, route flapping, wait times stemming from protocol reconvergence, and even dropped packets. The main benefits of graceful restart are uninterrupted packet forwarding and temporary suppression of all routing protocol updates. Graceful restart enables a router to pass through intermediate convergence states that are hidden from the rest of the network.

Three main types of graceful restart are available on Juniper Networks routing platforms:

- Graceful restart for aggregate and static routes and for routing protocols—Provides protection for aggregate and static routes and for Border Gateway Protocol (BGP), End System-to-Intermediate System (ES-IS), Intermediate System-to-Intermediate System (IS-IS), Open Shortest Path First (OSPF), Routing Information Protocol (RIP), next-generation RIP (RIPng), and Protocol Independent Multicast (PIM) sparse mode routing protocols.
- Graceful restart for MPLS-related protocols—Provides protection for Label Distribution Protocol (LDP), Resource Reservation Protocol (RSVP), circuit cross-connect (CCC), and translational cross-connect (TCC).
- Graceful restart for virtual private networks (VPNs)—Provides protection for Layer 2 and Layer 3 VPNs.

Graceful restart works similarly for routing protocols and MPLS protocols and combines components of these protocol types to enable graceful restart in VPNs. The main benefits of graceful restart are uninterrupted packet forwarding and temporary suppression of all routing protocol updates. Graceful restart thus enables a router to pass through intermediate convergence states that are hidden from the rest of the network.

Most graceful restart implementations define two types of routers—the restarting router and the helper router. The restarting router requires rapid restoration of forwarding state information so it can resume the forwarding of network traffic. The helper router assists

the restarting router in this process. Graceful restart configuration statements typically affect either the restarting router or the helper router.

Graceful Restart System Requirements

Graceful restart is supported on all routing platforms. To implement graceful restart for particular features, your system must meet these minimum requirements:

- Junos OS Release 5.3 or later for aggregate route, BGP, IS-IS, OSPF, RIP, RIPng, or static route graceful restart.
- Junos OS Release 5.5 or later for RSVP on egress provider edge (PE) routers.
- Junos OS Release 5.5 or later for LDP graceful restart.
- Junos OS Release 5.6 or later for the CCC, TCC, Layer 2 VPN, or Layer 3 VPN implementations of graceful restart.
- Junos OS Release 6.1 or later for RSVP graceful restart on ingress PE routers.
- Junos OS Release 6.4 or later for PIM sparse mode graceful restart.
- Junos OS Release 7.4 or later for ES-IS graceful restart (J Series Services Routers).
- Junos OS Release 8.5 or later for BFD session (helper mode only)—If a node is undergoing a graceful restart and its BFD sessions are distributed to the Packet Forwarding Engine, the peer node can help the peer with the graceful restart.
- Junos OS Release 9.2 or later for BGP to support helper mode without requiring that graceful restart be configured.

**Related
Documentation**

- [Graceful Restart Concepts on page 2085](#)

Aggregate and Static Routes

When you include the **graceful-restart** statement at the **[edit routing-options]** hierarchy level, any static routes or aggregated routes that have been configured are protected. Because no helper router assists in the restart, these routes are retained in the forwarding table while the router restarts (rather than being discarded or refreshed).

Graceful Restart and Routing Protocols

This section covers the following topics:

- [BGP on page 2087](#)
- [ES-IS on page 2087](#)
- [IS-IS on page 2087](#)
- [OSPF and OSPFv3 on page 2088](#)
- [PIM Sparse Mode on page 2089](#)
- [RIP and RIPng on page 2089](#)

BGP

When a router enabled for BGP graceful restart restarts, it retains BGP peer routes in its forwarding table and marks them as stale. However, it continues to forward traffic to other peers (or receiving peers) during the restart. To reestablish sessions, the restarting router sets the “restart state” bit in the BGP OPEN message and sends it to all participating peers. The receiving peers reply to the restarting router with messages containing end-of-routing-table markers. When the restarting router or switch receives all replies from the receiving peers, the restarting router performs route selection, the forwarding table is updated, and the routes previously marked as stale are discarded. At this point, all BGP sessions are reestablished and the restarting peer can receive and process BGP messages as usual.

While the restarting router does its processing, the receiving peers also temporarily retain routing information. When a receiving peer detects a TCP transport reset, it retains the routes received and marks the routes as stale. After the session is reestablished with the restarting router or switch, the stale routes are replaced with updated route information.

ES-IS

When graceful restart for ES-IS is enabled, the routes to end systems or intermediate systems are not removed from the forwarding table. The adjacencies are reestablished after restart is complete.

NOTE: ES-IS is supported only on the J Series Services Router.

IS-IS

Normally, IS-IS routers move neighbor adjacencies to the down state when changes occur. However, a router enabled for IS-IS graceful restart sends out Hello messages

with the Restart Request (RR) bit set in a restart type length value (TLV) message. This indicates to neighboring routers that a graceful restart is in progress and to leave the IS-IS adjacency intact. The neighboring routers must interpret and implement restart signaling themselves. Besides maintaining the adjacency, the neighbors send complete sequence number PDUs (CSNPs) to the restarting router and flood their entire database.

The restarting router never floods any of its own link-state PDUs (LSPs), including pseudonode LSPs, to IS-IS neighbors while undergoing graceful restart. This enables neighbors to reestablish their adjacencies without transitioning to the down state and enables the restarting router to reinitiate a smooth database synchronization.

OSPF and OSPFv3

When a router enabled for OSPF graceful restart restarts, it retains routes learned before the restart in its forwarding table. The router does not allow new OSPF link-state advertisements (LSAs) to update the routing table. This router continues to forward traffic to other OSPF neighbors (or helper routers), and sends only a limited number of LSAs during the restart period. To reestablish OSPF adjacencies with neighbors, the restarting router must send a grace LSA to all neighbors. In response, the helper routers enter helper mode and send an acknowledgement back to the restarting router. If there are no topology changes, the helper routers continue to advertise LSAs as if the restarting router had remained in continuous OSPF operation.

When the restarting router receives replies from all the helper routers, the restarting router selects routes, updates the forwarding table, and discards the old routes. At this point, full OSPF adjacencies are reestablished and the restarting router receives and processes OSPF LSAs as usual. When the helper routers no longer receive grace LSAs from the restarting router or the topology of the network changes, the helper routers also resume normal operation.

NOTE: For more information about the standard helper mode implementation, see RFC 3623, *Graceful OSPF Restart*.

Starting with Release 11.3, Junos OS supports the restart signaling-based helper mode for OSPF graceful restart configurations. The helper modes, both standard and restart signaling-based, are enabled by default. In restart signaling-based helper mode implementations, the restarting router relays the restart status to its neighbors only after the restart is complete. When the restart is complete, the restarting router sends hello messages to its helper routers with the **restart signal (RS)** bit set in the hello packet header. When a helper router receives a hello packet with the **RS** bit set in the header, the helper router returns a hello message to the restarting router. The reply hello message from the helper router contains the **ResyncState** flag and the **ResyncTimeout** timer that enable the restarting router to keep track of the helper routers that are syncing up with it. When all helpers complete the synchronization, the restarting router exits the restart mode.

**NOTE:**

For more information about restart signaling-based graceful restart helper mode implementation, see RFC 4811, *OSPF Out-of-Band Link State Database (LSDB) Resynchronization*, RFC 4812, *OSPF Restart Signaling*, and RFC 4813, *OSPF Link-Local Signaling*.

Restart signaling-based graceful restart helper mode is not supported for OSPFv3 configurations.

PIM Sparse Mode

PIM sparse mode uses a mechanism called a *generation identifier* to indicate the need for graceful restart. Generation identifiers are included by default in PIM hello messages. An initial generation identifier is created by each PIM neighbor to establish device capabilities. When one of the PIM neighbors restarts, it sends a new generation identifier to its neighbors. All neighbors that support graceful restart and are connected by point-to-point links assist by sending multicast updates to the restarting neighbor.

The restart phase completes when either the PIM state becomes stable or when the restart interval timer expires. If the neighbors do not support graceful restart or connect to each other using multipoint interfaces, the restarting router uses the restart interval timer to define the restart period.

RIP and RIPng

When a router enabled for RIP graceful restart restarts, routes that have been configured are protected. Because no helper router assists in the restart, these routes are retained in the forwarding table while the router restarts (rather than being discarded or refreshed).

Graceful Restart and MPLS-Related Protocols

This section contains the following topics:

- [LDP on page 2089](#)
- [RSVP on page 2090](#)
- [CCC and TCC on page 2090](#)

LDP

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also

enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

The reconnect time is configured in Junos OS as 60 seconds and is not user-configurable. The reconnect time is how long the helper router waits for the restarting router to establish a connection. If the connection is not established within the reconnect interval, graceful restart for the LDP session is terminated. The maximum reconnect time is 120 seconds and is not user-configurable. The maximum reconnect time is the maximum value that a helper router accepts from its restarting neighbor.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, so it can continue to forward traffic.

You can configure LDP graceful restart both in the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the protocol level for LDP only, and for a specific routing instance only.

RSVP

RSVP graceful restart enables a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not visible to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers. It is available for both point-to-point LSPs and point-to-multipoint LSPs.

CCC and TCC

CCC and TCC graceful restart enables Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the provider edge (PE) routers and provider (P) routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

 - [Example: Configuring Graceful Restart on page 2139](#)

Graceful Restart and Layer 2 and Layer 3 VPNs

VPN graceful restart uses three types of restart functionality:

1. BGP graceful restart functionality is used on all PE-to-PE BGP sessions. This affects sessions carrying any service signaling data for network layer reachability information (NLRI), for example, an IPv4 VPN or Layer 2 VPN NLRI.
2. OSPF, IS-IS, LDP, or RSVP graceful restart functionality is used in all core routers. Routes added by these protocols are used to resolve Layer 2 and Layer 3 VPN NLRI.
3. Protocol restart functionality is used for any Layer 3 protocol (RIP, OSPF, LDP, and so on) used between the PE and customer edge (CE) routers. This does not apply to Layer 2 VPNs because Layer 2 protocols used between the CE and PE routers do not have graceful restart capabilities.

Before VPN graceful restart can work properly, all of the components must restart gracefully. In other words, the routers must preserve their forwarding states and request neighbors to continue forwarding to the router in case of a restart. If all of the conditions are satisfied, VPN graceful restart imposes the following rules on a restarting router:

- The router must wait to receive all BGP NLRI information from other PE routers before advertising routes to the CE routers.
- The router must wait for all protocols in all routing instances to converge (or complete the restart process) before it sends CE router information to other PE routers. In other words, the router must wait for all instance information (whether derived from local configuration or advertisements received from a remote peer) to be processed before it sends this information to other PE routers.
- The router must preserve all forwarding state in the `instance.mpls.0` tables until the new labels and transit routes are allocated and announced to other PE routers (and CE routers in a carrier-of-carriers scenario).

If any condition is not met, VPN graceful restart does not succeed in providing uninterrupted forwarding between CE routers across the VPN infrastructure.

 - [Example: Configuring Graceful Restart on page 2139](#)

Graceful Restart on Logical Systems

Graceful restart for a logical system functions much as graceful restart does in the main router. The only difference is the location of the **graceful-restart** statement:

- For a logical system, include the **graceful-restart** statement at the **[edit logical-systems *logical-system-name* routing-options]** hierarchy level.
- For a routing instance inside a logical system, include the **graceful-restart** statement at both the **[edit logical-systems *logical-system-name* routing-options]** and **[edit logical-systems *logical-system-name* routing-instances *instance-name* routing-options]** hierarchy levels.

Unified ISSU

- [Upgrading Routers Using ISSU on page 2092](#)
- [Unified ISSU Concepts on page 2092](#)
- [Unified ISSU System Requirements on page 2097](#)

Upgrading Routers Using ISSU

Unified in-service software upgrade (ISSU) enables you to upgrade between two different Junos OS releases with no disruption on the control plane and with minimal disruption of traffic. ISSU is only supported by dual Routing Engine platforms. In addition, graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) must be enabled.

For additional information about using ISSU, see the [Junos OS High Availability Guide](#).

Unified ISSU Concepts

A unified in-service software upgrade (unified ISSU) enables you to upgrade between two different Junos OS Releases with no disruption on the control plane and with minimal disruption of traffic. Unified ISSU is only supported on dual Routing Engine platforms. In addition, the graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) must be enabled.

A unified ISSU provides the following benefits:

- Eliminates network downtime during software image upgrades
- Reduces operating costs, while delivering higher service levels
- Allows fast implementation of new features

NOTE: The master Routing Engine and backup Routing Engine must be running the same software version before you can perform a unified ISSU.

You cannot take any PICs online or offline during a unified ISSU.

NOTE: You can verify the unified ISSU-compatibility of the software, hardware, and the configuration on a device by issuing the **request system software validate in-service-upgrade** command. This command runs the validation checks, and shows whether the operating system, device components, and configurations are ISSU compatible or not. For more information about the **request system software validate in-service-upgrade** command, see *Junos OS Operational Mode Commands*.

NOTE: Unicast RPF-related statistics are not saved across a unified ISSU, and the unicast RPF counters are reset to zero during a unified ISSU.

To perform a unified ISSU, complete the following steps:

1. Enable graceful Routing Engine switchover and nonstop active routing. Verify that the Routing Engines and protocols are synchronized.
2. Download the new software package from the Juniper Networks Support website and then copy the package to the router.
3. Issue the **request system software in-service-upgrade** command on the master Routing Engine.

A Junos OS Release package comprises three distinct systems:

- Juniper Networks Operating System, which provides system control and all the features and functions of the Juniper Networks router that executes in the Routing Engines
- Juniper Networks Packet Forwarding Engine, which supports the high-performance traffic forwarding and packet handling capabilities
- Interface control

After the **request system software in-service-upgrade** command is issued, the following process occurs.

NOTE: In the illustrations, a solid line indicates the high-speed internal link between a Routing Engine and a Packet Forwarding Engine. A dotted line indicates the chassis process (chassisd), another method of communication between a Routing Engine and a Packet Forwarding Engine. RE0m and RE1s indicate master and backup (or standby) Routing Engines, respectively.

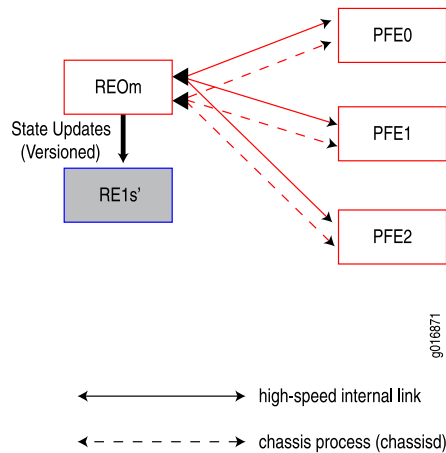

NOTE: The following process pertains to all supported routing platforms except the TX Matrix router. For information about the unified ISSU process on the TX Matrix router, see *Unified ISSU Process on the TX Matrix Router*. On M320 and T320 routers and on T640 and T1600 routers, the Packet Forwarding Engine resides on an FPC. However, on an M120 router, the Forwarding Engine Board (FEB) replaces the functions of a Packet Forwarding Engine. In the illustrations and steps, when considering an M120 router, you can regard the PFE as an FPC. As an additional step on an M120 router, after the FPCs and PICs have been upgraded, the FEBs are upgraded.

1. The master Routing Engine validates the router configuration to ensure that it can be committed using the new software version. Checks are made for disk space available for the `/var` file system on both Routing Engines, unsupported configurations, and for unsupported Physical Interface Cards (PICs). If there is not sufficient disk space available on either of the Routing Engines, the unified ISSU process fails and returns an error message saying that the Routing Engine does not have enough disk space available. However, unsupported PICs do not prevent a unified ISSU. The software issues a warning to indicate that these PICs will restart during the upgrade. Similarly, an unsupported protocol configuration does not prevent a unified ISSU. The software issues a warning that packet loss may occur for the protocol during the upgrade.

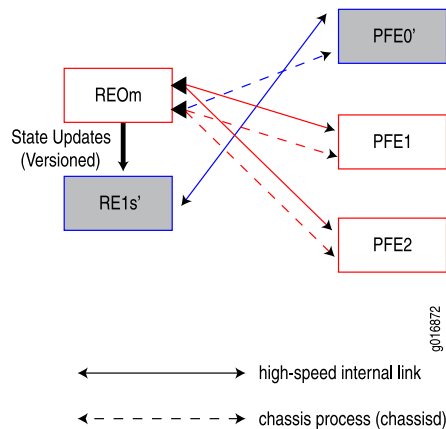

2. When the validation succeeds, the kernel state synchronization daemon (ksyncd) synchronizes the kernel on the backup Routing Engine with the master Routing Engine.
3. The backup Routing Engine is upgraded with the new software image. Before being upgraded, the backup Routing Engine gets the configuration file from the master Routing Engine and validates the configuration to ensure that it can be committed using the new software version. After being upgraded, it is resynchronized with the

master Routing Engine. In the illustration, an apostrophe (') indicates the device is running the new version of software.

4. The chassis process (chassisd) on the master Routing Engine prepares other software processes for the unified ISSU. When all the processes are ready, chassisd sends an ISSU_PREPARE message to the Flexible PIC Concentrators (FPCs) installed in the router.
5. The Packet Forwarding Engine on each FPC saves its state and downloads the new software image from the backup Routing Engine. Next, each Packet Forwarding Engine sends an ISSU_READY message to the chassis process (chassisd).

6. After receiving an ISSU_READY message from a Packet Forwarding Engine, the chassis process (chassisd) sends an ISSU_REBOOT message to the FPC on which the Packet Forwarding Engine resides. The FPC reboots with the new software image. After the FPC is rebooted, the Packet Forwarding Engine restores the FPC state and a high-speed internal link is established with the backup Routing Engine running the new software. The chassis process (chassisd) is also reestablished with the master Routing Engine.
7. After all Packet Forwarding Engines have sent a READY message using the chassis process (chassisd) on the master Routing Engine, other software processes are

prepared for a Routing Engine switchover. The system is ready for a switchover at this point.

NOTE: In the case of an M120 router, the FEBs are upgraded at this point. When all FEBs have been upgraded, the system is ready for a switchover.

- The Routing Engine switchover occurs and the backup Routing Engine becomes the new master Routing Engine.

9. The new backup Routing Engine is now upgraded to the new software image. (This step is skipped if the **no-old-master-upgrade** option is specified.)

10. When the backup Routing Engine has been successfully upgraded, the unified ISSU is complete.

- [Unified ISSU Support on MX Series 3D Universal Edge Routers on page 2108](#)

Unified ISSU Junos OS Release Support

In order to perform a unified ISSU, your device must be running a Junos OS Release that supports unified ISSU for the specific platform. See [“Unified ISSU Platform Support” on page 2098](#). You can use unified ISSU to upgrade from an ISSU-capable software release to a newer software release. However, note that:

- The unified ISSU process is aborted if the Junos OS version specified for installation is a version earlier than the one currently running on the device. To downgrade from an ISSU-capable release to a previous software release (ISSU-capable or not), use the

request system add command. Unlike an upgrade using the unified ISSU process, a downgrade using the **request system add** command can cause network disruptions and loss of data. For more information about the use of the **request system add** command, see the *Installation and Upgrade Guide*.

- The unified ISSU process is aborted if the specified upgrade has conflicts with the current configuration, components supported, and so forth.
- Unified ISSU does not support extension application packages developed using the Junos SDK.

Unified ISSU Platform Support

Table 154 on page 2098 lists the platforms on which a unified ISSU is supported.

Table 154: Unified ISSU Platform Support

Platform	Junos OS Release
EX9200 switch	12.3R3 or later
M120 router	9.2 or later
M320 router	9.0 or later
M10i router with Enhanced Compact Forwarding Engine Board (CFEB-E)	9.5 or later
MX Series devices	9.3 or later
NOTE: Unified ISSU for MX Series routers does not support IEEE 802.1ag OAM and IEEE 802.3ah protocols.	11.2 or later on MX Series 3D Universal Edge Routers (with Trio Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces).
T320 router	9.0 or later
T640 router	9.0 or later
T1600 router	9.1 or later
TX Matrix router	9.3 or later

Unified ISSU Protocol Support

Unified ISSU is dependent on nonstop active routing. Table 155 on page 2098 lists the protocols that are supported during a unified ISSU.

Table 155: Unified ISSU Protocol Support

Protocol	Junos OS Release
BGP	9.0 or later

Table 155: Unified ISSU Protocol Support (*continued*)

Protocol	Junos OS Release
DHCP access model (subscriber access)	11.2 or later
IS-IS	9.0 or later
LDP	9.0 or later
LDP-based virtual private LAN service (VPLS)	9.3 or later
Layer 2 circuits	9.2 or later
Layer 3 VPNs using LDP	9.2 or later
Link Aggregation Control Protocol (LACP) on MX Series routers	9.4 or later
OSPF/OSPFv3	9.0 or later
PPPoE access model (subscriber access)	11.4 or later
Protocol Independent Multicast (PIM)	9.3 or later
Routing Information Protocol (RIP)	9.1 or later

Unified ISSU Support for the Layer 2 Control Protocol Process

Unified ISSU supports the Layer 2 Control Protocol process (l2cpd) on MX Series 3D Universal Edge Routers. In a Layer 2 bridge environment, spanning tree protocols share information about port roles, bridge IDs, and root path costs between bridges using special data frames called Bridge Protocol Data Units (BPDUs). The transmission of BPDUs is controlled by the l2cpd process. Transmission of hello BPDUs is important in maintaining adjacencies on the peer systems.

The transmission of periodic packets on behalf of the l2cpd process is carried out by periodic packet management (PPM), which, by default, is configured to run on the Packet Forwarding Engine. The ppmd process on the Packet Forwarding Engine ensures that the BPDUs are transmitted even when the l2cpd process control plane is unavailable, and keeps the remote adjacencies alive during unified ISSU. However, if you want the distributed PPM (ppmd) process to run on the Routing Engine instead of the Packet Forwarding Engine, you can disable the ppmd process on the Packet Forwarding Engine, by including the **no-delegate-processing** statement at the [edit routing-options ppm] hierarchy level.

NOTE: The `delegate-processing` statement at the `[edit routing-options ppm]` hierarchy level, which was used to enable the `ppmd` process on the Packet Forwarding Engine in Junos OS Release 9.3 and earlier, has been deprecated as the `ppmd` process is enabled on the Packet Forwarding Engine by default in Junos OS Release 9.4 and later.

Unified ISSU enhancements and nonstop active bridging support for the `l2cpd` process ensure that the new master Routing Engine is able to take control during unified ISSU without any disruptions in the control plane and minimize the disruptions in the Layer 2 data plane during unified ISSU.

Unified ISSU Feature Support

Unified ISSU supports most Junos OS features in Junos OS Release 9.0. However, the following constraints apply:

- Link Aggregation Control Protocol (LACP)—Link changes are not processed until after the unified ISSU is complete.
- Automatic Protection Switching (APS)—Network changes are not processed until after the unified ISSU is complete.
- Ethernet Operation, Administration, and Management (OAM) as defined by IEEE 802.3ah and by IEEE 802.1ag—When a Routing Engine switchover occurs, the OAM hello times out, triggering protocol convergence.
- Ethernet circuit cross-connect (CCC) encapsulation—Circuit changes are not processed until after the unified ISSU is complete.
- Logical systems—On devices that have logical systems configured on them, only the master logical system supports unified ISSU.

Unified ISSU PIC Support

The following sections list the Physical Interface Cards (PICs) that are supported during a unified ISSU.

- [PIC Considerations on page 2101](#)
- [SONET/SDH PICs on page 2101](#)
- [Fast Ethernet and Gigabit Ethernet PICs on page 2103](#)
- [Channelized PICs on page 2104](#)
- [Tunnel Services PICs on page 2105](#)
- [ATM PICs on page 2105](#)
- [Serial PICs on page 2106](#)
- [DS3, E1, E3, and T1 PICs on page 2106](#)
- [Enhanced IQ PICs on page 2107](#)
- [Enhanced IQ2 Ethernet Services Engine \(ESE\) PIC on page 2107](#)

NOTE: For information about FPC types, FPC/PIC compatibility, and the initial Junos OS Release in which an FPC supported a particular PIC, see the PIC guide for your platform.

PIC Considerations

Take the following PIC restrictions into consideration before performing a unified ISSU:

- **Unsupported PICs**—If a PIC is not supported by unified ISSU, at the beginning of the upgrade the software issues a warning that the PIC will be brought offline. After the PIC is brought offline and the ISSU is complete, the PIC is brought back online with the new firmware.
- **PIC combinations**—For some PICs, newer Junos OS services can require significant Internet Processor ASIC memory, and some configuration rules might limit certain combinations of PICs on particular platforms. With a unified ISSU:
 - If a PIC combination is not supported by the software version that the device is being upgraded from, the upgrade will be aborted.
 - If a PIC combination is not supported by the software version to which the device is being upgraded, the in-service software upgrade will abort, even if the PIC combination is supported by the software version from which the device is being upgraded.
- **Interface statistics**—Interface statistics might be incorrect because:
 - During bootup of the new microkernel on the Packet Forwarding Engine (PFE), host-bound traffic is not handled and might be dropped, causing packet loss.
 - During the hardware update of the Packet Forwarding Engine and its interfaces, traffic is halted and discarded. (The duration of the hardware update depends on the number and type of interfaces and on the device configuration.)
 - During a unified ISSU, periodic statistics collection is halted. If hardware counters saturate or wrap around, the software does not display accurate interface statistics.
- **CIR oversubscription**—If oversubscription of committed rate information (CIR) is configured on logical interfaces:
 - And the sum of the CIR exceeds the physical interface's bandwidth, after a unified in-service software upgrade is performed, each logical interface might not be given its original CIR.
 - And the sum of the delay buffer rate configured on logical interfaces exceeds the physical interface's bandwidth, after a unified in-service software upgrade is performed, each logical interface might not receive its original delay-buffer-rate calculation.

SONET/SDH PICs

[Table 156 on page 2102](#) lists the SONET/SDH PICs that are supported during a unified ISSU.

Table 156: Unified ISSU PIC Support: SONET/SDH

PIC Type	Number of Ports	Model Number	Device

Fast Ethernet and Gigabit Ethernet PICs

Table 157 on page 2103 lists the Fast Ethernet and Gigabit Ethernet PICs that are supported during a unified ISSU.

NOTE: Starting with Junos OS Release 9.2, new Ethernet IQ2 PIC features might cause the software to reboot the PIC when a unified ISSU is performed. For information about applicable new Ethernet IQ2 PIC features, refer to the release notes for the specific Junos OS Release.

Table 157: Unified ISSU PIC Support: Fast Ethernet and Gigabit Ethernet

PIC Type	Number of Ports	Model Number	device

	2	PB-2OC12-ATM2-MM	M120, M320, T320, T640, T1600, TX Matrix
		PB-2OC12-ATM2-SMIR	
	1	PE-1OC12-ATM2-MM	M10i
		PE-1OC12-ATM2-SMIR	
OC48/STM16	1	PB-1OC48-ATM2-SFP	M120, M320, T320, T640, T1600, TX Matrix

Serial PICs

Unified ISSU supports the following 2-port EIA-530 serial PICs:

- PB-2EIA530 on M320 routers with Enhanced III FPCs, and on M120 routers
- PE-2EIA530 on M10i routers

DS3, E1, E3, and T1 PICs

Unified ISSU supports the following PICs on M120, M320, and T320 routers; T640 and T1600 routers; and the TX Matrix router:

- 4-Port DS3 PIC (PB-4DS3)
- 4-Port E1 Coaxial PIC (PB-4E1-COAX)
- 4-Port E1 RJ48 PIC (PB-4E1-RJ48)

- 4-port E3 IQ PIC (PB-4E3-QPP)
- 4-Port T1 PIC (PB-4T1-RJ48)

Unified ISSU supports the following PICs on M10i routers:

- 2-Port DS3 PIC (PE-2DS3)
- 4-Port DS3 PIC (PE-4DS3)
- 4-Port E1 PICs (PE-4E1-COAX and PE-4E1-RJ48)
- 2-Port E3 PIC (PE-2E3)
- 4-Port T1 PIC (PE-4T1-RJ48)
- 4-Port E3 IQ PIC (PE-4E3-QPP)

Enhanced IQ PICs

Unified ISSU supports the following PICs on M120, M320, and T320 routers; T640 and T1600 routers; and the TX Matrix router:

- 1-port Channelized OC12/STM4 enhanced IQ PIC (PB-1CHOC12-STM4-IQE-SFP)
- 1-port nonchannelized OC12/STM4 enhanced IQ PIC (PB-1OC12-STM4-IQE-SFP)
- 4-port Channelized DS3/E3 enhanced IQ PIC (PB-4CHDS3-E3-IQE-BNC)
- 4-port nonchannelized DS3/E3 enhanced IQ PIC (PB-4DS3-E3-IQE-BNC)
- 4-port nonchannelized SONET/SDH OC48/STM16 Enhanced IQ (IQE) PIC with SFP (PC-4OC48-STM16-IQE-SFP)

Unified ISSU supports 1-port Channelized OC48/STM16 Enhanced IQ (IQE) PIC with SFP (PB-1CHOC48-STM16-IQE-SFP) on MX Series routers.

Enhanced IQ2 Ethernet Services Engine (ESE) PIC

Unified ISSU supports the enhanced IQ2 ESE PICs listed in [Table 161 on page 2107](#).

Table 161: Unified ISSU Support: Enhanced IQ2 Ethernet Services Engine (ESE) PIC

Model Number	Number of Ports	Platform
PC-8GE-TYPE3-SFP-IQ2E	8	M120, M320, T320, T640, and TX Matrix.
PB-8GE-TYPE2-SFP-IQ2E	8	M120, M320, T320, T640, and TX Matrix.
PB-4GE-TYPE1-SFP-IQ2E	4	M120, M320, T320, and T640.
PC-1XGE-TYPE3-XFP-IQ2E	1	M120, M320, T320, T640, and TX Matrix.
PB-1CHOC48-STM16-IQE	1	M120, M320, T320, T640, and TX Matrix.
PE-4GE-TYPE1-SFP-IQ2E	4	M10i.
PE-4GE-TYPE1-SFP-IQ2	4	M10i.

Unified ISSU Support on MX Series 3D Universal Edge Routers

The following sections list the Dense Port Concentrators (DPCs), Flexible PIC Concentrators (FPCs), Modular Port Concentrators (MPCs), and Modular Interface Cards (MICs) that are supported during a unified ISSU on MX Series 3D Universal Edge Routers.

- [Unified ISSU DPC and FPC Support on MX Series 3D Universal Edge Routers on page 2108](#)
- [Unified ISSU MIC and MPC Support on MX Series 3D Universal Edge Routers on page 2108](#)
- [Unified ISSU Limitation on MX Series 3D Universal Edge Routers on page 2109](#)

Unified ISSU DPC and FPC Support on MX Series 3D Universal Edge Routers

Unified ISSU supports all Dense Port Concentrators (DPCs) except the Multiservices DPC on MX Series routers. Unified ISSU also supports Type 2 FPC (MX-FPC2) and Type 3 FPC (MX-FPC3) on MX Series routers. For more information about PICs supported on MX-FPC2 and MX-FPC3, see [Table 156 on page 2102](#). For more information about DPCs and FPCs on MX Series routers, go to http://www.juniper.net/techpubs/en_US/release-independent/junos/information-products/pathway-pages/mx-series/.

Unified ISSU MIC and MPC Support on MX Series 3D Universal Edge Routers

Unified ISSU supports all the Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) listed in [Table 162 on page 2108](#) and [Table 163 on page 2109](#). Unified ISSU is not supported on MX80 routers nor in an MX Series Virtual Chassis.

In the MPCs on MX Series routers, interface-specific and firewall filter statistics are preserved across a unified ISSU. During the unified ISSU, counter and policer operations are disabled.

To preserve statistics across a unified ISSU on MX Series routers with MPC/MIC interfaces, the router stores the statistics data as binary large objects. The router collects the statistics before the unified ISSU is initialized, and restores the statistics after the unified ISSU completes. No statistics are collected during the unified ISSU process.

To verify that statistics are preserved across the unified ISSU, you can issue CLI operational commands such as **show interfaces statistics** after the unified ISSU completes.

Table 162: Unified ISSU Support: MX Series 3D Universal Edge Routers

MPC Type	Number of Ports	Model Number	Platform
30-Gigabit Ethernet MPC	—	MX-MPC1-3D	MX Series 3D Universal Edge Routers
30-Gigabit Ethernet Queuing MPC	—	MX-MPC1-3D-Q	MX Series 3D Universal Edge Routers
60-Gigabit Ethernet MPC	—	MX-MPC2-3D	MX Series 3D Universal Edge Routers
60-Gigabit Ethernet Queuing MPC	—	MX-MPC2-3D-Q	MX Series 3D Universal Edge Routers

Table 162: Unified ISSU Support: MX Series 3D Universal Edge Routers (*continued*)

MPC Type	Number of Ports	Model Number	Platform
60-Gigabit Ethernet Enhanced Queuing MPC	—	MX-MPC2-3D-EQ	MX Series 3D Universal Edge Routers
10-Gigabit Ethernet MPC with SFP+	16	MPC-3D-16XGE-SFPP	MX Series 3D Universal Edge Routers

Table 163: Unified ISSU Support: MX Series 3D Universal Edge Routers

MIC Type	Number of Ports	Model Number	Platform
Gigabit Ethernet MIC with SFP	20	MIC-3D-20GE-SFP	MX Series 3D Universal Edge Routers
10-Gigabit Ethernet MICs with XFP	2	MIC-3D-2XGE-XFP	MX Series 3D Universal Edge Routers
10-Gigabit Ethernet MICs with XFP	4	MIC-3D-4XGE-XFP	MX Series 3D Universal Edge Routers
Tri-Rate Copper Ethernet MIC	40	MIC-3D-40GE-TX	MX Series 3D Universal Edge Routers

NOTE: Note that unified ISSU is supported only by the MICs listed in Table 163 on page 2109.

Unified ISSU Limitation on MX Series 3D Universal Edge Routers

Unified in-service software upgrade (unified ISSU) is currently not supported when clock synchronization is configured for Synchronous Ethernet, Precision Time Protocol (PTP), and hybrid mode on MX80 3D Universal Edge Routers and on the MICs and MPCEs on MX240, MX480, and MX960 routers.

- [Improving the Convergence Time for VRRP on page 2114](#)

Understanding VRRP

For Ethernet, Fast Ethernet, Gigabit Ethernet, 10-Gigabit Ethernet, and logical interfaces, you can configure the Virtual Router Redundancy Protocol (VRRP) or VRRP for IPv6. VRRP enables hosts on a LAN to make use of redundant routing platforms on that LAN without requiring more than the static configuration of a single default route on the hosts. The VRRP routing platforms share the IP address corresponding to the default route configured on the hosts. At any time, one of the VRRP routing platforms is the master (active) and the others are backups. If the master fails, one of the backup routers or switches becomes the new master router, providing a virtual default routing platform and enabling traffic on the LAN to be routed without relying on a single routing platform. Using VRRP, a backup router can take over a failed default router within a few seconds. This is done with minimum VRRP traffic and without any interaction with the hosts.

Routers running VRRP dynamically elect master and backup routers. You can also force assignment of master and backup routers using priorities from 1 through 255, with 255 being the highest priority. In VRRP operation, the default master router sends advertisements to backup routers at regular intervals. The default interval is 1 second. If a backup router does not receive an advertisement for a set period, the backup router with the next highest priority takes over as master and begins forwarding packets.

NOTE: To minimize network traffic, VRRP is designed in such a way that only the router that is acting as the master sends out VRRP advertisements at any given point in time. The backup routers do not send any advertisement until and unless they take over mastership.

VRRP for IPv6 provides a much faster switchover to an alternate default router than IPv6 Neighbor Discovery (ND) procedures. Typical deployments use only one backup router.

Figure 25 on page 2110 illustrates a basic VRRP topology. In this example, Routers A, B, and C are running VRRP and together they make up a virtual router. The IP address of this virtual router is 10.10.0.1 (the same address as the physical interface of Router A).

Figure 25: Basic VRRP

Because the virtual router uses the IP address of the physical interface of Router A, Router A is the master VRRP router, while Routers B and C function as backup VRRP routers.

Clients 1 through 3 are configured with the default gateway IP address of 10.10.0.1. As the master router, Router A forwards packets sent to its IP address. If the master virtual router fails, the router configured with the higher priority becomes the master virtual router and provides uninterrupted service for the LAN hosts. When Router A recovers, it becomes the master virtual router again.

VRRP is defined in RFC 3768, *Virtual Router Redundancy Protocol (VRRP)*. VRRP for IPv6 is defined in Internet draft draft-ietf-vrrp-ipv6-spec-08.txt, *Virtual Router Redundancy Protocol for IPv6*. See also Internet draft draft-ietf-vrrp-unified-mib-06.txt, *Definitions of Managed Objects for the VRRP over IPv4 and IPv6*.

NOTE: Even though VRRP, as defined in RFC 3768, does not support authentication, the Junos OS implementation of VRRP supports authentication as defined in RFC 2338. This support is achieved through the backward compatibility options in RFC 3768.

Junos OS Support for VRRPv3

Prior to Junos OS Release 12.2, Junos OS supported RFC 3768, *Virtual Router Redundancy Protocol (VRRP) for IPv4* and Internet draft draft-ietf-vrrp-ipv6-spec-08, *Virtual Router Redundancy Protocol for IPv6*.

Starting with Junos OS Release 12.2, Junos OS supports RFC 3768, *Virtual Router Redundancy Protocol (VRRP) for IPv4*. The support for VRRPv3 is implemented in compliance with RFC 5798, *Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv6*. Junos OS Release 12.2 also supports VRRP MIB for VRRPv3. The support for VRRP MIB for VRRPv3 is implemented in compliance with RFC 6527, *Definitions of Managed Objects for the Virtual Router Redundancy Protocol Version 3 (VRRPv3)*.

When you configure VRRP for IPv4 or IPv6 networks, you can enable VRRPv3 by configuring the **version-3** statement at the **[edit protocols vrrp]** hierarchy level.

Understanding VRRPv3 Behavioral Differences

You must consider the following aspects when enabling VRRPv3 for your IPv4 or IPv6 networks:

- Prior to Junos OS Release 12.2, when VRRP for IPv6 is configured without enabling VRRPv3, the VRRP checksum is calculated according to section 5.3.8 of RFC 3768, *Virtual Router Redundancy Protocol (VRRP)*. However, when VRRPv3 is enabled, the VRRP checksum is calculated according to section 5.3.7 of draft-ietf-vrrp-ipv6-spec-08.txt, *Virtual Router Redundancy Protocol for IPv6*.
- Starting with Junos OS Release 12.2, when VRRP for IPv6 is configured without enabling VRRPv3, the VRRP checksum is calculated according to section 5.2.8 of RFC 5798, *Virtual Router Redundancy Protocol (VRRP)*. However, when VRRPv3 is enabled, the

VRRP checksum is calculated according to section 5.3.7 of draft-ietf-vrrp-ipv6-spec-08.txt, *Virtual Router Redundancy Protocol for IPv6*.

NOTE: When enabling VRRPv3, you must ensure that VRRPv3 is enabled on all the VRRP routers in the network. This is because VRRPv3 does not interoperate with the previous versions of VRRP.

- The **tcpdump** utility calculates the VRRP checksum according to draft-ietf-vrrp-ipv6-spec-08.txt. Therefore, when **tcpdump** parses IPv6 VRRP packets that are received from older Junos OS releases (prior to Junos OS Release 12.2), the **bad vrrp cksum** message is displayed:

```
23:20:32.657328 Out
...
-----original packet-----
00:00:5e:00:02:03 > 33:33:00:00:00:12, ethertype IPv6 (0x86dd), length
94: (class 0xc0, hlim 255, next-header: VRRP (112), length: 40)
fe80::224:dcff:fe47:57f > ff02::12: VRRPv3-advertisement 40: vrid=3 prio=100
intvl=100(centisec) (bad vrrp cksum b4e2!) addrs(2):
fe80::200:5eff:fe00:3,2001:4818:f000:14::1
3333 0000 0012 0000 5e00 0203 86dd 6c00
0000 0028 70ff fe80 0000 0000 0000 0224
dcff fe47 057f ff02 0000 0000 0000 0000
0000 0000 0012 3103 6402 0064 b4e2 fe80
0000 0000 0000 0200 5eff fe00 0003 2001
4818 f000 0014 0000 0000 0000 0001
```

You can ignore this message because it does not indicate VRRP failure.

- When VRRPv3 is enabled, the **authentication-type** and **authentication-key** statements (for IPv4 VRRP) cannot be configured for any VRRP groups. Therefore, if authentication is required, you need to configure alternative non-VRRP authentication mechanisms.
- When VRRPv3 is enabled, the **advertise-interval** statement (for IPv4 VRRP) and the **inet6-advertise-interval** statement (for IPv6 VRRP) cannot be used to configure advertisement intervals. Instead, use the **fast-interval** statement to configure advertisement intervals.

Understanding VRRP Interoperability

Prior to 12.2, VRRP (IPv6) followed Internet draft draft-ietf-vrrp-ipv6-spec-08, but checksum was calculated based on RFC 3768 Section 5.3.8. Starting with 12.2, VRRP (IPv6) follows RFC 5798 and checksum is calculated based on RFC 5798 Section 5.2.8.

Moreover, when VRRPv3 is enabled, pseudo-header is included only when calculating IPv6 VRRP checksum. Pseudo-header is not included when calculating IPv4 VRRP checksum. Therefore, care must be taken to correctly calculate the IPv4 and IPv6 checksum values when VRRPv3 is enabled.

NOTE: Because of the differences in VRRP checksum calculations, IPv6 VRRP configured on routers that use Junos OS Release 12.2 and later releases does not interoperate with IPv6 VRRP configured in releases before Junos OS Release 12.2.

- If you have configured VRRPv3 (IPv4 or IPv6) on routers that use Junos OS Release 12.2 or later releases, it will not operate with the routers that use Junos OS Release 12.1 or earlier releases. This is because only Junos OS Release 12.2 and later releases support VRRPv3.
- VRRP (IPv4 or IPv6) configured on routers that use Junos OS Release 12.2 and later releases, interoperate with VRRP (IPv4 or IPv6) configured on routers that use releases prior to Junos OS Release 12.2.
- VRRPv3 for IPv4 does not interoperate with the previous versions of VRRP. If VRRPv2 IPv4 advertisement packets are received by a router on which VRRPv3 is enabled, the router transitions itself to the backup state to avoid creating multiple masters in the network. Due to this behavior, you must be cautious when enabling VRRPv3 on your existing VRRPv2 networks. See [“Understanding VRRPv2 to VRRPv3 Transition” on page 2113](#) for more information.

NOTE: VRRPv3 advertisement packets are ignored by the routers on which previous versions of VRRP are configured.

Understanding VRRPv2 to VRRPv3 Transition

You must enable VRRPv3 in your network only if VRRPv3 can be enabled on all the VRRP routers in your network. Even if VRRPv3 can be enabled on all the VRRP routers in your network, care must be taken to avoid traffic loss when you transition your network to VRRPv3. This is because it is practically not possible to configure VRRPv3 on all routers simultaneously. There is a small time frame in the transition period during which VRRPv2 and VRRPv3 coexist in the network. During this period, to avoid having multiple masters in the network, the VRRPv3 IPv4 routers switch to the backup state when they receive a VRRPv2 IPv4 advertisement packet. VRRPv2 IPv4 packets are always given the highest priority. Additionally, to avoid having multiple masters in your IPv6 network due to checksum differences, you need to disable VRRP for IPv6 on the backup routers.

NOTE: Configuration change from VRRPv2 to VRRPv3 (or VRRPv3 to VRRPv2) restarts the VRRP state machine on all the configured VRRP groups.

The following example illustrates the steps and events that take place during a VRRPv2 to VRRPv3 transition:

Consider a scenario where two VRRPv2 routers, R1 and R2, are configured in two groups, G1 and G2. The R1 router acts as the master for G1 and the R2 router acts as the master for G2. [Table 164 on page 2114](#) lists the transition steps and events for this setup:

Table 164: Example: VRRPv2 to VRRPv3 Transition Steps and Events

1. Upgrade the R1 router with Junos OS Release 12.2 or later.
 - R2 becomes master for both G1 and G2.
 - After the upgrade of the R1 router is completed, R1 becomes the master for G1. R2 remains as the master for G2.
2. Upgrade the R2 router with Junos OS Release 12.2 or later.
 - R1 becomes master for both G1 and G2.
 - After the upgrade of R2 router is completed, R2 becomes the master for G2. R1 remains as the master for G1.

For IPv4	For IPv6
3. Enable VRRPv3 on the R1 router. <ul style="list-style-type: none"> • Because VRRPv2 IPv4 advertisement packets are given higher priority, R1 becomes the backup for both G1 and G2. 	3. Deactivate the G1 and G2 groups on the R2 router. <ul style="list-style-type: none"> • G1 and G2 groups on the R1 router become master.
4. Enable VRRPv3 on the R2 router. <ul style="list-style-type: none"> • R1 becomes the master for G1 and R2 becomes the master for G2. 	4. Enable VRRPv3 on the R1 router. <ul style="list-style-type: none"> • R1 becomes master for both G1 and G2.
	5. Enable VRRPv3 on the R2 router.
	6. Activate G1 and G2 groups on the R2 router. <ul style="list-style-type: none"> • R2 becomes master for G2. • R1 remains as the master for G1.

Improving the Convergence Time for VRRP

You can enable faster convergence time for the configured Virtual Router Redundancy Protocol (VRRP), thereby reducing the traffic restoration time to less than 1 second. To improve the convergence time for the VRRP, perform the following tasks:

- **Configure the distributed periodic packet management process**—When the VRRP process is busy and does not send VRRP advertisements, the backup VRRP routers might assume that the master router is down and take over as the master router, causing unnecessary flaps. To address this problem and to reduce the load on the VRRP process, Junos OS uses the distributed periodic packet management (PPM) process to send VRRP advertisements on behalf of the VRRP process.

To configure the distributed PPM process, include the **delegate-processing** statement at the **[edit protocols vrrp]** hierarchy level.

- **Disable the skew timer**—The skew timer in VRRP is used to ensure that two backup routers do not switch to the master state at the same time in case of a failover situation. When there is only one master router and one backup router in the network deployment, you can disable the skew timer, thereby reducing the time required to transition to the master state.

To disable the skew timer, include the **skew-timer-disable** statement at the **[edit protocols vrrp]** hierarchy level.

- **Configure the number of fast advertisements that can be missed by a backup router before it starts transitioning to the master state**—The backup router waits until a certain number of advertisement packets are lost after which it transitions to the master state. This waiting time can be fatal in scenarios such as router failure or link failure. To avoid such a situation and to enable faster convergence time, in Junos OS Release 12.2 and later, you can configure a fast advertisement interval value that specifies the number of fast advertisements that can be missed by a backup router before it starts transitioning to the master state.

To configure the fast advertisement interval, include the **global-advertisements-threshold** statement at the **[edit protocols vrrp]** hierarchy level.

- **Configure inheritance of VRRP groups**—Junos OS enables you to configure VRRP groups on the various subnets of a virtual LAN (VLAN) to inherit the state and configuration of one of the groups, which is known as the active VRRP group. When the **vrrp-inherit-from** statement is included in the configuration, only the active VRRP group, from which the other VRRP groups inherit the state, sends out frequent VRRP advertisements and processes incoming VRRP advertisements. Use inherit groups for scaled configurations. For example, if you have 1000 VRRP groups with an advertisement interval of 100 ms, then use inherit groups.

To configure inheritance for a VRRP group, include the **vrrp-inherit-from** statement at the **[edit interfaces interface-name unit logical-unit-number family inet address address vrrp-group group-id]** hierarchy level.

NOTE:

- The reduction in convergence time is not applicable when VRRP is configured over integrated routing and bridging (IRB) interfaces, aggregated Ethernet interfaces, and multichassis link aggregation group (MC-LAG) interfaces.
 - Compared to other routers, the convergence time and the traffic restoration time are less for MX Series routers with MPCs.
 - Reduction in convergence time is applicable for all types of configurations at the physical interface but the convergence time might not be less than 1 second for all the configurations. The convergence time depends on the number of groups that are transitioning from the backup to the master state and the interval at which these groups are transitioning.

Configuring Graceful Routing Engine Switchover

This section contains the following topics:

- [Enabling Graceful Routing Engine Switchover on page 2117](#)
- [Synchronizing the Routing Engine Configuration on page 2117](#)
- [Verifying Graceful Routing Engine Switchover Operation on page 2117](#)

Enabling Graceful Routing Engine Switchover

By default, graceful Routing Engine switchover is disabled. To configure graceful Routing Engine switchover, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level.

```
[edit chassis redundancy]
graceful-switchover;
```

When you enable graceful Routing Engine switchover, the command-line interface (CLI) indicates which Routing Engine you are using. For example:

```
{master} [edit]
user@host#
```

To disable graceful Routing Engine switchover, delete the **graceful-switchover** statement from the **[edit chassis redundancy]** hierarchy level.

Synchronizing the Routing Engine Configuration

NOTE: A newly inserted backup Routing Engine automatically synchronizes its configuration with the master Routing Engine configuration.

When you configure graceful Routing Engine switchover, you can bring the backup Routing Engine online after the master Routing Engine is already running. There is no requirement to start the two Routing Engines simultaneously.

Verifying Graceful Routing Engine Switchover Operation

To verify whether graceful Routing Engine switchover is enabled, on the backup Routing Engine, issue the **show system switchover** command. When the output of the command indicates that the **Graceful switchover** field is set to **on**, graceful Routing Engine switchover is operational. The status of the kernel database and configuration database synchronization between Routing Engines is also provided. For example:

```
Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Peer state: Steady state
```

NOTE: You must issue the **show system switchover** command on the backup Routing Engine. This command is not supported on the master Routing Engine.

For more information about the **show system switchover** command, see the *Junos OS Operational Mode Commands*.

- [graceful-switchover on page 2127](#)

Resetting Local Statistics

When you enable graceful Routing Engine switchover, the master Routing Engine configuration is copied and loaded to the backup Routing Engine. User files, accounting information, and trace options information are not replicated to the backup Routing Engine.

When a graceful Routing Engine switchover occurs, local statistics such as process statistics and networking statistics are displayed as a cumulative value from the time the process first came online. Because processes on the master Routing Engine can start at different times from the processes on the backup Routing Engine, the statistics on the two Routing Engines for the same process might differ. After a graceful Routing Engine switchover, we recommend that you issue the **clear interface statistics (*interface-name* | all)** command to reset the cumulative values for local statistics. Forwarding statistics are not affected by graceful Routing Engine switchover.

For information about how to use the **clear** command to clear statistics and protocol database information, see the *Junos OS Operational Mode Commands*.

NOTE: The **clear firewall** command cannot be used to clear the Routing Engine filter counters on a backup Routing Engine that is enabled for graceful Routing Engine switchover.

      }
      linerate-mode;
      max-queues-per-interface (4 | 8);
      no-concatenate;
      no-mcast-replication;
      no-pre-classifier;
      port port-number {
        framing (e1 | e3 | sdh | sonet | t1 | t3);
      }
      q-pic-large-buffer {
        (large-scale | small-scale);
      }
      red-buffer-occupancy {
        weighted-averaged <instant-usage-weight-exponent weight-value>;
      }
      shdsl {
        pic-mode (1-port-atm | 2-port-atm);
      }
      traffic-manager {
        egress-shaping-overhead bytes;
        ingress-shaping-overhead bytes;
        mode {
          egress-only;
          ingress-and-egress;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

graceful-switchover

Syntax	<code>graceful-switchover;</code>
Hierarchy Level	[edit chassis redundancy]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For routing platforms with two Routing Engines, configure a master Routing Engine to switch over gracefully to a backup Routing Engine without interruption to packet forwarding.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	• Configuring Graceful Routing Engine Switchover on page 2117

Configuration: Graceful Restart

- [Example: Configuring Graceful Restart on page 2139](#)
- [Example: Managing Helper Modes for OSPF Graceful Restart on page 2164](#)

Enabling Graceful Restart

Graceful restart is disabled by default. You must configure graceful restart at the **[edit routing-options]** hierarchy level to enable the feature.

For graceful restart to function properly, graceful restart must be enabled on the **[edit routing-instance *instance-name* routing-options]** or **[edit routing-options]** hierarchy level.

For example:

```

routing-options {
  graceful-restart;
}

```

NOTE: If you configure graceful restart after a BGP or LDP session has been established, the BGP or LDP session restarts and the peers negotiate graceful restart capabilities.

To disable graceful restart, include the **disable** statement. To configure a time period for complete restart, include the **restart-duration** statement. You can specify a number between 120 and 900.

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

When you include the **graceful-restart** statement at the **[edit routing-options]** hierarchy level, graceful restart is also enabled for aggregate and static routes.

Configuring Routing Protocols Graceful Restart

This topic includes the following sections:

- [Enabling Graceful Restart on page 2128](#)
- [Configuring Graceful Restart Options for BGP on page 2129](#)
- [Configuring Graceful Restart Options for ES-IS on page 2130](#)
- [Configuring Graceful Restart Options for IS-IS on page 2130](#)
- [Configuring Graceful Restart Options for OSPF and OSPFv3 on page 2131](#)
- [Configuring Graceful Restart Options for RIP and RIPng on page 2132](#)
- [Configuring Graceful Restart Options for PIM Sparse Mode on page 2133](#)
- [Tracking Graceful Restart Events on page 2134](#)

Enabling Graceful Restart

By default, graceful restart is disabled. To enable graceful restart, include the **graceful-restart** statement at the **[edit routing-instance *instance-name* routing-options]** or **[edit routing-options]** hierarchy level.

For example:

```
routing-options {  
  graceful-restart;  
}
```

To configure the duration of the graceful restart period, include the **restart-duration** at the **[edit routing-options graceful-restart]** hierarchy level.

NOTE: Helper mode (the ability to assist a neighboring router attempting a graceful restart) is enabled by default when you start the routing platform, even if graceful restart is not enabled. You can disable helper mode on a per-protocol basis.

```
[edit]
routing-options {
  graceful-restart {
    disable;
    restart-duration seconds;
  }
}
```

To disable graceful restart globally, include the **disable** statement at the **[edit routing-options graceful-restart]** hierarchy level.

When graceful restart is enabled for all routing protocols at the **[edit routing-options graceful-restart]** hierarchy level, you can disable graceful restart on a per-protocol basis.

NOTE: If you configure graceful restart after a BGP or LDP session has been established, the BGP or LDP session restarts and the peers negotiate graceful restart capabilities. Also, the BGP peer routing statistics are reset to zero.

Configuring Graceful Restart Options for BGP

To configure the duration of the BGP graceful restart period, include the **restart-time** statement at the **[edit protocols bgp graceful-restart]** hierarchy level. To set the length of time the router waits to receive messages from restarting neighbors before declaring them down, include the **stale-routes-time** statement at the **[edit protocols bgp graceful-restart]** hierarchy level.

```
[edit]
protocols {
  bgp {
    graceful-restart {
      disable;
      restart-time seconds;
      stale-routes-time seconds;
    }
  }
}
routing-options {
  graceful-restart;
}
```

To disable BGP graceful restart capability for all BGP sessions, include the **disable** statement at the **[edit protocols bgp graceful-restart]** hierarchy level.

NOTE: To set BGP graceful restart properties or disable them for a group, include the desired statements at the `[edit protocols bgp group group-name graceful-restart]` hierarchy level.

To set BGP graceful restart properties or disable them for a specific neighbor in a group, include the desired statements at the `[edit protocols bgp group group-name neighbor ip-address graceful-restart]` hierarchy level.

NOTE: Configuring graceful restart for BGP resets the BGP peer routing statistics to zero. Also, existing BGP sessions restart, and the peers negotiate graceful restart capabilities.

Configuring Graceful Restart Options for ES-IS

On J Series Services Routers, to configure the duration of the ES-IS graceful restart period, include the `restart-duration` statement at the `[edit protocols esis graceful-restart]` hierarchy level.

```
[edit]
protocols {
  esis {
    graceful-restart {
      disable;
      restart-duration seconds;
    }
  }
}
routing-options {
  graceful-restart;
}
```

To disable ES-IS graceful restart capability, include the `disable` statement at the `[edit protocols esis graceful-restart]` hierarchy level.

Configuring Graceful Restart Options for IS-IS

To configure the duration of the IS-IS graceful restart period, include the `restart-duration` statement at the `[edit protocols isis graceful-restart]` hierarchy level.

```
[edit]
protocols {
  isis {
    graceful-restart {
      disable;
      helper-disable;
      restart-duration seconds;
    }
  }
}
routing-options {
  graceful-restart;
}
```

To disable IS-IS graceful restart helper capability, include the **helper-disable** statement at the **[edit protocols isis graceful-restart]** hierarchy level. To disable IS-IS graceful restart capability, include the **disable** statement at the **[edit protocols isis graceful-restart]** hierarchy level.

NOTE: If you configure Bidirectional Forwarding Detection (BFD) and graceful restart for IS-IS, graceful restart might not work as expected.

NOTE: You can also track graceful restart events with the **traceoptions** statement at the **[edit protocols isis]** hierarchy level. For more information, see [“Tracking Graceful Restart Events” on page 2134](#).

Configuring Graceful Restart Options for OSPF and OSPFv3

To configure the duration of the OSPF/OSPFv3 graceful restart period, include the **restart-duration** statement at the **[edit protocols (ospf | ospf3) graceful-restart]** hierarchy level. To specify the length of time for which the router notifies helper routers that it has completed graceful restart, include the **notify-duration** at the **[edit protocols (ospf | ospf3) graceful-restart]** hierarchy level. Strict OSPF link-state advertisement (LSA) checking results in the termination of graceful restart by a helping router. To disable strict LSA checking, include the **no-strict-lsa-checking** statement at the **[edit protocols (ospf | ospf3) graceful-restart]** hierarchy level.

```
[edit]
protocols {
  ospf | ospfv3 {
    graceful-restart {
      disable;
      helper-disable
      no-strict-lsa-checking;
      notify-duration seconds;
      restart-duration seconds;
    }
  }
}
routing-options {
  graceful-restart;
}
```

To disable OSPF/OSPFv3 graceful restart, include the **disable** statement at the **[edit protocols (ospf | ospf3) graceful-restart]** hierarchy level.

Starting with Release 11.3, the Junos OS supports both the standard (based on RFC 3623, *Graceful OSPF Restart*) and the restart signaling-based (as specified in RFC 4811, RFC 4812, and RFC 4813) helper modes for OSPF version 2 graceful restart configurations. Both the standard and restart signaling-based helper modes are enabled by default. To disable the helper mode for OSPF version 2 graceful restart configurations, include the **helper-disable <both | restart-signaling | standard>** statement at the **[edit protocols ospf graceful-restart]** hierarchy level. Note that the last committed statement always takes precedence over the previous one.

```
[edit protocols ospf]
  graceful-restart {
    helper-disable <both | restart-signaling | standard>
  }
```

To reenble the helper mode, delete the **helper-disable** statement from the configuration by using the **delete protocols ospf graceful-restart helper-disable <restart-signaling | standard | both>** command. In this case also, the last executed command takes precedence over the previous ones.

NOTE:

Restart signaling-based helper mode is not supported for OSPFv3 configurations. To disable helper mode for OSPFv3 configurations, include the **helper-disable** statement at the **[edit protocols ospfv3 graceful-restart]** hierarchy level.

TIP: You can also track graceful restart events with the **traceoptions** statement at the **[edit protocols (ospf | ospf3)]** hierarchy level. For more information, see [“Tracking Graceful Restart Events” on page 2134](#).

NOTE: You cannot enable OSPFv3 graceful restart between a routing platform running Junos OS Release 7.5 and earlier and a routing platform running Junos OS Release 7.6 or later. As a workaround, make sure both routing platforms use the same Junos OS version.

NOTE: If you configure BFD and graceful restart for OSPF, graceful restart might not work as expected.

Configuring Graceful Restart Options for RIP and RIPng

To configure the duration of the RIP or RIPng graceful restart period, include the **restart-time** statement at the **[edit protocols (rip | ripng) graceful-restart]** hierarchy level.

```
[edit]
protocols {
  (rip | ripng) {
    graceful-restart {
      disable;
      restart-time seconds;
    }
  }
}
routing-options {
  graceful-restart;
}
```

To disable RIP or RIPng graceful restart capability, include the **disable** statement at the **[edit protocols (rip | ripng) graceful-restart]** hierarchy level.

Configuring Graceful Restart Options for PIM Sparse Mode

PIM sparse mode continues to forward existing multicast packet streams during a graceful restart, but does not forward new streams until after the restart is complete. After a restart, the routing platform updates the forwarding state with any updates that were received from neighbors and occurred during the restart period. For example, the routing platform relearns the join and prune states of neighbors during the restart, but does not apply the changes to the forwarding table until after the restart.

PIM sparse mode-enabled routing platforms generate a unique 32-bit random number called a generation identifier. Generation identifiers are included by default in PIM hello messages, as specified in the IETF Internet draft *Protocol Independent Multicast - Sparse Mode (PIM-SM): Protocol Specification (Revised)*. When a routing platform receives PIM hellos containing generation identifiers on a point-to-point interface, Junos OS activates an algorithm that optimizes graceful restart.

Before PIM sparse mode graceful restart occurs, each routing platform creates a generation identifier and sends it to its multicast neighbors. If a PIM sparse mode-enabled routing platform restarts, it creates a new generation identifier and sends it to its neighbors. When a neighbor receives the new identifier, it resends multicast updates to the restarting router to allow it to exit graceful restart efficiently. The restart phase completes when either the PIM state becomes stable or when the restart interval timer expires.

If a routing platform does not support generation identifiers or if PIM is enabled on multipoint interfaces, the PIM sparse mode graceful restart algorithm does not activate, and a default restart timer is used as the restart mechanism.

To configure the duration of the PIM graceful restart period, include the **restart-duration** statement at the **[edit protocols pim graceful-restart]** hierarchy level:

```
[edit]
protocols {
  pim {
    graceful-restart {
      disable;
      restart-duration seconds;
    }
  }
}
routing-options {
  graceful-restart;
}
```

To disable PIM sparse mode graceful restart capability, include the **disable** statement at the **[edit protocols pim graceful-restart]** hierarchy level.

NOTE: Multicast forwarding can be interrupted in two ways. First, if the underlying routing protocol is unstable, multicast reverse-path-forwarding (RPF) checks can fail and cause an interruption. Second, because the forwarding table is not updated during the graceful restart period, new multicast streams are not forwarded until graceful restart is complete.

Tracking Graceful Restart Events

To track the progress of a graceful restart event, you can configure graceful restart trace options flags for IS-IS and OSPF/OSPFv3. To configure graceful restart trace options, include the **graceful-restart** statement at the **[edit protocols protocol traceoptions flag]** hierarchy level:

```
[edit protocols]
isis {
  traceoptions {
    flag graceful-restart;
  }
}
(ospf | ospf3) {
  traceoptions {
    flag graceful-restart;
  }
}
```

Configuring Graceful Restart for MPLS-Related Protocols

This section contains the following topics:

- [Configuring Graceful Restart Globally on page 2134](#)
- [Configuring Graceful Restart Options for RSVP, CCC, and TCC on page 2135](#)
- [Configuring Graceful Restart Options for LDP on page 2135](#)

Configuring Graceful Restart Globally

To configure graceful restart globally for all MPLS-related protocols, include the **graceful-restart** statement at the **[edit routing-options]** hierarchy level. To configure the duration of the graceful restart period, include the **restart-duration** at the **[edit routing-options graceful-restart]** hierarchy level:

```
[edit]
routing-options {
  graceful-restart {
    disable;
```

```

    restart-duration seconds;
  }
}

```

To disable graceful restart globally, include the **disable** statement at the **[edit routing-options graceful-restart]** hierarchy level.

Configuring Graceful Restart Options for RSVP, CCC, and TCC

Because CCC and TCC rely on RSVP, you must modify these three protocols as a single group.

To configure how long the router retains the state of its RSVP neighbors while they undergo a graceful restart, include the **maximum-helper-recovery-time** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to recover.

To configure the delay between when the router discovers that a neighboring router has gone down and when it declares the neighbor down, include the **maximum-helper-restart-time** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to restart.

```

[edit]
protocols {
  rsvp {
    graceful-restart {
      disable;
      helper-disable;
      maximum-helper-recovery-time;
      maximum-helper-restart-time;
    }
  }
}
routing-options {
  graceful-restart;
}

```

To disable RSVP, CCC, and TCC graceful restart, include the **disable** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level. To disable RSVP, CCC, and TCC helper capability, include the **helper-disable** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level.

Configuring Graceful Restart Options for LDP

When configuring graceful restart for LDP, you can include the following optional statements at the **[edit protocols ldp graceful-restart]** hierarchy level:

```

[edit protocols ldp graceful-restart]
disable;
helper-disable;
maximum-neighbor-reconnect-time seconds;
maximum-neighbor-recovery-time seconds;
reconnect-time seconds;
recovery-time seconds;

```

```
[edit routing-options]
graceful-restart;
```

The statements have the following effects on the graceful restart process:

- To configure the length of time required to reestablish a session after a graceful restart, include the **reconnect-time** statement; the range is 30 through 300 seconds. To limit the maximum reconnect time allowed from a restarting neighbor router, include the **maximum-neighbor-reconnect-time** statement; the range is 30 through 300 seconds.
- To configure the length of time that helper routers are required to maintain the old forwarding state during a graceful restart, include the **recovery-time** statement; the range is 120 through 1800 seconds. On the helper router, you can configure a statement that overrides the request from the restarting router and sets the maximum length of time the helper router will maintain the old forwarding state. To configure this feature, include the **maximum-neighbor-recovery-time** statement; the range is 140 through 1900 seconds.

NOTE: The value for the **recovery-time** and **maximum-neighbor-recovery-time** statements at the **[edit protocols ldp graceful-restart]** hierarchy level should be approximately 80 seconds longer than the value for the **restart-duration** statement at the **[edit routing-options graceful-restart]** hierarchy level. Otherwise, a warning message appears when you try to commit the configuration.

- To disable LDP graceful restart capability, include the **disable** statement. To disable LDP graceful restart helper capability, include the **helper-disable** statement.

Configuring VPN Graceful Restart

Graceful restart allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. Without graceful restart, a control plane restart disrupts any VPN services provided by the router. Graceful restart is supported on Layer 2 VPNs, Layer 3 VPNs, virtual-router routing instances, and VPLS.

To implement graceful restart for a Layer 2 VPN or Layer 3 VPN, perform the configuration tasks described in the following sections:

- [Configuring Graceful Restart Globally on page 2136](#)
- [Configuring Graceful Restart for the Routing Instance on page 2137](#)

Configuring Graceful Restart Globally

To enable graceful restart, include the **graceful-restart** statement at the **[edit routing-options]** hierarchy level. To configure a global duration for the graceful restart period, include the **restart-duration** statement at the **[edit routing-options graceful-restart]** hierarchy level.

```
[edit]
routing-options {
  graceful-restart {
```

```

    disable;
    restart-duration seconds;
  }
}

```

To disable graceful restart globally, include the **disable** statement at the **[edit routing-options graceful-restart]** hierarchy level.

Configuring Graceful Restart for the Routing Instance

For Layer 3 VPNs only, you must also configure graceful restart for all routing and MPLS-related protocols within a routing instance by including the **graceful-restart** statement at the **[edit routing-instances instance-name routing-options]** hierarchy level. Because you can configure multi-instance BGP and multi-instance LDP, graceful restart for a carrier-of-carriers scenario is supported. To configure the duration of the graceful restart period for the routing instance, include the **restart-duration** statement at the **[edit routing-instances instance-name routing-options]**.

```

[edit]
routing-instances {
  instance-name {
    routing-options {
      graceful-restart {
        disable;
        restart-duration seconds;
      }
    }
  }
}

```

You can disable graceful restart for individual protocols with the **disable** statement at the **[edit routing-instances instance-name protocols protocol-name graceful-restart]** hierarchy level.

Related Documentation

- [Graceful Restart Concepts on page 2085](#)
- [Graceful Restart System Requirements on page 2086](#)
- [Graceful Restart and Layer 2 and Layer 3 VPNs on page 2091](#)
- [Verifying Graceful Restart Operation on page 2271](#)
- [Example: Configuring Graceful Restart on page 2139](#)

Configuring Logical System Graceful Restart

Graceful restart for a logical system functions much as graceful restart does in the main router. The only difference is the location of the **graceful-restart** statement.

The following topics describe what to configure to implement graceful restart in a logical system:

- [Enabling Graceful Restart Globally on page 2138](#)
- [Configuring Graceful Restart for a Routing Instance on page 2138](#)

Enabling Graceful Restart Globally

To enable graceful restart in a logical system, include the **graceful-restart** statement at the **[edit logical-systems *logical-system-name* routing-options]** hierarchy level. To configure a global duration of the graceful restart period, include the **restart-duration** statement at the **[edit logical-systems *logical-system-name* routing-options graceful-restart]** hierarchy level.

```
[edit]
logical-systems {
  logical-system-name {
    routing-options {
      graceful-restart {
        disable;
        restart-duration seconds;
      }
    }
  }
}
```

To disable graceful restart globally, include the **disable** statement at the **[edit logical-systems *logical-system-name* routing-options graceful-restart]** hierarchy level.

Configuring Graceful Restart for a Routing Instance

For Layer 3 VPNs only, you must also configure graceful restart globally for a routing instance inside a logical system. To configure, include the **graceful-restart** statement at the **[edit logical-systems *logical-system-name* routing-instances *instance-name* routing-options]** hierarchy level. Because you can configure multi-instance BGP and multi-instance LDP, graceful restart for a carrier-of-carriers scenario is supported. To configure the duration of the graceful restart period for the routing instance, include the **restart-duration** statement at the **[edit logical-systems *logical-system-name* routing-instances *instance-name* routing-options]**.

```
[edit]
logical-systems {
  logical-system-name {
    routing-instances {
      instance-name {
        routing-options {
          graceful-restart {
            disable;
            restart-duration seconds;
          }
        }
      }
    }
  }
}
```

To disable graceful restart for individual protocols with the **disable** statement at the **[edit logical-systems *logical-system-name* routing-instances *instance-name* protocols *protocol-name* graceful-restart]** hierarchy level.

Related Documentation

- [Graceful Restart Concepts on page 2085](#)
- [Graceful Restart System Requirements on page 2086](#)

- [Graceful Restart on Logical Systems on page 2092](#)
- [Verifying Graceful Restart Operation on page 2271](#)
- [Example: Configuring Graceful Restart on page 2139](#)

Example: Configuring Graceful Restart

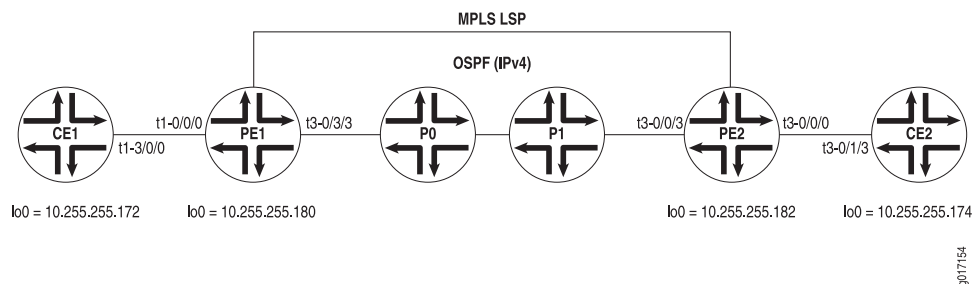

To enable graceful restart, include the **graceful-restart** statement at the **[edit routing-instance *instance-name* routing-options]** or **[edit routing-options]** hierarchy level as well as in the protocol level.

For example:

```
protocols {
  bgp {
    group ext {
      graceful-restart;
    }
  }
}
routing-options {
  graceful-restart;
}
```

Figure 26 on page 2139 shows a standard MPLS VPN network. Routers CE1 and CE2 are customer edge routers, PE1 and PE2 are provider edge routers, and P0 is a provider core router. Several Layer 3 VPNs are configured across this network, as well as one Layer 2 VPN. Interfaces are shown in the diagram and are not included in the configuration example that follows.

Figure 26: Layer 3 VPN Graceful Restart Topology

Router CE1 On Router CE1, configure the following protocols on the logical interfaces of **t3-3/1/0**: OSPF on unit 101, RIP on unit 102, BGP on unit 103, and IS-IS on unit 512. Also configure graceful restart, BGP, IS-IS, OSPF, and RIP on the main instance to be able to connect to the routing instances on Router PE1.

```
[edit]
interfaces {
  t3-3/1/0 {
    encapsulation frame-relay;
    unit 100 {
      dlci 100;
      family inet {
        address 10.96.100.2/30;
      }
    }
  }
}
```

```
    }
  }
  unit 101 {
    dlci 101;
    family inet {
      address 10.96.101.2/30;
    }
  }
  unit 102 {
    dlci 102;
    family inet {
      address 10.96.102.2/30;
    }
  }
  unit 103 {
    dlci 103;
    family inet {
      address 10.96.103.2/30;
    }
  }
  unit 512 {
    dlci 512;
    family inet {
      address 10.96.252.1/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.245.14.172/32;
      primary;
    }
    address 10.96.110.1/32;
    address 10.96.111.1/32;
    address 10.96.112.1/32;
    address 10.96.113.1/32;
    address 10.96.116.1/32;
  }
  family iso {

```

Router PE1 On Router PE1, configure graceful restart in the master instance, along with BGP, OSPF, MPLS, and LDP. Next, configure several protocol-specific instances of graceful restart. By including instances for BGP, OSPF, Layer 2 VPNs, RIP, and static routes, you can observe the wide range of options available when you implement graceful restart. Configure the following protocols in individual instances on the logical interfaces of **t3-0/0/0**: a static route on unit 100, OSPF on unit 101, RIP on unit 102, BGP on unit 103, and Frame Relay on unit 512 for the Layer 2 VPN instance.

```

Router CE2 On Router CE2, complete the Layer 2 and Layer 3 VPN configuration by mirroring the protocols already set on Routers PE2 and CE1. Specifically, configure the following on the logical interfaces of **t1-0/0/3**: OSPF on unit 201, RIP on unit 202, BGP on unit 203, and IS-IS on unit 612. Finally, configure graceful restart, BGP, IS-IS, OSPF, and RIP on the main instance to be able to connect to the routing instances on Router PE2.

```

Router PE1 Status During a Restart

Before you can verify that graceful restart is working, you must simulate a router restart. To cause the routing process to refresh and simulate a restart, use the **restart routing** operational mode command:

```

user@PE1> restart routing
Routing protocol daemon started, pid 3558

```

The following sample output is captured during the router restart:

```

user@PE1> show bgp neighbor
