YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <http://www.juniper.net/support/eula.html>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

Part 1	Configuration and Operations Automation Library	
Chapter 1	Configuration and Operations Automation Overview	3
	Overview	3
	Introduction to Junos Automation	3
	Junos Automation Overview	4
	Junos XML API and Junos XML Management Protocol	6
	Junos XML API and Junos XML Management Protocol Overview	6
	Advantages of Using the Junos XML Management Protocol and Junos XML API	7
	Extension Functions, Templates, and Parameters in the jcs Namespace	8
	Junos Script Automation: Extension Functions in the jcs Namespace Overview	8
	Junos Extension Functions in the jcs Namespace Summary	9
	Junos Extension Functions in the jcs Namespace	11
	Junos Script Automation: Named Templates in the jcs Namespace Overview	28
	Junos Named Templates in the jcs Namespace Summary	30
	Junos Named Templates in the jcs Namespace	30
	Junos Script Automation: Global Parameters and Variables in the junos.xml File	39
	XML	44
	XML Overview	44
	XML and Junos OS	46
	XSLT	47
	XSLT Overview	48
	XSLT Namespace	50
	XPath Overview	50
	XSLT Templates Overview	52

XSLT Parameters Overview	54
XSLT Variables Overview	57
XSLT Programming Instructions Overview	59
XSLT Recursion Overview	61
XSLT Context (Dot) Overview	62
SLAX	63
SLAX Overview	63
Converting Scripts Between SLAX and XSLT	65
SLAX Syntax Rules Overview	67
SLAX Elements and Element Attributes Overview	69
XPath Expressions Overview for SLAX	70
SLAX Templates Overview	71
SLAX Parameters Overview	74
SLAX Variables Overview	77
SLAX Statements Overview	79
XSLT Elements Without SLAX Equivalents	82
SLAX Operators	83
Configuration	85
Storing and Enabling Scripts	85
Storing and Enabling Scripts	86
Storing Scripts in Flash Memory	87
Storing Scripts and Script Functionality in the Script Library	88
Configuring a Remote Source for Scripts	89
Overview of Updating Scripts from a Remote Source	89
Using a Master Source Location for a Script	90
Using an Alternate Source Location for a Script	95
Configuring the Session Protocol for Scripts	98
Specifying the Session Protocol for Connections Using Junos Automation Scripts	98
SLAX Statements	111
apply-templates	112
call	112
else	114
else if	115
for-each	115
if	116
match	118
mode	118
param	119
priority	120
template	121
var	122
version	123
with	123
Standard XPath and XSLT Functions Used in Automation Scripts	125
concat()	125
contains()	125
count()	126
last()	126

	name()	126
	not()	127
	position()	127
	starts-with()	128
	string-length()	128
	substring-after()	128
	substring-before()	129
	Standard XSLT Elements and Attributes Used in Automation Scripts	129
	xsl:apply-templates	130
	xsl:call-template	131
	xsl:choose	132
	xsl:comment	132
	xsl:copy-of	133
	xsl:element	133
	xsl:for-each	134
	xsl:if	134
	xsl:import	135
	xsl:otherwise	136
	xsl:param	136
	xsl:stylesheet	137
	xsl:template	138
	xsl:text	139
	xsl:value-of	139
	xsl:variable	140
	xsl:when	141
	xsl:with-param	141
	Administration	142
	Operational Commands	142
	request system scripts convert	143
Chapter 2	Configuration Automation Developer Guide	145
	Overview	145
	Commit Scripts Overview	145
	Commit Script Overview	145
	Advantages of Using Commit Scripts	146
	How Commit Scripts Work	148
	Generating a Custom Warning, Error, or System Log Message	153
	Overview of Generating Custom Warning, Error, and System Log Messages	153
	Generating a Persistent or Transient Configuration Changes	154
	Overview of Generating Persistent or Transient Configuration Changes	154

Creating Custom Configuration Syntax with Macros	158
Overview of Creating Custom Configuration Syntax with Macros	158
How Macros Work	159
Configuration	164
Creating and Executing Commit Scripts	165
Avoiding Potential Conflicts When Using Multiple Commit Scripts	165
Required Boilerplate for Commit Scripts	166
XML Syntax for Common Commit Script Tasks	168
Design Considerations for Commit Scripts	169
Line-by-Line Explanation of Sample Commit Scripts	170
Controlling Execution of Commit Scripts During Commit Operations	174
Configuring Checksum Hashes for a Commit Script	177
Executing Large Commit Scripts	178
Generating a Custom Warning, Error, or System Log Message	178
Generating a Custom Warning, Error, or System Log Message	178
Tag Elements to Use When Generating Messages	181
Example: Generating a Custom Warning Message	183
Example: Generating a Custom Error Message	186
Example: Generating a Custom System Log Message	190
Generating a Persistent or Transient Configuration Changes	192
Generating a Persistent or Transient Change	192
Removing a Persistent or Transient Change	197
Tag Elements to Use When Generating Persistent and Transient Changes	198
Example: Generating a Persistent Change	199
Example: Generating a Transient Change	202
Creating Custom Configuration Syntax with Macros	207
Creating a Macro to Read the Custom Syntax and Generate Related Configuration Statements	207
Example: Creating Custom Configuration Syntax with Macros	208
Commit Script Examples	215
Example: Adding a Final then accept Term to a Firewall	215
Example: Adding T1 Interfaces to a RIP Group	220
Example: Assigning a Classifier	223
Example: Automatically Configuring Logical Interfaces and IP Addresses	227
Example: Configuring Administrative Groups for LSPs	234
Example: Configuring a Default Encapsulation Type	238
Example: Configuring Dual Routing Engines	242
Example: Configuring an Interior Gateway Protocol on an Interface	246
Example: Controlling IS-IS and MPLS Interfaces	251
Example: Controlling LDP Configuration	255
Example: Creating a Complex Configuration Based on a Simple Interface Configuration	259
Example: Imposing a Minimum MTU Setting	266
Example: Limiting the Number of ATM Virtual Circuits	268
Example: Limiting the Number of E1 Interfaces	272
Example: Loading a Base Configuration	281
Example: Prepending a Global Policy	295

Example: Preventing Import of the Full Routing Table	300
Example: Requiring Internal Clocking on T1 Interfaces	303
Example: Requiring and Restricting Configuration Statements	306
Configuration Statements	310
allow-transients	310
apply-macro	311
checksum	312
commit	313
direct-access	314
file (Commit Scripts)	314
optional	315
refresh (Commit Scripts)	315
refresh-from (Commit Scripts)	316
scripts	317
source (Commit Scripts)	318
traceoptions (Commit and Op Scripts)	319
Junos XML and XSLT Tag Elements Used in Commit Scripts	320
<change> (XSLT)	320
<syslog> (Junos XML)	320
<transient-change> (XSLT)	321
xnm:error (Junos XML)	321
xnm:warning (Junos XML)	323
Administration	324
Configuration and Operations Configuration Statements	324
Any Hierarchy Level	324
[edit system scripts] Hierarchy Level	324
Troubleshooting	325
Troubleshooting Commit Scripts	325
Displaying Commit Script Output	325
Tracing Commit Script Processing	326
Troubleshooting Commit Scripts	330
Chapter 3 Operations Automation Developer Guide	333
Overview	333
Op Scripts Overview	333
Op Script Overview	333
How Op Scripts Work	334
Configuration	334
Creating and Executing Op Scripts	335
Required Boilerplate for Op Scripts	335
Mapping Operational Mode Commands and Output Fields to Junos XML Notation	337
Using RPCs and Operational Mode Commands in Op Scripts	337
Declaring Arguments in Op Scripts	341
Configuring Help Text for Op Scripts	343
Enabling an Op Script and Defining a Script Alias	344
Executing an Op Script	345
Configuring Checksum Hashes for an Op Script	345
Executing an Op Script from a Remote Site	346

Disabling an Op Script	347
Op Script Examples	349
Example: Changing the Configuration Using an Op Script	349
Example: Customizing Output of the show interfaces terse Command Using an Op Script	354
Example: Displaying DNS Hostname Information Using an Op Script	364
Example: Exporting Files Using an Op Script	368
Example: Finding LSPs to Multiple Destinations Using an Op Script . . .	376
Example: Importing Files Using an Op Script	380
Example: Restarting an FPC Using an Op Script	385
Example: Searching Files Using an Op Script	388
Configuration Statements	392
[edit system scripts] Hierarchy Level	393
Any Hierarchy Level	393
arguments	394
checksum	395
command	396
description	396
file (Op Scripts)	397
op	398
no-allow-url	399
refresh (Op Scripts)	399
refresh-from (Op Scripts)	400
scripts	401
source (Op Scripts)	402
traceoptions (Commit and Op Scripts)	403
Troubleshooting	404
Troubleshooting Op Scripts	404
Tracing Op Script Processing	404
Chapter 4 Event Automation and Event Policy Developer Guide	409
Overview	409
Event Policy Overview	409
Event Notifications and Policies Overview	409
How Event Policies Work	410
Event Scripts Overview	412
Event Scripts Overview	412
Configuration	413
Triggering an Event Policy	413
Using Correlated Events to Trigger an Event Policy	413
Representing the Correlating Event in an Event Policy	416
Triggering an Event Policy Based on Event Count	417
Using Regular Expressions to Refine the Set of Events That Trigger a Policy	417
Generating Internal Events to Trigger Event Policies	419

Using Nonstandard System Log Messages to Trigger Event Policies . . .	419
Configuring Event Policy File Archiving	420
Event Policy File Archiving Overview	420
Example: Defining Destinations for File Archiving by Event Policies . . .	421
Example: Configuring an Event Policy to Upload Files	424
Configuring the Delay Before Files Are Uploaded by an Event Policy . . .	431
Configuring an Event Policy to Retry the File Upload Action	432
Configuring Event Policy Actions	433
Configuring an Event Policy to Execute Operational Mode	
Commands	433
Configuring an Event Policy to Change the Configuration	436
Executing Event Scripts in an Event Policy	449
Configuring Event Policies to Ignore an Event	454
Changing the User Privilege Level for an Event Policy Action	455
Configuring Event Policies to Raise SNMP Traps	455
Configuring the System Log Priority of the Triggering Event in an Event	
Policy	456
Configuring Event Policy Privileges	461
Changing the User Privilege Level for an Event Policy Action	461
Creating and Executing Event Scripts	462
Required Boilerplate for Event Scripts	462
Capturing and Using Event Details and Remote Execution Details in	
Event Scripts	464
Mapping Operational Mode Commands and Output Fields to Junos	
XML Notation	465
Using RPCs and Operational Mode Commands in Event Scripts	466
Enabling an Event Script	470
Executing an Event Script	470
Replacing an Event Script	470
Configuring Checksum Hashes for an Event Script	471
Examples	472
Example: Assigning a Transfer Delay to an Event Policy Action	472
Example: Associating an Optional User with an Event Policy Action . .	474
Example: Controlling Event Policy Using a Regular Expression	475
Example: Correlating Events Based on Event Attributes	475
Example: Correlating Events Based on Receipt of Other Events Within	
a Specified Time Interval	476
Example: Generating an Internal Event	476
Example: Ignoring Events Based on Receipt of Other Events	477
Example: Limiting Event Script Output Based on a Specific Event	
Type	478
Example: Raising an SNMP Trap in Response to an Event	479
Example: Representing the Correlating Event in an Event Policy	479
Example: Retrying the File Upload Action	480
Example: Triggering a Policy Based on Event Count	481
Example: Using Nonstandard System Log Messages to Trigger an Event	
Policy	483

Summary of Event Policy Configuration Statements	484
archive-sites	484
arguments	485
attributes-match	486
change-configuration	487
commands (Event Policy Change Configuration)	488
commands (Event Policy Execute Commands)	489
commit-options	490
destination	491
destinations	492
equals	493
event-options	494
event-script	496
events (Associating Events with a Policy)	497
events (Correlating Events with Each Other)	497
execute-commands	498
facility	498
generate-event	499
ignore	499
matches	500
not	500
output-filename	501
output-format	502
policy	503
priority-override	505
raise-trap	505
retry	506
retry-count	507
severity	508
starts-with	509
then	510
time-interval	511
time-of-day	512
traceoptions	513
transfer-delay	515
trigger	516
within	517
upload	518
user-name	519
Summary of Event Script Configuration Statements	520
checksum	520
event-script	521
file	522
refresh (Event Scripts)	523
refresh-from (Event Scripts)	523
remote-execution	524

traceoptions (Event Scripts)	526

	Administration	527
	Event Policy and Event Scripts Configuration Statements	527
	Any Hierarchy Level	527
	[edit event-options] Hierarchy Level	527
	Troubleshooting	529
	Troubleshooting Event Policy and Event Scripts	529
	Tracing Event Policy Processing	529
	Tracing Event Script Processing	532
Part 2	NETCONF XML Management Protocol Developer Guide	
Chapter 5	Introduction to the NETCONF XML Management Protocol and Junos XML API	539
	XML and Junos OS	539
	NETCONF XML Management Protocol and Junos XML API Overview	541
	XML Overview	542
	Junos XML and NETCONF XML Management Protocol Tag Elements	542
	Document Type Definition	543
	Advantages of Using the NETCONF XML Management Protocol and Junos XML API	543
	Overview of a NETCONF XML Management Protocol Session	544
Chapter 6	Using NETCONF XML Management Protocol and Junos XML Tag Elements	547
	XML and NETCONF XML Management Protocol Conventions Overview	547
	Request and Response Tag Elements	548
	Child Tag Elements of a Request Tag Element	548
	Child Tag Elements of a Response Tag Element	549
	Spaces, Newline Characters, and Other White Space	549
	XML Comments	550
	Predefined Entity References	550
	Mapping Commands to Junos XML Tag Elements	551
	Mapping for Command Options with Variable Values	552
	Mapping for Fixed-Form Command Options	552
	Mapping Configuration Statements to Junos XML Tag Elements	552
	Mapping for Hierarchy Levels and Container Statements	553
	Mapping for Objects That Have an Identifier	554
	Mapping for Single-Value and Fixed-Form Leaf Statements	555
	Mapping for Leaf Statements with Multiple Values	556
	Mapping for Multiple Options on One or More Lines	556
	Mapping for Comments About Configuration Statements	557
	Using the Same Configuration Tag Elements in Requests and Responses	558
Chapter 7	Controlling the NETCONF Session	561
	Client Application's Role in a NETCONF Session	561
	Establishing a NETCONF Session	562
	Generating Well-Formed XML Documents	562
	Prerequisites for Establishing an SSH Connection	563
	Establishing an SSH Connection	563
	Establishing an Outbound SSH Connection	568

Connecting to the NETCONF Server	573
Starting the NETCONF Session	574
Exchanging <hello> Tag Elements	574
Verifying Compatibility	576
Exchanging Information with the NETCONF Server	577
Sending a Request to the NETCONF Server	577
Request Classes	578
Including Attributes in the Opening <rpc> Tag	580
Parsing the NETCONF Server Response	580
NETCONF Server Response Classes	581
Using a Standard API to Parse Response Tag Elements	582
Handling an Error or Warning	583
Locking and Unlocking the Candidate Configuration	584
Locking the Candidate Configuration	584
Unlocking the Candidate Configuration	585
Terminating Another NETCONF Session	586
Ending a NETCONF Session and Closing the Connection	587
Displaying CLI Output as XML Tag Elements	587
Displaying the RPC Tags for a Command	588
Example of a NETCONF Session	589
Exchanging Initialization Tag Elements	589
Sending an Operational Request	590
Locking the Configuration	590
Changing the Configuration	591
Committing the Configuration	591
Unlocking the Configuration	592
Closing the NETCONF Session	592
Chapter 8 Requesting Information	593
Overview of the Request Procedure	593
Requesting Operational Information	594
Specifying the Output Format for Operational Information Requests in a NETCONF Session	596
Requesting Configuration Information	598
Requesting Information from the Committed or Candidate Configuration	599
Specifying the Scope of Configuration Information to Return	601
Requesting the Complete Configuration	602
Requesting a Hierarchy Level or Container Object Without an Identifier	602
Requesting All Configuration Objects of a Specified Type	604
Requesting Identifiers for Configuration Objects of a Specified Type	606
Requesting One Configuration Object	608
Requesting Specific Child Tags for a Configuration Object	610
Requesting Multiple Configuration Elements Simultaneously	612
Requesting an XML Schema for the Configuration Hierarchy	613
Creating the junos.xsd File	614
Example: Requesting an XML Schema	615
Requesting a Previous (Rollback) Configuration	617

	Comparing Two Previous (Rollback) Configurations	618
	Requesting the Rescue Configuration	620
Chapter 9	Changing Configuration Information	623
	Editing the Candidate Configuration	624
	Formatting the Configuration Data	625
	Delivery Mechanism: Data Files Versus Streaming Data	625
	Data Format: Junos XML versus CLI Configuration Statements	628
	Setting the Edit Configuration Mode	629
	Specifying the merge Data Mode	631
	Specifying the replace Data Mode	631
	Specifying the no-change Data Mode	632
	Handling Errors	633
	Replacing the Candidate Configuration	633
	Using <copy-config>	634
	Using <edit-config>	634
	Rolling Back a Configuration	635
	Deleting the Candidate Configuration	635
	Changing Individual Configuration Elements	636
	Merging Configuration Elements	637
	Replacing Configuration Elements	638
	Creating New Configuration Elements	639
	Deleting Configuration Elements	641
	Deleting a Hierarchy Level or Container Object	642
	Deleting a Configuration Object That Has an Identifier	642
	Deleting a Single-Value or Fixed-Form Option from a Configuration Object	643
	Deleting Values from a Multivalue Option of a Configuration Object	644
Chapter 10	Committing Configurations	647
	Verifying a Configuration Before Committing It	647
	Committing a Configuration	648
	Committing the Candidate Configuration	648
	Committing the Candidate Configuration Only After Confirmation	648
Chapter 11	Summary of NETCONF Tag Elements	651
]]>]]>	651
	<close-session/>	652
	<commit>	652
	<copy-config>	653

	<unlock-configuration/>	687
	<xnm:error>	687
	<xnm:warning>	689
Chapter 13	Summary of Attributes in Junos XML Tags	691
	junos:changed-localtime	691
	junos:changed-seconds	691
	junos:commit-localtime	692
	junos:commit-seconds	692
	junos:commit-user	693
	operation	693
	xmlns	694
Chapter 14	Writing NETCONF Perl Client Applications	697
	Overview of the NETCONF::Netconf::Manager Perl Module and Sample Scripts	697
	Downloading the NETCONF Perl Client and Prerequisites Package	698
	Installing the NETCONF Perl Client and Prerequisites Package	699
	Verifying the Installation and Version of Perl	699
	Extracting the NETCONF Perl Client and Sample Scripts	699
	Extracting and Installing the NETCONF Perl Client Prerequisites Package	700

	Installing the NETCONF Perl Client	702
	Tutorial: Writing Perl Client Applications	703
	Import Perl Modules and Declare Constants	703
	Connect to the NETCONF Server	704
	Satisfy Protocol Prerequisites	704
	Group Requests	704
	Obtain and Record Parameters Required by the NET::Netconf::Manager Object	704
	Obtain Application-Specific Parameters	707
	Establishing the Connection	708
	Submitting a Request to the NETCONF Server	708
	Providing Method Options or Attributes	709
	Submitting a Request	711
	Example: Get an Inventory of Hardware Components	712
	Example: Edit Configuration Statements	713
	Parsing and Formatting the Response from the NETCONF Server	716
	Parsing and Formatting an Operational Response	716
	Closing the Connection to the NETCONF Server	718
Part 3	NETCONF Java Toolkit Developer Guide	
Chapter 15	Overview and Installation	723
	NETCONF Java Toolkit Overview	723
	NETCONF XML Management Protocol and Junos XML API Overview	723
	NETCONF Java Toolkit Overview	724
	NETCONF Java Toolkit Installation	725
	Downloading and Installing the NETCONF Java Toolkit	725
	Downloading the NETCONF Java Toolkit	726
	Installing the NETCONF Java Toolkit	726
	Satisfying Requirements for SSHv2 Connections	726
Chapter 16	Using the NETCONF Java Toolkit	729
	NETCONF Java Toolkit Classes	729
	NETCONF Java Toolkit Class: Device	729
	NETCONF Java Toolkit Class: NetconfSession	731
	NETCONF Java Toolkit Class: XMLBuilder	732
	NETCONF Java Toolkit Class: XML	733
	NETCONF Java Toolkit Program Files	737
	Creating NETCONF Java Toolkit Program Files	737
	Creating and Executing a NETCONF Java Toolkit Program File	737
	Example: Using the NETCONF Java Toolkit to Execute an Operational Request RPC	739
	Using the NETCONF Java Toolkit to Parse an RPC Reply	743
	Troubleshooting Exception Errors in a NETCONF Java Toolkit Program	745
	Troubleshooting Connection Errors: Socket Timed Out	745
	Troubleshooting Connection Errors: No Connection	746
	Troubleshooting Authentication Errors	746
	Troubleshooting NETCONF Session Errors	747

	Performing Operational and Configuration Tasks	748
	Using the NETCONF Java Toolkit to Perform Operational Tasks	748
	Using Device Object Methods to Execute RPCs and Operational	
	Commands	748
	Example: Using the NETCONF Java Toolkit to Execute CLI	
	Commands	749
	Using the NETCONF Java Toolkit to Perform Configuration Tasks	752
	Using Device Object Methods to Load Configuration Changes	752
	Example: Using the NETCONF Java Toolkit to Load and Commit a	
	Configuration	754
	Example: Using the NETCONF Java Toolkit to Load Set Configuration	
	Commands	758
	NETCONF Java Toolkit Examples	762
	Example: Using the NETCONF Java Toolkit to Execute an Operational	
	Request RPC	762
	Example: Using the NETCONF Java Toolkit to Print Component	
	Temperatures	766
Part 4	Junos XML Management Protocol Developer Guide	
Chapter 17	Introduction to the Junos XML Management Protocol and Junos XML	
	API	773
	XML and Junos OS	773
	Junos XML API and Junos XML Management Protocol Overview	775
	XML Overview	776
	Tag Elements	776
	Attributes	777
	Namespaces	777
	Document Type Definition	778
	Advantages of Using the Junos XML Management Protocol and Junos XML	
	API	778
	Parsing Device Output	778
	Displaying Device Output	779
	Overview of a Junos XML Protocol Session	779
Chapter 18	Using Junos XML Management Protocol and Junos XML Tag Elements . .	781
	XML and Junos XML Management Protocol Conventions Overview	781
	Request and Response Tag Elements	782
	Child Tag Elements of a Request Tag Element	783
	Child Tag Elements of a Response Tag Element	783
	Spaces, Newline Characters, and Other White Space	783
	XML Comments	784
	XML Processing Instructions	784
	Predefined Entity References	784
	Mapping Commands to Junos XML Tag Elements	786
	Mapping for Command Options with Variable Values	786
	Mapping for Fixed-Form Command Options	787
	Mapping Configuration Statements to Junos XML Tag Elements	787
	Mapping for Hierarchy Levels and Container Statements	787
	Mapping for Objects That Have an Identifier	788

Chapter 19

Mapping for Single-Value and Fixed-Form Leaf Statements	789
Mapping for Leaf Statements with Multiple Values	790
Mapping for Multiple Options on One or More Lines	791
Mapping for Comments About Configuration Statements	792
Using the Same Configuration Tag Elements in Requests and Responses	793
Controlling the Junos XML Management Protocol Session	795
Client Application's Role in a Junos XML Protocol Session	795
Establishing a Junos XML Management Protocol Session	796
Supported Access Protocols	797
Prerequisites for Establishing a Connection	797
Prerequisites for All Access Protocols	797
Prerequisites for Clear-Text Connections	799
Prerequisites for SSH Connections	800
Prerequisites for Outbound SSH Connections	801
Prerequisites for SSL Connections	805
Prerequisites for Telnet Connections	807
Connecting to the Junos XML Protocol Server	807
Connecting to the Junos XML Protocol Server from the Client	
Application	807
Connecting to the Junos XML Protocol Server from the CLI	808
Starting the Junos XML Protocol Session	808
Emitting the Initialization PI and Tag	809
Parsing the Initialization PI and Tag from the Junos XML Protocol	
Server	811
Verifying Software Compatibility	813
Supported Software Versions	813
Authenticating with the Junos XML Protocol Server	813
Submitting an Authentication Request	814
Interpreting the Authentication Response	815
Exchanging Information with the Junos XML Protocol Server	816
Sending a Request to the Junos XML Protocol Server	816
Request Classes	816
Including Attributes in the Opening <rpc> Tag	818
Parsing the Junos XML Protocol Server Response	819
xmlns:junos Attribute	819
Junos XML Protocol Server Response Classes	819
Using a Standard API to Parse Response Tag Elements	821
Handling an Error or Warning	821
Halting a Request	822
Locking and Unlocking the Candidate Configuration or Creating a Private	
Copy	823
Locking the Candidate Configuration	824
Unlocking the Candidate Configuration	825
Terminating Another Junos XML Protocol Session	825
Creating a Private Copy of the Configuration	826
Ending a Junos XML Protocol Session and Closing the Connection	827
Displaying CLI Output as XML Tag Elements	828
Displaying the RPC Tags for a Command	828

	Example of a Junos XML Protocol Session	829
	Exchanging Initialization PIs and Tag Elements	829
	Sending an Operational Request	829
	Locking the Configuration	830
	Changing the Configuration	830
	Committing the Configuration	831
	Unlocking the Configuration	831
	Closing the Junos XML Protocol Session	832
Chapter 20	Requesting Information	833
	Overview of the Request Procedure	834
	Requesting Operational Information	834
	Specifying the Output Format for Operational Information Requests in a Junos XML Protocol Session	836
	Requesting Configuration Information	838
	Specifying the Source and Output Format of Configuration Information	839
	Requesting Information from the Committed or Candidate Configuration	840
	Requesting Output as Formatted ASCII Text or Junos XML Tag Elements	842
	Requesting an Indicator for Identifiers	844
	Requesting a Change Indicator for Configuration Elements	846
	Displaying Commit-Script-Style XML Data	849
	Specifying the Output Format for Configuration Groups and Interface Ranges	850
	Specifying Whether Configuration Groups and Interface Ranges Are Displayed Separately	851
	Displaying the Source Group for Inherited Configuration Elements	852
	Examples: Specifying Output Format for Configuration Groups	854
	Displaying the Source Interface Range for Inherited Configuration Elements	857
	Comparing Configuration Changes with a Prior Version	858
	Specifying the Scope of Configuration Information to Return	859
	Requesting the Complete Configuration	860
	Requesting a Hierarchy Level or Container Object Without an Identifier	861
	Requesting All Configuration Objects of a Specified Type	862
	Requesting a Specified Number of Configuration Objects	863
	Requesting Identifiers Only	865
	Requesting One Configuration Object	867
	Requesting a Subset of Objects by Using Regular Expressions	869
	Requesting Multiple Configuration Elements Simultaneously	872
	Requesting an XML Schema for the Configuration Hierarchy	873
	Creating the junos.xsd File	874
	Example: Requesting an XML Schema	875
	Requesting a Previous (Rollback) Configuration	876
	Comparing Two Previous (Rollback) Configurations	878
	Requesting the Rescue Configuration	879

Chapter 21	Changing Configuration Information	881
	Overview of Configuration Changes	881
	Specifying the Source and Format of New Configuration Data	883
	Providing Configuration Data in a File	883
	Providing Configuration Data as a Data Stream	884
	Defining the Configuration Data Format	885
	Replacing the Entire Configuration	887
	Replacing the Configuration with New Data	887
	Rolling Back to a Previous or Rescue Configuration	888
	Creating, Modifying, or Deleting Configuration Elements	888
	Merging Configuration Elements	890
	Replacing Configuration Elements	893
	Creating New Configuration Elements	895
	Replacing Configuration Elements Only If They Have Changed	896
	Deleting Configuration Elements	897
	Deleting a Hierarchy Level or Container Object	897
	Deleting a Configuration Object That Has an Identifier	898
	Deleting a Single-Value or Fixed-Form Option from a Configuration Object	900
	Deleting Values from a Multivalue Option of a Configuration Object	901
	Reordering Elements in Configuration Objects	903
	Renaming a Configuration Object	906
	Protecting or Unprotecting a Configuration Object	908
	Changing a Configuration Element's Activation State	910
	Deactivating a Newly Created Element	911
	Deactivating or Reactivating an Existing Element	912
	Changing a Configuration Element's Activation State Simultaneously with Other Changes	913
	Replacing an Element and Setting Its Activation State	913
	Using Junos XML Tag Elements for the Replacement Element	914
	Using Formatted ASCII Text for the Replacement Element	914
	Reordering an Element and Setting Its Activation State	915
	Renaming an Object and Setting Its Activation State	915
	Example: Replacing an Object and Deactivating It	916
Chapter 22	Committing a Configuration	919
	Verifying a Configuration Before Committing It	919
	Committing the Candidate Configuration	920
	Committing a Private Copy of the Configuration	921
	Committing a Configuration at a Specified Time	922
	Committing the Candidate Configuration Only After Confirmation	923
	Committing and Synchronizing a Configuration on Redundant Control Planes	926
	Synchronizing the Configuration on Both Routing Engines	927
	Example: Synchronizing the Configuration on Both Routing Engines	928
	Forcing a Synchronized Commit Operation	929
	Example: Forcing a Synchronization	930

	Synchronizing Configurations Simultaneously with Other Operations	930
	Verifying the Configuration on Both Routing Engines	930
	Scheduling Synchronization for a Specified Time	931
	Synchronizing Configurations but Requiring Confirmation	931
	Logging a Message About Synchronized Configurations	932
	Logging a Message About a Commit Operation	932
Chapter 23	Summary of Junos XML Protocol Tag Elements	935
	<abort/>	935
	<abort-acknowledgement/>	935
	<authentication-response>	936
	<challenge>	936
	<checksum-information>	937
	<close-configuration/>	938
	<commit-configuration>	938
	<commit-results>	942
	<database-status>	943
	<database-status-information>	944
	<end-session/>	944
	<get-checksum-information>	945
	<get-configuration>	945
	<junoscript>	948
	<kill-session>	949
	<load-configuration>	950
	<load-configuration-results>	953
	<lock-configuration/>	954
	<open-configuration>	954
	<reason>	955
	<request-end-session/>	956
	<request-login>	956
	<routing-engine>	957
	<rpc>	957
	<rpc-reply>	958
	<unlock-configuration/>	959
	<?xml?>	959
	<xnm:error>	959
	<xnm:warning>	961
Chapter 24	Summary of Attributes in Junos XML Tags	963
	active	963
	count	964
	delete	964
	inactive	965
	insert	966
	junos:changed	967
	junos:changed-localtime	968
	junos:changed-seconds	968
	junos:commit-localtime	968
	junos:commit-seconds	969
	junos:commit-user	969

	junos:group	970
	junos:interface-range	970
	junos:key	971
	junos:position	972
	junos:total	972
	matching	973
	protect	974
	recurse	974
	rename	975
	replace	976
	start	977
	unprotect	977
	xmlns	978
Chapter 25	Writing Junos XML Protocol Perl Client Applications	979
	Overview of the Junos::Device Perl Module and Sample Scripts	979
	Downloading the Junos XML Protocol Perl Client and Prerequisites Package . .	980
	Installing the Junos XML Protocol Perl Client and Prerequisites Package	981
	Verifying Installation and Version of Perl	981
	Extracting the Junos XML Protocol Perl Client and Sample Scripts	982
	Extracting and Installing the Junos XML Protocol Perl Client Prerequisites Package	982
	Installing the Junos XML Protocol Perl Client	984
	Tutorial: Writing Perl Client Applications	984
	Import Perl Modules and Declare Constants	985
	Connect to the Junos XML Protocol Server	985
	Satisfying Protocol Prerequisites	986
	Group Requests	986
	Obtain and Record Parameters Required by the JUNOS::Device Object	986
	Obtaining Application-Specific Parameters	989
	Converting Disallowed Characters	990
	Establishing the Connection	992
	Submitting a Request to the Junos XML Protocol Server	992
	Providing Method Options or Attributes	993
	Submitting a Request	995
	Example: Getting an Inventory of Hardware Components	996
	Example: Loading Configuration Statements	997
	Parsing and Formatting the Response from the Junos XML Protocol Server	1001
	Parsing and Formatting an Operational Response	1001
	Parsing and Outputting Configuration Data	1003
	Closing the Connection to the Junos XML Protocol Server	1007
	Mapping CLI Commands to Perl Methods	1007
Chapter 26	Writing Junos XML Protocol C Client Applications	1009
	Establishing a Junos XML Protocol Session	1009
	Accessing and Editing Device Configurations	1010

Part 5

Chapter 27

Junos XML API Configuration Reference for Security Devices

Tag Elements Beginning with A 1021

<access-point> configuration/wlan	1021
<access-point-options> configuration/wlan/access-point	1022
<access-point-queues> configuration/wlan/access-point/radio/quality-of-service	1022
<action> configuration/security/gprs/gtp/profile/apn/imsi-prefix	1023
<action> configuration/protocols/oam/ethernet/connectivity-fault-management/action-profile	1023
<action-profile> configuration/security/datapath-debug	1024
<action-profile> configuration/protocols/oam/ethernet/connectivity-fault-management	1024
<address> configuration/security/ike/gateway	1025

About the Documentation

- [Documentation and Release Notes on page ccxci](#)
- [Supported Platforms on page ccxci](#)
- [Using the Examples in This Manual on page ccxci](#)
- [Documentation Conventions on page ccxciii](#)
- [Documentation Feedback on page ccxciv](#)
- [Requesting Technical Support on page ccxcv](#)

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <http://www.juniper.net/techpubs/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <http://www.juniper.net/books>.

Supported Platforms

For the features described in this document, the following platforms are supported:

- [SRX Series](#)

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xml;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see the *CLI User Guide*.

Documentation Conventions

Table 1 on page [ccxciii](#) defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.

Table 2 on page [ccxciii](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the configure command: user@host> configure
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> show chassis alarms No alarms currently active
<i>Italic text like this</i>	<ul style="list-style-type: none"> Introduces or emphasizes important new terms. Identifies guide names. Identifies RFC and Internet draft titles. 	<ul style="list-style-type: none"> A policy <i>term</i> is a named structure that defines match conditions and actions. <i>Junos OS CLI User Guide</i> RFC 1997, <i>BGP Communities Attribute</i>

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# set system domain-name <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> To configure a stub area, include the stub statement at the [edit protocols ospf area area-id] hierarchy level. The console port is labeled CONSOLE.
< > (angle brackets)	Encloses optional keywords or variables.	stub <default-metric <i>metric</i> >;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	broadcast multicast (<i>string1</i> <i>string2</i> <i>string3</i>)
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	rsvp { # Required for dynamic MPLS only
[] (square brackets)	Encloses a variable for which you can substitute one or more values.	community name members [<i>community-ids</i>]
Indentation and braces ({ })	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	
GUI Conventions		
Bold text like this	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> In the Logical Interfaces box, select All Interfaces. To cancel the configuration, click Cancel.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select Protocols>Ospf .

Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can send your comments to techpubs-comments@juniper.net, or fill out the documentation feedback form at

<https://www.juniper.net/cgi-bin/docbugreport/>. If you are using e-mail, be sure to include the following information with your comments:

- Document or topic name
- URL or page number
- Software release version (if applicable)

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or JNASC support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <http://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <http://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <http://www.juniper.net/customers/support/>
- Search for known bugs: <http://www2.juniper.net/kb/>
- Find product documentation: <http://www.juniper.net/techpubs/>
- Find solutions and answer questions using our Knowledge Base: <http://kb.juniper.net/>
- Download the latest versions of software and review release notes: <http://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <https://www.juniper.net/alerts/>
- Join and participate in the Juniper Networks Community Forum: <http://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <http://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://tools.juniper.net/SerialNumberEntitlementSearch/>

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <http://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <http://www.juniper.net/support/requesting-support.html>.

Introduction to Junos Automation

- [Junos Automation Overview on page 4](#)

Junos Automation Overview

Junos OS automation consists of a suite of tools used to automate operational and configuration tasks on network devices running Junos OS. The Junos automation tool kit is part of the standard Junos operating system available on all switches, routers, and security devices running Junos OS. Junos automation tools, which leverage the native XML capabilities of Junos OS, include commit scripts, operation (op) scripts, event policies and event scripts, and macros.

Junos automation simplifies complex configurations and reduces potential configuration errors. It saves time by automating operational and configuration tasks. It also speeds troubleshooting and maximizes network uptime by warning of potential problems and automatically responding to system events.

Junos automation can capture the knowledge and expertise of experienced network operators and administrators and allow a business to leverage this combined expertise across the organization.

Junos automation scripts can be written in either of two scripting languages: Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX). XSLT is a standard for processing Extensible Markup Language (XML) data and is designed to convert one XML document into another. SLAX is an alternative to XSLT. It has a simple syntax that follows the style of C and PERL, but retains the same semantics as XSLT. Programmers who are familiar with C often find it easier to learn and use SLAX. Scripts written in one language are easily converted to the other.

The following sections describe the different types of functionality for Junos automation:

- [Junos Configuration Automation: Commit Scripts on page 4](#)
- [Junos Operations Automation: Op Scripts on page 5](#)
- [Junos Event Automation: Event Scripts and Event Policy on page 5](#)

Junos Configuration Automation: Commit Scripts

Junos configuration automation uses commit scripts to automate the commit process. Junos OS commit scripts enforce custom configuration rules. When a candidate configuration is committed, it is inspected by each active commit script. If a configuration violates your custom rules, the script can instruct Junos OS to take appropriate action. A commit script can perform the following actions:

- Generate and display custom warning messages to the user
- Generate and log custom system log (syslog) messages
- Change the configuration to conform to the custom configuration rules
- Generate a commit error and halt the commit operation

Commit scripts, when used in conjunction with macros, allow you to simplify the Junos configuration and, at the same time, extend it with your own custom configuration syntax.

Junos Operations Automation: Op Scripts

Junos operations automation uses op scripts to automate operational tasks and network troubleshooting. Junos OS op scripts can be executed manually in the CLI or upon user login, or they can be called from another script. Op scripts can process user arguments and can be constructed to:

- Create custom operational mode commands
- Execute a series of operational mode commands
- Customize the output of operational mode commands
- Shorten troubleshooting time by gathering operational information and iteratively narrowing down the cause of a network problem
- Perform controlled configuration changes
- Monitor the overall status of a device by creating a general operation script that periodically checks network warning parameters, such as high CPU usage.

Junos Event Automation: Event Scripts and Event Policy

Junos event automation uses event policy and event scripts to instruct Junos OS to perform actions in response to system events.

Event Policy

An event policy is an if-then-else construct that defines actions to be executed by the software on receipt of an event such as a system log message or SNMP trap. Event policies can be executed in response to a single system event or to correlated system events. For each policy, you can configure multiple actions including:

- Ignore the event
- Upload a file to a specified destination
- Execute Junos OS operational mode commands
- Execute Junos OS event scripts

Event Scripts

Junos OS event scripts are triggered automatically by defined event policies in response to a system event and can instruct Junos OS to take immediate action. An event script automates network troubleshooting and network management by doing the following:

- Automatically diagnose and fix problems in the network
- Monitor the overall status of a device
- Run automatically as part of an event policy that detects periodic error conditions
- Change the configuration in response to a problem

Junos XML API and Junos XML Management Protocol Overview

The Junos XML Management Protocol is an XML-based protocol that client applications use to request and change configuration information on routing, switching, and security platforms running Junos OS. It uses an XML-based data encoding for the configuration data and remote procedure calls. The protocol defines basic operations that are equivalent to configuration mode commands in the Junos OS command-line interface (CLI). Applications use the protocol operations to display, edit, and commit configuration statements (among other operations), just as administrators use CLI configuration mode commands such as **show**, **set**, and **commit** to perform those operations.

The Junos XML API is an XML representation of Junos configuration statements and operational mode commands. Junos XML configuration tag elements are the content to which the Junos XML protocol operations apply. Junos XML operational tag elements are equivalent in function to operational mode commands in the CLI, which administrators use to retrieve status information for a device.

Client applications request information and change the configuration on a device by encoding the request with tag elements from the Junos XML management protocol and Junos XML API and sending it to the Junos XML protocol server on the device. The Junos XML protocol server is integrated into Junos OS and does not appear as a separate entry in process listings. The Junos XML protocol server directs the request to the appropriate software modules within the device, encodes the response in Junos XML and Junos XML protocol tag elements, and returns the result to the client application. For example, to request information about the status of a device's interfaces, a client application sends the Junos XML API **<get-interface-information>** request tag element. The Junos XML protocol server gathers the information from the interface process and returns it in the Junos XML API **<interface-information>** response tag element.

You can use the Junos XML management protocol and Junos XML API to configure devices running Junos OS or request information about the device configuration or operation. You can write client applications to interact with the Junos XML protocol server, and you can also utilize the Junos XML protocol to build custom end-user interfaces for configuration and information retrieval and display, such as a Web browser-based interface.

Advantages of Using the Junos XML Management Protocol and Junos XML API

The Junos XML management protocol and Junos XML API fully document all options for every supported Junos operational request, all statements in the Junos configuration hierarchy, and basic operations that are equivalent to configuration mode commands. The tag names clearly indicate the function of an element in an operational or configuration request or a configuration statement.

The combination of meaningful tag names and the structural rules in a DTD makes it easy to understand the content and structure of an XML-tagged data set or document. Junos XML and Junos XML protocol tag elements make it straightforward for client applications that request information from a device to parse the output and find specific information.

Parsing Device Output

The following example illustrates how the Junos XML API makes it easier to parse device output and extract the needed information. The example compares formatted ASCII and XML-tagged versions of output from a device running Junos OS.

The formatted ASCII follows:

```
Physical interface: fxp0, Enabled, Physical link is Up
Interface index: 4, SNMP ifIndex: 3
```

The corresponding XML-tagged version is:

```
<interface>
  <name>fxp0</name>
  <admin-status>enabled</admin-status>
  <operational-status>up</operational-status>
  <index>4</index>
  <snmp-index>3</snmp-index>
</interface>
```

When a client application needs to extract a specific value from formatted ASCII output, it must rely on the value's location, expressed either absolutely or with respect to labels or values in adjacent fields. Suppose that the client application wants to extract the interface index. It can use a regular-expression matching utility to locate specific strings, but one difficulty is that the number of digits in the interface index is not necessarily predictable. The client application cannot simply read a certain number of characters after the **Interface index:** label, but must instead extract everything between the label and the subsequent label **SNMP ifIndex** and also account for the included comma.

A problem arises if the format or ordering of text output changes in a later version of the Junos OS. For example, if a **Logical index** field is added following the interface index number, the new formatted ASCII might appear as follows:

```
Physical interface: fxp0, Enabled, Physical link is Up
Interface index: 4, Logical index: 12, SNMP ifIndex: 3
```

An application that extracts the interface index number delimited by the **Interface index:** and **SNMP ifIndex:** labels now obtains an incorrect result. The application must be updated manually to search for the **Logical index:** label as the new delimiter.

In contrast, the structured nature of XML-tagged output enables a client application to retrieve the interface index by extracting everything within the opening `<index>` tag and closing `</index>` tag. The application does not have to rely on an element's position in the output string, so the Junos XML protocol server can emit the child tag elements in any order within the `<interface>` tag element. Adding a new `<logical-index>` tag element in a future release does not affect an application's ability to locate the `<index>` tag element and extract its contents.

Displaying Device Output

XML-tagged output is also easier to transform into different display formats than formatted ASCII output. For instance, you might want to display different amounts of detail about a given device component at different times. When a device returns formatted ASCII output, you have to write special routines and data structures in your display program to extract and show the appropriate information for a given detail level. In contrast, the inherent structure of XML output is an ideal basis for a display program's own structures. It is also easy to use the same extraction routine for several levels of detail, simply ignoring the tag elements you do not need when creating a less detailed display.

Junos Script Automation: Extension Functions in the jcs Namespace Overview

The Junos OS extension functions are used in commit, op, and event scripts to accomplish scripting tasks more easily. Extension functions allow you to perform operations that are difficult or impossible to perform in XPath. The library provides logic, data manipulation, input and output, and utility functions.

The Junos OS extension functions are defined in the namespace with the associated Uniform Resource Identifier (URI) `http://xml.juniper.net/junos/commit-scripts/1.0`. To use the Junos extension functions in scripts, you must include the namespace URI in your style sheet declaration. Generally, the **jcs** prefix is mapped to the URI, and you then use the extension functions by prepending the **jcs** prefix to the function name. This avoids

name conflicts with standard XSLT functions. During processing, the **jcs:** prefix is expanded into the URI reference.

To call an extension function in a script, you include any required variable declarations, a variable call with the **select="jcs:function-name()"** attribute for XSLT scripts or a simple function call for SLAX scripts, and pass along any required or optional arguments. Arguments must be passed into the function in the precise order specified by the function definition. This is different from a template, where the parameters are assigned by name and can appear in any order. The return value of an extension function must always either be assigned to a variable or designated as output.

The following example maps the **jcs** prefix to the namespace identified by the URI <http://xml.juniper.net/junos/commit-scripts/1.0>, which defines the extension functions used in commit, op, and event scripts. The script then calls the **jcs:invoke()** function with one argument.

XSLT Syntax

```
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  ...
  <xsl:variable name="result" select="jcs:invoke($command)"/>
  ...
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
...
var $result = jcs:invoke($command);
...
```

[Junos Extension Functions in the jcs Namespace Summary](#)

The Junos extension functions are summarized in the following table.

Table 3: Junos Extension Functions

Function	Type	Description
jcs:break-lines()	Data manipulation	Break a simple element into multiple elements, delimited by newlines.
jcs:close()	Utility	Close a previously opened connection handle.

Table 3: Junos Extension Functions (*continued*)

Function	Type	Description
<code>jcs:dampen()</code>	Utility	Prevent the same operation from being repeatedly executed within a script.
<code>jcs:empty()</code>	Logic	Evaluate a node set or string argument to determine if it is an empty value.
<code>jcs:execute()</code>	Utility	Execute a remote procedure call (RPC) within the context of a specified connection handle.
<code>jcs:first-of()</code>	Logic	Return the first nonempty (non-null) item in a list. If all objects in the list are empty, the default expression is returned.
<code>jcs:get-hello()</code>	Utility	Return the session ID and the capabilities of the NETCONF server during a NETCONF session.
<code>jcs:get-input()</code>	Input/output control	Invoke a CLI prompt and wait for user input. If the script is run non-interactively, the function returns an empty value. This function cannot be used with event scripts.
<code>jcs:get-protocol()</code>	Utility	Return the session protocol associated with the connection handle.
<code>jcs:get-secret()</code>	Input/output control	Invoke a CLI prompt and wait for user input. The input is not echoed back to the user.
<code>jcs:hostname()</code>	Utility	Return the fully qualified domain name associated with a given IPv4 or IPv6 address, provided the DNS server is configured on the router.
<code>jcs:invoke()</code>	Utility	Invoke an RPC on the local device.
<code>jcs:open()</code>	Utility	Return a connection handle that can be used to execute RPCs.
<code>jcs:output()</code>	Input/output control	Generate unformatted output text that is immediately sent to the CLI session.
<code>jcs:parse-ip()</code>	Data manipulation	Parse an IPv4 or IPv6 address and return the host IP address, protocol family, prefix length, network address, and network mask.
<code>jcs:printf()</code>	Input/output control	Generate formatted output text. Most standard printf formats are supported, in addition to some Junos OS-specific formats. The function returns a formatted string but does not print it on call.
<code>jcs:progress()</code>	Input/output control	Issue a progress message containing the single argument immediately to the CLI session provided that the detail flag was specified when the script was invoked.

Table 3: Junos Extension Functions (*continued*)

Function	Type	Description
<code>jcs:regex()</code>	Data manipulation	Evaluate a regular expression against a given string argument and return any matches.
<code>jcs:sleep()</code>	Utility	Cause the script to sleep for a specified time.
<code>jcs:split()</code>	Data manipulation	Split a string into an array of substrings delimited by a regular expression pattern.
<code>jcs:sysctl()</code>	Utility	Return the value of the given <code>sysctl</code> value as a string or an integer.
<code>jcs:syslog()</code>	Input/output control	Log messages with the specified priority to the system log file.
<code>jcs:trace()</code>	Input/output control	Issue a trace message, which is sent to the trace file.

- [jcs:sysctl\(\) Function on page 26](#)
- [jcs:syslog\(\) Function on page 26](#)
- [jcs:trace\(\) Function on page 28](#)

jcs:break-lines() Function

SLAX Syntax	<code>var \$lines = jcs:break-lines(<i>expression</i>);</code>
XSLT Syntax	<code><xsl:variable name="lines" select="jcs:break-lines(<i>expression</i>)"/></code>
Description	Break a simple element into multiple elements, delimited by newlines. This is especially useful for large output elements such as those returned by the show pfe command.
Parameters	<ul style="list-style-type: none">• <i>expression</i>—Original output.
Return Value	<ul style="list-style-type: none">• <i>\$lines</i>—Output broken up into lines.
Usage Examples	<pre>var \$lines = jcs:break-lines(\$output); for-each (\$lines) { ... }</pre>

jcs:close() Function

SLAX Syntax	<code>var \$results = jcs:close(<i>connection</i>);</code>
XSLT Syntax	<code><xsl:variable name="results" select="jcs:close(<i>connection</i>)"/></code>
Description	Close a previously opened connection handle.
Parameters	<ul style="list-style-type: none">• <i>connection</i>—a connection handle generated by a call to the jcs:open() function.
Usage Examples	<p>The following example closes the connection handle \$connection, which was originally generated by a call to the jcs:open() function:</p> <pre>var \$connection = jcs:open(); var \$result = jcs:close(\$connection);</pre>

jcs:dampen() Function

SLAX Syntax	<code>var \$result = jcs:dampen(<i>tag-string</i>, <i>max</i>, <i>interval</i>);</code>
XSLT Syntax	<code><xsl:variable name="result" select="jcs:dampen(<i>tag-string</i>, <i>max</i>, <i>interval</i>)"/></code>

Description	Prevent the same operation from being repeatedly executed within a script. The dampen function returns false if the number of calls to the jcs:dampen() function exceeds a max number of calls in the time interval interval . Otherwise the function returns true . The function parameters include an arbitrary string that is used to distinguish different calls to the jcs:dampen() function. This tag is stored in the /var/run directory on the device.
Parameters	<ul style="list-style-type: none"> • interval—Time interval, in minutes. • max—Maximum number of calls to the jcs:dampen() function with a given tag allowed before the function returns false. This limit is based on the number of calls within a specified time interval. • tag-string—Arbitrary string used to distinguish different calls to the jcs:dampen() function.
Return Value	<ul style="list-style-type: none"> • result—Boolean value based on the number of calls to jcs:dampen() with a given tag and within a specified time. If the number of calls for a given tag exceeds max, the return value is false. If the number of calls is less than max, the return value is true.
Usage Examples	In the following example, if the jcs:dampen() function with the tag 'mytag1' is called less than three times in a 10-minute interval, the function returns true . If the function is called more than three times within 10 minutes, the function returns false .

```

if (jcs:dampen('mytag1', 3, 10)) {
    /* Code for situations when jcs:dampen() with */
    /* the tag 'mytag1' is called less than three times */
    /* within 10 minutes */
} else {
    /* Code for situations when jcs:dampen() with */
    /* the tag 'mytag1' exceeds the three call maximum */
    /* limit within 10 minutes */
}

```

jcs:empty() Function

SLAX Syntax	<code>var \$result = jcs:empty(<i>node-set</i> <i>string</i>);</code>
XSLT Syntax	<code><xsl:variable name="result" select="jcs:empty(<i>node-set</i> <i>string</i>)"/></code>
Description	Test for the presence of a value and return true if the node set or string argument evaluates to an empty value.
Parameters	<ul style="list-style-type: none"> • (<i>node-set</i> <i>string</i>)—Argument to test for the presence of a value.
Return Value	<ul style="list-style-type: none"> • result—Boolean value that is true if the argument is empty.
Usage Examples	In the following example, if \$set is empty, the script executes the enclosed code block.

```

if ( jcs:empty($set) ) {
    /* Code to handle true value ($set is empty) */
}

```

The following example tests whether the **description** node for interface fe-0/0/0 is empty. If the description is missing, a message tag is output.

```
if (jcs:empty(interfaces/interface[name="fe-0/0/0"]/description)) {
  <message> "interface " _name _ " is missing description";
}
```

jcs:execute() Function

SLAX Syntax `var $result = jcs:execute(connection, rpc);`

XSLT Syntax `<xsl:variable name="result" select="jcs:execute(connection, rpc)"/>`

Description Execute a remote procedure call (RPC) within the context of a specified connection handle. Any number of RPCs may be executed within the context of the connection handle until it is closed with the **jcs:close()** function.

Parameters • **connection**—Connection handle generated by a call to the **jcs:open()** function.
• **rpc**—Remote procedure call (RPC) to execute.

Return Value • **result**—Results of the executed RPC, which includes the contents of the **<rpc-reply>** element, but not the **<rpc-reply>** tag itself. This **\$result** variable is the same as that produced by the **jcs:invoke()** function. By default, the results are in XML format equivalent to the output produced with the **| display xml** option in the CLI.

Usage Examples In the following example, the **\$rpc** variable is declared and initialized with the Junos XML **<get-interface-information>** element. A call to the **jcs:open()** function generates a connection handle to the remote device at IP address 10.10.10.1. The user's login and passphrase are provided as arguments to **jcs:open()** to provide access the remote device. The code calls **jcs:execute()** and passes in the connection handle and RPC as arguments. Junos OS on the remote device processes the RPC and returns the results, which are stored in the **\$results** variable.

```
var $rpc = <get-interface-information>;
var $connection = jcs:open('10.10.10.1', 'bsmith', 'test123');
var $results = jcs:execute($connection, $rpc);
expr $results;
```

In XSLT:

```
<xsl:variable name="connection" select="jcs:open('10.10.10.1', 'bsmith', 'test123')"/>
<xsl:variable name="rpc">
  <get-interface-information/>
</xsl:variable>
<xsl:variable name="results" select="jcs:execute($connection, $rpc)"/>
<xsl:value-of select="$results"/>
```

jcs:first-of() Function

SLAX Syntax `var $result = jcs:first-of(object, "expression");`

XSLT Syntax `<xsl:variable name="result" select="jcs:first-of(object, 'expression')"/>`

- Description** Return the first nonempty (non-null) item in a list. If all objects in the list are empty, the default expression is returned. This function provides the same functionality as an `if / else-if / else` construct but in a much more concise format.
- Parameters**
- *expression*—Default value returned if all objects in the list are empty.
 - *object*—List of objects.
- Return Value**
- *result*—First nonempty (non-null) item in the object list. If all objects in the list are empty, the default expression is returned.
- Usage Examples** In the following example, if the value of **\$a** is empty, **\$b** is checked. If the value of **\$b** is empty, **\$c** is checked. If the value of **\$c** is empty, **\$d** is checked. If the value of **\$d** is empty, the string "none" is returned.

```
jcs:first-of($a, $b, $c, $d, "none")
```

In the following example, for each physical interface, the script checks for a description of each logical-interface. If a logical interface description does not exist, the function returns the description of the (parent) physical interface. If the parent physical interface description does not exist, the function returns a message that no description was found.

```
var $rpc = <get-interface-information>;
var $results = jcs:invoke($rpc);
for-each ($results/physical-interface/logical-interface) {
    var $description = jcs:first-of(description, ../description, "no description found");
}
```

The equivalent XSLT code is:

```
<xsl:variable name="rpc">
  <get-interface-information/>
</xsl:variable>
<xsl:variable name="results" select="jcs:invoke($rpc)"/>
<xsl:for-each select="$results/physical-interface/logical-interface">
  <xsl:variable name="description"
    select="jcs:first-of(description, ../description, 'no description found')"/>
</xsl:for-each>
```

The code for the **description** variable declaration in the previous examples would be equivalent to the following more verbose `if / else-if / else` construct:

```
var $description = {
  if (description) {
    expr description;
  }
  else if (../description) {
    expr ../description;
  }
  else {
    expr "no description found";
  }
}
```

See also ["Example: Displaying DNS Hostname Information Using an Op Script"](#) on page 364.

***jcs:get-hello()* Function**

SLAX Syntax `var $capabilities = jcs:get-hello(connection);`

XSLT Syntax `<xsl:variable name="capabilities" select="jcs:get-hello(connection)"/>`

Description Return the session ID and the capabilities of the NETCONF server during a NETCONF session.

During session establishment, the NETCONF server and client application each emit a **<hello>** tag element to specify which operations, or *capabilities*, they support from among those defined in the NETCONF specification or published as proprietary extensions. The **<hello>** tag element encloses the **<capabilities>** tag element and the **<session-id>** tag element, which specifies the session ID for this NETCONF session.

Within the **<capabilities>** tag element, a **<capability>** tag element specifies each supported function. Each capability defined in the NETCONF specification is represented by a uniform resource name (URN). Capabilities defined by individual vendors are represented by uniform resource identifiers (URIs), which can be URNs or URLs.

Parameters • ***connection***—Connection handle generated by a call to the **jcs:open()** function.

Return Value • ***capabilities***—XML node-set that specifies which operations, or *capabilities*, the NETCONF server supports. The node-set also includes the session ID.

Usage Examples In the following code snippet, the user, bsmith, establishes a NETCONF session on the default port with the remote device, fivestar, which is running Junos OS. Since the code does not specify a value for the password, the user is prompted for a password during script execution. Once authentication is established, the code calls the **jcs:get-hello()** function and stores the return value in the variable **\$hello**, which is then printed to the CLI.

```
var $netconf := {
  <method> "netconf";
  <username> "bsmith";
}
var $connection = jcs:open("fivestar", $netconf);
var $hello = jcs:get-hello($connection);
expr jcs:output($hello);
expr jcs:close($connection);
```

The CLI displays the following output:

```
bsmith@fivestar's password:
```

```

***jcs:get-input()* Function**

SLAX Syntax	<code>var \$user-input = jcs:get-input(<i>string</i>);</code>
XSLT Syntax	<code><xsl:variable name="user-input" select="jcs:get-input(<i>string</i>)"/></code>
Description	Invoke a CLI prompt and wait for user input. The user input is defined as a string for subsequent use. If the script is run non-interactively, the function returns an empty value. This function cannot be used with event scripts.
Parameters	<ul style="list-style-type: none"> <i>string</i>—CLI prompt text.
Return Value	<ul style="list-style-type: none"> <i>user-input</i>—Text typed by the user and stored as a string. The return value will be empty if the script is run non-interactively.
Usage Examples	In the following example, the user is prompted to enter a login name. The user's input is stored in the variable \$username :

```
var $username = jcs:get-input("Enter login id: ");
```

***jcs:get-protocol()* Function**

SLAX Syntax	<code>var \$protocol = jcs:get-protocol(<i>connection</i>);</code>
XSLT Syntax	<code><xsl:variable name="protocol" select="jcs:get-protocol(<i>connection</i>)"/></code>
Description	Return the session protocol associated with the connection handle. The protocol values are junoscript , netconf , and junos-netconf .
Parameters	<ul style="list-style-type: none"> <i>connection</i>—Connection handle generated by a call to the jcs:open() function.
Return Value	<ul style="list-style-type: none"> <i>protocol</i>—Session protocol associated with the connection handle. The values are junoscript, netconf, or junos-netconf.
Usage Examples	In the following code snippet, the user, bsmith, establishes a NETCONF session on the default port with the remote device, fivestar. Since the code does not specify a value for the password, the user is prompted for a password during script execution. Once authentication is established, the code calls the jcs:get-protocol() function and stores the return value in the variable \$protocol , which is then printed to the CLI.

```
var $netconf := {
  <method> "netconf";
  <username> "bsmith";
}
var $connection = jcs:open("fivestar", $netconf);
var $protocol = jcs:get-protocol($connection);
expr jcs:output($protocol);
expr jcs:close($connection);
```

The CLI displays the following output:

```
bsmith@fivestar's password:
```

```
netconf
```

jcs:get-secret() Function

SLAX Syntax `var $user-input = jcs:get-secret(string);`

XSLT Syntax `<xsl:variable name="user-input" select="jcs:get-secret(string)"/>`

Description Invoke a CLI prompt and wait for user input. Unlike the **jcs:get-input()** function, the input is not echoed back to the user, which makes the function useful for obtaining passwords. The user input is defined as a string for subsequent use. This function cannot be used with event scripts.

Parameters • *string*—CLI prompt text.

Return Value • *user-input*—Text typed by the user and stored as a string.

Usage Examples The following example shows how to prompt for a password that is not echoed back to the user:

```
var $password = jcs:get-secret("Enter password: ");
```

jcs:hostname() Function

SLAX Syntax `var $name = jcs:hostname(expression);`

XSLT Syntax `<xsl:variable name="name" select="jcs:hostname(expression)"/>`

Description Return the fully qualified domain name associated with a given IPv4 or IPv6 address. The DNS server must be configured on the device in order to resolve the domain name.

Parameters • *expression*—IPv4 or IPv6 address.

Return Value • *name*—Hostname associated with the IP address.

Usage Examples The following example initializes the variable **address** with the IP address 10.10.10.1. The **\$address** variable is passed as the argument to the **jcs:hostname()** function. If the DNS server is configured on the device, the function will resolve the IP address return the fully qualified domain name, which is stored in the variable **host**.

```
var $address = "10.10.10.1";  
var $host = jcs:hostname($address);
```

In XSLT:

```
<xsl:variable name="address" select="10.10.10.1">  
<xsl:variable name="host" select="jcs:hostname($address)"/>
```

jcs:invoke() Function

SLAX Syntax `var $result = jcs:invoke(rpc);`

XSLT Syntax `<xsl:variable name="result" select="jcs:invoke(rpc)"/>`

Description Invoke a remote procedure call (RPC) on the local device. The function is called with one argument, either a string containing a Junos XML or Junos XML protocol RPC method name or a tree containing an RPC. The result is the contents of the `<rpc-reply>` element, not including the `<rpc-reply>` tag. An RPC allows you to perform functions equivalent to the Junos OS operational mode commands.

Parameters • *rpc*—String containing a Junos XML or Junos XML protocol RPC method name or a tree containing an RPC.

Return Value • **result**—Results of the executed RPC, which includes the contents of the `<rpc-reply>` element, but not the `<rpc-reply>` tag itself. By default, the results are in XML format equivalent to the output produced with the `| display xml` option in the CLI.

Usage Examples In the following example, there is a test to see if the **interface** argument is included on the command line when the script is executed. If the argument is provided, the operational mode output of the **show interfaces terse** command is narrowed to include information about that interface only.

```
<xsl:param name="interface"/>
<xsl:variable name="rpc">
  <get-interface-information>
    <terse/>
    <xsl:if test="$interface">
      <interface-name>
        <xsl:value-of select="$interface"/>
      </interface-name>
    </xsl:if>
  </get-interface-information>
</xsl:variable>
<xsl:variable name="out" select="jcs:invoke($rpc)"/>
```

In this example, the **jcs:invoke()** function calls an RPC without modifying the output:

```
<xsl:variable name="sw" select="jcs:invoke('get-software-information')"/>
```

jcs:open() Function

SLAX Syntax `var $connection = jcs:open();`

```
var $connection = jcs:open(remote-hostname, <username>, <passphrase>);
```

```
var $connection = jcs:open(remote-hostname, <session-options>);
```

XSLT Syntax `<xsl:variable name="connection" select="jcs:open()"/>`

```
<xsl:variable name="connection" select="jcs:open(remote-hostname, <username>,
<passphrase>)/>
```

```
<xsl:variable name="connection" select="jcs:open(remote-hostname,
<session-options>)/>
```

Description Return a connection handle that can be used to execute remote procedure calls (RPCs) using the `jcs:execute()` extension function. To execute an RPC on a remote device, an SSH session must be established. In order for the script to establish the connection, you must either configure the SSH host key information for the remote device on the local device where the script will be executed, or the SSH host key information for the remote device must exist in the known hosts file of the user executing the script.

Starting with Junos OS Release 11.4, the new parameter, ***session-options***, supports the option to create a session either with the Junos XML protocol server on devices running Junos OS or with the NETCONF server on devices where NETCONF service over SSH is enabled. Previously, the function supported only sessions with the Junos XML protocol server on devices running Junos OS.

The connection handle is closed with the `jcs:close()` function.

- Parameters**
- ***remote-hostname***—Domain name or IP address of the remote router, switch, or security device. If you are opening a local connection, do not pass this value. If you specify a session type, this parameter is required.
 - ***username***—(Optional) User's login name. If you do not specify a username and it is required for the connection, the script uses the local name of the user executing the script.
 - ***passphrase***—(Optional) User's login passphrase. If you do not specify a passphrase and it is required for authentication, you should be prompted for one during script execution by the device to which you are connecting.
 - ***session-options***—(Optional) XML node-set that specifies the session protocol and connection parameters. The structure of the node-set is:

```
var $session-options := {  
  <method> ("junoscript" | "netconf" | "junos-netconf");  
  <username> "username";  
  <passphrase> "passphrase";  
  <password> "passphrase";  
  <port> "port-number";  
}
```
 - **<method>**—(Optional) Session protocol. The protocol is one of three values: **junoscript**, **netconf**, or **junos-netconf**. If you do not specify a protocol, a **junoscript** session is created by default. A **<method>** value of **junoscript** establishes a session with the Junos XML protocol server on a device running Junos OS. A **<method>** value of **netconf** establishes a session with a NETCONF server over an SSHv2 connection. A **<method>** value of **junos-netconf** establishes a proprietary session with a NETCONF server over an SSHv2 connection on a device running Junos OS.
 - **<username>**—(Optional) User's login name. If you do not specify a username and it is required for the connection, the script uses the local name of the user executing the script.

- **<passphrase> or <password>**—(Optional) User's login passphrase. If you do not specify a passphrase and it is required for authentication, you should be prompted for one during script execution by the device to which you are connecting.
- **<port>**—(Optional) Server port number for **netconf** and **junos-netconf** sessions. For NETCONF sessions, **jcs:open()** connects to the NETCONF server at the default port 830. If you specify a value for **<port>**, **jcs:open()** connects to the given port instead. Specifying a port number has no impact on **junoscript** sessions, which are always established over SSH port 22.

Return Value • **connection**—Connection handle to the remote host.

Usage Examples The following example shows how to connect to a local device:

```
var $connection = jcs:open();
```

The following example shows how to connect to a remote device:

```
var $connection = jcs:open(remote-hostname);
```

The following example shows how the user, bsmith, with the passphrase test123 obtains a connection handle to the remote device, fivestar:

```
var $connection = jcs:open("fivestar", "bsmith", "test123");
```

The following example shows how the user, bsmith, with the passphrase test123 creates a **junos-netconf** session with a device running Junos OS:

```
var $options := {
  <method> "junos-netconf";
  <username> "bsmith";
  <passphrase> "test123";
}
var $connection = jcs:open("fivestar", $options);
```

jcs:output() Function

SLAX Syntax `expr jcs:output('string');`

XSLT Syntax `<xsl:value-of select="jcs:output('string')"/>`

Description Generate unformatted output text that is immediately sent to the CLI session. In contrast, most script output is output at the end of the script.

Parameters • **string**—Text that is output immediately to the CLI session.

Usage Examples SLAX syntax:

```
expr jcs:output('The VPN is up.');
```

XSLT syntax:

```
<xsl:value-of select="jcs:output('The VPN is up.')"/>
```

***jcs:parse-ip()* Function**

SLAX Syntax `var $result = jcs:parse-ip("ipaddress/(prefix-length | netmask)");`

XSLT Syntax `<xsl:variable name="result" select="jcs:parse-ip('ipaddress/(prefix-length | netmask)')"/>`

Description Parse an IPv4 or IPv6 address.

- Parameters**
- **ipaddress**—IPv4 or IPv6 address.
 - **prefix-length**—Prefix length defining the number of bits used in the network prefix portion of the address.
 - **netmask**—Netmask defining the network prefix portion of the address.

- Return Value**
- **result**—An array containing:
 - Host IP address (or **NULL** in the case of an error)
 - Protocol family (inet for IPv4 or inet6 for IPv6)
 - Prefix length
 - Network address
 - Network mask in dotted decimal notation for IPv4 addresses (left blank for IPv6 addresses)

Usage Examples In the following examples, an IPv4 address and an IPv6 address are parsed and the resulting output is detailed:

```
var $addr = jcs:parse-ip("10.1.2.10/255.255.255.0");
```

- **\$addr[1]** contains the host address **10.1.2.10**.
- **\$addr[2]** contains the protocol family **inet**.
- **\$addr[3]** contains the prefix length **24**.
- **\$addr[4]** contains the network address **10.1.2.0**.
- **\$addr[5]** contains the netmask for IPv4 **255.255.255.0**.

```
var $addr = jcs:parse-ip("2001:DB8::c50:8a:800:200C:417A/32");
```

- **\$addr[1]** contains the host address **2001:db8:0:c50:8a:800:200c:417a**.
- **\$addr[2]** contains the protocol family **inet6**.
- **\$addr[3]** contains the prefix length **32**.
- **\$addr[4]** contains the network address **2001:db8::**.
- **\$addr[5]** is blank for IPv6 (**""**).

***jcs:printf()* Function**

SLAX Syntax `expr jcs:printf(expression);`

XSLT Syntax `<xsl:value-of select="jcs:printf(expression)"/>`

Description Generate formatted output text. Most standard **printf** formats are supported, in addition to some Junos OS–specific formats. The function returns a formatted string but does not print it on call. To use the following Junos OS modifiers, place the modifier between the percent sign (%) and the conversion specifier.

- **j1**—operator emits the field only if it changed from the last time the function was called. This assumes that the expression's format string is unchanged.
- **jc**—operator capitalizes the first letter of the associated output string.
- **jt{TAG}**—operator emits the tag if the associated argument is not empty.

Parameters • *expression*—format string containing an arbitrary number of format specifiers and associated arguments to output.

Usage Examples In the following example, the **j1** operator suppresses printing the interface identifier **so-0/0/0** in the second line of output, because the identifier argument has not changed from the first printing. The **jc** operator capitalizes the output strings **up** and **down**. The **jt{--}** operator does not print the **{--}** tag in the first line of output, because the associated output argument is an empty string. However, the tag is printed in the second line because the associated output is the non-empty string **test**.

```
<xsl:value-of select="jcs:printf('%-24j1s %-5jcs %-5jcs %s%jt{ -- }s\n',
    'so-0/0/0', 'up', 'down', '10.1.2.3', '')"/>
<xsl:value-of select="jcs:printf('%-24j1s %-5jcs %-5jcs %s%jt{ -- }s\n',
    'so-0/0/0', 'down', 'down', '10.1.2.3', 'test')"/>
```

produces the following output:

```
so-0/0/0          Up      Down  10.1.2.3
                  Down    Down  10.1.2.3 -- test
```

jcs:progress() Function

SLAX Syntax `expr jcs:progress('string');`

XSLT Syntax `<xsl:value-of select="jcs:progress('string')"/>`

Description Issue a progress message containing the single argument immediately to the CLI session provided that the **detail** flag was specified when the script was invoked.

Parameters • *string*—text output to CLI session

Usage Examples SLAX syntax:

```
expr jcs:progress('Working...');
```

XSLT syntax:

```
<xsl:value-of select="jcs:progress('Working...')"/>
```

The script must be invoked with the **detail** flag in order for the progress message to appear in the CLI session.

```
user@host> op script1.slax detail
```

```
2010-10-01 16:27:54 PDT: running op script 'script1.slax'
2010-10-01 16:27:54 PDT: opening op script '/var/db/scripts/op/script1.slax'
2010-10-01 16:27:54 PDT: reading op script 'script1.slax'
2010-10-01 16:27:54 PDT: Working...
2010-10-01 16:28:14 PDT: inspecting op output 'script1.slax'
2010-10-01 16:28:14 PDT: finished op script 'script1.slax'
```

jcs:regex() Function

SLAX Syntax `var $result = jcs:regex(pattern, string);`

XSLT Syntax `<xsl:variable name="result" select="jcs:regex(pattern, string)"/>`

Description Evaluate a regular expression against a given string argument and return any matches. This function requires two arguments: the regular expression and the string to which the regular expression is compared.

Parameters • *pattern*—Regular expression that is evaluated against the string argument.
• *string*—String within which to search for matches of the specified regular expression.

Return Value • *result*—Array of strings that match the given regex pattern within the string argument.

Usage Examples In the following example, the regex pattern consists of four distinct groups. The first group consists of the entire expression. The three subsequent groups are each of the parentheses–enclosed expressions within the main expression. The results for each *jcs:regex()* function call contain an array of the matches of the regex pattern to each of the specified strings.

```
var $pattern = "([0-9]+)(:*)([a-z]*)";
var $a = jcs:regex($pattern, "123:xyz");
var $b = jcs:regex($pattern, "r2d2");
var $c = jcs:regex($pattern, "test999!!!");

$a[1] == "123:xyz" # string that matches the full reg expression
$a[2] == "123"    # ([0-9]+)
$a[3] == ":"      # (:)
$a[4] == "xyz"    # ([a-z]*)
$b[1] == "2d"     # string that matches the full reg expression
$b[2] == "2"      # ([0-9]+)
$b[3] == ""       # (:) [empty match]
$b[4] == "d"      # ([a-z]*)
$c[1] == "999"    # string that matches the full reg expression
$c[2] == "999"    # ([0-9]+)
$c[3] == ""       # (:) [empty match]
$c[4] == ""       # ([a-z]*) [empty match]
```

jcs:sleep() Function

SLAX Syntax `expr jcs:sleep(seconds, <milliseconds>);`

XSLT Syntax	<code><xsl:value-of select="jcs:sleep(<i>seconds</i>, <<i>milliseconds</i>>)" /></code>
Description	Cause the script to pause for a specified number of seconds and (optionally) milliseconds. You can use this function to help determine how a device component works over time. To do this, write a script that issues a command, calls the jcs:sleep() function, and then reissues the same command.
Parameters	<ul style="list-style-type: none"> • <i>milliseconds</i>—(Optional) Number of milliseconds the script should sleep. • <i>seconds</i>—Number of seconds the script should sleep.
Usage Examples	<p>In the following example, jcs:sleep(1) causes the script to sleep for 1 second, and jcs:sleep(0, 10) causes the script to sleep for 10 milliseconds.</p> <p>SLAX syntax:</p> <pre>expr jcs:sleep(1); expr jcs:sleep(0, 10);</pre> <p>XSLT syntax:</p> <pre><xsl:value-of select="jcs:sleep(1)" /> <xsl:value-of select="jcs:sleep(0, 10)" /></pre> <p><i>jcs:split()</i> Function</p>
SLAX Syntax	<code>var \$substrings = jcs:split(<i>expression</i>, <i>string</i>, <<i>limit</i>>);</code>
XSLT Syntax	<code><xsl:variable name="substrings" select="jcs:split(<i>expression</i>, <i>string</i>, <<i>limit</i>>)" /></code>
Description	Split a string into an array of substrings delimited by a regular expression pattern. If the optional integer argument <i>limit</i> is specified, the function splits the entire string into <i>limit</i> number of substrings. If there are more than <i>limit</i> number of matches, the substrings include the first <i>limit</i> -1 matches as well as the remaining portion of the original string for the last match.
Parameters	<ul style="list-style-type: none"> • <i>expression</i>—Regular expression pattern used as the delimiter. • <i>limit</i>—(Optional) Number of substrings into which to break the original string. • <i>string</i>—Original string.
Return Value	<ul style="list-style-type: none"> • <i>\$substrings</i>—Array of <i>limit</i> number of substrings. If <i>limit</i> is not specified, the result array size is equal to the number of substrings extracted from the original string as determined by the specified delimiter.
Usage Examples	<p>In the following example, the original string is "123:abc:456:xyz:789". The jcs:split() function breaks this string into substrings that are delimited by the regular expression pattern, which in this case is a colon(:). The optional parameter <i>limit</i> is not specified, so the function returns an array containing all the substrings that are bounded by the delimiter(:).</p> <pre>var \$pattern = "(:)"; var \$substrings = jcs:split(\$pattern, "123:abc:456:xyz:789");</pre>

returns:

```
$substrings[1] == "123"
$substrings[2] == "abc"
$substrings[3] == "456"
$substrings[4] == "xyz"
$substrings[5] == "789"
```

The following example uses the same original string and regular expression as the previous example, but in this case, the optional parameter *limit* is included. Specifying *limit*=2 causes the function to return an array containing only two substrings. The substrings include the first match, which is "123" (the same first match as in the previous example) and a second match, which is the remaining portion of the original string after the first occurrence of the delimiter.

```
var $pattern = "(:)";
var $substrings = jcs:split($pattern, "123:abc:456:xyz:789", 2);
```

returns:

```
$substrings[1] == "123"
$substrings[2] == "abc:456:xyz:789"
```

jcs:sysctl() Function

SLAX Syntax	var \$value = jcs:sysctl(sysctl-value, "(i s)");
XSLT Syntax	<xsl:variable name="value" select="jcs:sysctl(sysctl-value, '(i s)')"/>
Description	Return the given sysctl value as a string or an integer. Use the "i" argument to specify an integer. Use the "s" argument to specify a string.
Parameters	<ul style="list-style-type: none"> sysctl-value—sysctl value to convert to a string or integer.
Return Value	<ul style="list-style-type: none"> \$value—Returned string or integer value.
Usage Examples	var \$value = jcs:sysctl("kern.hostname", "s");

jcs:syslog() Function

SLAX Syntax	expr jcs:syslog(priority, message, <message2>, <message3> ...);
XSLT Syntax	<xsl:value-of select="jcs:syslog(priority, message, <message2>, <message3>)" />
Description	Log messages with the specified priority to the system log file. The priority can be expressed as a facility.severity string or as a calculated integer. The message argument is a string or variable that is written to the system log file. Optionally, additional strings or variables can be included in the argument list. The message argument is concatenated with any additional message arguments, and the concatenated string is written to the system log file. The syslog file is specified at the [edit system syslog] hierarchy level of the configuration.
Parameters	<ul style="list-style-type: none"> message—String or variable that is output to the system log file.

- **message2**—(Optional) Any additional number of strings or variable names passed as arguments to the function. These are concatenated with the **message** argument and output to the system log file.
- **priority**—Priority given to the syslog message. The priority can be specified as a **facility.severity** string, or it can be expressed as an integer calculated from the corresponding numeric values of the facility and severity strings. [Table 4 on page 27](#) and [Table 5 on page 27](#) show the facility and severity strings available and their corresponding numeric values.

The integer value of the **priority** parameter is calculated by multiplying the facility string numeric value by 8 and adding the severity string numeric value. For example, if the **facility.severity** string pair is "pfe.alert", the priority value is 161 ((20 x 8) + 1).

Table 4: Facility Strings

Facility String	Description	Numeric Value
auth	Authorization system	4
change	Configuration change log	22
conflict	Configuration conflict log	21
daemon	Various system processes	3
external	Local external applications	18
firewall	Firewall filtering system	19
ftp	FTP processes	11
interact	Commands executed by the UI	23
pfe	Packet Forwarding Engine	20
user	User processes	1

Table 5: Severity Strings

Severity String	Description	Numeric Value
alert	Conditions that should be corrected immediately	1
crit	Critical conditions	2
debug	Debug messages	7
emerg or panic	Panic conditions	0
err or error	Error conditions	3

Table 5: Severity Strings (*continued*)

Severity String	Description	Numeric Value
info	Informational messages	6
notice	Conditions that should be specially handled	5
warn or warning	Warning messages	4

Usage Examples The following three examples log **pfe** messages with an **alert** priority. The string **"mymessage"** is output to the system log file. All three examples are equivalent:

```
expr jcs:syslog("pfe.alert", "mymessage");
```

```
expr jcs:syslog(161, "mymessage");
```

```
var $message = "mymessage";
expr jcs:syslog("pfe.alert", $message);
```

The following example logs **pfe** messages with an **alert** priority similar to the previous example. In this example, however, there are additional string arguments. For this case, the concatenated string **"mymessage mymessage2"** is output to the system log file.

```
expr jcs:syslog("pfe.alert", "mymessage ", "mymessage2");
```

jcs:trace() Function

SLAX Syntax `expr jcs:trace('expression');`

XSLT Syntax `<xsl:value-of select="jcs:trace('expression')"/>`

Description Issue a trace message, which is sent to the trace file. You must configure **traceoptions** under the respective script type in the configuration hierarchy in order to output the **jcs:trace** message to the trace file. The output goes to configured trace file. If **traceoptions** is enabled, but no trace file is explicitly configured, the output goes to the default trace file for that script type.

Parameters

- expression**—String that is output to the trace file.

Usage Examples SLAX syntax:

```
expr jcs:trace('test');
```

XSLT syntax:

```
<xsl:value-of select="jcs:trace('test')"/>
```

Junos Script Automation: Named Templates in the jcs Namespace Overview

Junos OS provides several named templates to make scripting tasks easier in commit, op, and event scripts. The named templates reside in the **junos.xsl** import file, which is

included with the standard Junos OS installation available on all switches, routers, and security devices running Junos OS.

The Junos OS named templates are defined in the namespace with the associated Uniform Resource Identifier (URI) `http://xml.juniper.net/junos/commit-scripts/1.0`. The templates use the `jcs:` prefix to avoid conflicting with standard XSLT templates or user-defined templates of the same name in a script. To use the Junos named templates in a script, you must include the namespace URI in your style sheet declaration. Map the `jcs` prefix to the URI by including the `xmlns:jcs` attribute in the opening `<xsl:stylesheet>` tag element for XSLT scripts or by including the `ns jcs` statement in SLAX scripts. You must also import the `junos.xml` file into the script by including the `<xsl:import/>` tag element in XSLT scripts or the `import` statement in SLAX scripts and specifying the `junos.xml` file location.

To call a named template in a script, include the `<xsl:call-template name="template-name">` element for XSLT scripts or the `call` statement for SLAX scripts and pass along any required or optional parameters. Template parameters are assigned by name and can appear in any order. This differs from functions where the arguments must be passed into the function in the precise order specified by the function definition.

The following example imports the `junos.xml` file into a script and maps the `jcs` prefix to the namespace identified by the URI `http://xml.juniper.net/junos/commit-scripts/1.0`. The script demonstrates a call to the `jcs:edit-path` template.

XSLT Syntax

```
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../import/junos.xml"/>
  ...
  <xsl:for-each select="interfaces/interface[starts-with(name, 'so-')]">
    <xnm:warning>
      <xsl:call-template name="jcs:edit-path"/>
      <message>interface configured</message>
    </xnm:warning>
  </xsl:for-each>
  ...
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xml";
...
for-each ( interfaces/interface[starts-with(name,'so-')] ) {
  <xnm:warning> {
    call jcs:edit-path();
    <message> "interface configured";
  }
}
...
```

For more information about attributes and tag elements to include in your scripts, see [“Required Boilerplate for Commit Scripts” on page 166](#), [“Required Boilerplate for Op Scripts” on page 335](#), and [“Required Boilerplate for Event Scripts” on page 462](#).

Junos Named Templates in the jcs Namespace Summary

The Junos named templates are summarized in the following table:

Table 6: Junos Named Templates

Template	Description
<code>jcs:edit-path</code>	Generate an <code><edit-path></code> element suitable for inclusion in an <code><xnm:error></code> or <code><xnm:warning></code> element.
<code>jcs:emit-change</code>	Generate a <code><change></code> or <code><transient-change></code> element, which results in a persistent or transient change to the configuration.
<code>jcs:emit-comment</code>	Emit a simple comment that indicates a change was made by a commit script.
<code>jcs:grep</code>	Search a file for all instances matching a specified regular expression and write the matching strings and corresponding lines to the result tree.
<code>jcs:load-configuration</code>	Make structured changes to the Junos OS configuration using an op script.
<code>jcs:statement</code>	Generate a <code><statement></code> element suitable for inclusion in an <code><xnm:error></code> or <code><xnm:warning></code> element.

- [jcs:statement Template on page 38](#)

jcs:edit-path Template

XSLT Syntax	<pre><xsl:call-template name="jcs:edit-path"> <xsl:with-param name="dot" select="expression"/> </xsl:call-template></pre>
SLAX Syntax	<pre>call jcs:edit-path(\$dot=expression);</pre>
Description	<p>Generate an <edit-path> element suitable for inclusion in an <xnm:error> or <xnm:warning> element. This template converts a location in the configuration hierarchy into the standard text representation that you would see in the Junos OS configuration mode banner. By default, the location of the configuration error is passed into the jcs:edit-path template as the value of dot. This location defaults to ".", the current position in the XML hierarchy. You can alter the default by including a valid XPath expression for the dot parameter when you call the template.</p>
Parameters	<p>dot—XPath expression specifying the hierarchy level. The default location is the position in the XML hierarchy that the script is currently evaluating. You can alter the default when you call the template by including a valid XPath expression either for the \$dot parameter in SLAX scripts or for the select attribute of the dot parameter in XSLT scripts.</p>
Usage Examples	<p>The following example demonstrates how to call the jcs:edit-path template in a commit script and set the context to the [edit chassis] hierarchy level:</p> <pre><xsl:if test="not(chassis/source-route)"> <xnm:warning> <xsl:call-template name="jcs:edit-path"> <xsl:with-param name="dot" select="chassis"/> </xsl:call-template> <message>IP source-route processing is not enabled.</message> </xnm:warning> </xsl:if></pre> <p>When you commit a configuration that does not enable IP source routing, the code generates an <xnm:warning> element, which results in the following command-line interface (CLI) output:</p> <pre>user@host# commit [edit chassis] # The hierarchy level is generated by the jcs:edit-path template. warning: IP source-route processing is not enabled. commit complete</pre>

jcs:emit-change Template

XSLT Syntax	<pre><xsl:call-template name="jcs:emit-change"> <xsl:with-param name="content"> ... </xsl:with-param> <xsl:with-param name="dot" select="expression"/> <xsl:with-param name="message"></pre>
--------------------	--

	<pre> <xsl:text>message</xsl:text> </xsl:with-param> <xsl:with-param name="name" select="name(\$dot)"/> <xsl:with-param name="tag" select="(change transient-change)"/> </xsl:call-template> </pre>
SLAX Syntax	<pre> call jcs:emit-change(\$dot=expression, \$name = name(\$dot), \$tag = "(change transient-change)" { with \$content = { ... } with \$message = { expr "message"; } } </pre>
Description	Generate a <change> or <transient-change> element, which results in a persistent or transient change to the configuration.
Parameters	<p>This template includes the following optional parameters:</p> <ul style="list-style-type: none"> • content—Content of the persistent or transient change, relative to dot. • dot—XPath expression specifying the hierarchy level at which the change will be made. The default location is the position in the XML hierarchy that the script is currently evaluating. You can alter the default when you call the template by including a valid XPath expression either for the \$dot parameter in SLAX scripts or for the select attribute of the dot parameter in XSLT scripts. • message—Warning message displayed in the CLI notifying the user that the configuration has been changed. The message parameter automatically includes the edit path, which defaults to the current location in the XML hierarchy. To change the default edit path, specify a valid XPath expression either for the \$dot parameter in SLAX scripts or for the select attribute of the dot parameter in XSLT scripts. • name—Allows you to refer to the current element or attribute. The name() XPath function returns the name of an element or attribute. The name parameter defaults to the value name(\$dot), which is the name of the element in dot (which in turn defaults to “.”, which is the current element). • tag—Type of change to generate. By default, the jcs:emit-change template generates a persistent change, as designated by the 'change' expression. To specify a transient change, you must include the tag parameter and include the 'transient-change' expression.
Usage Examples	<p>The following example demonstrates how to call the jcs:emit-change template in a commit script:</p> <pre> <xsl:template match="configuration"> <xsl:for-each select="interfaces/interface/unit[family/iso]"> <xsl:if test="not(family/mps)"> <xsl:call-template name="jcs:emit-change"> <xsl:with-param name="message"> <xsl:text>Adding 'family mpls' to ISO-enabled interface</xsl:text> </xsl:with-param> </xsl:call-template> </xsl:if> </xsl:for-each> </xsl:template> </pre>

```

    </xsl:with-param>
    <xsl:with-param name="content">
      <family>
        <mpls/>
      </family>
    </xsl:with-param>
  </xsl:call-template>
</xsl:if>
</xsl:for-each>
</xsl:template>

```

When you commit a configuration that includes one or more interfaces that have IS-IS enabled but do not have the **family mpls** statement included at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level, the **jcs:emit-change** template adds the **family mpls** statement to the configuration and generates the following CLI output:

```

[edit]
user@host# commit
[edit interfaces interface so-1/2/3 unit 0]
  warning: Adding 'family mpls' to IS0-enabled interface
[edit interfaces interface so-1/2/3 unit 0]
  warning: Adding IS0-enabled interface so-1/2/3.0 to [protocols mpls]
[edit interfaces interface so-1/3/2 unit 0]
  warning: Adding 'family mpls' to IS0-enabled interface
[edit interfaces interface so-1/3/2 unit 0]
  warning: Adding IS0-enabled interface so-1/3/2.0 to [protocols mpls]
commit complete

```

The **content** parameter of the **jcs:emit-change** template provides a simpler method for specifying a change to the configuration. For example, consider the following code:

```

<xsl:with-param name="content">
  <family>
    <mpls/>
  </family>
</xsl:with-param>

```

The **jcs:emit-change** template converts the **content** parameter into a **<change>** request. The **<change>** request inserts the provided partial configuration content into the complete hierarchy of the current context node. Thus, the **jcs:emit-change** template changes the hierarchy information in the **content** parameter into the following code:

```

<change>
  <interfaces>
    <interface>
      <name><xsl:value-of select="name"/></name>
      <unit>
        <name><xsl:value-of select="unit/name"/></name>
        <family>
          <mpls/>
        </family>
      </unit>
    </interface>
  </interfaces>
</change>

```

If a transient change is required, the **tag** parameter can be passed in as 'transient-change', as shown here:

```
<xsl:with-param name="tag" select="'transient-change'"/>
```

The extra quotation marks are required to allow XSLT to distinguish between the string "transient-change" and the contents of a node named "transient-change". If the change is relative to a node other than the context node, the parameter "dot" can be set to that node, as shown in the following example, where context is set to the **[edit chassis]** hierarchy level:

```
<xsl:for-each select="interfaces/interface/unit">
...
<xsl:call-template name="jcs:emit-change">
  <xsl:with-param name="dot" select="chassis"/>
...

```

See also [“Example: Imposing a Minimum MTU Setting” on page 266](#).

jcs:emit-comment Template

XSLT Syntax

```
<junos:comment>
  <xsl:text>...</xsl:text>
</junos:comment>
```

Description

Emit a simple comment that indicates a change was made by a commit script. The template contains a **<junos:comment>** element. You never call the **jcs:emit-comment** template directly. Rather, you include its **<junos:comment>** element and the child element **<xsl:text>** inside a call to the **jcs:emit-change** template, a **<change>** element, or a **<transient-change>** element.

Usage Examples

The following example demonstrates how to call this template in a commit script:

```
<xsl:call-template name="jcs:emit-change">
  <xsl:with-param name="content">
    <term>
      <name>very-last</name>
      <junos:comment>
        <xsl:text>This term was added by a commit script</xsl:text>
      </junos:comment>
    </term>
  </xsl:with-param>
</xsl:call-template>
```

When you issue the **show firewall** configuration mode command, the following output appears:

```
[edit]
user@host# show firewall
family inet {
  term very-last {
    /* This term was added by a commit script */
    then accept;
```

```
    }
}
```

jcs:grep Template

XSLT Syntax `<xsl:call-template name="jcs:grep">`
 `<xsl:with-param name="filename" select="filename"/>`
 `<xsl:with-param name="pattern" select="pattern"/>`
 `</xsl:call-template>`

SLAX Syntax `call jcs:grep($filename=filename, $pattern=pattern);`

Description Search the given input file for all instances matching the specified regular expression and write the matching strings and corresponding lines to the result tree. The pattern is matched to each line of the file. The template does not support matching a pattern spanning multiple lines.

If the regular expression contains a syntax error, the template generates an error for every line of the file. For each match, the template adds a **<match>** element, which contains **<input>** and **<output>** child tags, to the result tree. The template writes the matching string to the **<output>** element and writes the corresponding matching line to the **<input>** element.

```
<match> {
  <input>
  <output>
}
```

Starting with Junos OS Release 11.1, if an absolute path is not specified for the input file, the default path is relative to the user's home directory for op scripts, and it is relative to the **/var/tmp/** directory for commit scripts and for event scripts that are enabled at the **[edit event-options event-script]** hierarchy level. For event scripts that are enabled at the **[edit system scripts]** hierarchy level, the default path is relative to the top-level directory, **/.**

Parameters • **filename**—(Mandatory) Absolute or relative path and filename of the file to search.

Starting with Junos OS Release 11.1, if you do not specify an absolute path, the path is relative to the user's home directory for op scripts, and it is relative to the **/var/tmp/** directory for commit scripts and for event scripts that are enabled at the **[edit event-options event-script]** hierarchy level. For event scripts that are enabled at the **[edit system scripts]** hierarchy level, the default path is relative to the top-level directory, **/.**

• **pattern**—(Mandatory) Regular expression.

Usage Examples [“Example: Searching Files Using an Op Script” on page 388](#)

jcs:load-configuration Template

XSLT Syntax `<xsl:call-template name="jcs:load-configuration">`
 `<xsl:with-param name="action" select="(merge | override | replace)"/>`
 `<xsl:with-param name="commit-options" select="node-set"/>`
 `<xsl:with-param name="configuration" select="configuration-data"/>`

	<pre> <xsl:with-param name="connection" select="connection-handle"/> </xsl:call-template> </pre>
SLAX Syntax	<pre> call jcs:load-configuration(\$action="(merge override replace)", \$commit-options=node-set, \$configuration=configuration-data, \$conconnection=connection-handle); </pre>
Description	<p>Make structured changes to the Junos OS configuration using an op script. When called, the template locks the configuration database, loads the configuration changes, commits the configuration, and then unlocks the configuration database.</p> <p>The jcs:load-configuration template makes changes to the configuration in configure exclusive mode. In this mode, Junos OS locks the candidate <i>global</i> configuration for as long as the script accesses the shared database and makes changes to the configuration without interference from other users.</p> <p>If another user is currently editing the configuration in configure exclusive mode or if the database is already locked when the template is called, the call fails. In addition, if there are existing, uncommitted changes to the configuration when the template is called, the commit will fail. If the template call is successful but the commit fails, Junos OS discards the uncommitted changes and rolls back the configuration.</p>
Parameters	<ul style="list-style-type: none"> • action—Specifies how to load the configuration changes with respect to the candidate configuration. The following options are supported: <ul style="list-style-type: none"> • merge—Combine the candidate configuration and the incoming configuration changes. If the candidate configuration and the incoming configuration contain conflicting statements, the incoming statements override those in the candidate configuration. • override—Replace the entire candidate configuration. • replace—Replace existing statements in the candidate configuration with the tags of the same name that are marked with replace: in the incoming configuration. If there is no existing statement of the same name in the candidate configuration, the statement is added to the candidate configuration. • commit-options—Node-set defining options that customize the commit command. The default value is null. Supported commit options are: <ul style="list-style-type: none"> • check—Check the correctness of the candidate configuration syntax, but do not commit the changes. • force-synchronize—Force the commit on the other Routing Engine (ignore any warnings). • log—Write the specified message to the commit log. This is identical to the CLI configuration mode command commit comment. • synchronize—Synchronize the commit on both Routing Engines. • configuration—XML configuration changes. • connection—Connection handle generated by a call to the jcs:open() function.

Usage Examples The following example calls the **jcs:load-configuration** template to modify the configuration to disable an interface. The interface name is supplied by the user and stored in the variable **interface-name**. All of the values required for the **jcs:load-configuration** template are defined as variables, which are then passed into the template as arguments.

In this example, the configuration data that includes the changes to the configuration are stored in the variable **disable**. This is the value used for the **configuration** parameter of the **jcs:load-configuration** template. The **load-action** variable is initialized to **merge**, which merges the configuration changes in the **disable** variable with the candidate configuration. This is the equivalent of the CLI configuration mode command **load merge**.

The **options** variable uses the **:=** operator to create a node-set, which is passed to the template as the value of the **commit-options** parameter. This example uses the **synchronize** commit option. If the commit succeeds, it will commit the configuration changes on both Routing Engines. The **log** tag is also included to add the description of the commit to the commit log file for future reference.

The call to the **jcs:open()** function opens a connection with the Junos OS management process (mgd) and returns a connection handle that is stored in the **conn** variable. All of the defined variables are passed as arguments to the **jcs:load-configuration** template at the time that it is called.

SLAX syntax:

```
var $disable = {
  <configuration> {
    <interfaces> {
      <interface> {
        <name> $interface-name;
        <disable>;
      }
    }
  }
}
var $load-action = "merge";
var $options := {
  <commit-options> {
    <synchronize>;
    <log> "disabling interface on both routing engines";
  }
}
var $conn = jcs:open();

var $disable-results := {
  call jcs:load-configuration($action=$load-action, $commit-options=$options,
    $configuration = $disable, $connection = $conn);
}
if ($disable-results//xnm:error) {
  for-each ($disable-results//xnm:error) {
    <output> message;
  }
}
var $close-results = jcs:close($conn);
```

The `:=` operator copies the results of the `jcs:load-configuration` template call to a temporary variable and runs the `node-set` function on that variable. The `:=` operator ensures that the `disable-results` variable is a node-set rather than a result tree fragment so that the script can access the contents. The `if` code block is included to output any error messages that may indicate a problem in committing the configuration. The `jcs:close` function closes the connection.

In XSLT, the code corresponding to the SLAX call to `jcs:load-configuration` template is:

```
<xsl:variable name="disable-results-temp">
  <xsl:call-template name="jcs:load-configuration">
    <xsl:with-param name="action" select="$load-action"/>
    <xsl:with-param name="commit-options" select="$options"/>
    <xsl:with-param name="configuration" select="$disable"/>
    <xsl:with-param name="connection" select="$conn"/>
  </xsl:call-template>
</xsl:variable>

<xsl:variable xmlns ext="http://xmlsoft.org/XSLT/namespace" \
  name="disable-results" select="ext:node-set($disable-results-temp)"/>
```

jcs:statement Template

XSLT Syntax	<pre><xsl:call-template name="jcs:statement"> <xsl:with-param name="dot" select="expression"/> </xsl:call-template></pre>
SLAX Syntax	<code>call jcs:statement(\$dot=expression);</code>
Description	Generate a <code><statement></code> element suitable for inclusion in an <code><xnm:error></code> or <code><xnm:warning></code> element. This location defaults to <code>" . "</code> , the current position in the XML hierarchy. If the error is not at the current position in the XML hierarchy, you can alter the default when you call the template by including a valid XPath expression either for the <code>\$dot</code> parameter in SLAX scripts or for the <code>select</code> attribute of the <code>dot</code> parameter in XSLT scripts.
Parameters	dot —XPath expression specifying the hierarchy level. The default location is the position in the XML hierarchy that the script is currently evaluating. You can alter the default when you call the template by including a valid XPath expression either for the <code>\$dot</code> parameter in SLAX scripts or for the <code>select</code> attribute of the <code>dot</code> parameter in XSLT scripts.
Usage Examples	The following example demonstrates how to call the <code>jcs:statement</code> template in a commit script:

```
<xnm:error>
  <xsl:call-template name="jcs:edit-path"/>
  <xsl:call-template name="jcs:statement">
    <xsl:with-param name="dot" select="mtu"/>
  </xsl:call-template>
  <message>
    <xsl:text>SONET interfaces must have a minimum MTU of </xsl:text>
    <xsl:value-of select="$min-mtu"/>
    <xsl:text>. </xsl:text>
  </message>
</xnm:error>
```

When you commit a configuration that includes a SONET/SDH interface with a maximum transmission unit (MTU) setting less than a specified minimum, the `<xnm:error>` element results in the following CLI output:

```
[edit]
user@host# commit
[edit interfaces interface so-1/2/3]
  'mtu 576;' # mtu statement generated by the jcs:statement template
  SONET interfaces must have a minimum MTU of 2048.
error: 1 error reported by commit scripts
error: commit script failure
```

The test of the MTU setting is not performed in the `<xnm:error>` element. For the full example, see [“Example: Imposing a Minimum MTU Setting” on page 266](#).

Junos Script Automation: Global Parameters and Variables in the `junos.xml` File

The `junos.xml` import file declares several predefined parameters and a global variable of type node-set, which provide information about the Junos OS environment that is useful for creating scripts that respond to a variety of complex scenarios. The global parameters and variable are available for use in any commit, op, or event script that imports the `junos.xml` file.

To use the parameters or variable in a script, you must import the `junos.xml` file by including the `<xsl:import>` tag in the style sheet declaration of an XSLT script or by including the `import` statement in a SLAX script and specifying the `junos.xml` file location as shown in the following sample code:

XSLT Syntax	<pre><?xml version="1.0"?> <xsl:stylesheet version="1.0"> <xsl:import href="../../import/junos.xml"/> ... </xsl:stylesheet></pre>
SLAX Syntax	<pre>version 1.0; import "../../import/junos.xml";</pre>

The default arguments are described in detail in the following sections:

- [Global Parameters on page 39](#)
- [Global Variable on page 40](#)

Global Parameters

Several predefined global parameters are available for use in commit, op, and event scripts. The parameters provide information about the Junos OS environment. [Table 7 on page 39](#) describes the built-in arguments.

Table 7: Predefined Parameters Available to Automation Scripts

Name	Description	Example
<code>\$hostname</code>	Hostname of the local device	Tokyo

Table 7: Predefined Parameters Available to Automation Scripts (*continued*)

Name	Description	Example
<code>\$localtime</code>	Local time when the script is executed	Fri Dec 10 11:42:21 2010
<code>\$localtime-iso</code>	Local time, in ISO format, when the script is executed	2010-12-10 11:42:21 PST
<code>\$product</code>	Model of the local device	m10i
<code>\$script</code>	Filename of the executing script	test.slax
<code>\$user</code>	Local name of the user executing the script	root

The predefined global parameters are declared in the **junos.xml** file. You do not need to declare these parameters in a script in order to use them. Access the value of the global parameters in a script by prefixing the parameter name with the dollar sign (\$), as shown in the following example:

SLAX syntax:

```
if ($user != "root") {
    var $script-message = $user _ " does not have permission to execute " _ $script;
    expr jcs:output($script-message);
}
```

XSLT syntax:

```
<xsl:if test="$user != 'root'">
    <xsl:variable name="script-message"
        select="concat($user, ' does not have permission to execute ', $script)"/>
    <xsl:value-of select="jcs:output($script-message)"/>
</xsl:if>
```

Global Variable

Starting with Junos OS Release 11.1, Junos OS also provides a single global variable, **\$junos-context**, which is accessible for use in all commit, op, or event scripts that import the **junos.xml** file. The **\$junos-context** variable is a node-set, which has elements that mirror the original global parameters described in [“Global Parameters” on page 39](#) as well as additional elements with information about the Junos OS environment, such as whether a script is executed on the master Routing Engine.

The **\$junos-context** variable contains the **<junos-context>** node and the following hierarchy, which is common to and embedded in the source tree of all scripts:

```
<junos-context>
  <chassis></chassis>
  <hostname></hostname>
  <localtime></localtime>
  <localtime-iso></localtime-iso>
  <pid></pid>
  <product></product>
```

```

<re-master/>
<routing-engine-name></routing-engine-name>
<script-type></script-type>
<tty></tty>
<user-context>
  <class-name></class-name>
  <login-name></login-name>
  <uid></uid>
  <user></user>
</user-context>
</junos-context>

```

Additionally, script-specific information is available depending on the type of script executed. For op scripts, the **<op-context>** element is also included in the source tree provided to an op script:

```

<junos-context>
  <op-context>
    <via-url/>
  </op-context>
</junos-context>

```

For commit scripts, the **<commit-context>** element is also included in the source tree provided to a commit script:

```

<junos-context>
  <commit-context>
    <commit-comment>"This is a test commit"</commit-comment>
    <commit-boot/>
    <commit-check/>
    <commit-sync/>
    <commit-confirm/>
  </commit-context>
</junos-context>

```

[Table 8 on page 42](#) identifies each node of the **\$junos-context** variable node-set, provides a brief description of the node, and gives examples of values for any elements that are not input to a script as an empty tag.

Table 8: Global Variable \$junos-context Available to Automation Scripts

Parent Node	Node	Description	Example content
<junos-context>	<chassis>	Specifies whether the script is executed on a component of a routing matrix, the Root System Domain (RSD), or a Protected System Domain (PSD)	scc, lcc (TX Matrix) psd, rsd (JCS) others
	<hostname>	Hostname of the local device	Tokyo
	<localtime>	Local time when the script is executed	Fri Dec 10 11:42:21 2010
	<localtime-iso>	Local time, in ISO format, when the script is executed	2010-12-10 11:42:21 PST
	<pid>	cscript process ID	5257
	<product>	Model of the local device	m10i
	<re-master/>	Empty element included if the script is executed on the master Routing Engine	
	<routing-engine-name>	Routing Engine on which the script is executed	re0
	<tty>	TTY of the user's session	/dev/ttyl
	<script-type>	Type of script being executed	op
<junos-context> <user-context>	<class-name>	Login class of the user executing the script	superuser
	<login-name>	Login name of the user executing the script. For AAA access, this is the RADIUS/TACACS username.	jsmith
	<uid>	User ID number of the user executing the script as defined in the device configuration	2999
	<user>	Local name of the user executing the script. Junos OS uses the local name for authentication. It might differ from the login-name used for AAA authentication.	root
<junos-context> <op-context> (op scripts only)	<via-url>	Empty element included if the remote op script is executed using the op url command	

Table 8: Global Variable \$junos-context Available to Automation Scripts (*continued*)

Parent Node	Node	Description	Example content
<junos-context> <commit-context> (commit scripts only)	<commit-boot/>	Empty element included when the commit occurs at boot time	
	<commit-check/>	Empty element included when a commit check is performed	
	<commit-comment>	User comment regarding the commit	Commit to fix forwarding issue
	<commit-confirm/>	Empty element included when a commit confirmed is performed	
	<commit-sync/>	Empty element included when a commit synchronize is performed	

The **\$junos-context** variable is a node-set. Therefore, you can access the child elements throughout a script by including the proper XPath expression. The following example commit script writes a message to the system log file if the commit is performed during initial boot-up. The message is given a facility value of **daemon** and a severity value of **info**. For more information, see [jcs:syslog\(\) Function](#).

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";

import "../import/junos.xsl";

match configuration {
  if ($junos-context/commit-context/commit-boot) {
    expr jcs:syslog("daemon.info", "This is boot-time commit");
  }
  else {
    /* Do this ... */
  }
}
```

XML Overview

Extensible Markup Language (XML) is a language for defining a set of markers, called *tags*, that are applied to a data set or document to describe the function of individual elements and codify the hierarchical relationships between them. Tags look much like Hypertext Markup Language (HTML) tags, but XML is actually a metalanguage used to define tags that best suit the kind of data being marked.

For more details about XML, see *A Technical Introduction to XML* at <http://www.xml.com/pub/a/98/10/guide0.html> and the additional reference material at the <http://www.xml.com> site.

The official XML specification from the World Wide Web Consortium (W3C), *Extensible Markup Language (XML) 1.0*, is available at <http://www.w3.org/TR/REC-xml>.

The following sections discuss general aspects of XML:

- [Tag Elements on page 44](#)
- [Attributes on page 45](#)
- [Namespaces on page 45](#)
- [Document Type Definition on page 46](#)

Tag Elements

XML has three types of tags: opening tags, closing tags, and empty tags. XML tag names are enclosed in angle brackets and are case sensitive. Items in an XML-compliant document or data set are always enclosed in paired opening and closing tags, and the tags must be properly nested. That is, you must close the tags in the same order in which you opened them. XML is stricter in this respect than HTML, which sometimes uses only opening tags. The following examples show paired opening and closing tags enclosing a value. The closing tags are indicated by the forward slash at the start of the tag name.

```
<interface-state>enabled</interface-state>
<input-bytes>25378</input-bytes>
```

The term *tag element* refers to a three-part set: opening tag, contents, and closing tag. The content can be an alphanumeric character string as in the preceding examples, or can itself be a *container* tag element, which contains other tag elements. For simplicity, the term *tag* is often used interchangeably with *tag element* or *element*.

If a tag element is *empty*—has no contents—it can be represented either as paired opening and closing tags with nothing between them, or as a single tag with a forward slash after the tag name. For example, the notation `<snmp-trap-flag/>` is equivalent to `<snmp-trap-flag></snmp-trap-flag>`.

As the preceding examples show, angle brackets enclose the name of the tag element. This is an XML convention, and the brackets are a required part of the complete tag

element name. They are not to be confused with the angle brackets used in the documentation to indicate optional parts of Junos OS CLI command strings.

Junos XML and Junos XML protocol tag elements obey the XML convention that the tag element name indicates the kind of information enclosed by the tags. For example, the name of the Junos XML **<interface-state>** tag element indicates that it contains a description of the current status of an interface on the device, whereas the name of the **<input-bytes>** tag element indicates that its contents specify the number of bytes received.

When discussing tag elements in text, this documentation conventionally uses just the opening tag to represent the complete tag element (opening tag, contents, and closing tag). For example, the documentation refers to the **<input-bytes>** tag to indicate the entire **<input-bytes>number-of-bytes</input-bytes>** tag element.

Attributes

XML elements can contain associated properties in the form of *attributes*, which specify additional information about an element. Attributes appear in the opening tag of an element and consist of an attribute name and value pair. The attribute syntax consists of the attribute name followed by an equals sign and then the attribute value enclosed in quotation marks. An XML element can have multiple attributes. Multiple attributes are separated by spaces and can appear in any order.

In the following example, the **configuration** tag element has two attributes, **junos:changed-seconds** and **junos:changed-localtime**.

```
<configuration junos:changed-seconds="1279908006"
junos:changed-localtime="2010-07-23 11:00:06 PDT">
```

The value of the **junos:changed-seconds** attribute is "1279908006", and the value of the **junos:changed-localtime** attribute is "2010-07-23 11:00:06 PDT".

Namespaces

Namespaces allow an XML document to contain the same tag, attribute, or function names for different purposes and avoid name conflicts. For example, many namespaces may define a **print** function, and each may exhibit a different functionality. To use the functionality defined in one specific namespace, you must associate that function with the namespace that defines the desired functionality.

To refer to a tag, attribute, or function from a defined namespace, you must first provide the namespace Uniform Resource Identifier (URI) in your style sheet declaration. You then qualify a tag, attribute, or function from the namespace with the URI. Since a URI is often lengthy, generally a shorter prefix is mapped to the URI.

In the following example the **jcs** prefix is mapped to the namespace identified by the URI <http://xml.juniper.net/junos/commit-scripts/1.0>, which defines extension functions used in commit, op, and event scripts. The **jcs** prefix is then prepended to the **output** function, which is defined in that namespace.

```
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
...
```

```
<xsl:value-of select="jcs:output('The VPN is up.')" />
</xsl:stylesheet>
```

During processing, the prefix is expanded into the URI reference. Although there may be multiple namespaces that define an **output** element or function, the use of **jcs:output** explicitly defines which **output** function is used. You can choose any prefix to refer to the contents in a namespace, but there must be an existing declaration in the XML document that binds the prefix to the associated URI.

Document Type Definition

An XML-tagged document or data set is *structured*, because a set of rules specifies the ordering and interrelationships of the items in it. The rules define the contexts in which each tagged item can—and in some cases must—occur. A file called a *document type definition*, or *DTD*, lists every tag element that can appear in the document or data set, defines the parent-child relationships between the tags, and specifies other tag characteristics. The same DTD can apply to many XML documents or data sets.

XML and Junos OS

Extensible Markup Language (XML) is a standard for representing and communicating information. It is a metalanguage for defining customized tags that are applied to a data set or document to describe the function of individual elements and codify the hierarchical relationships between them. Junos OS natively supports XML for the operation and configuration of devices running Junos OS.

The Junos OS command-line interface (CLI) and the Junos OS infrastructure communicate using XML. When you issue an operational mode command in the CLI, the CLI converts the command into XML format for processing. After processing, Junos OS returns the output in the form of an XML document, which the CLI converts back into a readable format for display. Remote client applications also use XML-based data encoding for operational and configuration requests on devices running Junos OS.

The Junos XML API is an XML representation of Junos configuration statements and operational mode commands. It defines an XML equivalent for all statements in the Junos configuration hierarchy and many of the commands that you issue in CLI operational mode. Each operational mode command with a Junos XML counterpart maps to a request tag element and, if necessary, a response tag element.

You can view the XML-formatted output of any operational mode command by issuing the command in the CLI and adding the **| display xml** option. The following example shows the text-formatted and XML-formatted output for the **show chassis alarms** operational mode command:

```
user@host> show chassis alarms
No alarms currently active
```

```
user@host> show chassis alarms | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.4B1/junos">
  <alarm-information xmlns="http://xml.juniper.net/junos/10.4B1/junos-alarm">
```

```

    <alarm-summary>
      <no-active-alarms/>
    </alarm-summary>
  </alarm-information>
</cli>
  <banner></banner>
</cli>
</rpc-reply>

```

You can view the Junos XML API representation of any operational mode command by issuing the command in the CLI and adding the **| display xml rpc** option. The following example shows the Junos XML API tag element for the **show chassis alarms** command.

```

user@host> show chassis alarms | display xml rpc
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.4B1/junos">
  <rpc>
    <get-alarm-information>
    </get-alarm-information>
  </rpc>
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>

```

As shown in the previous example, the **| display xml rpc** option displays the command's corresponding Junos XML API request tag element that is sent to Junos OS for processing whenever the command is issued. In contrast, the **| display xml** option displays the actual output of the processed command in XML format.

When you issue the **show chassis alarms** operational mode command, the CLI converts the command into its equivalent Junos XML API request tag **<get-alarm-information>** and sends the XML request to the Junos infrastructure for processing. Junos OS processes the request and returns the **<alarm-information>** response tag element to the CLI. The CLI then converts the XML output into the “No alarms currently active” message that is displayed to the user.

Junos automation scripts use XML to communicate with the host device. Junos OS provides XML-formatted input to a script. The script processes the input source tree and then returns XML-formatted output to Junos OS. The script type determines the XML input document that is sent to the script as well as the output document that is returned to Junos OS for processing. Commit script input consists of an XML representation of the post-inheritance candidate configuration file. Event scripts receive an XML document containing the description of the triggering event. All script input documents contain a common node-set with information pertaining to the Junos OS environment.

XSLT Overview

Commit scripts, op scripts, and event scripts can be written in Extensible Stylesheet Language Transformations (XSLT), which is a standard for processing Extensible Markup Language (XML) data. XSLT is developed by the World Wide Web Consortium (W3C) and is accessible at <http://www.w3c.org/TR/xslt>.

- [XSLT Advantages on page 48](#)
- [XSLT Engine on page 49](#)
- [XSLT Concepts on page 49](#)

XSLT Advantages

XSLT is a natural match for Junos OS, with its native XML capabilities. XSLT performs XML-to-XML transformations, turning one XML hierarchy into another. It offers a great degree of freedom and power in the way in which it transforms the input XML, allowing everything from making minor changes to the existing hierarchy (such as additions or deletions) to building a completely new document hierarchy.

Because XSLT was created to allow generic XML-to-XML transformations, it is a natural choice for both inspecting configuration syntax (which Junos OS can easily express in XML) and for generating errors and warnings (which Junos OS communicates internally as XML). XSLT includes powerful mechanisms for finding configuration statements that match specific criteria. XSLT can then generate the appropriate XML result tree from these configuration statements to instruct the Junos OS user-interface (UI) components to perform the desired behavior.

Although XSLT provides a powerful scripting ability, its focus is specific and limited. It does not make Junos OS vulnerable to arbitrary or malicious programmers. XSLT restricts programmers from performing haphazard operations, such as opening random Transmission Control Protocol (TCP) ports, forking numerous processes, or sending e-mail. The only action available in XSLT is to generate XML, and the XML is interpreted by the UI according to fixed semantics. An XSLT script can output only XML data, which is directly processed by the UI infrastructure to allow only the specific abilities listed above—generating error, warning, and system log messages, and persistent and transient configuration changes. This means that the impact of commit scripts, op scripts, and event scripts on the device is well-defined and can be viewed inside the command-line interface (CLI), using commands added for that purpose.

XSLT Engine

XSLT is a language for transforming one XML document into another XML document. The basic model is that an XSLT engine (or processor) reads a script (or style sheet) and an XML document. The XSLT engine uses the instructions in the script to process the XML document by traversing the document's hierarchy. The script indicates what portion of the tree should be traversed, how it should be inspected, and what XML should be generated at each point. For commit scripts, op scripts, and event scripts, the XSLT engine is a function of the Junos OS management process (mgd).

Figure 1 on page 49 shows the relationship between an XSLT commit script and the XSLT engine.

Figure 1: Flow of XSLT Commit Script Through the XSLT Engine

XSLT Concepts

XSLT has seven basic concepts. These are summarized in Table 9 on page 49.

Table 9: XSLT Concepts

XSLT Concepts	Description
XPath	Expression syntax for specifying a node in the input document
Templates	Mechanism for mapping input hierarchies to instructions that handle them
Parameters	Mechanism for passing arguments to templates
Variables	Mechanism for defining read-only references to nodes
Programming instructions	Mechanism for defining logic in XSLT
Recursion	Mechanism by which templates call themselves to facilitate looping
Context (Dot)	Node currently being inspected in the input document

XSLT Namespace

The XSLT namespace has the Uniform Resource Identifier (URI) <http://www.w3.org/1999/XSL/Transform>. The namespace must be included in the style sheet declaration of a script in order for the XSLT processor to recognize and use XSLT elements and attributes. The following example declares the XSLT namespace and associates the **xsl** prefix with the URI.

```
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
  <xsl:template match="route">
    ...
  </xsl:template>
</xsl:stylesheet>
```

Once the XSLT namespace is declared in a script, you use elements and attributes from the namespace by adding the associated prefix, which in this case is **xsl**, to the tag or attribute name. In the preceding example, the XSLT processor knows to treat **xsl:template** as an XSLT instruction. During processing, the **xsl** prefix is expanded into the URI reference, and the functionality of the **template** element is defined by the XSLT namespace. For more information about namespaces, see [“XML Overview” on page 44](#).

XPath Overview

XSLT uses the XML Path Language (XPath) standard to specify and locate elements in the input document's XML hierarchy. XPath's powerful expression syntax enables you to define complex criteria for selecting portions of the XML input document.

Nodes and Axes

XPath views every piece of the document hierarchy as a *node*. For commit scripts, op scripts, and event scripts, the important types of nodes are *element nodes*, *text nodes*, and *attribute nodes*. Consider the following XML tags:

```
<system>
  <host-name>my-router</host-name>
  <accounting inactive="inactive">
</system>
```

These XML tag elements show examples of the following types of XPath nodes:

- **<host-name>my-router</host-name>**—Element node
- **my-router**—Text node
- **inactive="inactive"**—Attribute node

Nodes are viewed as being arranged in certain *axes*. The *ancestor axis* points from a node up through its series of parent nodes. The *child axis* points through the list of an element node's direct child nodes. The *attribute axis* points through the list of an element node's

set of attributes. The *following-sibling axis* points through the nodes that follow a node but are under the same parent. The *descendant axis* contains all the descendents of a node. There are numerous other axes that are not listed here.

Each XPath expression is evaluated from a particular node, which is referred to as the *context node* (or simply *context*). The context node is the node at which the XSLT processor is currently looking. XSLT changes the context as the document's hierarchy is traversed, and XPath expressions are evaluated from that particular context node.

NOTE: In Junos OS commit scripts, the context node concept corresponds to Junos OS hierarchy levels. For example, the `/configuration/system/domain-name` XPath expression sets the context node to the `[edit system domain-name]` hierarchy level.

We recommend including the `<xsl:template match="configuration">` template in all commit scripts. This element allows you to exclude the `/configuration/` root element from all XPath expressions in programming instructions (such as `<xsl:for-each>` or `<xsl:if>`) in the script, thus allowing you to begin XPath expressions at a Junos hierarchy level (for example, `system/domain-name`). For more information, see [“Required Boilerplate for Commit Scripts” on page 166](#).

Path and Predicate Syntax

An XPath expression contains two types of syntax, a path syntax and a predicate syntax. Path syntax specifies which nodes to inspect in terms of their path locations on one of the axes in the document's hierarchy from the current context node. Several examples of path syntax follow:

- **accounting-options**—Selects an element node named **accounting-options** that is a child of the current context.
- **server/name**—Selects an element node named **name** that is a child of an element named **server** that is a child of the current context.
- **/configuration/system/domain-name**—Selects an element node named **domain-name** that is the child of an element named **system** that is the child of the root element of the document (**configuration**).
- **parent::system/host-name**—Selects an element node named **host-name** that is the child of an element named **system** that is the parent of the current context node. The **parent::** axis can be abbreviated as two periods (**..**).

The predicate syntax allows you to perform tests at each node selected by the path syntax. Only nodes that pass the test are included in the result set. A predicate appears inside square brackets (**[]**) after a path node. Following are several examples of predicate syntax:

- **server[name = '10.1.1.1']**—Selects an element named **server** that is a child of the current context and has a child element named **name** whose value is **10.1.1.1**.

- ***[@inactive]**—Selects any node (* matches any node) that is a child of the current context and that has an attribute (@ selects nodes from the **attribute** axis) named **inactive**.
- **route[starts-with(next-hop, '10.10.')**—Selects an element named **route** that is a child of the current context and that has a child element named **next-hop** whose value starts with the string **10.10..**

The **starts-with** function is one of many functions that are built into XPath. XPath also supports relational tests, equality tests, and many more features not listed here.

XPath Operators

XPath supports standard logical operators, such as AND and | (or); comparison operators, such as =, !=, <, and >; and numerical operators, such as +, -, and *.

In XSLT, you always have to represent the less-than (<) operator as **<** and the less-than-or-equal-to (<=) operator as **<=** because XSLT scripts are XML documents, and less-than signs are represented this way in XML.

For more information about XPath functions and operators, consult a comprehensive XPath reference guide. XPath is fully described in the W3C specification at <http://w3c.org/TR/xpath>.

XSLT Templates Overview

An XSLT script consists of one or more sets of rules called *templates*. Each template is a segment of code that contains rules to apply when a specified node is matched. You use the **<xsl:template>** element to build templates.

There are two types of templates, named and unnamed (or match), and they are described in the following sections.

- [Unnamed \(Match\) Templates on page 52](#)
- [Named Templates on page 53](#)

Unnamed (Match) Templates

Unnamed templates, also known as match templates, include a **match** attribute that contains an XPath expression to specify the criteria for nodes upon which the template should be invoked. In the following example, the template applies to the element named **route** that is a child of the current context and that has a child element named **next-hop** whose value starts with the string **10.10..**

```
<xsl:template match="route[starts-with(next-hop, '10.10.')] ">
  <!-- ... body of the template ... -->
</xsl:template>
```

By default, when XSLT processes a document, it recursively traverses the entire document hierarchy, inspecting each node, looking for a template that matches the current node. When a matching template is found, the contents of that template are evaluated.

The **<xsl:apply-templates>** element can be used inside an unnamed template to limit and control XSLT's default, hierarchical traversal of nodes. If the **<xsl:apply-templates>** element has a **select** attribute, only nodes matching the XPath expression defined by

the attribute are traversed. Otherwise all children of the context node are traversed. If the **select** attribute is included, but does not match any nodes, nothing is traversed and nothing happens.

In the following example, the template rule matches the **<route>** element in the XML hierarchy. All the nodes containing a **changed** attribute are processed. All **<route>** elements containing a **changed** attribute are replaced with a **<new>** element.

```
<xsl:template match="route">
  <new>
    <xsl:apply-templates select="*[@changed]"/>
  </new>
</xsl:template>
```

Using unnamed templates allows the script to ignore the location of a tag in the XML hierarchy. For example, if you want to convert all **<author>** tags into **<div class="author">** tags, using templates enables you to write a single rule that converts all **<author>** tags, regardless of their location in the input XML document.

For more information about how unnamed templates are used in scripts, see *xsl:template match="/" Template*.

Named Templates

Named templates operate like functions in traditional programming languages, although with a verbose syntax. When the complexity of a script increases or a code segment appears in multiple places, you can modularize the code and create named templates. Like functions, named templates accept arguments and run only when explicitly called.

You create a named template by using the **<xsl:template>** element and defining the **name** attribute, which is similar to a function name in traditional programming languages. Use the **<xsl:param>** tag and its **name** attribute to define parameters for the named template, and optionally include the **select** attribute to declare default values for each parameter. The **select** attribute can contain XPath expressions. If the **select** attribute is not defined, the parameter defaults to an empty string.

The following example creates a template named **my-template** and defines three parameters, one of which defaults to the string **false**, and one of which defaults to the contents of the element node named **name** that is a child of the current context node. If the script calls the template and does not pass in a parameter, the default value is used.

```
<xsl:template name="my-template">
  <xsl:param name="a"/>
  <xsl:param name="b" select="'false'"/>
  <xsl:param name="c" select="name"/>
  <!-- ... body of the template ... -->
</xsl:template>
```

To invoke a named template in a script, use the **<xsl:call-template>** element. The **name** attribute is required and defines the name of the template being called. When processed, the **<xsl:call-template>** element is replaced by the contents of the **<xsl:template>** element it names.

When you invoke a named template, you can pass arguments into the template by including the `<xsl:with-param>` child element and specifying the **name** attribute. The value of the `<xsl:with-param>` **name** attribute must match a parameter defined in the actual template; otherwise the parameter is ignored. Optionally, you can set a value for each parameter with either the **select** attribute or the content of the `<xsl:with-param>` element. If you do not define a value for the parameter in the calling environment, the script passes in the current value of the parameter if it was previously initialized, or it generates an error if the parameter was never declared. For more information about passing parameters, see [“XSLT Parameters Overview” on page 54](#).

In the following example, the template **my-template** is called with the parameter **c** containing the contents of the element node named **other-name** that is a child of the current context node.

```
<xsl:call-template name="my-template">
  <xsl:with-param name="c" select="other-name"/>
</xsl:call-template>
```

For an example showing how to use named templates in a commit script, see [“Example: Requiring and Restricting Configuration Statements” on page 306](#).

XSLT Parameters Overview

Parameters can be passed to either named or unnamed templates. Inside the template, parameters must be declared and can then be referenced by prefixing their name with the dollar sign (\$).

Declaring Parameters

The scope of a parameter can be global or local. A parameter whose value is set by Junos at script initialization must be defined as a global parameter. Global parameter declarations are placed just after the style sheet declarations. A script can assign a default value to the global parameter, which is used in the event that Junos does not give a value to the parameter.

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0"
  xmlns:ext="http://xmlsoft.org/XSLT/namespace" version="1.0">
```

```
<!-- global parameter -->
<xsl:param name="interface1"/>
```

Local parameters must be declared at the beginning of a block and their scope is limited to the block in which they are declared. Inside a template, you declare parameters using the `<xsl:param>` tag and **name** attribute. Optionally, declare default values for each parameter by including the **select** attribute, which can contain XPath expressions. If a template is invoked without the parameter, the default expression is evaluated, and the results are assigned to the parameter. If you do not define a default value in the template, the parameter defaults to an empty string.

The following named template **print-host-name** declares the parameter **message** and defines a default value:

```
<xsl:template name="print-host-name">
  <xsl:param name="message"
    select="concat('host-name: ', system/host-name)"/>
  <xsl:value-of select="$message"/>
</xsl:template>
```

The template accesses the value of the **message** parameter by prefixing the parameter name with the dollar sign (\$).

Passing Parameters

When you invoke a template, you pass arguments into the template using the `<xsl:with-param>` element and **name** attribute. The value of the `<xsl:with-param>` **name** attribute must match the name of a parameter defined in the actual template; otherwise the parameter is ignored. Optionally, for each parameter you pass to a template, you can define a value using either the **select** attribute or the contents of the `<xsl:with-param>` element.

The parameter value that gets used in a template depends on how the template is called. The following three examples, which call the **print-host-name** template, illustrate the possible calling environments.

If you call a template but do not include the `<xsl:with-param>` element for a specific parameter, the default expression defined in the template is evaluated, and the results are assigned to the parameter. If there is no default value for that parameter in the template, the parameter defaults to an empty string. The following example calls the named template **print-host-name** but does not include any parameters in the call. In this case, the named template will use the default value for the **message** parameter that was defined in the **print-host-name** template, or an empty string if no default exists.

```
<xsl:template match="configuration">
  <xsl:call-template name="print-host-name"/>
</xsl:template>
```

If you call a template and include a parameter, but do not define a value for the parameter in the calling environment, the script passes in the current value of the parameter if it was previously initialized, or it generates an error if the parameter was never declared. The following example calls the named template **print-host-name** and passes in the **message** parameter, but does not include a value. If **message** is declared and initialized in the script, and the scope is visible to the block, the current value of **message** is used. If **message** is declared in the script but not initialized, the value of **message** will be an empty string. If **message** has not been declared, the script produces an error.

```
<xsl:template match="configuration">
  <xsl:call-template name="print-host-name">
    <xsl:with-param name="message"/>
  </xsl:call-template>
</xsl:template>
```

If you call a template, include the parameter, and define a value for the parameter, the template uses the provided value. The following example calls the named template **print-host-name** with the **message** parameter and a defined value, so the template uses the new value.

```
<xsl:template match="configuration">
  <xsl:call-template name="print-host-name">
    <xsl:with-param name="message"
      select=concat('Host-name passed in: ', system/host-name)"/>
  </xsl:call-template>
</xsl:template>
```

Example: Parameters and Match Templates

The following template matches on **/**, the root of the XML document. It then generates an element named **<outside>**, which is added to the output document, and instructs the Junos OS management process (mgd) to recursively apply templates to the **configuration/system** subtree. The parameter **host** is used in the processing of any matching nodes. The value of the **host** parameter is the value of the **host-name** statement at the **[edit system]** level of the configuration hierarchy.

```
<xsl:template match="/">
  <outside>
    <xsl:apply-templates select="configuration/system">
      <xsl:with-param name="host" select="configuration/system/host-name"/>
    </xsl:apply-templates>
  </outside>
</xsl:template>
```

The following template matches the **<system>** element, which is the top of the subtree selected in the previous example. The **host** parameter is declared with no default value. An **<inside>** element is generated, which contains the value of the **host** parameter that was defined in the **<xsl:with-param>** tag in the previous example.

```
<xsl:template match="system">
  <xsl:param name="host"/>
  <inside>
    <xsl:value-of select="$host"/>
  </inside>
</xsl:template>
```

Example: Parameters and Named Templates

The following named template **report-changed** declares two parameters: **dot**, which defaults to the current node, and **changed**, which defaults to the **changed** attribute of the node **\$dot**.

```
<xsl:template name="report-changed">
  <xsl:param name="dot" select="."/>
  <xsl:param name="changed" select="$dot/@changed"/>
  <!-- ... -->
</xsl:template>
```

The next stanza calls the **report-changed** template and defines a source for the **changed** attribute different from the default source defined in the **report-changed** template. When the **report-changed** template is invoked, it will use the newly defined source for the **changed** attribute in place of the default source.

```
<xsl:template match="system">
  <xsl:call-template name="report-changed">
    <xsl:with-param name="changed" select="../@changed"/>
  </xsl:call-template>
</xsl:template>
```

Likewise, the template call can include the **dot** parameter and define a source other than the default current node, as shown here:

```
<xsl:template match="system">
  <xsl:call-template name="report-changed">
    <xsl:with-param name="dot" select="../"/>
  </xsl:call-template>
</xsl:template>
```

XSLT Variables Overview

You declare variables using the **<xsl:variable>** element. The **name** attribute specifies the name of the variable, which is case-sensitive. Once you declare a variable, you can reference it within an XPath expression using the variable name prefixed with a dollar sign (\$).

Variables are immutable; you can set the value of a variable only when you declare the variable, after which point, the value is fixed. You initialize a variable by including the **select** attribute and an expression in the **<xsl:variable>** tag. The following example declares and initializes the variable **location**. The **location** variable is then used to initialize the **message** variable.

```
<xsl:variable name="location" select="$dot/@location"/>
<xsl:variable name="message" select="concat('We are in ', $location, ' now.')" />
```

You can define both local and global variables. Variables are global if they are children of the **<xsl:stylesheet>** element. Otherwise, they are local. The value of a global variable

is accessible anywhere in the style sheet. The scope of a local variable is limited to the template or code block in which it is defined.

XSLT variables can store any values that you can calculate or statically define. This includes data structures, XML hierarchies, and combinations of text and parameters. For example, you could assign the XML output of an operational mode command to a variable and then access the hierarchy within the variable.

The following template declares the **message** variable. The **message** variable includes both text and parameter values. The template generates a system log message by referring to the value of the message variable. The resulting system log message is as follows:

Device *device-name* was changed on *date* by user '*user*.'

```
<xsl:template name="emit-syslog">
  <xsl:param name="user"/>
  <xsl:param name="date"/>
  <xsl:param name="device"/>
  <xsl:variable name="message">
    <xsl:text>Device </xsl:text>
    <xsl:value-of select="$device"/>
    <xsl:text> was changed on </xsl:text>
    <xsl:value-of select="$date"/>
    <xsl:text> by user '</xsl:text>
    <xsl:value-of select="$user"/>
    <xsl:text>.'</xsl:text>
  </xsl:variable>
  <syslog>
    <message>
      <xsl:value-of select="$message"/>
    </message>
  </syslog>
</xsl:template>
```

Table 10 on page 58 provides examples of XSLT variable declarations along with pseudocode explanations.

Table 10: Examples and Pseudocode for XSLT Variable Declaration

Variable Declaration	Pseudocode Explanation
<code><xsl:variable name="mpls" select="protocols/mpls"/></code>	Assigns the [edit protocols mpls] hierarchy level to the variable named mpls .
<code><xsl:variable name="color" select="data[name = 'color']/value"/></code>	Assigns the value of the color macro parameter to a variable named color . The <data> element in the XPath expression is useful in commit script macros. For more information, see "Creating a Macro to Read the Custom Syntax and Generate Related Configuration Statements" on page 207 .

XSLT Programming Instructions Overview

XSLT has a number of traditional programming instructions. Their form tends to be verbose, because their syntax is built from XML elements.

The XSLT programming instructions most commonly used in commit, op, and event scripts, which provide flow control within a script, are described in the following sections:

- [<xsl:choose> Programming Instruction on page 59](#)
- [<xsl:for-each> Programming Instruction on page 59](#)
- [<xsl:if> Programming Instruction on page 60](#)
- [Sample XSLT Programming Instructions and Pseudocode on page 60](#)

<xsl:choose> Programming Instruction

The **<xsl:choose>** instruction is a conditional construct that causes different instructions to be processed in different circumstances. It is similar to a switch statement in traditional programming languages. The **<xsl:choose>** instruction contains one or more **<xsl:when>** elements, each of which tests an XPath expression. If the test evaluates to true, the XSLT processor executes the instructions in the **<xsl:when>** element. After the XSLT processor finds an XPath expression in an **<xsl:when>** element that evaluates to true, the XSLT processor ignores all subsequent **<xsl:when>** elements contained in the **<xsl:choose>** instruction, even if their XPath expressions evaluate to true. In other words, the XSLT processor processes only the instructions contained in the first **<xsl:when>** element whose **test** attribute evaluates to true. If none of the **<xsl:when>** elements' **test** attributes evaluate to true, the content of the optional **<xsl:otherwise>** element, if one is present, is processed.

The **<xsl:choose>** instruction is similar to a switch statement in other programming languages. The **<xsl:when>** element is the “case” of the switch statement, and you can add any number of **<xsl:when>** elements. The **<xsl:otherwise>** element is the “default” of the switch statement.

```
<xsl:choose>
  <xsl:when test="xpath-expression">
    ...
  </xsl:when>
  <xsl:when test="another-xpath-expression">
    ...
  </xsl:when>
  <xsl:otherwise>
    ...
  </xsl:otherwise>
</xsl:choose>
```

<xsl:for-each> Programming Instruction

The **<xsl:for-each>** element tells the XSLT processor to gather together a set of nodes and process them one by one. The nodes are selected by the XPath expression specified by the **select** attribute. Each of the nodes is then processed according to the instructions held in the **<xsl:for-each>** construct.

```
<xsl:for-each select="xpath-expression">
```

```
...
</xsl:for-each>
```

Code inside the `<xsl:for-each>` instruction is evaluated recursively for each node that matches the XPath expression. That is, the current context is moved to each node selected by the `<xsl:for-each>` clause, and processing is relative to that current context.

In the following example, the `<xsl:for-each>` construct recursively processes each node in the **[system syslog file]** hierarchy. It updates the current context to each matching node and prints the value of the **name** element, if one exists, that is a child of the current context.

```
<xsl:for-each select="system/syslog/file">
  <xsl:value-of select="name"/>
</xsl:for-each>
```

`<xsl:if>` Programming Instruction

An `<xsl:if>` programming instruction is a conditional construct that causes instructions to be processed if the XPath expression held in the **test** attribute evaluates to **true**.

```
<xsl:if test="xpath-expression">
  ...executed if test expression evaluates to true
</xsl:if>
```

There is no corresponding else clause.

Sample XSLT Programming Instructions and Pseudocode

Table 11 on page 60 presents examples that use several XSLT programming instructions along with pseudocode explanations.

Table 11: Examples and Pseudocode for XSLT Programming Instructions

Programming Instruction	Pseudocode Explanation
<pre><xsl:choose> <xsl:when test="system/host-name"> <change> <system> <host-name>M320</host-name> </system> </change> </xsl:when> <xsl:otherwise> <xnm:error> <message> Missing [edit system host-name] M320. </message> </xnm:error> </xsl:otherwise> </xsl:choose></pre>	<p>When the host-name statement is included at the [edit system] hierarchy level, change the hostname to M320.</p> <p>Otherwise, issue the warning message: Missing [edit system host-name] M320.</p>
<pre><xsl:for-each select="interfaces/interface[starts-with(name, 'ge-')]/unit"></pre>	<p>For each Gigabit Ethernet interface configured at the [edit interfaces ge-fpc/pic/port unit logical-unit-number] hierarchy level.</p>

Table 11: Examples and Pseudocode for XSLT Programming Instructions (*continued*)

Programming Instruction	Pseudocode Explanation
<code><xsl:for-each select="data[not(value)]/name"></code>	<p>Select any macro parameter that does not contain a parameter value.</p> <p>In other words, match all apply-macro statements of the following form:</p> <pre> apply-macro <i>apply-macro-name</i> { <i>parameter-name</i>; } </pre> <p>And ignore all apply-macro statements of the form:</p> <pre> apply-macro <i>apply-macro-name</i> { <i>parameter-name</i> <i>parameter-value</i>; } </pre>
<code><xsl:if test="not(system/host-name)"></code>	If the host-name statement is not included at the [edit system] hierarchy level.
<code><xsl:if test="apply-macro[name = 'no-igp']"></code>	If the apply-macro statement named no-igp is included at the current hierarchy level.
<code><xsl:if test="not(..../apply-macro[name = 'no-ldp'])"></code>	If the apply-macro statement with the name no-ldp is not included two hierarchy levels above the current hierarchy level.

XSLT Recursion Overview

XSLT depends on recursion as a looping mechanism. Recursion occurs when a section of code calls itself, either directly or indirectly. Both named and unnamed templates can use recursion, and different templates can use mutual recursion, one calling another that in turn calls the first.

To avoid infinite recursion and excessive consumption of system resources, the Junos OS management process (mgd) limits the maximum recursion to 5000 levels. If this limit is reached, the script fails.

In the following example, an unnamed template matches on a `<count>` element. It then calls the `<count-to-max>` template, passing the value of the `count` element as `max`. The `<count-to-max>` template starts by declaring both the `max` and `cur` parameters and setting the default value of each to 1 (one). Although the optional default value for `max` is one, the template will use the value passed in from the `count` template. Then the current value of `$cur` is emitted in an `<out>` element. Finally, if `$cur` is less than `$max`, the `<count-to-max>` template recursively invokes itself, passing `$cur + 1` as `cur`. This recursive pass then outputs the next number and repeats the recursion until `$cur` equals `$max`.

```
<xsl:template match="count">
  <xsl:call-template name="count-to-max">
    <xsl:with-param name="max" select="."/>
  </xsl:call-template>
</xsl:template>

<xsl:template name="count-to-max">
  <xsl:param name="cur" select="1"/>
  <xsl:param name="max" select="1"/>

  <out><xsl:value-of select="$cur"/></out>

  <xsl:if test="$cur < $max">
    <xsl:call-template name="count-to-max">
      <xsl:with-param name="cur" select="$cur + 1"/>
      <xsl:with-param name="max" select="$max"/>
    </xsl:call-template>
  </xsl:if>
</xsl:template>
```

Given a `max` value of 10, the values contained in the `<out>` tag are 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10.

XSLT Context (Dot) Overview

The current context node changes as an `<xsl:apply-templates>` instruction traverses the document hierarchy and as an `<xsl:for-each>` instruction examines each node that matches an XPath expression. All relative node references are relative to the current context node. This node is abbreviated `"."` (read: dot) and can be referred to in XPath expressions, allowing explicit references to the current node.

The following example contains four uses for `"."`. The `system` node is saved in the `system` variable for use inside the `<xsl:for-each>` instruction, where the value of `"."` will have changed. The `for-each select` expression uses `"."` to mean the value of the `name` element. The `"."` is then used to pull the value of the `name` element into the `<tag>` element. The `<xsl:if>` test then uses `"."` to reference the value of the current context node.

```
<xsl:template match="system">
  <xsl:variable name="system" select="."/>
  <xsl:for-each select="name-server/name[starts-with(., '10.')] ">
    <tag><xsl:value-of select="."/></tag>
    <xsl:if test=".= '10.1.1.1'">
      <match>
        <xsl:value-of select="$system/host-name"/>
      </match>
    </xsl:if>
  </xsl:for-each>
```

```
</xsl:template>
```

SLAX Overview

Stylesheet Language Alternative Syntax (SLAX) is a language for writing Junos OS commit scripts, op scripts, and event scripts. It is an alternative to Extensible Stylesheet Language Transformations (XSLT). SLAX has a distinct syntax similar to that of C and Perl, but the same semantics as XSLT.

- [SLAX Advantages on page 63](#)
- [How SLAX Works on page 64](#)

SLAX Advantages

XSLT is a powerful and effective tool for handling Extensible Markup Language (XML) that works well for machine-to-machine communication, but its XML-based syntax is inconvenient for the development of complex programs.

SLAX has a simple syntax that follows the style of C and PERL. It provides a practical and succinct way to code, thus allowing you to create readable, maintainable commit, op, and event scripts. SLAX removes XPath expressions and programming instructions from XML elements. XML angle brackets and quotation marks are replaced by parentheses and curly brackets (`{ }`), which are the familiar delimiters of C and PERL.

The benefits of SLAX are particularly strong for programmers who are not already accustomed to XSLT, because SLAX allows them to concentrate on the new programming topics introduced by XSLT, rather than concentrating on learning a new syntax. For example, SLAX allows you to:

- Use **if**, **else if**, and **else** statements instead of `<xsl:choose>` and `<xsl:if>` elements
- Put test expressions in parentheses (`()`)
- Use the double equal sign (`==`) to test equality instead of the single equal sign (`=`)
- Use curly braces to show containment instead of closing tags

- Perform concatenation using the underscore (_) operator, as in PERL, version 6
- Write text strings using simple quotation marks (") instead of the `<xsl:text>` element
- Define named templates with a syntax resembling a function definition
- Invoke named templates with a syntax resembling a function call
- Simplify namespace declarations
- Reduce the clutter in your scripts
- Write more readable scripts

How SLAX Works

SLAX functions as a preprocessor for XSLT. Junos OS internally translates SLAX programming instructions (such as `if` and `else` statements) into the equivalent XSLT instructions (such as `<xsl:if>` and `<xsl:choose>` elements). After this translation, the XSLT transformation engine—which, for Junos OS, is the Junos OS management (mgd) process—is invoked.

SLAX does not affect the expressiveness of XSLT; it only makes XSLT easier to use. The underlying SLAX constructs are completely native to XSLT. SLAX adds nothing to the XSLT engine. The SLAX parser parses an input document and builds an XML tree identical to the one produced when the XML parser reads an XSLT document.

Figure 2 on page 64 shows the flow of SLAX script input and output.

Figure 2: SLAX Script Input and Output

Converting Scripts Between SLAX and XSLT

SLAX is a C-like alternative syntax to XSLT and can be viewed as a preprocessor for XSLT. Before Junos OS invokes the XSLT processor, the software converts any SLAX constructs in the script (such as **if/then/else**) to equivalent XSLT constructs (such as **<xsl:choose>** and **<xsl:if>**). For more information about SLAX, see “[SLAX Overview](#)” on [page 63](#).

You can use the **request system scripts convert** operational mode command to convert a script written in SLAX or XSLT into the alternate language. If you have existing XSLT scripts, conversion to SLAX allows C and PERL programmers to more easily read and maintain the scripts. In addition, converting a script and studying the results facilitates learning the differences between the two languages.

The following sections explain how to convert a script from one language to the other:

- [Converting a Script from SLAX to XSLT on page 65](#)
- [Converting a Script from XSLT to SLAX on page 66](#)

Converting a Script from SLAX to XSLT

To convert a SLAX script to XSLT, issue the **request system scripts convert slax-to-xslt** operational mode command, and specify the source file, the destination directory, and, optionally, a destination file. The source script is the basis for the new script. The source script is not overwritten by the new script.

The command syntax is:

```
user@host> request system scripts convert slax-to-xslt source source destination dest
```

The following three examples show the command using a source and destination directory relevant to the default storage location for the type of script being converted:

```
user@host> request system scripts convert slax-to-xslt source /var/db/scripts/op/script1.slax
destination /var/db/scripts/op/script1.xml
conversion complete
```

```
user@host> request system scripts convert slax-to-xslt source /var/db/scripts/event/script1.slax
destination /var/db/scripts/event/script1.xml
conversion complete
```

```
user@host> request system scripts convert slax-to-xslt source
/var/db/scripts/commit/script1.slax destination /var/db/scripts/commit/script1.xml
conversion complete
```

When you issue the **slax-to-xslt** conversion command, the **script1.slax** file remains unchanged in the source directory and a new script called **script1.xml** is added to the destination directory.

```
user@host> file list /var/db/scripts/op
script1.slax
script1.xml
```

If you specify only the destination directory and do not specify a destination filename, the generated file is named **SLAX-Conversion-Temp.xxxxx** where **xxxxx** is a randomly generated series of characters.

```
user@host> request system scripts convert slax-to-xslt source /var/db/scripts/op/script1.slax
destination /var/db/scripts/op/
conversion complete
```

```
user@host> file list /var/db/scripts/op
SLAX-Conversion-Temp.S1hIr
script1.slax
```

Converting a Script from XSLT to SLAX

To convert an XSLT script to SLAX, issue the **request system scripts convert xslt-to-slax** operational mode command, and specify the source file, the destination directory, and, optionally, a destination file. The source script is the basis for the new script. The source script is not overwritten by the new script.

The command syntax is:

```
user@host> request system scripts convert xslt-to-slax source source destination dest
```

The following three examples show the command using a source and destination directory relevant to the default storage location for the type of script being converted:

```
user@host> request system scripts convert xslt-to-slax source /var/db/scripts/op/script1.xml
destination /var/db/scripts/op/script1.slax
conversion complete
```

```
user@host> request system scripts convert xslt-to-slax source /var/db/scripts/event/script1.xml
destination /var/db/scripts/event/script1.slax
conversion complete
```

```
user@host> request system scripts convert xslt-to-slax source /var/db/scripts/commit/script1.xml
destination /var/db/scripts/commit/script1.slax
conversion complete
```

When you issue the **xslt-to-slax** conversion command, the **script1.xml** file remains unchanged in the source directory, and a new script called **script1.slax** is added to the destination directory.

```
user@host> file list /var/db/scripts/op
script1.slax
script1.xml
```

If you specify only the destination directory and do not specify a destination filename, the generated file is named **SLAX-Conversion-Temp.xxxxx** where **xxxxx** is a randomly generated series of characters.

```
user@host> request system scripts convert xslt-to-slax source /var/db/scripts/op/script1.xml
destination /var/db/scripts/op/
conversion complete
```

```
user@host> file list /var/db/scripts/op
SLAX-Conversion-Temp.Vosnd
```

```
script1.xsl
```

Related Documentation

SLAX Syntax Rules Overview

SLAX syntax rules are similar to those of traditional programming languages like C and PERL. The following sections discuss general aspects of SLAX syntax rules:

- [Code Blocks on page 67](#)
- [Comments on page 67](#)
- [Line Termination on page 68](#)
- [Strings on page 68](#)

Code Blocks

SLAX delimits blocks of code with curly braces. Code blocks, which may define the boundaries of an element, a hierarchy, or a segment of code, can be at the same level as or nested within other code blocks. Declarations defined within a particular code block have a scope that is limited to that block.

The following example shows two blocks of code. Curly braces define the bounds of the **match** / block. The second block, containing the **<op-script-results>** element, is nested within the first.

```
match / {
  <op-script-results> {
    <output> "Script summary:";
  }
}
```

Comments

In SLAX, you can add comments anywhere in a script. Commenting a script increases readability for all users, including the author, who may need to return to a script long after it was originally written. It is recommended that you add comments throughout a script as you write it.

In SLAX, you insert comments in the traditional C style, beginning with **/*** and ending with ***/**. For example:

```
/* This is a comment. */
```

Multi-line comments follow the same format. In the following example, the additional **"*"** characters are added to the beginning of the lines for readability, but they are not required.

```
/* Script Title
 * Author: Jane Doe
 * Last modified: 01/01/10
 * Summary of modifications: ...
 */
```

The XSLT equivalent is:

```
<!-- Script Title
Author: Jane Doe
Last modified: 01/01/10
Summary of modifications: ...
-->
```

The following example inserts a comment into the script to remind the programmer that the output is sent to the console.

```
match / {
  <op-script-results> {
    /* Output script summary to the console */
    <output> "Script summary: ...";
  }
}
```

Line Termination

As with many traditional programming languages, SLAX statements are terminated with a semicolon.

In the following example, the namespace declarations, import statement, and output element are all terminated with a semicolon. Lines that begin or end a block are not terminated with a semicolon.

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match / {
  <op-script-results> {
    <output> "Script summary:";
    /* ... */
  }
}
```

Strings

Strings are sequences of text characters. SLAX strings can be enclosed in either single quotes or double quotes. However, you must close the string with the same type of quote used to open the string. Strings can be concatenated together using the SLAX concatenation operation, which is the underscore (_).

For example:

```
match / {
  <op-script-results> {
    /* Output script summary to the console */
    <output> "Script" _ "summary: ...";
  }
}
```

**Related
Documentation**

- [SLAX Elements and Element Attributes Overview on page 69](#)

- [SLAX Overview on page 63](#)
- [SLAX Statements Overview on page 79](#)[SLAX Templates Overview on page 71](#)
- [SLAX Templates Overview on page 71](#)
- [SLAX Variables Overview on page 77](#)

SLAX Elements and Element Attributes Overview

SLAX Elements

SLAX elements are written with only the opening tag. The contents of the tag appear immediately following the opening tag. The contents can be either a simple expression or a more complex expression placed inside curly braces. For example:

```
<top> {  
  <one>;  
  <two> {  
    <three>;  
    <four>;  
    <five> {  
      <six>;  
    }  
  }  
}
```

The XSLT equivalent is:

```
<top>  
  <one/>  
  <two>  
    <three/>  
    <four/>  
    <five>  
      <six/>  
    </five>  
  </two>  
</top>
```

Using these nesting techniques and removing the closing tag reduces clutter and increases code clarity.

SLAX Element Attributes

SLAX element attributes follow the style of XML. Attributes are included in the opening tag and consist of an attribute name and value pair. The attribute syntax consists of the attribute name followed by an equals sign and then the attribute value enclosed in quotation marks. Multiple attributes are separated by spaces.

```
<element attr1="one" attr2="two">;
```

Where XSLT allows attribute value templates using curly braces, SLAX uses the normal expression syntax. Attribute values can include any XPath syntax, including quoted strings, parameters, variables, numbers, and the SLAX concatenation operator, which is an underscore (_). In the following example, the SLAX element **location** has two attributes, **state** and **zip**:

```
<location state=$location/state zip=$location/zip5 _ "-" _ $location/zip4>;
```

The XSLT equivalent is:

```
<location state="{ $location/state }"
  zip="{concat($location/zip5, '-', $location/zip4) }"/>
```

In SLAX, curly braces placed inside quote strings are not interpreted as attribute value templates. Instead, they are interpreted as plain-text curly braces.

An escape sequence causes a character to be treated as plain text and not as a special operator. For example, in HTML, an ampersand (&) followed by **lt** causes the less-than symbol (<) to be printed.

In XSLT, the double curly braces ({ and }) are escape sequences that cause opening and closing curly braces to be treated as plain text. When a SLAX script is converted to XSLT, the curly braces inside quote strings are converted to double curly braces:

```
<avt sign="{here}">;
```

The XSLT equivalent is:

```
<avt sign="{ {here} }"/>
```

XPath Expressions Overview for SLAX

XPath expressions can appear either as the contents of an XML element or as the contents of an **expr** (expression) statement. In either case, the value is translated to either an **<xsl:text>** element, which outputs literal text, or to an **<xsl:value-of>** element, which extracts data from an XML structure.

You encode strings using quotation marks (single or double). The concatenation operator is the underscore (_), as in PERL 6.

In this example, the contents of the **<three>** and **<four>** elements are identical, and the content of the **<five>** element differs only in the use of the XPath **concat()** function. The resulting output is the same in all three cases.

```
<top> {
  <one> "test";
  <two> "The answer is " _ results/answer _ ".";
  <three> results/count _ " attempts made by " _ results/user;
  <four> {
    expr results/count _ " attempts made by " _ results/user;
  }
  <five> {
    expr results/count;
    expr " attempts made by ";
  }
}
```

```

    expr results/user;
  }
  <six> results/message;
}

```

The XSLT equivalent is:

```

<top>
  <one><xsl:text>test</xsl:text></one>
  <two>
    <xsl:value-of select='concat("The answer is ", results/answer, ".")' />
  </two>
  <three>
    <xsl:value-of select='concat(results/count, " attempts made by ", results/user)' />
  </three>
  <four>
    <xsl:value-of select='concat(results/count, " attempts made by ", results/user)' />
  </four>
  <five>
    <xsl:value-of select="results/count" />
    <xsl:text> attempts made by </xsl:text>
    <xsl:value-of select="results/user" />
  </five>
  <six><xsl:value-of select='results/message' /></six>
</top>

```

SLAX Templates Overview

A SLAX script consists of one or more sets of rules called *templates*. Each template is a segment of code that contains rules to apply when a specified node is matched.

There are two types of templates, named and unnamed (or match), and they are described in the following sections.

- [Unnamed \(Match\) Templates on page 71](#)
- [Named Templates on page 72](#)

Unnamed (Match) Templates

Unnamed templates, also known as match templates, contain a **match** statement with an XPath expression to specify the criteria for nodes upon which the template should be invoked. In the following commit script sample, the template matches the top-level element in the configuration hierarchy.

```

match configuration {

```

```
    /* ...body of the template goes here */  
}
```

By default, the processor recursively traverses the entire document hierarchy, inspecting each node, looking for a template that matches the current node. When a matching template is found, the contents of that template are evaluated.

The **apply-templates** statement can be used inside an unnamed template to limit and control the default, hierarchical traversal of nodes. This statement accepts an optional XPath expression, which is equivalent to the **select** attribute in an **<xsl:apply-templates>** element. If an optional XPath expression is included, only nodes matching the XPath expression are traversed. Otherwise all children of the context node are traversed. If the XPath expression is included but does not match any nodes, nothing is traversed and nothing happens.

In the following example, the template rule matches the **<route>** element in the XML hierarchy. All the nodes containing a **changed** attribute are processed. All **route** elements containing a **changed** attribute are replaced with a **new** element.

```
match route {  
  <new> {  
    apply-templates *[@changed];  
  }  
}
```

The XSLT equivalent:

```
<xsl:template match="route">  
  <new>  
    <xsl:apply-templates select="*[@changed]"/>  
  </new>  
</xsl:template>
```

Using unnamed templates allows the script to ignore the location of a tag in the XML hierarchy. For example, if you want to convert all **<author>** tags into **<div class="author">** tags, using templates enables you to write a single rule that converts all **<author>** tags, regardless of their location in the input XML document.

Named Templates

Named templates operate like functions in traditional programming languages. When the complexity of a script increases or a code segment appears in multiple places, you can modularize the code and create named templates. Like functions, named templates accept arguments and run only when explicitly called.

In SLAX, the named template definition consists of the **template** keyword, the template name, a set of parameters, and a braces-delimited block of code. Parameter declarations can be inline and consist of the parameter name, and, optionally, a default value. Or you can declare parameters inside the template block using the **param** statement. If a default value is not defined, the parameter defaults to an empty string.

The following example creates a template named **my-template** and defines three parameters, one of which defaults to the string **false**, and one of which defaults to the contents of the element node named **name** that is a child of the current context node. If the script calls the template and does not pass in a parameter, the default value is used.

```
template my-template ($a, $b = "false", $c = name) {
    /* ... body of the template ... */
}
```

An alternate method is to declare the parameters within the template using the **param** statement. The following code is identical to the previous example:

```
template my-template {
    param $a;
    param $b = "false";
    param $c = name;
    /* ... body of the template ... */
}
```

In SLAX, you invoke named templates using the **call** statement, which consists of the **call** keyword and template name followed by a set of parameter bindings. These bindings are a comma-separated list of parameter names that are passed into the template from the calling environment. Parameter assignments are made by name and not by position in the list. Alternatively, you can declare parameters inside the **call** block using the **with** statement. Parameters passed into a template must match a parameter defined in the actual template; otherwise the parameter is ignored. Optionally, you can set a value for each parameter. If you do not define a value for the parameter in the calling environment, the script passes in the current value of the parameter if it was previously initialized, or it generates an error if the parameter was never declared. For more information about passing parameters, see [“SLAX Parameters Overview” on page 74](#).

In the following example, the template **my-template** is called with the parameter **c** containing the contents of the element node named **other-name** that is a child of the current context node.

```
call my-template {
    with $c = other-name;
}
```

In the following example, the **name-servers-template** declares two parameters **name-servers** and **size**. The **size** parameter is given a default value of zero. The **match** template, which declares and initializes **\$name-servers**, calls the **name-servers-template** three times.

The first call to the template does not include any parameters. Thus **name-servers** will default to an empty string, and **size** will default to a value of zero as defined in the template. The second call includes the **name-servers** and **size** parameters but only supplies a value for the **size** parameter. Thus **name-servers** has the value defined by its initialization in the script, and **size** is equal to the number of **name-servers** elements in the configuration hierarchy. The last call is identical to the second call, but it supplies the parameters using the **with** statement syntax.

```
match configuration {
    param $name-servers = name-servers/name;
    call name-servers-template();
    call name-servers-template($name-servers, $size = count($name-servers));
}
```

```

call name-servers-template() {
    with $name-servers;
    with $size = count($name-servers);
}
}
template name-servers-template($name-servers, $size = 0) {
    <output> "template called with size " _ $size;
}

```

The XSLT equivalent is:

```

<xsl:template match="configuration">
    <xsl:variable name="name-servers" select="name-servers/name"/>
    <xsl:call-template name="name-servers-template"/>
    <xsl:call-template name="name-servers-template">
        <xsl:with-param name="name-servers" select="$name-servers"/>
        <xsl:with-param name="size" select="count($name-servers)"/>
    </xsl:call-template>
    <xsl:call-template name="name-servers-template">
        <xsl:with-param name="name-servers" select="$name-servers"/>
        <xsl:with-param name="size" select="count($name-servers)"/>
    </xsl:call-template>
</xsl:template>

<xsl:template name="name-servers-template">
    <xsl:param name="name-servers"/>
    <xsl:param name="size" select="0"/>
    <output>
        <xsl:value-of select="concat('template called with size ', $size)"/>
    </output>
</xsl:template>

```

SLAX Parameters Overview

Parameters can be passed to either named or unnamed templates. Inside the template, parameters must be declared and can then be referenced by prefixing their name with the dollar sign (\$).

Declaring Parameters

In SLAX, you declare parameters using the **param** statement. Optionally, you can define an initial value for each parameter in the declaration. For example:

```
param $dot = .;
```

The scope of a parameter can be global or local. A parameter whose value is set by Junos at script initialization must be defined as a global parameter. Global parameter declarations are placed just after the style sheet declarations. A script can assign a default value to the global parameter, which is used in the event that Junos does not give a value to the parameter.

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
ns ext = "http://xmlsoft.org/XSLT/namespace";

/* global parameter */
param $interface1 = "fxp0";
```

Local parameters must be declared at the beginning of a block and their scope is limited to the block in which they are declared. In a template, you declare parameters either in a parameter list or by using the **param** statement in the template block. Optionally, declare default values for each template parameter. If a template is invoked without the parameter, the default expression is evaluated, and the results are assigned to the parameter. If you do not define a default value in the template, the parameter defaults to an empty string.

The following named template **print-host-name** declares the parameter **message** and defines a default value:

```
template print-host-name ($message = "host name: " _ system/host-name) {
  <xnm:warning> {
    <message> $message;
  }
}
```

An alternative, but equivalent, declaration is:

```
template print-host-name () {
  param $message = "host name: " _ system/host-name;
  <xnm:warning> {
    <message> $message;
  }
}
```

The template declares **message** and accesses its value by prefixing the parameter name with the dollar sign (\$). In XSLT, the parameter name is prefixed by the dollar sign when you access it but not when you declare it.

Passing Parameters

When you invoke a template, you pass arguments into the template either in an argument list or by using the **with** statement. The name of the parameter supplied in the calling environment must match the name of a parameter defined in the actual template; otherwise the parameter is ignored. Optionally, for each parameter you pass to a template, you can define a value using an equal sign (=) and a value expression. In the following example, the two calls to the named template **print-host-name** are identical:

```
match configuration {
```

```
    call print-host-name($message = "passing in host name: " _ system/host-name);
}
match configuration {
    call print-host-name() {
        with $message = "passing in host name: " _ system/host-name;
    }
}
```

The parameter value that gets used in a template depends on how the template is called. The following three examples, which call the **print-host-name** template, illustrate the possible calling environments.

If you call a template but do not include a specific parameter, the default expression defined in the template is evaluated, and the results are assigned to the parameter. If there is no default value for that parameter in the template, the parameter defaults to an empty string. The following example calls the named template **print-host-name** but does not include any parameters in the call. In this case, the named template will use the default value for the **message** parameter that was defined in the **print-host-name** template, or an empty string if no default exists.

```
match configuration {
    call print-host-name();
}
```

If you call a template and include a parameter, but do not define a value for the parameter in the calling environment, the script passes in the current value of the parameter if it was previously initialized, or it generates an error if the parameter was never declared. The following example calls the named template **print-host-name** and passes in the **message** parameter but does not include a value. If **message** is declared and initialized in the script, and the scope is visible to the block, the current value of **message** is used. If **message** is declared in the script but not initialized, the value of **message** will be an empty string. If **message** has not been declared, the script produces an error.

```
match configuration {
    call print-host-name($message);
    /* If $message was initialized previously, the current value is used;
    * If $message was declared but not initialized, an empty string is used;
    * If $message was never declared, the call generates an error. */
}
```

If you call a template, include the parameter, and define a value for the parameter, the template uses the provided value. The following example calls the named template **print-host-name** with the **message** parameter and a defined value, so the template uses the new value.

```
match configuration {
    call print-host-name($message = "passing in host name: " _ system/host-name);
}
```

Example: Parameters and Match Templates

The following example matches the top level **configuration** hierarchy element and then instructs the Junos OS management process (mgd) to recursively apply templates to the **system/host-name** subtree. The parameters **message** and **domain** are used in the processing of any matching nodes.

```
match configuration {
  var $domain = domain-name;
  apply-templates system/host-name {
    with $message = "Invalid host-name";
    with $domain;
  }
}

match host-name {
  param $message = "Error";
  param $domain;
  <hello> $message _ ":: " _ . _ " (" _ $domain _ ")";
}
```

The XSLT equivalent is:

```
<xsl:template match="configuration">
  <xsl:apply-templates select="system/host-name">
    <xsl:with-param name="message" select="'Invalid host-name'"/>
    <xsl:with-param name="domain" select="$domain"/>
  </xsl:apply-templates>
</xsl:template>

<xsl:template match="host-name">
  <xsl:param name="message" select="'Error'"/>
  <xsl:param name="domain"/>
  <hello>
    <xsl:value-of select="concat($message, ':: ', ' (' , $domain, ')')"/>
  </hello>
</xsl:template>
```

SLAX Variables Overview

In SLAX, you declare variables using the **var** statement. In the declaration, the variable name is prefixed with the dollar sign (\$), unlike the XSLT declaration, where the dollar sign does not prefix the value of the **name** attribute of the **<xsl:variable>** element. Once you declare a variable, you can reference it within an XPath expression using the variable name prefixed with a dollar sign (\$).

Variables are immutable; you can set the value of a variable only when you declare the variable, after which point, the value is fixed. You initialize a variable by following the variable name with an equal sign (=) and an expression. The following example declares and initializes the variable **location**. The **location** variable is then used to initialize the **message** variable.

```
var $location = $dot/@location;  
var $message = "We are in " _ $location _ " now.";
```

The XSLT equivalent is:

```
<xsl:variable name="location" select="$dot/@location"/>  
<xsl:variable name="message" select="concat('We are in ', $location, ' now.')" />
```

You can define both local and global variables. Variables are global if they are defined outside of any template. Otherwise, they are local. The value of a global variable is accessible anywhere in the style sheet. The scope of a local variable is limited to the template or code block in which it is defined.

SLAX variables can store any values that you can calculate or statically define. This includes data structures, XML hierarchies, and combinations of text and parameters. For example, you could assign the XML output of an operational mode command to a variable and then access the hierarchy within the variable.

Variables are immutable. As such, you can never change the value of a variable after it is defined in the declaration. Although you cannot directly update the value of a variable, you can mimic the effect by recursively calling a function and passing in the value of the variable as a parameter. For example:

```
var $count = 1;  
match / {  
  call update-count($myparam = $count);  
}  
template update-count($myparam) {  
  expr $count _ ", " $myparam _ "\n";  
  if ($myparam != 4) {  
    call update-count($myparam = $myparam + 1)  
  }  
}
```

Executing the op script in the CLI produces the following output in the log file. Although the **count** variable must remain fixed, **myparam** is updated with each call to the template.

```
1, 1  
1, 2  
1, 3  
1, 4  
1, 5
```

SLAX Statements Overview

This section lists some commonly used SLAX statements, with brief examples and XSLT equivalents.

- [for-each Statement on page 79](#)
- [if, else if, and else Statements on page 80](#)
- [match Statement on page 81](#)
- [ns Statement on page 81](#)
- [version Statement on page 82](#)

for-each Statement

The SLAX **for-each** statement functions like the `<xsl:for-each>` element. The statement consists of the **for-each** keyword, a parentheses-delimited expression, and a curly braces-delimited block. The **for-each** statement tells the processor to gather together a set of nodes and process them one by one. The nodes are selected by the specified XPath expression. Each of the nodes is then processed according to the instructions held in the **for-each** code block.

```
for-each (xpath-expression) {
  ...
}
```

Code inside the **for-each** instruction is evaluated recursively for each node that matches the XPath expression. That is, the current context is moved to each node selected by the **for-each** clause, and processing is relative to that current context.

In the following example, the **inventory** variable stores the inventory hierarchy. The **for-each** statement recursively processes each **chassis-sub-module** node that is a child of **chassis-module** that is a child of the **chassis** node. For each **chassis-sub-module** element that contains a **part-number** with a value equal to the specified part number, a **message** element is created that includes the name of the chassis module and the name and description of the chassis sub module.

```
for-each ($inventory/chassis/chassis-module/
  chassis-sub-module[part-number = '750-000610']) {
  <message> "Down rev PIC in " ../name _ " " _name _ ": " _description;
}
```

The XSLT equivalent is:

```
<xsl:for-each select="$inventory/chassis/chassis-module/
  chassis-sub-module[part-number = '750-000610']">
  <message>
    <xsl:value-of select="concat('Down rev PIC in ', ../name, ', ', name, ': ',
      description)"/>
  </message>
</xsl:for-each>
```

if, else if, and else Statements

SLAX supports **if**, **else if**, and **else** statements. The **if** statement is a conditional construct that causes instructions to be processed if the specified XPath expression evaluates to true. The **if** construct may have one or more associated **else if** clauses, each of which tests an XPath expression. If the expression in the **if** statement evaluates to false, the processor checks each **else if** expression. If a statement evaluates to true, the script executes the instructions in the associated block and ignores all subsequent **else if** and **else** statements. The optional **else** clause is the default code that is executed in the event that all associated **if** and **else-if** expressions evaluate to false. If all of the **if** and **else if** statements evaluate to false, and the **else** statement is not present, no action is taken.

The expressions that appear in parentheses are extended XPath expressions, which support the double equal sign (==) in place of XPath's single equal sign (=).

```
if (expression) {
    /* If block Statement */
}
else if (expression) {
    /* else if block statement */
}
else {
    /* else block statement */
}
```

During script processing, an **if** statement that does not have an associated **else if** or **else** statement is transformed into an `<xsl:if>` element. If either the **else if** or **else** clauses are present, the **if** statement and associated **else if** and **else** blocks are transformed into an `<xsl:choose>` element.

```
if (starts-with(name, "fe-")) {
    if (mtu < 1500) {
        /* Select Fast Ethernet interfaces with low MTUs */
    }
}
else {
    if (mtu > 8096) {
        /* Select non-Fast Ethernet interfaces with high MTUs */
    }
}
```

The XSLT equivalent is:

```
<xsl:choose>
  <xsl:when test="starts-with(name, 'fe-')">
    <xsl:if test="mtu < 1500">
      <!-- Select Fast Ethernet interfaces with low MTUs -->
    </xsl:if>
  </xsl:when>
  <xsl:otherwise>
    <xsl:if test="mtu > 8096">
      <!-- Select non-Fast Ethernet interfaces with high MTUs -->
    </xsl:if>
  </xsl:otherwise>
</xsl:choose>
```

match Statement

You specify basic match templates using the **match** statement, followed by an expression specifying when the template should be allowed and a block of statements enclosed in a set of braces.

```
match configuration {
  <xnm:error> {
    <message> "...";
  }
}
```

The XSLT equivalent is:

```
<xsl:template match="configuration">
  <xnm:error>
    <message> ...</message>
  </xnm:error>
</xsl:template>
```

For more information about constructing match templates, see [“SLAX Templates Overview” on page 71](#).

ns Statement

You specify namespace definitions using the SLAX **ns** statement. This consists of the **ns** keyword, a prefix string, an equal sign, and a namespace Uniform Resource Identifier (URI). To define the default namespace, use only the **ns** keyword and a namespace URI.

```
ns junos = "http://www.juniper.net/junos/";
```

The **ns** statement can appear after the **version** statement at the beginning of the style sheet or at the beginning of any block.

```
ns a = "http://example.com/1";
ns "http://example.com/global";
ns b = "http://example.com/2";
match / {
  ns c = "http://example.com/3";
  <top> {
    ns a = "http://example.com/4";
    apply-templates commit-script-input/configuration;
  }
}
```

When it appears at the beginning of the style sheet, the **ns** statement can include either the **exclude** or **extension** keyword. The keyword instructs the parser to add the namespace prefix to the **exclude-result-prefixes** or **extension-element-prefixes** attribute.

```
ns exclude foo = "http://example.com/foo";
ns extension jcs = "http://xml.juniper.net/jcs";
```

The XSLT equivalent is:

```
<xsl:stylesheet xmlns:foo="http://example.com/foo"
  xmlns:jcs="http://xml.juniper.net/jcs"
  exclude-result-prefixes="foo"
  extension-element-prefixes="jcs">
  <!-- ... -->
```

```
</xsl:stylesheet>
```

version Statement

All SLAX style sheets must begin with a **version** statement, which specifies the version number for the SLAX language. The current version is **1.0**. SLAX version 1.0 uses XML version 1.0 and XSLT version 1.1.

```
version 1.0;
```

The XSLT equivalent is:

```
<xsl:stylesheet version="1.0">
```

Related Documentation

- [for-each on page 115](#)
- [if on page 116](#)
- [match on page 118](#)
- [version on page 123](#)

XSLT Elements Without SLAX Equivalents

Some XSLT elements are not directly translated into SLAX statements. Some examples of XSLT elements for which there are no SLAX equivalents are **<xsl:fallback>**, **<xsl:output>**, and **<xsl:sort>**.

You can encode these elements directly as normal SLAX elements in the XSLT namespace. For example, you can include the **<xsl:output>** and **<xsl:sort>** elements in a SLAX script, as shown here:

```
<xsl:output method="xml" indent="yes" media-type="image/svg">;  
match * {  
  for-each (configuration/interfaces/unit) {  
    <xsl:sort order="ascending">;  
  }  
}
```

When you include XSLT namespace elements in a SLAX script, do not include closing tags. For empty tags, do not include a forward slash (/) after the tag name. The examples shown in this section demonstrate the correct syntax.

The following XSLT snippet contains a combination of elements, some of which have SLAX counterparts and some of which do not:

```
<xsl:loop select="title">  
  <xsl:fallback>  
    <xsl:for-each select="title">  
      <xsl:value-of select="."/>  
    </xsl:for-each>  
  </xsl:fallback>  
</xsl:loop>
```

The SLAX conversion uses the XSLT namespace for XSLT elements that do not have SLAX counterparts:

```
<xsl:loop select = "title"> {
  <xsl:fallback> {
    for-each (title) {
      expr.;
    }
  }
}
```

SLAX Operators

SLAX provides a variety of operators, which add great versatility to the SLAX scripting language. [Table 12 on page 83](#) summarizes the available operators and provides an example and an explanation of each.

Table 12: SLAX Operators

Name	Operator	Example / Explanation
Addition	+	var \$example = 1 + 1; Assigns the value of 1 + 1 to the \$example variable.
Subtraction, Negation	-	var \$example = 1 - 1; Assigns the value of 1 - 1 to the \$example variable; when used as an unary operator, it changes the sign of a number from positive to negative or from negative to positive.
Multiplication	*	<output>5 * 10; Results in the value 50 being written to the console.
Division	div	<output>\$bit-count div 8; Divides the bits by eight, returning the byte count, and displays the result on the console (requires that \$bit-count has been initialized).
Modulo	mod	<output>10 mod 3; Returns the division remainder of two numbers. In this example, the expression writes 1 to the console.
Equals	==	\$mtu == 1500 If \$mtu is 1500 then the expression resolves to true, otherwise it returns false (requires that \$mtu has been initialized).
Does not equal	!=	\$mtu != 1500 If \$mtu equals 1500 then the result is false, otherwise it returns true (requires that \$mtu has been initialized)

Table 12: SLAX Operators (*continued*)

Name	Operator	Example / Explanation
Less than	<	<p>\$hop-count < 15</p> <p>Returns true if the value to the left of the operator is less than the value to the right, otherwise it returns false. In this example, if \$hop-count is less than 15, the expression returns true (requires that \$hop-count has been initialized).</p>
Less than or equal to	<=	<p>\$hop-count <= 14</p> <p>Returns true if the value to the left of the operator is either less than the value to the right or equal to it, otherwise it returns false. In this example, if \$hop-count is 14 or less, the expression returns true (requires that \$hop-count has been initialized).</p>
Greater than	>	<p>\$hop-count > 0</p> <p>Returns true if the value to the left of the operator is greater than the value to the right, otherwise it returns false. In this example, if \$hop-count is greater than zero, the expression returns true (requires that \$hop-count has been initialized).</p>
Greater than or equal to	>=	<p>\$hop-count >= 1</p> <p>Returns true if the value to the left of the operator is either greater than the value to the right or equal to it, otherwise it returns false. In this example, if \$hop-count is one or greater, the expression returns true (requires that \$hop-count has been initialized).</p>
Parentheses	()	<p>var \$result = (\$byte-count * 8) + 150;</p> <p>Used to create complex expressions. Parentheses function the same way as in a mathematical expression, with the expression within the parentheses evaluated first. Parentheses can be nested; the innermost set of parentheses is evaluated first, then the next set, and so on.</p>
And	&&	<p>\$byte-count > 500000 && \$byte-count < 1000000</p> <p>Evaluates two expressions and returns one boolean result. If either of the two expressions evaluates to false, then the combined expression evaluates to false.</p>
Or		<p>\$mtu-size != 1500 \$mtu-size > 2000</p> <p>Evaluates two expressions and returns one boolean result. If either of the two expressions evaluates to true, then the combined expression evaluates to true.</p>
String concatenation	_ (underscore)	<p>var \$combined-string = \$host-name _ " is located at " _ \$location;</p> <p>Concatenates multiple strings (note that strings cannot be combined using the + operator in SLAX). In the example, if \$host-name is "r1" and \$location is "HQ" then the value of \$combined-string is "r1 is located at HQ".</p>

Table 12: SLAX Operators (*continued*)

Name	Operator	Example / Explanation
Node-Set Union		<pre>var \$all-interface-nodes = \$fe-interface-nodes \$ge-interface-nodes;</pre> <p>Creates a union of two node-sets. All the nodes from one set combine with the nodes in the second set. This is useful when a script needs to perform a similar operation over XML nodes that are pulled from multiple sources.</p>
Result Tree Fragment to Node-Set Conversion	:=	<pre>var \$new-node-set := \$rtf-variable;</pre> <p>A result tree fragment contains an unparsed XML data structure. It is not possible to retrieve any of the embedded XML information from this data type. The := operator converts a variable from a result tree fragment into a node-set. The script can then tell Junos OS to search the node-set for the appropriate information and extract it. Only Junos OS Release 9.2 and beyond support this operator.</p>

Storing and Enabling Scripts

- [Storing and Enabling Scripts on page 86](#)
- [Storing Scripts in Flash Memory on page 87](#)
- [Storing Scripts and Script Functionality in the Script Library on page 88](#)

Storing and Enabling Scripts

To use a script on a switch, router, or security device, you must copy the script to the device and enable it in the configuration.

1. Create the script.
2. Copy the script to the appropriate directory on the device for that script type. Only users who belong to the Junos OS **super-user** login class can access and edit files in the script directories on a device running Junos OS.

By default, scripts are stored in and executed from the **/var/db/scripts** directory on the device's hard drive under the subdirectory appropriate to the script type. EX Series switches use the default directory **/config/db/scripts**. You can also store scripts on the flash drive under the **/config/scripts** directory.

commit script—Copy the script to the **/var/db/scripts/commit** directory on the hard drive or the **/config/scripts/commit** directory on the flash drive.

op script—Copy the script to the **/var/db/scripts/op** directory on the hard drive or the **/config/scripts/op** directory on the flash drive.

event script—Copy the script to the **/var/db/scripts/event** directory on the hard drive or the **/config/scripts/event** directory on the flash drive.

NOTE: If the device has dual Routing Engines and you want to enable the script to execute on both Routing Engines, you must copy it to the appropriate directory on both Routing Engines. The **commit synchronize** command does not automatically copy scripts between Routing Engines.

3. Enable the script by including the **file filename** statement at the appropriate hierarchy level for that script type.

commit script—Include the **file filename** statement at the **[edit system scripts commit]** hierarchy level. For instructions, see [“Controlling Execution of Commit Scripts During Commit Operations”](#) on page 174.

op script—Include the **file filename** statement at the **[edit system scripts op]** hierarchy level. For instructions, see [“Enabling an Op Script and Defining a Script Alias”](#) on page 344.

event script—Include the **file filename** statement at the **[edit event-options event-script]** hierarchy level. For instructions, see [“Enabling an Event Script”](#) on page 470.

4. If you store scripts in and load them from flash memory, include the **load-scripts-from-flash** statement at the **[edit system scripts]** hierarchy level. For detailed information about storing scripts in flash memory, see [“Storing Scripts in Flash Memory”](#) on page 87.

```
[edit]
user@host# set system scripts load-scripts-from-flash
```

5. Issue the **commit** command.

```
[edit]
user@host# commit
```

Newly enabled commit scripts do not execute during the commit operation, but execute automatically during each subsequent commit operation. After the commit operation completes, an op script can be executed on the device. See [“Executing an Op Script” on page 345](#). After the commit operation completes, the event script is loaded into memory and ready for automatic execution in response to system log events. For more information, see [“Executing Event Scripts in an Event Policy” on page 449](#).

Related Documentation

- [Storing Scripts in Flash Memory on page 87](#)
- [Controlling Execution of Commit Scripts During Commit Operations on page 174](#)

Storing Scripts in Flash Memory

By default, scripts are stored in and executed from the **/var/db/scripts/** directory on the device's hard drive under the subdirectory appropriate to the script type.

NOTE: EX Series switches use the default directory **/config/db/scripts/**.

To store scripts in and load them from flash memory instead, include the **load-scripts-from-flash** statement at the **[edit system scripts]** hierarchy level:

```
[edit]
user@host# set system scripts load-scripts-from-flash
```

When you add the **load-scripts-from-flash** statement in the configuration, all commit, event, operation, and script library scripts are loaded from the **/config/scripts/** directory on the flash drive under the subdirectory appropriate to the script type. You must manually move scripts from the hard drive to the flash drive. They are not moved automatically. Similarly, if you delete the **load-scripts-from-flash** statement from the configuration, you must manually copy the scripts from the flash drive to the hard drive to ensure that the current versions of the scripts are executed. Changing the scripts' physical location has no effect on their operation.

The **/var/run/scripts/** directory always links to the directory from which the scripts are loaded. If you do not set the **load-scripts-from-flash** statement in the configuration, **/var/run/scripts/** points to the **/var/db/scripts/** directory on the device's hard drive. If you set the **load-scripts-from-flash** statement in the configuration, **/var/run/scripts/** points to the **/config/scripts/** directory in flash memory.

To view the scripts currently on the device, list the contents of **/var/run/scripts/type/**, where *type* is the subdirectory appropriate to the script type. In the following example, the **load-scripts-from-flash** statement is not configured. In this case, **/var/run/scripts/commit/** points to the **/var/db/scripts/commit/** directory on the hard drive. Listing the files for **/var/run/scripts/commit/** is identical to listing the files in the **/var/db/scripts/commit/** directory.

```
user@host>file list /var/run/scripts/commit
```

```

/var/run/scripts/commit:
commit-changes-load-replace.slax
commit-protect.slax

user@host> file list /var/db/scripts/commit

/var/db/scripts/commit:
commit-changes-load-replace.slax
commit-protect.slax

user@host> file list /config/scripts/commit

/config/scripts/commit:

```

Storing Scripts and Script Functionality in the Script Library

Starting with Junos OS Release 11.1, Junos OS provides a dedicated directory for script libraries, where users can store scripts or script functionality that then can be imported into any commit, event, or op script. Upon installation, Junos OS creates the **/var/db/scripts/lib/** directory with permissions identical to the **commit/**, **event/**, and **op/** directories at the same hierarchy level.

NOTE: On EX Series switches, Junos OS creates the **/config/db/scripts/lib/** directory.

Junos OS will not overwrite or erase any files in an existing **lib/** directory upon installation or upgrade.

If you configure the **load-scripts-from-flash** option at the **[edit system scripts]** hierarchy level, Junos OS creates the **/config/scripts/lib/** directory. When you add or remove the **load-scripts-from-flash** statement in the configuration, you must manually move scripts and script libraries from the hard drive to the flash drive, or vice versa, as appropriate. They are not moved automatically.

To import a script from the script library, include the **<xsl:import>** tag in the style sheet declaration of an XSLT script or include the **import** statement in a SLAX script and specify the file location as shown in the following sample code, which imports the **/var/db/scripts/lib/test.xml** file:

XSLT Syntax	<pre> <?xml version="1.0"?> <xsl:stylesheet version="1.0"> <xsl:import href="../../lib/test.xml"/> ... </xsl:stylesheet> </pre>
-------------	---

SLAX Syntax	<pre> version 1.0; import "../../lib/test.xml"; </pre>
-------------	--

Configuring a Remote Source for Scripts

- [Overview of Updating Scripts from a Remote Source on page 89](#)
- [Using a Master Source Location for a Script on page 90](#)
- [Using an Alternate Source Location for a Script on page 95](#)

Overview of Updating Scripts from a Remote Source

You can update the scripts on a device running Junos OS by retrieving a copy of them from a remote machine (which can be another device running Junos OS or a regular networked computer). This eases file management, because it enables you to update a script in a single location and have devices update their copies from that location. Each device continues to use its locally stored scripts, only updating a script when you issue the appropriate configuration mode command.

For each script, you can define a remote location that houses the master copy of the script, by specifying its URL with the **source** statement at the hierarchy level where you configured the script. When you then issue the **set refresh** configuration mode command for a script, the device running Junos OS updates its local copy by retrieving the remote master copy from that URL.

You can also store a copy of a particular script at a remote location other than the master source. This is convenient when, for example, the master source cannot be accessed due to network issues or other problems. When you issue the **set refresh-from** command for the script, you specify the URL for the remote script as an option to the command.

You can use the **set refresh** and **set refresh-from** commands to update either an individual commit script or all enabled commit scripts on the device. When you issue the **set refresh** or **set refresh-from** command, the switch, router, or security device immediately attempts to connect to the appropriate remote source for each script. If successful, the device updates the local script with the remote source. If a problem occurs, a set of error messages is returned.

Issuing the **set refresh** or **set refresh-from** command does not add the **refresh** and **refresh-from** statements to the configuration. In other words, the **set** command behaves differently for these statements than for others. It behaves like an operational mode command by executing an operation, instead of adding a statement to the configuration.

If a device has dual Routing Engines and you want the script to be updated on both Routing Engines, you must include the **refresh** or **refresh-from** statements in the configuration of both Routing Engines. The **commit synchronize** command does not cause the **refresh** or **refresh-from** statement to update scripts on both Routing Engines.

The **refresh** and **refresh-from** statements are mutually exclusive.

CAUTION: For commit scripts, we recommend that you do not automate the update function by including the **refresh** statement as a commit script change element. Even though this might seem like a good way to ensure that the

most current commit script is always used, we recommend against it for the following reasons:

- Automated update means that the network must be operational for the commit operation to succeed. If the network goes down after you make a configuration error, you cannot recover quickly.
- If multiple commit scripts need to be updated during each commit operation, the network response time can slow down.
- Automated update is always the last action performed during a commit operation. Consequently, the updated commit script executes only during the next commit operation. This is because commit scripts are applied to the candidate configuration before the software copies any persistent changes generated by the scripts to the candidate configuration. In contrast, if you perform the update operation manually, the updated commit script takes effect as expected, that is, immediately after you commit the refresh statement in the configuration.
- If you automate the update operation, the refresh-from statement has no effect, because the refresh-from URL conflicts with and is overridden by the source statement URL. For information about the refresh-from statement, see [“Using an Alternate Source Location for a Script” on page 95](#).

Using a Master Source Location for a Script

- [Configuring and Refreshing from the Master Source for a Script on page 90](#)
- [Example: Configuring and Refreshing from the Master Source for a Script on page 92](#)

Configuring and Refreshing from the Master Source for a Script

You can store a master copy of each script in a central repository. This eases file management because you can make changes to the master script in one place and then update the copy on each device where the script is currently enabled. This section discusses the following concepts:

- [Configuring the Master Source for a Script on page 91](#)
- [Updating a Script from the Master Source on page 91](#)

Configuring the Master Source for a Script

To specify the location of the master source for a script, include the **source** statement at the hierarchy level where the script is configured. Including the **source** statement in the configuration does not affect the local copy of the script until you issue the **set refresh** command. At that point, the master copy is retrieved from the specified URL and overwrites the local copy.

The hierarchy location for the **source** statement depends on the script type and filename.

commit script—Include the **source** statement at the **[edit system scripts commit file filename]** hierarchy level.

```
[edit system scripts commit file filename]
user@R1# set source url
```

op script—Include the **source** statement at the **[edit system scripts op file filename]** hierarchy level.

```
[edit system scripts op file filename]
user@R1# set source url
```

event script—Include the **source** statement at the **[edit event-options event-script file filename]** hierarchy level.

```
[edit event-options event-script file filename]
user@R1# set source url
```

Where

- **filename**—Name of the script.
- **url**—URL of the script's master source file. Specify the source as a Hypertext Transfer Protocol (HTTP) URL, FTP URL, or secure copy (scp)-style remote file specification.

Updating a Script from the Master Source

If you configure a master source for one or more scripts on a device, you can refresh the scripts on that device by issuing the **set refresh** configuration mode command. You can update a single script or all scripts of a given script type that have a master source location configured.

When you issue the **set refresh** command, the switch, router, or security device immediately attempts to connect to the machine that houses the master source for the script file and retrieve a copy of the file. The master copy overwrites the local script stored in the scripts directory on the device. If a master source is not defined for a script, that script is not updated and a warning is issued. For commit scripts, the updated commit script is executed when you next issue the **commit** command.

The update operation occurs as soon as you issue the **set refresh** command. The **refresh** statement is not added to the configuration. Thus the **set refresh** command behaves like an operational mode command, instead of adding a statement to the configuration.

If the device has dual Routing Engines and you want to update a script on both Routing Engines, you must issue the **set refresh** command on each Routing Engine separately.

The **commit synchronize** command does not cause the **refresh** statement to update scripts on both Routing Engines.

To update a single script from its master source, issue the **set refresh** command at the hierarchy level where the script is configured. The **source** statement specifying the master source location must already be configured.

commit script—Issue the **set refresh** command at the [edit system scripts commit file *filename*] hierarchy level.

```
[edit system scripts commit file filename]  
user@R1# set refresh
```

op script—Issue the **set refresh** command at the [edit system scripts op file *filename*] hierarchy level.

```
[edit system scripts op file filename]  
user@R1# set refresh
```

event script—Issue the **set refresh** command at the [edit event-options event-script file *filename*] hierarchy level.

```
[edit event-options event-script file filename]  
user@R1# set refresh
```

Where *filename* is the name of the script.

To update all enabled scripts of a given script type from their master source files, issue the **set refresh** command at the hierarchy level for that script type.

commit scripts—Issue the **set refresh** command at the [edit system scripts commit] hierarchy level:

```
[edit system scripts commit]  
user@R1# set refresh
```

op scripts—Issue the **set refresh** command at the [edit system scripts op] hierarchy level:

```
[edit system scripts op]  
user@R1# set refresh
```

event scripts—Issue the **set refresh** command at the [edit event-options event-script] hierarchy level:

```
[edit event-options event-script]  
user@R1# set refresh
```

Example: Configuring and Refreshing from the Master Source for a Script

The following example configures a master source file for an op script on a device running Junos OS. The remote source is defined as an HTTP URL. The example uses the master source to update the local copy of the script on the device.

- [Requirements on page 93](#)
- [Overview on page 93](#)

- [Configuration on page 93](#)
- [Verification on page 94](#)

Requirements

- Routing, switching, or security device running Junos OS.

Overview

You can store a master copy of each script in a central repository. You can make changes to the master script in one place and then update the local copy of the script on devices where the script is enabled.

This example enables the `op` script `iso.xml` on a device running Junos OS and then configures a master source location for the script. The remote source for the `iso.xml` file is the HTTP URL `http://my.example.com/pub/scripts/iso.xml`.

Once you configure the master source location, you refresh the local script by issuing the `set refresh` configuration mode command at the hierarchy level where you configured the script. In this example, you would issue the `set refresh` command at the `[edit system scripts op file iso.xml]` hierarchy level.

Configuration

Step-by-Step Procedure

To download, enable, and configure the master source location for the script:

1. Copy the script to the `/var/db/scripts/op/` directory on the device.
2. In configuration mode, configure the `file` statement to enable the `iso.xml` script.

```
[edit system scripts op]
user@R1# set file iso.xml
```
3. To configure the master source for the `iso.xml` file, include the `source` statement and source location at the `[edit system scripts op file iso.xml]` hierarchy level.

```
[edit system scripts op file iso.xml]
user@R1# set source http://my.example.com/pub/scripts/iso.xml
```
4. Issue the `commit and-quit` command to commit the configuration and exit to operational mode.

```
[edit]
user@R1# commit and-quit
```

Results

```
system {
  scripts {
    op {
      file iso.xml {
        source http://my.example.com/pub/scripts/iso.xml;
      }
    }
  }
}
```

Verifying the Script

Purpose Verify that the script is on the device and enabled in the configuration.

Action Issue the **file list** operational mode command to view the files in the specified directory. The **detail** option provides additional information such as permissions, file size, and modified date.

```
user@R1> file list /var/db/scripts/op detail
```

```
/var/db/scripts/op:
total 128
-rw-r--r--  1 root  admin  13897 Feb 10  2011 iso.xml
...
```

Issue the **show configuration system scripts op** operational mode command to list the op scripts currently enabled on the device.

```
user@R1> show configuration system scripts op
file iso.xml
```

Refreshing the Script from the Master Source

Step-by-Step Procedure To refresh the local copy of the script from the master source file:

1. In configuration mode, issue the **set refresh** command at the **[edit system scripts op file iso.xml]** hierarchy level.

```
[edit system scripts op file iso.xml]
user@R1# set refresh
```

Verification

Verifying the Updated Script

Purpose After refreshing the script, verify that the local copy is updated.

Action Issue the **file list** operational mode command with the **detail** option to view the files in the specified directory. Verify that the modified date reflects the refreshed version.

```
user@R1> file list /var/db/scripts/op detail
```

```
/var/db/scripts/op:
total 128
-rw-r--r--  1 root  admin  14128 May 26  2011 iso.xml
...
```

- [refresh \(Event Scripts\) on page 523](#)

Using an Alternate Source Location for a Script

- [Refreshing a Script from an Alternate Location on page 95](#)
- [Example: Refreshing a Script from an Alternate Source on page 96](#)

Refreshing a Script from an Alternate Location

In addition to updating a script from the master source defined by the **source** statement at the **[edit event-options event-script file filename]** hierarchy level, you also can update a script from an alternate location. This is convenient when, for example, the master source cannot be accessed due to network issues or other problems.

When you issue the **set refresh-from** command, the switch, router, or security device immediately attempts to connect to the machine that houses the alternate source for the script file and retrieve a copy of the file. The copy overwrites the local script stored in the scripts directory on the device. If a copy of the source is not available, that script is not updated and a warning is issued. For commit scripts, the updated commit script is executed when you next issue the **commit** command.

The update operation occurs as soon as you issue the **set refresh-from** command. The **refresh-from** statement is not added to the configuration. Thus the **set refresh-from** command behaves like an operational mode command, instead of adding a statement to the configuration.

If a device has dual Routing Engines and you want the script to be updated on both Routing Engines, you must issue the **set refresh-from** command on each Routing Engine separately. The **commit synchronize** command does not cause the **refresh-from** statement to update scripts on both Routing Engines.

When you issue the **set refresh-from** command, Junos OS creates a folder in the **/var/tmp** directory. This folder is used for file transfer. After the transfer and refresh operations are complete, Junos OS deletes the temporary folder.

To update a single script from the alternate source, issue the **set refresh-from** command at the hierarchy level where the script is configured, and specify the location of the remote file.

commit script—Issue the **set refresh-from** command at the **[edit system scripts commit file filename]** hierarchy level.

```
[edit system scripts commit file filename]
user@R1# set refresh-from url
```

op script—Issue the **set refresh-from** command at the **[edit system scripts op file filename]** hierarchy level.

```
[edit system scripts op file filename]
user@R1# set refresh-from url
```

event script—Issue the **set refresh-from** command at the **[edit event-options event-script file filename]** hierarchy level.

```
[edit event-options event-script file filename]
user@R1# set refresh-from url
```

To update all enabled scripts of a given script type from an alternate source, issue the **set refresh-from** command at the hierarchy level for that script type, and specify the location of the remote directory that houses the scripts.

commit script—Issue the **set refresh-from** command at the **[edit system scripts commit]** hierarchy level.

```
[edit system scripts commit]
user@R1# set refresh-from url
```

op script—Issue the **set refresh-from** command at the **[edit system scripts op]** hierarchy level.

```
[edit system scripts op]
user@R1# set refresh-from url
```

event script—Issue the **set refresh-from** command at the **[edit event-options event-script]** hierarchy level.

```
[edit event-options event-script]
user@R1# set refresh-from url
```

Where

url—URL of the remote script or directory. Specify the source as a Hypertext Transfer Protocol (HTTP) URL, FTP URL, or secure copy (scp)-style remote file specification.

Example: Refreshing a Script from an Alternate Source

The following example uses an alternate source location to update the local copy of the script on a device running Junos OS. The remote source is defined as an HTTP URL.

- [Requirements on page 96](#)
- [Overview on page 96](#)
- [Configuration on page 97](#)
- [Verification on page 98](#)

Requirements

- Routing, switching, or security device running Junos OS.

Overview

You can update a script from a location other than that of the master source. This is convenient when, for example, the master source cannot be accessed due to network issues or other problems. You can refresh a single script or all scripts of a given type from the alternate location.

This example enables the op script **iso.xsl** on a device running Junos OS and then refreshes the script from a location other than the master source location. The remote source for the **iso.xsl** file is the HTTP URL **http://my.example.com/pub/scripts2/iso.xsl**.

You refresh the local script by issuing the **set refresh-from** configuration mode command at the hierarchy level where you configured the script. In this example, you would issue the **set refresh-from** command at the **[edit system scripts op file iso.xsl]** hierarchy level.

Configuration**Step-by-Step Procedure**

To download and enable the script:

1. Copy the script to the `/var/db/scripts/op/` directory on the device.
2. In configuration mode, configure the `file` statement to enable the `iso.xml` script.

```
[edit system scripts op]
user@R1# set file iso.xml
```

3. Issue the `commit and-quit` command to commit the configuration and exit to operational mode.

```
[edit]
user@R1# commit and-quit
```

Results

```
system {
  scripts {
    op {
      file iso.xml;
    }
  }
}
```

Verifying the Script

Purpose Verify that the script is on the device and enabled in the configuration.

Action Issue the `file list` operational mode command to view the files in the specified directory. The `detail` option provides additional information such as permissions, file size, and modified date.

```
user@R1> file list /var/db/scripts/op detail
```

```
/var/db/scripts/op:
total 128
-rw-r--r--  1 root  admin  13897 Feb 10  2011 iso.xml
...
```

Issue the `show configuration system scripts op` operational mode command to list the `op` scripts currently enabled on the device.

```
user@R1> show configuration system scripts op
file iso.xml
```

Refreshing the Script from the Alternate Location**Step-by-Step Procedure**

To refresh the local copy of the script from the alternate location:

1. In configuration mode, issue the `set refresh-from` command at the `[edit system scripts op file iso.xml]` hierarchy level.

```
[edit system scripts op file iso.xml]
user@R1# set refresh-from http://my.example.com/pub/scripts2/iso.xml
```

Verification

Verifying the Updated Script

Purpose After refreshing the script, verify that the local copy is updated.

Action Issue the **file list** operational mode command with the **detail** option to view the files in the specified directory. Verify that the modified date reflects the refreshed version.

```
user@R1> file list /var/db/scripts/op detail

/var/db/scripts/op:
total 128
-rw-r--r--  1 root  admin  14128 May 26  2011 iso.xsl
...
```

Session Protocol in Junos Automation Scripts Overview

The Junos XML management protocol is a Juniper Networks proprietary protocol used to request information from and configure devices running Junos OS. The NETCONF XML management protocol is a standard used to request and change configuration information on a routing, switching, or security device. The NETCONF protocol is defined in [RFC 4741](#), *NETCONF Configuration Protocol*, which is available at <http://www.ietf.org/rfc/rfc4741.txt>.

Starting with Junos OS Release 11.4, the **jcs:open()** function includes the option to create a session either with the Junos XML protocol server on devices running Junos OS or with the NETCONF server on devices where NETCONF service over SSH is enabled. Previously, the function supported only sessions with the Junos XML protocol server on devices running Junos OS. The additional support for NETCONF sessions permits automation scripts to configure and manage devices in a multi-vendor environment.

The **jcs:open()** function supports the following session protocol types:

- **junoscript**—Session with the Junos XML protocol server on a routing, switching, or security device running Junos OS. This session type supports the operations defined in the Junos XML protocol and the Junos XML API, which are used to configure devices running Junos OS or to request information about the device configuration or operation. This is the default session type.
- **netconf**—Session with the NETCONF XML protocol server on a routing, switching, or security device over an SSHv2 connection. The device to which the connection is made must be enabled for NETCONF service over SSH. NETCONF over SSH is described in [RFC 4742, Using the NETCONF Configuration Protocol over Secure SHell \(SSH\)](#), which is available at <http://www.ietf.org/rfc/rfc4742.txt>.
- **junos-netconf**—Proprietary session with the NETCONF XML protocol server over an SSHv2 connection on a routing, switching, or security device running Junos OS.

The NETCONF server on a device running Junos OS has the additional capabilities defined in <http://xml.juniper.net/netconf/junos/1.0>. The NETCONF server on these devices supports NETCONF XML protocol operations, most Junos XML protocol operations, and the tag elements defined in the Junos XML API. For **netconf** and **junos-netconf** sessions with devices running Junos OS, you should use only native NETCONF XML protocol operations and the extensions available in the Junos XML protocol.

The syntax for the `jcs:open()` function when specifying a session protocol is:

SLAX Syntax `var $connection = jcs:open(remote-hostname, session-options);`

XSLT Syntax `<xsl:variable name="connection" select="jcs:open(remote-hostname,session-options)"/>`

The *session-options* parameter is an XML node-set that specifies the session type and connection parameters. The session type is one of three values: **junoscript**, **netconf**, or **junos-netconf**. If you do not specify a session type, the default is **junoscript**, which opens a session with the Junos XML protocol server only on devices running Junos OS. The format of the node-set is:

```
var $session-options := {
  <method> ("junoscript" | "netconf" | "junos-netconf");
  <username> "username";
  <passphrase> "passphrase";
  <password> "passphrase";
  <port> "port-number";
}
```

If you do not specify a username and it is required for the connection, the script uses the local name of the user executing the script. The `<passphrase>` and `<password>` elements serve the same purpose. If you do not specify a passphrase or password element and it is required for authentication, you should be prompted for one during script execution by the device to which you are connecting.

Optionally, you can specify the server port number for **netconf** and **junos-netconf** sessions. The default NETCONF server port number is 830. If you do not specify a port number for a **netconf** or **junos-netconf** session, `jcs:open()` connects to the NETCONF server using port 830. However, if you specify a port number, `jcs:open()` connects to the given port

instead. Specifying a port number has no impact on **junoscript** sessions, which are always established over SSH port 22.

To verify the protocol for a specific connection, call the **jcs:get-protocol(connection)** extension function and pass the connection handle as the argument. The function returns "junoscript", "netconf", or "junos-netconf", depending on the session type.

During session establishment with a NETCONF server, the client application and NETCONF server each emit a **<hello>** tag element to specify which operations, or *capabilities*, they support from among those defined in the NETCONF specification or published as proprietary extensions. In **netconf** and **junos-netconf** sessions, you can retrieve the session capabilities of the NETCONF server by calling the **jcs:get-hello(connection)** extension function.

For example, the NETCONF server on a typical device running Junos OS might return the following capabilities:

```
<hello>
  <capabilities>
    <capability>urn:ietf:params:xml:ns:netconf:base:1.0</capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:candidate:1.0
    </capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:confirmed-commit:1.0
    </capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:validate:1.0
    </capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:url:1.0?protocol=http,ftp,file
    </capability>
    <capability>http://xml.juniper.net/netconf/junos/1.0</capability>
    <capability>http://xml.juniper.net/dmi/system/1.0</capability>
  </capabilities>
  <session-id>20826</session-id>
</hello>
```

Example: Specifying the Session Protocol for a Connection Using an Automation Script

The following example demonstrates how to specify the session protocol within a Junos automation script when creating a connection with a remote device. Specifically, the example op script establishes a NETCONF session with a remote device running Junos OS, retrieves and prints the NETCONF server capabilities, and then updates and commits the configuration on that device.

- [Requirements on page 100](#)
- [Overview and Script on page 101](#)
- [Configuration on page 106](#)
- [Verification on page 106](#)
- [Troubleshooting on page 109](#)

Requirements

- Routing, switching, or security device running Junos OS Release 11.4 or later.

- Client application can log in to the device where the NETCONF server resides.
- NETCONF service over SSH is enabled on the device where the NETCONF server resides.

Overview and Script

Starting with Junos OS Release 11.4, the `jcs:open()` function includes the option to create a session either with the Junos XML protocol server on devices running Junos OS or with the NETCONF server on devices where NETCONF service over SSH is enabled. In the following example, the script creates a connection and establishes a NETCONF session with a remote device running Junos OS. If the connection and session are successfully established, the script updates the configuration on the remote device to add the `ftp` statement to the `[edit system services]` hierarchy level. The script also retrieves and prints the session protocol and the capabilities of the NETCONF server.

The script takes one argument, `remote-host`, which is the IP address or hostname of the remote device. The `arguments` variable is declared at the global level of the script so that the argument name and description are visible in the command-line interface (CLI) when a user requires context-sensitive help.

The variable `netconf` is a node-set that specifies the session protocol and the connection parameters for the remote device. The value of the `<method>` element is set to "netconf" to establish a session with the NETCONF server over an SSHv2 connection. The `<username>` element specifies the username for the connection. If you do not specify a username and it is required for the connection, the script uses the local name of the user executing the script. In this example, the passphrase and port are not specified. If a passphrase is required for authentication, the remote device should prompt for one during script execution. The script establishes the session using the default NETCONF port 830.

If the connection and establishment of the NETCONF session are successful, the script executes remote procedure calls (RPCs). The RPCs contain the tag elements `<lock>`, `<edit-config>`, `<commit>`, and `<unlock>`, which are NETCONF operations to lock, edit, commit, and unlock the candidate configuration. The script stores the RPC for each task in a separate variable. The results for each RPC are also stored separately and parsed for errors. The script only executes each subsequent step if the previous step is successful. For example, if the script cannot lock the configuration, it does not execute the RPCs to edit, commit, or unlock the configuration.

The variable `rpc-edit-config` contains the tag element `<edit-config>`, which is a NETCONF operation to modify a configuration. The child element, `<config>`, includes the modified portion of the configuration that is merged with the candidate configuration on the device. If errors are encountered, the script calls the `copy-of` statement to copy the result tree fragment variable to the results tree so that the error message prints to the CLI during script execution.

SLAX Syntax

</xsl:stylesheet>

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **netconf-session.xml** or **netconf-session.slax** as appropriate, and copy it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **netconf-session.xml** or **netconf-session.slax** as appropriate.

```

[edit system scripts op]
bsmith@local-host# set file netconf-session.(slax | xml)

```

3. Issue the **commit and-quit** command.

```

[edit]
bsmith@local-host# commit and-quit

```

4. Execute the op script on the local device by issuing the **op netconf-session** operational mode command and include any necessary arguments.

In this example, the user, bsmith, is connecting to the remote device, fivestar. The remote device has dual routing engines, so the **commit** operation returns a warning that the **commit synchronize** command should be used to commit the new candidate configuration to both routing engines.

```

bsmith@local-host> op netconf-session remote-host fivestar
bsmith@fivestar's password:
Session protocol: netconf
Commit error or warning:
graceful-switchover is enabled, commit synchronize should be used

```

Verification

Confirm that the device is working properly.

- [Verifying Op Script Execution on page 106](#)
- [Verifying the Configuration Changes on page 108](#)

Verifying Op Script Execution

Purpose Verify that the script behaves as expected.

Action Review the script output in the CLI and in the op script log file. Take particular note of any errors that occurred during execution. The default op script log file is

`/var/log/op-script.log`. If the log file is significantly lengthy, limit the display by appending the `| last number-of-lines` option to the `show log` command and specify the number of lines to print to the CLI. The output within the `<op-script-results>` element is relevant to the script execution.

```
bsmith@local-host> show log op-script.log | last 100
...output omitted for brevity...
<op-script-results xmlns:junos="http://xml.juniper.net/junos/*/junos"
xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm" xml
ns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0"
xmlns:ext="http://xmlsoft.org/XSLT/namespace">
<output>
Session protocol: netconf
</output>
<hello>
  <capabilities>
    <capability>urn:ietf:params:xml:ns:netconf:base:1.0</capability>
    <capability>urn:ietf:params:xml:ns:netconf:capability:candidate:1.0
    </capability>
    <capability>urn:ietf:params:xml:ns:netconf:capability:confirmed-commit:1.0
    </capability>
    <capability>urn:ietf:params:xml:ns:netconf:capability:validate:1.0</capability>

    <capability>
      urn:ietf:params:xml:ns:netconf:capability:url:1.0?protocol=http,ftp,file
    </capability>
    <capability>http://xml.juniper.net/netconf/junos/1.0</capability>
    <capability>http://xml.juniper.net/dmi/system/1.0</capability>
  </capabilities>
  <session-id>29087</session-id>
</hello>
  <output>Commit error or warning:
graceful-switchover is enabled, commit synchronize should be used
</output>
  <rpc-error>
<error-severity>warning</error-severity>
<error-message>
graceful-switchover is enabled, commit synchronize should be used
</error-message>
</rpc-error>
  <ok/>
</op-script-results>
```

You can also obtain more descriptive script output on a device running Junos OS by including the `| display xml` option when you execute an op script.

```
bsmith@local-host> op netconf-session remote-host fivestar | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/11.4D0/junos">
  <output>
    Session protocol: netconf
  </output>
  <hello>
    <capabilities>
      <capability>
        urn:ietf:params:xml:ns:netconf:base:1.0
      </capability>
      <capability>
        urn:ietf:params:xml:ns:netconf:capability:candidate:1.0
      </capability>
      <capability>
```

```

        urn:ietf:params:xml:ns:netconf:capability:confirmed-commit:1.0
    </capability>
    <capability>
        urn:ietf:params:xml:ns:netconf:capability:validate:1.0
    </capability>
    <capability>
        urn:ietf:params:xml:ns:netconf:capability:url:1.0?protocol=http,ftp,file
    </capability>
    <capability>
        http://xml.juniper.net/netconf/junos/1.0
    </capability>
    <capability>
        http://xml.juniper.net/dmi/system/1.0
    </capability>
</capabilities>
<session-id>
    29087
</session-id>
</hello>
<output>
    Commit error or warning:
    graceful-switchover is enabled, commit synchronize should be used
</output>
<rpc-error>
    <error-severity>
        warning
    </error-severity>
    <error-message>
        graceful-switchover is enabled, commit synchronize should be used
    </error-message>
</rpc-error>
<ok/>
</op-script-results>
<cli>
    <banner></banner>
</cli>
</rpc-reply>

```

Meaning This example creates a NETCONF session on a remote device running Junos OS. The capabilities of the NETCONF server include both standard NETCONF operations and Juniper Networks proprietary extensions, which are defined in <http://xml.juniper.net/netconf/junos/1.0> and <http://xml.juniper.net/dmi/system/1.0>. The RPC results for the **commit** operation include one warning, but the commit operation is still successful.

Verifying the Configuration Changes

Purpose Verify that the commit was successful by viewing the configuration change and the commit log on the remote device.

Action On the remote device, execute the **show configuration system services** operational mode command to view the **[edit system services]** hierarchy level of the configuration. If the script is successful, the configuration includes the **ftp** statement.

```
bsmith@fivestar> show configuration system services
ftp;
netconf {
    ssh;
}
```

Additionally, you can review the commit log. On the remote device, execute the **show system commit** operational mode command to view the commit log. In this example, the log confirms that bsmith committed the candidate configuration in a NETCONF session at the given date and time.

```
bsmith@fivestar> show system commit
0   2011-07-11 12:04:01 PDT by bsmith via netconf

Troubleshooting

- [Troubleshooting Connection Errors on page 109](#)
- [Troubleshooting Configuration Lock Errors on page 110](#)
- [Troubleshooting Configuration Syntax Errors on page 111](#)

Troubleshooting Connection Errors

Problem The script generates the following error message:

```
hello packet:1:(0) Document is empty
hello packet:1:(0) Start tag expected, '<' not found
error: netconf: could not read hello
error: did not receive hello packet from server
error: Error in creating the session with "fivestar" server
No connection - exiting script
```

Potential causes for the connection error include:

- The device or interface to which you are connecting is down or unavailable.
- The script argument for the IP address or DNS name of the remote device is incorrect.
- The connection timeout value was exceeded before establishing the connection.
- The user authentication for the remote device is not valid or is entered incorrectly.
- You are trying to establish a NETCONF session, and NETCONF over SSH is not enabled on the device where the NETCONF server resides, or it is enabled on a different port.

Solution Ensure that the remote device is up and running and that the user has access to the device. Also verify that you supplied the correct argument for the IP address or DNS name of the remote device when executing the script.

For NETCONF sessions, ensure that you have enabled NETCONF over SSH on the device where the NETCONF server resides. Since the example program does not specify a specific port number for the NETCONF session, the session is established on the default

NETCONF-over-SSH port, 830. To verify whether NETCONF over SSH is enabled on the default port for a device running Junos OS, enter the following operational mode command on the remote device:

```
bsmith@fivestar> show configuration system services
```

```
netconf {
  ssh;
}
```

If the **netconf** configuration hierarchy is absent on the remote device, issue the following statements in configuration mode to enable NETCONF over SSH on the default port:

```
[edit]
bsmith@fivestar# set system services netconf ssh
bsmith@fivestar# commit
```

If the **netconf** configuration hierarchy specifies a port other than the default port, include the port number in the XML node-set that you pass to the **jcs:open()** function. For example, the following device is configured for NETCONF over SSH on port 12345:

```
bsmith@fivestar> show configuration system services
netconf {
  ssh {
    port 12345;
  }
}
```

To create a NETCONF session on the alternate port, include the new port number in the XML node-set.

```
var $netconf := {
  <method> "netconf";
  <username> "bsmith";
  <port> "12345";
}
var $connection = jcs:open($remote-host, $netconf);
...
```

Troubleshooting Configuration Lock Errors

Problem The script generates one of the following error messages:

```
configuration database locked by:
  root terminal p0 (pid 24113) on since 2011-07-11 11:48:06 PDT, idle 00:07:59

Users currently editing the configuration:
  root terminal p1 (pid 24279) on since 2011-07-11 12:28:30 PDT
  {master}[edit]

configuration database modified
```

Solution Another user currently has a lock on the candidate configuration or has modified the candidate configuration but has not yet committed the configuration. Wait until the lock is released, and then execute the program.

Troubleshooting Configuration Syntax Errors

Problem The following error message prints to the CLI:

```
Configuration error: syntax error
Configuration not committed.
```

Examine the result tree for additional information. In this case, the result tree shows the following error message:

```
<rpc-error>
  <error-severity>
    error
  </error-severity>
  <error-info>
    <bad-element>
      ftp2
    </bad-element>
  </error-info>
  <error-message>
    syntax error
  </error-message>
</rpc-error>
```

Solution The **<bad-element>** tag element indicates that the configuration statement is not valid. Correct the configuration hierarchy and run the script. In this example error, the user entered the tag **<ftp2>** instead of **<ftp>**. Since that is not an acceptable element in the configuration, the NETCONF server returns an error.

apply-templates

Syntax	<code>apply-templates <i>expression</i>;</code>
Description	Apply one or more templates, according to the value of the node-set expression. If a node-set expression is not specified, the script recursively processes all child nodes of the current node. If a node-set expression is specified, the processor only applies templates to the child elements that match the node-set expression. The template statement dictates which elements are transformed according to which template. The templates that are applied are passed the parameters specified by the with statement within the apply-templates statement block.
Attributes	<i>expression</i> —(Optional) Selects the nodes to which the processor applies templates. By default, the processor applies templates to the child nodes of the current node.
SLAX Example	<pre>match configuration { apply-templates system/host-name; }</pre>
XSLT Equivalent	<pre><xsl:template match="configuration"> <xsl:apply-templates select="system/host-name"/> </xsl:template></pre>
Usage Examples	See “ Example: Adding a Final then accept Term to a Firewall ” on page 215 and “ Example: Preventing Import of the Full Routing Table ” on page 300.
Related Documentation	<ul style="list-style-type: none">• SLAX Templates Overview on page 71• call on page 112• match on page 118• mode on page 118• priority on page 120• template on page 121• with on page 123

call

Syntax	<code>call <i>template-name</i> (<i>parameter-name</i> = <i>value</i>) { /* code */ }</code>
---------------	--

Description Call a named template. You can pass parameters into the template by including a comma-separated list of parameters, with the parameter name and an optional equal sign (=) and value expression. If a value is not specified, the current value of the parameter is passed to the template.

You can declare additional parameters inside the code block using the **with** statement.

Attributes *template-name*—Specifies the name of the template to call.

SLAX Example

```
match configuration {
  var $name-servers = name-servers/name;
  call temp();
  call temp($name-servers, $size = count($name-servers));
  call temp() {
    with $name-servers;
    with $size = count($name-servers);
  }

  template temp($name-servers, $size = 0) {
    <output> "template called with size " _ $size;
  }
}
```

XSLT Equivalent

```
<xsl:template match="configuration">
  <xsl:variable name="name-servers" select="name-servers/name"/>
  <xsl:call-template name="temp"/>
  <xsl:call-template name="temp">
    <xsl:with-param name="name-servers" select="$name-servers"/>
    <xsl:with-param name="size" select="count($name-servers)"/>
  </xsl:call-template>
  <xsl:call-template name="temp">
    <xsl:with-param name="name-servers" select="$name-servers"/>
    <xsl:with-param name="size" select="count($name-servers)"/>
  </xsl:call-template>
</xsl:template>

<xsl:template name="temp">
  <xsl:param name="name-servers"/>
  <xsl:param name="size" select="0"/>
  <output>
    <xsl:value-of select="concat('template called with size ', $size)"/>
  </output>
</xsl:template>
```

Usage Examples See [“Example: Requiring and Restricting Configuration Statements” on page 306](#), [“Example: Imposing a Minimum MTU Setting” on page 266](#), and [“Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227](#).

- [template on page 121](#)
- [with on page 123](#)

else

Syntax

```
if (expression) {
    /* code */
}
else {
    /* code */
}
```

Description Include a default set of instructions that are processed if the preceding **if** and **else if** statements evaluate to FALSE.

SLAX Example

```
if (starts-with(name, "fe-")) {
    if (mtu < 1500) {
        /* Select the Fast Ethernet interfaces with low MTUs */
    }
}
else {
    if (mtu > 8096) {
        /* Select the non-Fast Ethernet interfaces with high MTUs */
    }
}
```

XSLT Equivalent

```
<xsl:choose>
  <xsl:when select="starts-with(name, 'fe-')">
    <xsl:if test="mtu &lt; 1500">
      <!-- Select with Fast Ethernet interfaces with low MTUs -->
    </xsl:if>
  </xsl:when>
  <xsl:otherwise>
    <xsl:if test="mtu &gt; 8096">
      <!-- Select the non-Fast Ethernet interfaces with high MTUs -->
    </xsl:if>
  </xsl:otherwise>
</xsl:choose>
```

Usage Examples See [“Example: Configuring Dual Routing Engines” on page 242](#) and [“Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227](#).

- Related Documentation**
- [SLAX Statements Overview on page 79](#)
 - [else if on page 115](#)
 - [for-each on page 115](#)
 - [if on page 116](#)

else if

Syntax

```

if (expression) {
    /* code */
}
else if (expression) {
    /* code */
}

```

Description Include instructions that are processed if the expression defined in the preceding **if** statement evaluates to FALSE and the expression defined in the **else if** statement evaluates to TRUE. Multiple **else if** statements can be included, but the processor only executes the instructions contained in the first **else if** statement whose expression evaluates to TRUE. All subsequent **else if** statements are ignored.

SLAX Example

```

var $description2 = {
    if (description) {
        expr description;
    }
    else if (../description) {
        expr ../description;
    }
    else {
        expr "no description found";
    }
}

```

XSLT Equivalent

```

<xsl:variable name="description2">
  <xsl:choose>
    <xsl:when test="description">
      <xsl:value-of select="description"/>
    </xsl:when>
    <xsl:when test="../description">
      <xsl:value-of select="../description"/>
    </xsl:when>
    <xsl:otherwise>unknown</xsl:otherwise>
  </xsl:choose>
</xsl:variable>

```

Usage Examples See [“Example: Configuring Dual Routing Engines” on page 242](#) and [“Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227](#).

Related Documentation

- [for-each on page 115](#)
- [if on page 116](#)

for-each

Syntax

```

for-each (expression) {

```

```

    /* code */
}

```

Description Include a looping mechanism that repeats script processing for each XML element in the specified node-set. The element nodes are selected by the value of the XPath expression. Each of the nodes is then processed according to the instructions contained in the **for-each** code block.

The statement consists of the **for-each** keyword, the parentheses-delimited XPath expression, and a curly braces-delimited block. The SLAX **for-each** statement functions like the `<xsl:for-each>` element.

Attributes *expression*—Specifies an XPath expression that selects the nodes to be processed.

SLAX Example

```

for-each ($inventory/chassis/chassis-module/
  chassis-sub-module[part-number == '750-000610']) {
  <message> "Down rev PIC in " ../name _ " " _name _ ": " _description;
}

```

XSLT Equivalent

```

<xsl:for-each select="$inventory/chassis/chassis-module/
  chassis-sub-module[part-number == '750-000610']">
  <message>
    <xsl:value-of select="concat('Down rev PIC in ', ../name, ', ', name, ': ',
      description)"/>
  </message>
</xsl:for-each>

```

Usage Examples See [“Example: Requiring and Restricting Configuration Statements”](#) on page 306, [“Example: Imposing a Minimum MTU Setting”](#) on page 266, [“Example: Limiting the Number of E1 Interfaces”](#) on page 272, [“Example: Adding T1 Interfaces to a RIP Group”](#) on page 220, [“Example: Configuring Administrative Groups for LSPs”](#) on page 234, and [“Example: Configuring Dual Routing Engines”](#) on page 242.

- [if](#) on page 116
- [xsl:for-each](#) on page 134

if

Syntax

```

if (expression) {
  /* code */
}
else if (expression) {
  /* code */
}

```

```

else {
    /* code */
}

```

Description Include a conditional construct that causes instructions to be processed if the Boolean expression evaluates to TRUE.

Optionally, you can include multiple **else if** statements following an **if** statement to perform additional conditional tests if the expression in the **if** statement evaluates to FALSE. Multiple **else if** statements can be included, but the processor only executes the instructions contained in the first **else if** statement whose expression evaluates to TRUE; all subsequent **else if** statements are ignored. The optional **else** statement includes a default set of instructions that are processed if the expressions defined in all associated **if** and **else if** statements evaluate to FALSE.

Attributes *expression*—Specifies the expression to evaluate.

SLAX Example

```

var $description2 = {
    if (description) {
        expr description;
    }
    else if (../description) {
        expr ../description;
    }
    else {
        expr "no description found";
    }
}

```

XSLT Equivalent

```

<xsl:variable name="description2">
  <xsl:choose>
    <xsl:when test="description">
      <xsl:value-of select="description"/>
    </xsl:when>
    <xsl:when test="../description">
      <xsl:value-of select="../description"/>
    </xsl:when>
    <xsl:otherwise>unknown</xsl:otherwise>
  </xsl:choose>
</xsl:variable>

```

Usage Examples See [“Example: Configuring Dual Routing Engines” on page 242](#), [“Example: Preventing Import of the Full Routing Table” on page 300](#), and [“Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227](#).

match

Syntax	<pre>match <i>expression</i> { <i>statements</i>; }</pre>
Description	Declare a template that contains rules to apply when a specified node is matched. The match statement associates the template with an XML element. The match statement can also be used to define a template for a whole branch of the XML document. For example, match / matches the root element of the document.
Attributes	expression —XPath expression specifying the nodes to which to apply the template.
SLAX Example	<pre>match host-name { <hello> .; }</pre>
XSLT Equivalent	<pre><xsl:template match="host-name"> <hello> <xsl:value-of select="."/> </hello> </xsl:template></pre>
Usage Examples	“Example: Adding a Final then accept Term to a Firewall” on page 215 , “Example: Configuring Dual Routing Engines” on page 242 , and “Example: Preventing Import of the Full Routing Table” on page 300 .
Related Documentation	<ul style="list-style-type: none"> • apply-templates on page 112 • call on page 112 • mode on page 118 • priority on page 120 • template on page 121 • with on page 123

mode

Syntax	<pre>mode <i>qualified-name</i>;</pre>
Description	<p>Indicate the mode in which a template needs to be applied for the template to be used. If templates are applied in the specified mode, the match statement is used to determine whether the template can be used with the particular node. If more than one template matches a node in the specified mode, the priority statement determines which template is used. The highest priority wins. If no priority is specified explicitly, the priority of a template is determined by the match statement.</p>

This statement is comparable to the **mode** attribute of the **<xsl:template>** element. You can include this statement inside a SLAX **match** or **apply-templates** statement.

SLAX Example

```

match * {
  mode "one";
  <one> .;
}

match * {
  mode "two";
  <two> string-length(.);
}

match / {
  apply-templates version {
    mode "one";
  }
  apply-templates version {
    mode "two";
  }
}

```

XSLT Equivalent

```

<xsl:template match="*" mode="one">
  <one>
    <xsl:value-of select="."/>
  </one>
</xsl:template>

<xsl:template match="*" mode="two">
  <two>
    <xsl:value-of select="string-length(.)"/>
  </two>
</xsl:template>

<xsl:template match="/">
  <xsl:apply-templates select="version" mode="one"/>
  <xsl:apply-templates select="version" mode="two"/>
</xsl:template>

```

Usage Examples

See [“Example: Adding a Final then accept Term to a Firewall”](#) on page 215.

Related Documentation

- [apply-templates on page 112](#)
- [call on page 112](#)
- [match on page 118](#)
- [priority on page 120](#)
- [template on page 121](#)
- [with on page 123](#)
- [xsl:template on page 138](#)

param**Syntax**

```
param $name=value;
```

Description	<p>Declare a parameter for a template or for the style sheet as a whole. Template parameters declared with the param statement must be placed inside the template code block. A global parameter, the scope of which is the entire style sheet, must be declared at the top level of the style sheet. You can include an initial value by following the parameter name with an equal sign (=) and a value expression. A parameter whose value is set by Junos OS at script initialization must be defined as a global parameter.</p> <p>In SLAX, parameter and variable names are declared and accessed using the dollar sign (\$). This is unlike the name attribute of <code><xsl:variable></code> and <code><xsl:parameter></code> elements, which do not include the dollar sign in the declaration.</p>
Attributes	<p>\$name—Defines the name of the parameter.</p> <p>value—Defines the default value for the parameter, which is used if the person or client application that executes the script does not explicitly provide a value.</p>
SLAX Example	<pre>param \$vrf; param \$dot = .;</pre>
XSLT Equivalent	<pre><xsl:param name="vrf"/> <xsl:param name="dot" select="."/></pre>
Usage Examples	See “Example: Requiring and Restricting Configuration Statements” on page 306 , “Example: Imposing a Minimum MTU Setting” on page 266 , “Example: Limiting the Number of E1 Interfaces” on page 272 , “Example: Limiting the Number of ATM Virtual Circuits” on page 268 , and “Example: Preventing Import of the Full Routing Table” on page 300 .
Related Documentation	<ul style="list-style-type: none">• SLAX Parameters Overview on page 74• SLAX Templates Overview on page 71• template on page 121• var on page 122• with on page 123

priority

Syntax	<pre>priority <i>number</i>;</pre>
Description	<p>If more than one template matches a node in the specified mode, this statement determines which template is used. The highest priority wins. If no priority is specified explicitly, the priority of a template is determined by the match statement.</p> <p>This statement is comparable to the priority attribute of the <code><xsl:template></code> element. You can include this statement inside a SLAX match statement.</p>
SLAX Example	<pre>match * { priority 10; <output> .;</pre>

```
}
```

XSLT Equivalent

```
<xsl:template match="*" priority="10">
  <output>
    <xsl:value-of select="."/>
  </output>
</xsl:template>
```

Usage Examples None of the examples in this manual use this statement.

template

Syntax

```
template qualified-name (parameter-name = value) {
  /* code */
}
```

Description Declare a named template. You can include a comma-separated list of parameter declarations, with the parameter name and an optional equal sign (=) and value expression. You can declare additional parameters inside the code block using the **param** statement. You can invoke the template using the **call** statement.

SLAX Example

```
match configuration {
  var $name-servers = name-servers/name;
  call temp();
  call temp($name-servers, $size = count($name-servers));
  call temp() {
    with $name-servers;
    with $size = count($name-servers);
  }

  template temp($name-servers, $size = 0) {
    <output> "template called with size " _ $size;
  }
}
```

XSLT Equivalent

```
<xsl:template match="configuration">
  <xsl:variable name="name-servers" select="name-servers/name"/>
  <xsl:call-template name="temp"/>
  <xsl:call-template name="temp">
    <xsl:with-param name="name-servers" select="$name-servers"/>
```

```

        <xsl:with-param name="size" select="count($name-servers)"/>
    </xsl:call-template>
    <xsl:call-template name="temp">
        <xsl:with-param name="name-servers" select="$name-servers"/>
        <xsl:with-param name="size" select="count($name-servers)"/>
    </xsl:call-template>
</xsl:template>

<xsl:template name="temp">
    <xsl:param name="name-servers"/>
    <xsl:param name="size" select="0"/>
    <output>
        <xsl:value-of select="concat('template called with size ', $size)"/>
    </output>
</xsl:template>

```

Usage Examples See “Example: Adding a Final then accept Term to a Firewall” on page 215 and “Example: Adding T1 Interfaces to a RIP Group” on page 220.

 - [with on page 123](#)

var

Syntax `var $name=value;`

Description Declare a local or global variable. A variable is global if it is defined outside of any template. Otherwise, it is local. The value of a global variable is accessible anywhere in the style sheet. The scope of a local variable is limited to the template or code block in which it is defined. You initialize a variable by following the variable name with an equal sign (=) and an expression.

Attributes **\$name**—Specifies the name of the variable. After declaration, the variable can be referred to within expressions using this name, including the \$ character.

value—Defines the default value for the variable, which is used if the person or client application that executes the script does not explicitly provide a value.

SLAX Example `var $vrf;`
 `var $location = $dot/@location;`
 `var $message = "We are in "_$location_" now.";`

XSLT Equivalent	<pre><xsl:variable name="vrf"/> <xsl:variable name="location" select="\$dot/location"/> <xsl:variable name="message" select="concat('We are in ', \$location, now.')" /></pre>
Usage Examples	See “Example: Limiting the Number of E1 Interfaces” on page 272, “Example: Limiting the Number of ATM Virtual Circuits” on page 268, “Example: Configuring Administrative Groups for LSPs” on page 234, and “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227.
Related Documentation	<ul style="list-style-type: none"> • SLAX Variables Overview on page 77 • param on page 119

version

Syntax	version 1.0;
Description	<p>Specify the version of SLAX that is being used. All SLAX style sheets must begin with a version statement.</p> <p>Version 1.0 uses XML version 1.0 and XSLT version 1.1.</p> <p>In addition, the xsl namespace is implicitly defined as follows:</p> <pre>xmlns:xsl="http://www.w3.org/1999/XSL/Transform"</pre>
Attributes	version-number —Specifies the version of SLAX. Junos OS supports SLAX version 1.0.
SLAX Example	version 1.0;
XSLT Equivalent	<xsl:stylesheet version="1.0">
Usage Examples	“Example: Adding a Final then accept Term to a Firewall” on page 215, “Example: Assigning a Classifier” on page 223, “Example: Imposing a Minimum MTU Setting” on page 266, “Example: Changing the Configuration Using an Op Script” on page 349, and “Example: Restarting an FPC Using an Op Script” on page 385.
Related Documentation	<ul style="list-style-type: none"> • Required Boilerplate for Commit Scripts on page 166 • Required Boilerplate for Event Scripts on page 462 • Required Boilerplate for Op Scripts on page 335 • SLAX Syntax Rules Overview on page 67

with

Syntax	with <i>\$name</i> = <i>value</i> ;
---------------	-------------------------------------

Description	<p>Specify a parameter to pass into a template. You can use this statement when you apply templates with the apply-templates statement or invoke templates with the call statement.</p> <p>Optionally, you can specify a value for the parameter by including an equal sign (=) and a value expression. If no value is specified, the current value of the parameter is passed to the template.</p>
Attributes	<p>\$name—Name of the variable or parameter for which the value is being passed.</p> <p>value—Value of the parameter being passed to the template.</p>
SLAX Example	<pre> match configuration { var \$domain = domain-name; apply-templates system/host-name { with \$message = "Invalid host-name"; with \$domain; } } match host-name { param \$message = "Error"; param \$domain; <hello> \$message _ "::" _ . _ " (" _ \$domain _ ")"; } </pre>
XSLT Equivalent	<pre> <xsl:template match="configuration"> <xsl:apply-templates select="system/host-name"> <xsl:with-param name="message" select="Invalid host-name"/> <xsl:with-param name="domain" select="\$domain"/> </xsl:apply-templates> </xsl:template> <xsl:template match="host-name"> <xsl:param name="message" select="Error"/> <xsl:param name="domain"/> <hello> <xsl:value-of select="concat(\$message, '::', '(', \$domain, ')')"/> </hello> </xsl:template> </pre>
Usage Examples	<p>See “Example: Configuring Dual Routing Engines” on page 242, “Example: Preventing Import of the Full Routing Table” on page 300, and “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227.</p>
Related Documentation	<ul style="list-style-type: none"> • SLAX Parameters Overview on page 74 • SLAX Templates Overview on page 71 • apply-templates on page 112 • call on page 112 • match on page 118

- [string-length\(\) on page 128](#)
- [substring-after\(\) on page 128](#)
- [substring-before\(\) on page 129](#)

concat()

Syntax *string concat(string, string+)*

Description Return the concatenation of the arguments.

Usage Examples See “Example: Limiting the Number of E1 Interfaces” on page 272, “Example: Controlling IS-IS and MPLS Interfaces” on page 251, “Example: Adding T1 Interfaces to a RIP Group” on page 220, “Example: Configuring Administrative Groups for LSPs” on page 234, and “Example: Configuring Dual Routing Engines” on page 242.

- [string-length\(\) on page 128](#)
- [substring-after\(\) on page 128](#)
- [substring-before\(\) on page 129](#)

contains()

Syntax *boolean contains(string, string)*

Description Return TRUE if the first string argument contains the second string argument, otherwise return FALSE.

Usage Examples See [“Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227.](#)

- Related Documentation**
- [concat\(\) on page 125](#)
 - [starts-with\(\) on page 128](#)
 - [string-length\(\) on page 128](#)
 - [substring-after\(\) on page 128](#)
 - [substring-before\(\) on page 129](#)

count()

Syntax *number* count(*node-set*)

Description Return the number of nodes in the argument node-set.

Usage Examples See [“Example: Limiting the Number of EI Interfaces” on page 272.](#)

- Related Documentation**
- [last\(\) on page 126](#)
 - [name\(\) on page 126](#)
 - [not\(\) on page 127](#)
 - [position\(\) on page 127](#)

last()

Syntax *number* last()

Description Return the index of the last node in the list that is currently being evaluated, which is equal to the number of items in the processed node list.

Usage Examples See [“Example: Limiting the Number of EI Interfaces” on page 272.](#)

- Related Documentation**
- [count\(\) on page 126](#)
 - [name\(\) on page 126](#)
 - [not\(\) on page 127](#)
 - [position\(\) on page 127](#)

name()

Syntax *string* name(<*node-set*>)

Description Return the full name of the first node in the node set, including the prefix for its namespace declared in the source document. If no argument is passed, the function returns the full name of the context node.

Usage Examples See [jcs:emit-change Template](#).

Related Documentation

- [count\(\)](#) on page 126
- [last\(\)](#) on page 126
- [not\(\)](#) on page 127
- [position\(\)](#) on page 127

[not\(\)](#)

Syntax *boolean not(boolean)*

Description Return TRUE if the argument is FALSE, and FALSE if the argument is TRUE.

Usage Examples See “Example: Requiring and Restricting Configuration Statements” on page 306, “Example: Controlling IS-IS and MPLS Interfaces” on page 251, “Example: Configuring a Default Encapsulation Type” on page 238, “Example: Controlling LDP Configuration” on page 255, “Example: Adding a Final then accept Term to a Firewall” on page 215, “Example: Configuring Administrative Groups for LSPs” on page 234, “Example: Configuring Dual Routing Engines” on page 242, and “Example: Preventing Import of the Full Routing Table” on page 300.

- [not\(\)](#) on page 127

starts-with()

Syntax	<i>boolean</i> starts-with(<i>string</i> , <i>string</i>)
Description	Return TRUE if the first string argument starts with the second string argument, otherwise return FALSE.
Usage Examples	See “Example: Imposing a Minimum MTU Setting” on page 266, “Example: Limiting the Number of E1 Interfaces” on page 272, “Example: Limiting the Number of ATM Virtual Circuits” on page 268, “Example: Adding T1 Interfaces to a RIP Group” on page 220, “Example: Configuring a Default Encapsulation Type” on page 238, and “Example: Configuring Dual Routing Engines” on page 242.
Related Documentation	<ul style="list-style-type: none">• concat() on page 125• contains() on page 125• string-length() on page 128• substring-after() on page 128• string-length() on page 128• substring-after() on page 128• substring-before() on page 129

string-length()

Syntax	<i>number</i> string-length(< <i>string</i> >)
Description	Return the number of characters in the string. If the argument is omitted, it returns the string value of the context node.
Usage Examples	See “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227.
Related Documentation	<ul style="list-style-type: none">• concat() on page 125• contains() on page 125• starts-with() on page 128• substring-after() on page 128• substring-before() on page 129

substring-after()

Syntax	<i>string</i> substring-after(<i>string</i> , <i>string</i>)
---------------	--

Description	Return the portion of the first string argument that follows the occurrence of the second argument substring within the first. If the second string is not contained in the first string, or if the second string is empty, the function returns an empty string.
Usage Examples	See “Example: Limiting the Number of E1 Interfaces” on page 272 and “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227.
Related Documentation	<ul style="list-style-type: none"> • concat() on page 125 • contains() on page 125 • starts-with() on page 128 • string-length() on page 128 • substring-before() on page 129
Syntax	<i>string</i> substring-before(<i>string</i> , <i>string</i>)
Description	Return the portion of the first string argument that precedes the occurrence of the second argument substring within the first. If the second string is not contained in the first string, or if the second string is empty, the function returns an empty string.
Usage Examples	See “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227.
Related Documentation	<ul style="list-style-type: none"> • concat() on page 125 • contains() on page 125 • starts-with() on page 128 • string-length() on page 128 • substring-after() on page 128

- [xsl:variable on page 140](#)
- [xsl:when on page 141](#)
- [xsl:with-param on page 141](#)

[xsl:apply-templates](#)

Syntax	<pre><xsl:apply-templates select="node-set-expression"> <xsl:with-param name="qualified-name" select="expression"> ... </xsl:with-param> </xsl:apply-templates></pre>
Description	Apply one or more templates, according to the value of the select attribute. If the select attribute is not included, the script recursively processes all child nodes of the current node. If the select attribute is present, the processor only applies templates to the child elements that match the expression of the select attribute, which must evaluate to a node-set. The <xsl:template> instruction dictates which elements are transformed according to which template. The templates that are applied are passed the parameters specified by the <xsl:with-param> elements within the <xsl:apply-templates> instruction.
Attributes	select —(Optional) Selects the nodes to which the processor applies templates. By default, the processor applies templates to the child nodes of the current node.
Usage Examples	See “ Example: Adding a Final then accept Term to a Firewall ” on page 215 and “ Example: Preventing Import of the Full Routing Table ” on page 300.
Related Documentation	<ul style="list-style-type: none">• XSLT Templates Overview on page 52• xsl:call-template on page 131• xsl:param on page 136• xsl:template on page 138• xsl:variable on page 140• xsl:with-param on page 141

xsl:call-template

Syntax	<pre><xsl:call-template name="<i>qualified-name</i>"> <xsl:with-param name="<i>qualified-name</i>" select="<i>expression</i>"> ... </xsl:with-param> </xsl:call-template></pre>
Description	Call a named template. The <xsl:with-param> elements within the <xsl:call-template> instruction define the parameters that are passed to the template.
Attributes	name —Specifies the name of the template to call.
Usage Examples	See “ Example: Requiring and Restricting Configuration Statements ” on page 306, “ Example: Imposing a Minimum MTU Setting ” on page 266, and “ Example: Automatically Configuring Logical Interfaces and IP Addresses ” on page 227.
Related Documentation	<ul style="list-style-type: none">• XSLT Templates Overview on page 52• xsl:apply-templates on page 130• xsl:param on page 136• xsl:template on page 138• xsl:variable on page 140• xsl:with-param on page 141

xsl:choose

Syntax

```
<xsl:choose>
  <xsl:when test="boolean-expression">
    ...
  </xsl:when>
  <xsl:otherwise>
    ...
  </xsl:otherwise>
</xsl:choose>
```

Description Evaluate multiple conditional tests, and execute instructions for the first test that evaluates to TRUE or execute an optional default set of instructions if all tests evaluate to FALSE. The **<xsl:choose>** instruction contains one or more **<xsl:when>** elements, each of which tests a Boolean expression. If the test evaluates to TRUE, the XSLT processor executes the instructions in the **<xsl:when>** element, and ignores all subsequent **<xsl:when>** elements. The XSLT processor processes only the instructions contained in the first **<xsl:when>** element whose **test** attribute evaluates to TRUE. If none of the **<xsl:when>** elements' **test** attributes evaluate to TRUE, the content of the optional **<xsl:otherwise>** element, if one is present, is processed.

Usage Examples See [“Example: Configuring Dual Routing Engines” on page 242](#), [“Example: Preventing Import of the Full Routing Table” on page 300](#), and [“Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227](#).

Related Documentation

- [xsl:otherwise on page 136](#)
- [xsl:when on page 141](#)

xsl:comment

Syntax

```
<xsl:comment>
  ...
</xsl:comment>
```

Description Generate a comment node within the final document. The content within the **<xsl:comment>** element determines the value of the comment. The content must not contain two hyphens next to each other (- -); this sequence is not allowed in comments.

XSLT files can contain ordinary comments delimited by **<!--** and **-->** such as **<!-- ... Insert your comment here ... -->**, but these are ignored by the processor. To generate a comment within the final document, use an **<xsl:comment>** element.

Usage Examples See [“Example: Adding a Final then accept Term to a Firewall” on page 215](#).

- Related Documentation**
- [xsl:import on page 135](#)
 - [xsl:stylesheet on page 137](#)

xsl:copy-of

- Syntax** `<xsl:copy-of select="expression"/>`
- Description** Create a copy of what is selected by the expression defined in the **select** attribute. Namespace nodes, child nodes, and attributes of the current node are automatically copied as well.
- Attributes** **select**—Specifies an expression to select the nodes to be copied.
- Usage Examples** See “[Example: Requiring and Restricting Configuration Statements](#)” on page 306.

- Related Documentation**
- [xsl:element on page 133](#)
 - [xsl:text on page 139](#)
 - [xsl:value-of on page 139](#)

xsl:element

- Syntax** `<xsl:element name="expression"/>`
- Description** Create an element node in the output document.
- Attributes** **name**—Specifies the name of the element to be created. The value of the **name** attribute can be set to an expression that is extracted from the input XML document and evaluated at run time. To do this, enclose an XML element in curly brackets (`{ }`), as in `<xsl:element name="{ $isis-level-1 }">`.
- Usage Examples** See “[Example: Creating a Complex Configuration Based on a Simple Interface Configuration](#)” on page 259.
- Related Documentation**
- [xsl:copy-of on page 133](#)
 - [xsl:text on page 139](#)
 - [xsl:value-of on page 139](#)

xsl:for-each

Syntax	<pre><xsl:for-each select="<i>node-set-expression</i>"> ... </xsl:for-each></pre>
Description	Include a looping mechanism that repeats XSL processing for each XML element in the specified node-set. The element nodes are selected by the XPath expression defined by the select attribute. Each of the nodes is then processed according to the instructions contained in the <xsl:for-each> element.
Attributes	select —Specifies an XPath expression that selects the nodes to be processed.
Usage Examples	See “Example: Requiring and Restricting Configuration Statements” on page 306, “Example: Imposing a Minimum MTU Setting” on page 266, “Example: Limiting the Number of E1 Interfaces” on page 272, “Example: Adding T1 Interfaces to a RIP Group” on page 220, “Example: Configuring Administrative Groups for LSPs” on page 234, and “Example: Configuring Dual Routing Engines” on page 242.
Related Documentation	<ul style="list-style-type: none">• XSLT Programming Instructions Overview on page 59• XPath Overview on page 50• xsl:choose on page 132• xsl:if on page 134• xsl:otherwise on page 136• xsl:when on page 141

xsl:if

Syntax	<pre><xsl:if test="<i>expression</i>"> ... </xsl:if></pre>
Description	Include a conditional construct that causes instructions to be processed if the expression held in the test attribute evaluates to TRUE.
Attributes	test —Specifies the expression to evaluate.
Usage Examples	See “Example: Requiring and Restricting Configuration Statements” on page 306, “Example: Limiting the Number of E1 Interfaces” on page 272, “Example: Adding T1 Interfaces to a RIP Group” on page 220, and “Example: Configuring Dual Routing Engines” on page 242.
Related Documentation	<ul style="list-style-type: none">• XSLT Programming Instructions Overview on page 59• xsl:choose on page 132• xsl:for-each on page 134

- [xsl:otherwise on page 136](#)
- [xsl:when on page 141](#)

xsl:import

Syntax `<xsl:import href="../../import/junos.xsl"/>`

Description Import rules from an external style sheet. Provides access to all the declarations and templates within the imported style sheet, and allows you to override them with your own if needed. Any **<xsl:import>** elements must be the first elements within the style sheet, the first children of the **<xsl:stylesheet>** document element. The path can be any URI. The `../../import/junos.xsl` path shown in the syntax is standard for all commit scripts, op scripts, and event scripts.

Imported rules are overwritten by any subsequent matching rules within the importing style sheet. If more than one style sheet is imported, the style sheets imported last override each previous import where the rules match.

Attributes **href**—Specifies the location of the imported style sheet.

Usage Examples See [“Example: Adding a Final then accept Term to a Firewall” on page 215](#), [“Example: Configuring a Default Encapsulation Type” on page 238](#), [“Example: Configuring Dual Routing Engines” on page 242](#), [“Example: Controlling IS-IS and MPLS Interfaces” on page 251](#), [“Example: Prepending a Global Policy” on page 295](#), and [“Example: Preventing Import of the Full Routing Table” on page 300](#).

- [Required Boilerplate for Event Scripts on page 462](#)
- [Required Boilerplate for Op Scripts on page 335](#)
- [xsl:stylesheet on page 137](#)

xsl:otherwise

Syntax	<pre><xsl:otherwise> ... </xsl:otherwise></pre>
Description	Within an <xsl:choose> instruction, include a default set of instructions that are processed if none of the expressions defined in the test attributes of the <xsl:when> elements evaluate to TRUE.
Usage Examples	See “Example: Configuring Dual Routing Engines” on page 242 and “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227 .
Related Documentation	<ul style="list-style-type: none">• XSLT Programming Instructions Overview on page 59• xsl:choose on page 132• xsl:for-each on page 134• xsl:if on page 134• xsl:when on page 141

xsl:param

Syntax	<pre><xsl:param name="<i>qualified-name</i>" select="<i>expression</i>"> ... </xsl:param></pre>
Description	Declare a parameter for a template or for the style sheet as a whole. A template parameter must be declared within the template element. A global parameter, the scope of which is the entire style sheet, must be declared at the top level of the style sheet.
Attributes	<p>name—Defines the name of the parameter.</p> <p>select—(Optional) XPath expression defining the default value for the parameter, which is used if the person or client application that executes the script does not explicitly provide a value. The select attribute or the content of the <xsl:param> element can define the default value. Do not specify both a select attribute and content; we recommend using the select attribute so as not to create a result tree fragment.</p>
Usage Examples	See “Example: Requiring and Restricting Configuration Statements” on page 306 , “Example: Imposing a Minimum MTU Setting” on page 266 , “Example: Limiting the Number of E1 Interfaces” on page 272 , “Example: Limiting the Number of ATM Virtual Circuits” on page 268 , and “Example: Preventing Import of the Full Routing Table” on page 300 .

- [xsl:template on page 138](#)
- [xsl:variable on page 140](#)
- [xsl:with-param on page 141](#)

[xsl:stylesheet](#)

Syntax	<pre><xsl:stylesheet version="1.0" xmlns:ext="URI"> <xsl:import href="../../import/junos.xml"/> ... </xsl:stylesheet></pre>
Description	<p>Include the document element for the style sheet. This element defines the root element of the style sheet, which contains all the top-level elements such as global variable and parameter declarations, import elements, and templates. Optionally, namespace mappings, which include an extension prefix and Uniform Resource Identifier (URI), can be included as attributes in the opening <xsl:stylesheet> tag.</p> <p>Any <xsl:import> elements must be the first elements within the style sheet, the first children of the <xsl:stylesheet> document element. The path can be any Uniform Resource Identifier (URI). The ../import/junos.xml path shown in the syntax is standard for all commit scripts, op scripts, and event scripts.</p>
Attributes	<p>version—Specifies the version of XSLT that is being used. Junos OS supports XSLT version 1.0.</p> <p>xmlns:ext="URI"—(Optional) Maps a namespace prefix to the URI for extension elements.</p>
Usage Examples	<p>See “Example: Adding a Final then accept Term to a Firewall” on page 215, “Example: Configuring Administrative Groups for LSPs” on page 234, “Example: Configuring a Default Encapsulation Type” on page 238, and “Example: Customizing Output of the show interfaces terse Command Using an Op Script” on page 354.</p>
Related Documentation	<ul style="list-style-type: none"> • Required Boilerplate for Commit Scripts on page 166 • Required Boilerplate for Event Scripts on page 462 • Required Boilerplate for Op Scripts on page 335 • XSLT Namespace on page 50 • xsl:import on page 135

xsl:template

Syntax	<pre> <xsl:template match="<i>pattern</i>" mode="<i>qualified-name</i>" name="<i>qualified-name</i>" priority="<i>integer</i>"> <xsl:param name="<i>qualified-name</i>" select="<i>expression</i>"> ... </xsl:param> ... </xsl:stylesheet> </pre>
Description	<p>Declare a template that contains rules to apply when a specified node is matched. The match attribute associates the template with an XML element. The match attribute can also be used to define a template for a whole branch of an XML document. For example, match="/" matches the root element of the document. Although the match and name attributes are optional, one of the two attributes must be included in the template definition.</p> <p>When templates are applied to a node set using the <xsl:apply-templates> instruction, they might be applied in a particular mode; the mode attribute in the <xsl:template> instruction indicates the mode in which a template needs to be applied for the template to be used. If templates are applied in the specified mode, the match attribute is used to determine whether the template can be used with the particular node. If more than one template matches a node in the specified mode, the priority attribute determines which template is used. The highest priority wins. If no priority is specified explicitly, the priority of a template is determined by the match attribute.</p> <p>You can pass template parameters using the <xsl:with-param> element. To receive a parameter, the template must contain an <xsl:param> element that declares a parameter of that name. These parameters are listed before the body of the template, which is used to process the node and create a result.</p>
Attributes	<p>match—(Optional) XPath expression specifying the nodes to which to apply the template. If this attribute is omitted, the name attribute must be included.</p> <p>mode—(Optional) Indicate the mode in which a template needs to be applied for the template to be used.</p> <p>name—(Optional) Specify a name for the template. Named templates can be explicitly called with the <xsl:call-template> element. If the name attribute is omitted, the match attribute must be included.</p> <p>priority—(Optional) Specify a numeric priority for the template.</p>
Usage Examples	<p>See “Example: Adding a Final then accept Term to a Firewall” on page 215, “Example: Adding T1 Interfaces to a RIP Group” on page 220, “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227, “Example: Requiring and Restricting Configuration Statements” on page 306, and “Example: Customizing Output of the show interfaces terse Command Using an Op Script” on page 354.</p>

 - [xsl:param on page 136](#)
 - [xsl:variable on page 140](#)
 - [xsl:with-param on page 141](#)

xsl:text

- Syntax** `<xsl:text>`
 `...`
 `</xsl:text>`
- Description** Insert literal text in the output.
- Usage Examples** See “[Example: Requiring and Restricting Configuration Statements](#)” on page 306, “[Example: Imposing a Minimum MTU Setting](#)” on page 266, “[Example: Limiting the Number of E1 Interfaces](#)” on page 272, “[Example: Controlling IS-IS and MPLS Interfaces](#)” on page 251, and “[Example: Adding a Final then accept Term to a Firewall](#)” on page 215.

xsl:value-of

- Syntax** `<xsl:value-of select="expression"/>`
- Description** Extract the value of an XML element and insert it into the output. The **select** attribute specifies the XPath expression that is evaluated. In the XPath expression, use **@** to access attributes of elements. Use **.** to access the contents of the element itself. If the result is a node set, the `<xsl:value-of>` instruction adds the string value of the first node in that node set; none of the structure of the node is preserved. To preserve the structure of the node, you must use the `<xsl:copy-of>` instruction instead.
- Attributes** **select**—XPath expression specifying the node or attribute to evaluate.
- Usage Examples** See “[Example: Imposing a Minimum MTU Setting](#)” on page 266, “[Example: Limiting the Number of E1 Interfaces](#)” on page 272, “[Example: Controlling IS-IS and MPLS Interfaces](#)” on page 251, “[Example: Configuring Administrative Groups for LSPs](#)” on page 234, and “[Example: Automatically Configuring Logical Interfaces and IP Addresses](#)” on page 227.
- Related Documentation**
- [xsl:copy-of on page 133](#)

xsl:variable

Syntax	<pre><xsl:variable name="<i>qualified-name</i>" select="<i>expression</i>"> ... </xsl:variable></pre>
Description	Declare a local or global variable. If the <xsl:variable> instruction appears at the top level of the style sheet as a child of the <xsl:stylesheet> document element, it is a global variable with a scope that includes the entire style sheet. Otherwise, it is a local variable with a scope of its following siblings and their descendants.
Attributes	<p>name—Specifies the name of the variable. After declaration, the variable can be referred to within XPath expressions using this name, prefixed with the \$ character.</p> <p>select—(Optional) Determines the value of the variable. The value of the variable is determined either by the select attribute or by the contents of the <xsl:variable> element. Do not specify both a select attribute and some content; we recommend using the select attribute so as not to create a result tree fragment.</p>
Usage Examples	See “Example: Limiting the Number of E1 Interfaces” on page 272, “Example: Limiting the Number of ATM Virtual Circuits” on page 268, “Example: Configuring Administrative Groups for LSPs” on page 234, and “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227.
Related Documentation	<ul style="list-style-type: none">• XSLT Variables Overview on page 57• xsl:apply-templates on page 130• xsl:call-template on page 131• xsl:param on page 136• xsl:template on page 138• xsl:with-param on page 141

xsl:when

Syntax	<pre><xsl:when test="boolean-expression"> ... </xsl:when></pre>
Description	Within an <xsl:choose> instruction, specify a set of processing instructions that are executed when the expression specified in the test attribute evaluates to TRUE. The XSLT processor processes only the instructions contained in the first <xsl:when> element whose test attribute evaluates to TRUE. If none of the <xsl:when> elements' test attributes evaluate to TRUE, the content of the <xsl:otherwise> element, if there is one, is processed.
Attributes	test —Specifies a Boolean expression.
Usage Examples	See “Example: Configuring Dual Routing Engines” on page 242 , “Example: Preventing Import of the Full Routing Table” on page 300 , and “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227 .
Related Documentation	<ul style="list-style-type: none"> • XSLT Programming Instructions Overview on page 59 • xsl:choose on page 132 • xsl:for-each on page 134 • xsl:if on page 134 • xsl:otherwise on page 136

xsl:with-param

Syntax	<pre><xsl:with-param name="qualified-name" select="expression"> ... </xsl:with-param></pre>
Description	Specify a parameter to pass into a template. This element can be used when applying templates with the <xsl:apply-templates> instruction or when calling templates with the <xsl:call-template> instruction.
Attributes	<p>name—Specifies the name of the parameter.</p> <p>select—(Optional) XPath expression specifying the value of the parameter. The value of the parameter is determined either by the select attribute or by the contents of the <xsl:with-param> element. Do not specify both a select attribute and content. We recommend using the select attribute to set the parameter so as to prevent the parameter from being passed a result tree fragment as its value.</p>
Usage Examples	See “Example: Configuring Dual Routing Engines” on page 242 , “Example: Preventing Import of the Full Routing Table” on page 300 , and “Example: Automatically Configuring Logical Interfaces and IP Addresses” on page 227 .

Operational Commands

request system scripts convert

Syntax	<code>request system scripts convert (slax-to-xslt xslt-to-slax) source <i>source/filename</i> destination <i>destination/<filename></i></code>
Release Information	Command introduced in Junos OS Release 8.2. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Convert an Extensible Stylesheet Language Transformations (XSLT) script to Stylesheet Language, Alternative syntax (SLAX), or convert a SLAX script to XSLT.
Options	<p>destination <i>destination/<filename></i>—Specify a destination for the converted file.</p> <p>Optionally, you can specify a filename for the converted file. If you do not specify a filename, the software assigns one automatically. The default destination filename is the same as the source filename, except the file extension is altered. For example, the software converts a source file called test.xml to test.slax. The software converts a source file called test1.slax to test1.xml.</p> <p>slax-to-xslt—Convert a SLAX script to XSLT.</p> <p>source <i>source/filename</i>—Specify a source file that you want to convert.</p> <p>xslt-to-slax—Convert an XSLT script to SLAX.</p>
Required Privilege Level	maintenance
List of Sample Output	request system scripts convert slax-to-xslt on page 143 request system scripts convert xslt-to-slax on page 143
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system scripts convert slax-to-xslt

```
user@host> request system scripts convert slax-to-xslt source /var/db/scripts/op/script1.slax
destination /var/db/scripts/op
conversion complete
```

request system scripts convert xslt-to-slax

```
user@host> request system scripts convert xslt-to-slax source /var/db/scripts/commit/script1.xml
destination /var/db/scripts/commit
conversion complete
```

- [How Commit Scripts Work on page 148](#)

Commit Script Overview

Junos OS commit scripts enforce custom configuration rules during the commit process. When a candidate configuration is committed, it is inspected by each active commit script. If a configuration violates your custom rules, the script can instruct Junos OS to take appropriate action. A commit script can perform the following actions:

- Generate and display custom warning messages to the user
- Generate and log custom system log (syslog) messages
- Change the configuration to conform to the custom business rules
- Generate a commit error and halt the commit operation

Commit scripts are based on the Junos XML management protocol and the Junos XML API. The Junos XML management protocol is an XML based RPC mechanism, and the

Junos XML API is an XML representation of Junos configuration statements and operational mode commands.

Commit scripts can be written in either the Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) scripting language. Commit scripts use the XML Path Language (XPath) to locate the configuration objects to be inspected and XSLT or SLAX constructs to specify the actions to perform on the configuration objects. The actions can change the configuration or generate messages about it. For more information about XSLT, see [“XSLT Overview” on page 48](#). For more information about SLAX, see [“SLAX Overview” on page 63](#).

Additionally, you can create *macros*, which allow you to create custom configuration syntax that simplifies the task of configuring a device running Junos OS. By itself, your custom syntax has no operational impact on the device. A corresponding commit script macro uses your custom syntax as input data for generating standard Junos OS configuration statements that execute your intended operational impact.

To view the device's current configuration in the Extensible Markup Language (XML), using the command-line interface's (CLI's) operational mode, issue the **show configuration | display xml** command. To view your configuration in commit-script-style XML, issue the **show configuration | display commit-scripts view** command. Commit-script-style XML view displays the configuration in the format that would be input to a commit script.

Advantages of Using Commit Scripts

Reducing human error in a network configuration can significantly improve network uptime. Commit scripts enable you to control operational practices and enforce operational policy, thereby decreasing the possibility of human error. Restricting device configurations in accordance with custom design rules can vastly improve network reliability.

Consider the following examples of actions you can perform with commit scripts:

- Basic sanity test—Ensure that the **[edit interfaces]** and **[edit protocols]** hierarchies have not been accidentally deleted.
- Consistency check—Ensure that every T1 interface configured at the **[edit interfaces]** hierarchy level is also configured at the **[edit protocols rip]** hierarchy level.
- Dual Routing Engine configuration test—Ensure that the **re0** and **re1** configuration groups are set up correctly. When you use configuration groups, the inherited values can be overridden in the target configuration. A commit script can determine if an individual target configuration element is blocking proper inheritance of the configuration group settings.
- Interface density—Ensure that a channelized interface does not have too many channels configured.

- Link scaling—Ensure that SONET/SDH interfaces never have a maximum transmission unit (MTU) size less than 4 kilobytes (KB).
- Import policy check—Ensure that an interior gateway protocol (IGP) does not use an import policy that imports the full routing table.
- Cross-protocol checks—Ensure that all LDP-enabled interfaces are configured for an IGP, or ensure that all IGP-enabled interfaces are configured for LDP.
- IGP design check—Ensure that Level 1 IS-IS routers are never enabled.

When a candidate configuration does not adhere to your design rules, a commit script can instruct Junos OS to generate custom warnings, system log messages, or error messages that block the commit operation from succeeding. In addition, the commit script can change the configuration in accordance with your rules and then proceed with the commit operation.

Consider a network design that requires every interface on which the International Organization for Standardization (ISO) family of protocols is enabled to also have MPLS enabled. At commit time, a commit script inspects the configuration and issues an error if this requirement is not met. This error causes the commit operation to fail and forces the user to update the configuration to comply.

Instead of an error, the commit script can issue a warning about the configuration problem and then automatically correct it by changing the configuration to enable MPLS on all interfaces. A system log message can also be generated, indicating that corrective action was taken.

Another option is to define a macro that enables ISO protocols and MPLS when the macro is applied to an interface. Configuring this macro simplifies the configuration task while ensuring that both protocols are configured together.

Finally, you can have the commit script correct the configuration using a *transient change*. In our example, a transient change allows MPLS to always be enabled on ISO-enabled interfaces without having the configuration statements appear in the candidate configuration.

NOTE: Transient changes cause a change to be generated in the *checkout configuration* but not in the candidate configuration. The checkout configuration is the configuration database that is checked for standard Junos OS syntax just before a configuration becomes active. This means transient changes are not saved in the configuration if the associated commit script is deleted or deactivated. The `show configuration | display commit-scripts` command displays all the statements that are in the configuration, including statements that were generated by transient changes. For more information, see [“Overview of Generating Persistent or Transient Configuration Changes” on page 154](#).

- [Commit Script Overview on page 145](#)

How Commit Scripts Work

You enable commit scripts by listing the names of one or more commit script files at the **[edit system scripts commit]** hierarchy level. These scripts contain instructions that enforce custom configuration rules. Commit scripts are invoked during the commit process before the standard Junos OS validity checks are performed.

When you perform a commit operation, Junos OS executes each script in turn, passing the information in the candidate configuration to the scripts. The script inspects the configuration, performs the necessary tests and validations, and generates a set of instructions for performing certain actions. These actions include generating error, warning, and system log messages. If errors are generated, the commit operation fails and the candidate configuration remains unchanged. This is the same behavior that occurs with standard commit errors.

Commit scripts can also generate changes to the system configuration. Because the changes are loaded before the standard validation checks are performed, they are validated for correct syntax, just like statements already present in the configuration before the script is applied. If the syntax is correct, the configuration is activated and becomes the active, operational device configuration.

Figure 3 on page 148 shows the flow of commit script input and output.

Figure 3: Commit Script Input and Output

Commit scripts cannot make configuration changes to protected statements or within protected hierarchies. If a commit script attempts to modify or delete a protected statement or hierarchy, Junos OS issues a warning that the change cannot be made. Failure to modify a protected configuration element does not halt the commit script or the commit process.

The following sections discuss several important concepts related to the commit script input and output:

- [Commit Script Input on page 148](#)
- [Commit Script Output on page 149](#)
- [Commit Scripts and the Junos OS Commit Model on page 150](#)

Commit Script Input

The input for a commit script is the postinheritance candidate configuration in Junos XML API format. The term *postinheritance* means that all configuration group values have been inherited by their targets in the candidate configuration and the inactive portions

of the configuration have been removed. For more information about configuration groups, see the *CLI User Guide*.

When you issue the **commit** command, Junos OS automatically generates the candidate configuration in XML format and reads it into the management (mgd) process, at which time the input is evaluated by any commit scripts.

To display the XML format of the postinheritance configuration, issue the **show | display commit-scripts view** command:

```
[edit]
user@host# show | display commit-scripts view
```

To display all configuration groups data, including script-generated changes to the groups, issue the **show groups | display commit-scripts** command:

```
[edit]
user@host# show groups | display commit-scripts
```

To save the commit script input to a file, add the **save** command to the command line:

```
[edit]
user@host# show | display commit-scripts view | save filename.xml
```

By default, the file is placed in your home directory on the switch, router, or security device.

Commit Script Output

To specify the desired commit script output—including warning, error, and system log messages, persistent changes, and transient changes—the script can contain tags that appear in any order, in any number. The tags for specifying output are as follows:

- **<xnm:warning>**—Generates a warning message
- **<xnm:error>**—Generates an error message.
- **<syslog><message>**—Generates a system log message.
- **<change>**—Generates a persistent change to the configuration.
- **<transient-change>**—Generates a transient change to the configuration.
- **<xsl:call-template name="jcs:emit-change">**
 <xsl:with-param name="content">—Generates a persistent change relative to the current context node as defined by an XPath expression.
- **<xsl:call-template name="jcs:emit-change">**
 <xsl:with-param name="tag" select="'transient-change'"/>
 <xsl:with-param name="content">—Generates a transient change relative to the current context node as defined by an XPath expression.
- **<xsl:call-template name="jcs:emit-change">**
 <xsl:with-param name="message">
 <xsl:text>—Generates a warning message in conjunction with a configuration change. You can use this set of tags to generate a notification that the configuration has been changed.

Junos OS processes this output and performs the appropriate actions. Errors and warnings are passed back to the Junos OS CLI or to a Junos XML protocol client application. The presence of an error automatically causes the commit operation to fail. Persistent and transient changes are loaded into the appropriate configuration database.

To test the output of error, warning, and system log messages from commit scripts, issue the **commit check | display xml** command:

```
[edit]
user@host# commit check | display xml
```

To display a detailed trace of commit script processing, issue the **commit check | display detail** command:

```
[edit]
user@host# commit check | display detail
```

NOTE: System log messages do not appear in the trace output, so you cannot use the commit check operation to test script-generated system log messages. Furthermore, system log messages are written to the system log during a commit operation, but not during a commit check operation.

Commit Scripts and the Junos OS Commit Model

Junos OS uses a commit model to update the device's configuration. This model allows you to make a series of changes to a candidate configuration without affecting the operation of the device. When the changes are complete, you can commit the configuration. The commit operation saves the candidate configuration changes into the current configuration.

When you commit a set of changes in the candidate configuration, two methods are used to forward these changes to the current configuration:

- Standard commit model—Used when no commit scripts are active on the device.
- Commit script model—Incorporates commit scripts into the commit model.

Standard Commit Model

In the standard commit model, the management (mgd) process validates the candidate configuration based on standard Junos validation rules. If the configuration file is valid, it becomes the current active configuration. [Figure 4 on page 151](#) and the accompanying discussion explain how the standard commit model works:

Figure 4: Standard Commit Model

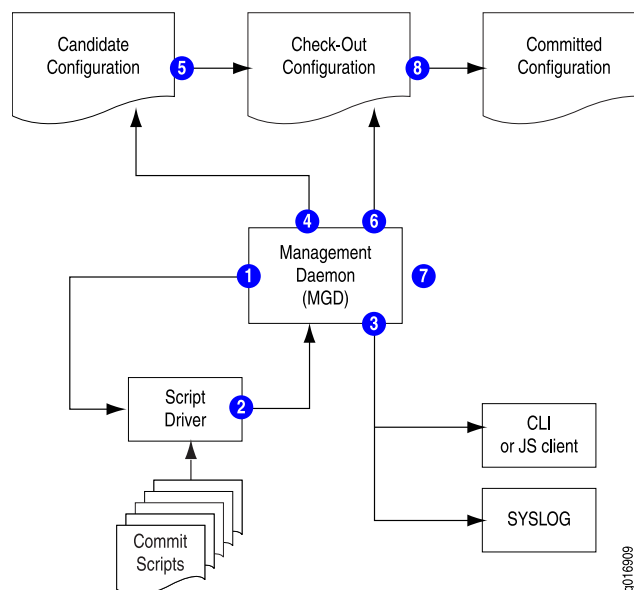

In the standard commit model, the software performs the following steps:

1. When the candidate configuration is committed, it is copied to become the checkout configuration.
2. The mgd process validates the checkout configuration.
3. If no error occurs, the checkout configuration is copied as the current active configuration.

Commit Model with Commit Scripts

When commit scripts are added to the standard commit model, the process becomes more complex. The mgd process first passes an XML-formatted checkout configuration to a script driver, which handles the verification of the checkout configuration by the commit scripts. When verification is complete, the script driver returns an XML *action file* to the mgd process. The mgd process follows the instructions in the action file to update the candidate and checkout configurations, issue messages to the CLI, and write information to the system log as required. After processing the action file, the mgd process performs the standard Junos OS validation. [Figure 5 on page 151](#) and the accompanying discussion explain this process.

Figure 5: Commit Model with Commit Scripts Added

In the commit script model, Junos OS performs the following steps:

1. When the candidate configuration is committed, the mgd process sends the XML-formatted candidate configuration to the script driver.
2. Each enabled commit script is invoked against the candidate configuration, and each script can generate a set of actions for the mgd process to perform. The actions are collected in an XML action file.
3. The mgd process performs the following actions in response to **<error>**, **<warning>**, and **<syslog>** tag elements in the action file:
 - **<error>**—The mgd process halts the commit process (that is, the commit operation fails), returns an error message to the CLI or Junos XML protocol client, and takes no further action.
 - **<warning>**—The mgd process forwards the message to the CLI or the Junos XML protocol client.
 - **<syslog>**—The mgd process forwards the message to the system log process.
4. If the action file includes any **<change>** tag elements, the mgd process loads the requested changes into the candidate configuration.
5. The candidate configuration is copied to become the checkout configuration.
6. If the action file includes any **<transient-change>** tag elements, the mgd process loads the requested changes into the checkout configuration.
7. The mgd process validates the checkout configuration.
8. If there are no validation errors, the checkout configuration is copied to become the current active configuration.

NOTE: Commit scripts cannot make configuration changes to protected statements or within protected hierarchies. If a commit script attempts to modify or delete a protected statement or hierarchy, Junos OS issues a warning that the change cannot be made. Failure to modify a protected configuration element does not halt the commit script or the commit process.

Changes that are made to the candidate configuration during the commit operation are not evaluated by the custom rules during that commit operation. However, persistent changes are maintained in the candidate configuration and are evaluated by the custom rules during subsequent commit operations. For more information about how commit scripts change the candidate configuration, see [“Avoiding Potential Conflicts When Using Multiple Commit Scripts” on page 165](#).

Transient changes are never evaluated by the custom rules in commit scripts, because they are made to the checkout configuration only after the commit scripts have evaluated the candidate configuration and the candidate is copied to become the checkout configuration. To remove a transient change from the configuration, remove, disable, or deactivate the commit script (as discussed in [“Controlling Execution of Commit Scripts](#)

[During Commit Operations” on page 174](#)), or comment out the code that generates the transient change.

For more information about differences between persistent and transient changes, see [“Overview of Generating Persistent or Transient Configuration Changes” on page 154](#).

Generating a Custom Warning, Error, or System Log Message

- [Overview of Generating Custom Warning, Error, and System Log Messages on page 153](#)

[Overview of Generating Custom Warning, Error, and System Log Messages](#)

You can use a commit script to specify configuration rules that you always want to enforce. If a rule is broken, the commit script can emit a warning, error, or system log message.

In the Junos OS command-line interface (CLI), warning messages are emitted during commit operations to alert you that the configuration is not complete or contains a syntax error. If a custom configuration rule is broken, a custom warning message notifies you about the problem. The commit script causes the warning message to be passed back to the Junos OS CLI or to a Junos XML protocol client application. Unlike error messages, warning messages do not cause the commit operation to fail, so they are used for configuration problems that do not affect network traffic. A warning is best used as a response to configuration settings that do not adhere to recommended practices. An example of this type of configuration setting might be assignment of the same user ID to different users.

Alternatively, you can generate a custom warning message for a serious configuration problem, and specify an automatic configuration change that rectifies the problem. For more information about the use of warning messages in conjunction with automatic configuration changes, see [“Overview of Generating Persistent or Transient Configuration Changes” on page 154](#).

Unlike warning messages, a custom error message causes the commit operation to fail and notifies the user about the configuration problem. The commit script causes the error message to be passed back to the Junos OS CLI or to a Junos XML protocol client application. Because error messages cause the commit operation to fail, they are used for problems that affect network traffic. An error message is best used as a response to configuration settings that you want to disallow—for example, when required statements are omitted from the configuration.

Junos OS generates system log messages (also called syslog messages) to record events that occur on the device, including the following:

- Routine operations, such as creation of an OSPF protocol adjacency or a user login into the configuration database
- Failure and error conditions, such as failure to access a configuration file or unexpected closure of a connection to a child or peer process

- Emergency or critical conditions, such as device power-down due to excessive temperature

Each system log message identifies the Junos OS process that generated the message and briefly describes the operation or error that occurred. The *Junos OS System Log Messages Reference* provides more detailed information about system log messages.

With commit scripts, you can cause custom system log messages to be generated in response to particular events that you define. For example, if a configuration rule is broken, a custom message can be generated to record this occurrence. If the commit script corrects the configuration, a custom message can indicate that corrective action was taken.

Generating a Persistent or Transient Configuration Changes

- [Overview of Generating Persistent or Transient Configuration Changes on page 154](#)

Overview of Generating Persistent or Transient Configuration Changes

Junos OS commit scripts enforce custom configuration rules. When a candidate configuration includes statements that you have decided must not be included in your configuration, or when the candidate configuration omits statements that you have decided are required, commit scripts can automatically change the configuration and thereby correct the problem.

- [Differences Between Persistent and Transient Changes on page 154](#)
- [Interaction of Configuration Changes and Configuration Groups on page 157](#)
- [Tag Elements and Templates for Generating Changes on page 158](#)

Differences Between Persistent and Transient Changes

Configuration changes made by commit scripts can be *persistent* or *transient*.

A persistent change remains in the candidate configuration and affects routing operations until you explicitly delete it, even if you subsequently remove or disable the commit script that generated the change and reissue the **commit** command. In other words, removing the commit script does not cause a persistent change to be removed from the configuration.

A transient change, in contrast, is made in the *checkout configuration* but not in the candidate configuration. The checkout configuration is the configuration database that is inspected for standard Junos OS syntax just before it is copied to become the active configuration on the device. If you subsequently remove or disable the commit script

that made the change and reissue the **commit** command, the change is no longer made to the checkout configuration and so does not affect the active configuration. In other words, removing the commit script effectively removes a transient change from the configuration.

A common use for transient changes is to eliminate the need to repeatedly configure and display well-known policies, thus allowing these policies to be enforced implicitly. For example, if MPLS must be enabled on every interface with an International Organization for Standardization (ISO) protocol enabled, the change can be transient, so that the repetitive or redundant configuration data need not be carried or displayed in the candidate configuration. Furthermore, transient changes allow you to write script instructions that apply the change only if a set of conditions is met.

Persistent and transient changes are loaded into the configuration in the same manner that the **load replace** configuration mode command loads an incoming configuration. When generating a persistent or transient change, adding the **replace="replace"** attribute to a configuration element produces the same behavior as a **replace:** tag in a **load replace** operation.

By default, Junos OS merges the incoming configuration and the candidate configuration. New statements and hierarchies are added, and conflicting statements are overridden. When generating a persistent or transient change, if you add the **replace="replace"** attribute to a configuration element, Junos OS replaces the existing configuration element with the incoming configuration element. If the **replace="replace"** attribute is added to a configuration element, but there is no existing element of the same name in the current configuration, the incoming configuration element is added into the configuration. Elements that do not have the **replace** attribute are merged into the configuration.

Persistent and transient changes are loaded before the standard Junos validation checks are performed. This means any configuration changes introduced by a commit script are validated for correct syntax. If the syntax is correct, the new configuration becomes the active, operational device configuration.

Protected elements in the configuration hierarchy cannot be modified or deleted by either a persistent or a transient change. If a commit script attempts to modify or delete a protected statement or hierarchy, Junos OS issues a warning that the change cannot be made, and proceeds with the commit.

Persistent and transient changes have several important differences, as described in [Table 13 on page 155](#).

Table 13: Differences Between Persistent and Transient Changes

Persistent Changes	Transient Changes
A persistent change is represented in a commit script by the <change> tag.	A transient change is represented in a commit script by the <transient-change> tag.
Another way to represent a persistent change is with the content parameter inside a call to the jcs:emit-change template.	Another way to represent a transient change is to use the content parameter and the tag transient parameter inside a call to the jcs:emit-change template.
The jcs:emit-change template is a helper template contained in the junos.xsl import file.	

Table 13: Differences Between Persistent and Transient Changes (*continued*)

Persistent Changes	Transient Changes
You can use persistent changes to perform any Junos XML protocol operation, such as activate, deactivate, delete, insert (reorder), comment (annotate), and replace sections of the configuration.	Like persistent changes, you can use transient changes to perform any Junos XML protocol operation. However, some Junos XML protocol operations do not make sense to use with transient changes, such as generating comments and inactive settings.
Persistent changes are always loaded during the commit process if no errors are generated by any commit scripts or by the standard Junos OS validity check.	<p>For transient changes to be loaded, you must include the allow-transients statement at the [edit system scripts commit] hierarchy level. If you enable a commit script that generates transient changes and you do not include the allow-transients statement in the configuration, the CLI generates an error message and the commit operation fails.</p> <p>Like persistent changes, transient changes must pass the standard Junos OS validity check.</p> <p>You cannot use a commit script to generate the allow-transients statement at the [edit system scripts commit] hierarchy level. Rather, you must include this statement directly by using the CLI.</p>
<p>Persistent changes work like the load replace configuration mode command, and the change is added to the candidate configuration.</p> <p>When generating a persistent change, if you add the replace="replace" attribute to a configuration element, Junos OS replaces the existing element in the candidate configuration with the incoming configuration element. If there is no existing element of the same name in the candidate configuration, the incoming configuration element is added into the configuration. Elements that do not have the replace attribute are merged into the configuration.</p>	<p>Transient changes work like the load replace configuration mode command, and the change is added to the checkout configuration.</p> <p>When generating a transient change, if you add the replace="replace" attribute to a configuration element, Junos OS replaces the existing element in the checkout configuration with the incoming configuration element. If there is no existing element of the same name in the checkout configuration, the incoming configuration element is added into the configuration. Elements that do not have the replace attribute are merged into the configuration.</p> <p>Transient changes are not copied to the candidate configuration. For this reason, transient changes are not saved in the configuration if the associated commit script is deleted or deactivated.</p>
<p>After a persistent change is committed, the software treats it like a change you make by directly editing and committing the candidate configuration.</p> <p>After the persistent changes are copied to the candidate configuration, they are copied to the checkout configuration. If the changes pass the standard Junos OS validity checks, the changes are propagated to the switch, router, or security device components.</p>	Each time a transient change is committed, the software updates the checkout configuration database. After the transient changes pass the standard Junos OS validity checks, the changes are propagated to the device components.

Table 13: Differences Between Persistent and Transient Changes (*continued*)

Persistent Changes	Transient Changes
<p>After committing a script that causes a persistent change to be generated, you can view the persistent change by issuing the show configuration mode command:</p> <pre>user@host# show</pre> <p>This command displays persistent changes only, not transient changes.</p>	<p>After committing a script that causes a transient change to be generated, you can view the transient change by issuing the show display commit-scripts configuration mode command:</p> <pre>user@host# show display commit-scripts</pre> <p>This command displays both persistent and transient changes.</p>
<p>Persistent changes must conform to your custom configuration design rules as dictated by commit scripts.</p> <p>This does not become apparent until after a second commit operation because persistent changes are not evaluated by commit script rules on the current commit operation. The subsequent commit operation fails if the persistent changes do not conform to the rules imposed by the commit scripts configured during the first commit operation.</p>	<p>Transient changes are never tested by and do not need to conform to your custom rules. This is caused by the order of operations in the Junos OS commit model, which is explained in detail in “Commit Scripts and the Junos OS Commit Model” on page 150.</p>
<p>A persistent change remains in the configuration even if you delete, disable, or deactivate the commit script instructions that generated the change.</p>	<p>If you delete, disable, or deactivate the commit script instructions that generate a transient change, the change is removed from the configuration after the next commit operation. In short, if the associated instructions or the entire commit script is removed, the transient change is also removed.</p>
<p>As with direct CLI configuration, you can remove a persistent change by rolling back to a previous configuration that did not include the change and issuing the commit command. However, if you do not disable or deactivate the associated commit script, and the problem that originally caused the change to be generated still exists, the change is automatically regenerated when you issue another commit command.</p>	<p>You cannot remove a transient change by rolling back to a previous configuration.</p>
<p>You can alter persistent changes directly by editing the configuration using the CLI.</p>	<p>You cannot directly alter or delete a transient change by using the Junos OS CLI, because the change is not in the candidate configuration.</p> <p>To alter the contents of a transient change, you must alter the statements in the commit script that generates the transient change.</p>

Interaction of Configuration Changes and Configuration Groups

Any configuration change you can make by directly editing the configuration using the Junos OS command-line interface (CLI) can also be generated by a commit script as a persistent or transient change. This includes values specified at a specific hierarchy level or in configuration groups. As with direct CLI configuration, values specified in the *target* override values inherited from a configuration group. The target is the statement to which you apply a configuration group by including the **apply-groups** statement.

If you define persistent or transient changes as belonging to a configuration group, the configuration groups are applied in the order you specify in the **apply-groups** statements,

which you can include at any hierarchy level except the top level. You can also disable inheritance of a configuration group by including the **apply-groups-except** statement at any hierarchy level except the top level.

CAUTION: Each commit script inspects the postinheritance view of the configuration. If a candidate configuration contains a configuration group, be careful when using a commit script to change the related target configuration, because doing so might alter the intended inheritance from the configuration group.

Also be careful when using a commit script to change a configuration group, because the configuration group might be generated by an application that performs a load replace operation on the group during each commit operation.

For more information about configuration groups, see the *CLI User Guide*.

Tag Elements and Templates for Generating Changes

To generate changes, you can use the **jcs:emit-change** template, which implicitly includes **<change>** and **<transient-change>** XML elements; or you can explicitly include **<change>** and **<transient-change>** XML elements. Using the **jcs:emit-change** template allows you to set the hierarchical context of the change once rather than multiple times.

The **<change>** and **<transient-change>** elements are similar to the **<load-configuration>** operation defined by the Junos XML management protocol. The possible contents of the **<change>** and **<transient-change>** elements are the same as the contents of the **<configuration>** tag element used in the Junos XML protocol operation **<load-configuration>**. For complete details about the **<load-configuration>** element, see the *Junos XML Management Protocol Developer Guide*.

Creating Custom Configuration Syntax with Macros

- [Overview of Creating Custom Configuration Syntax with Macros on page 158](#)
- [How Macros Work on page 159](#)

Overview of Creating Custom Configuration Syntax with Macros

Using commit script macros, you can create a custom configuration language based on simplified syntax that is relevant to your network design. This means you can use your own aliases for frequently used configuration statements.

Commit scripts generally impose restrictions on the Junos OS configuration and automatically correct configuration mistakes when they occur (as discussed in “[Overview of Generating Persistent or Transient Configuration Changes](#)” on page 154). However, macros are useful for an entirely different reason. Commit scripts that contain macros do not generally correct configuration mistakes, nor do they necessarily restrict configuration. Instead, they provide a way to simplify and speed configuration tasks, thereby preventing mistakes from occurring at all.

For a detailed example of how macros can save time and effort, see “[Example: Automatically Configuring Logical Interfaces and IP Addresses](#)” on page 227.

 - [Creating a Macro to Read the Custom Syntax and Generate Related Configuration Statements on page 207](#)
 - [Example: Creating Custom Configuration Syntax with Macros on page 208](#)

How Macros Work

Your custom syntax serves as input to a commit script. The output of the commit script is standard Junos OS configuration syntax, as shown in [Figure 6 on page 159](#). The standard Junos OS statements are added to the configuration to cause your intended operational changes.

Figure 6: Macro Input and Output

Macros use either permanent or transient change elements to expand your custom syntax into standard Junos OS configuration statements. If you use transient changes, the custom syntax appears in the candidate configuration, and the standard Junos OS syntax is copied to the checkout configuration only. If you use persistent changes, both the custom syntax and the standard Junos OS syntax appear in the candidate configuration.

This section discusses the following topics:

- [Creating a Custom Syntax on page 159](#)
- [<data> Element on page 160](#)
- [Expanding the Custom Syntax on page 162](#)
- [Other Ways to Use Macros on page 164](#)

Creating a Custom Syntax

Macros work by locating **apply-macro** statements that you include in the candidate configuration and using the values specified in the **apply-macro** statement as parameters to a set of instructions defined in a commit script. In effect, your custom configuration syntax serves a dual purpose. The syntax allows you to simplify your configuration tasks, and it provides to the script the data necessary to generate a complex configuration.

To enter custom syntax, you include the **apply-macro** statement at any hierarchy level and specify any data that you want inside the **apply-macro** statement:

```

apply-macro macro-name {
  parameter-name parameter-value;
}
  
```

You can include the **apply-macro** statement at any level of the configuration hierarchy. In this sense, the **apply-macro** statement is similar to the **apply-groups** statement. Each **apply-macro** statement must be uniquely named, relative to other **apply-macro** statements at the same hierarchy level.

An **apply-macro** statement can contain a set of parameters with optional values. The corresponding commit script can refer to the macro name, its parameters, or the

parameters' values. When the script inspects the configuration and finds the data, the script performs the actions specified by a persistent or transient change element.

For example, given the following configuration stanza, you can write script instructions to generate a standard configuration based on the name of the parameter:

```
protocols {
  mpls {
    apply-macro blue-type-lsp {
      color blue;
    }
  }
}
```

The following `<xsl:for-each>` programming instruction finds **apply-macro** statements at the **[edit protocols mpls]** hierarchy level that contain a parameter named **color**:

```
<xsl:for-each select="protocols/mps/apply-macro[data/name = 'color']">
```

The following instruction creates a variable named **color** and assigns to the variable the value of the **color** parameter, which in this case is **blue**:

```
<xsl:variable name="color" select="data[name = 'color']/value"/>
```

The following instruction adds the **admin-groups** statement to the configuration and assigns the value of the **\$color** variable to the group name:

```
<transient-change>
  <protocols>
    <mps>
      <admin-groups>
        <name>
          <xsl:value-of select="$color"/>
        </name>
      </admin-groups>
    </mps>
  </protocols>
</transient-change>
```

The resulting configuration statements are as follows:

```
protocols {
  mpls {
    admin-groups {
      blue;
    }
  }
}
```

<data> Element

In the XML rendering of the custom syntax within an **apply-macro** statement, parameters and their values are contained in **<name>** and **<value>** elements, respectively. The **<name>** and **<value>** elements are sibling children of the **<data>** element. For example, the **apply-macro blue-type-lsp** statement contains six parameters, as follows:

```
[edit protocols mpls]
apply-macro blue-type-lsp {
  10.1.1.1;
```

```

10.2.2.2;
10.3.3.3;
10.4.4.4;
color blue;
group-value 0;
}

```

The parameters and values are rendered in Junos XML tag elements as follows:

```

[edit protocols mpls]
user@host# show | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <configuration>
    <protocols>
      <mpls>
        <apply-macro>
          <name>blue-type-lsp</name>
          <data>
            <name>10.1.1.1</name>
          </data>
          <data>
            <name>10.2.2.2</name>
          </data>
          <data>
            <name>10.3.3.3</name>
          </data>
          <data>
            <name>10.4.4.4</name>
          </data>
          <data>
            <name>color</name>
            <value>blue</value>
          </data>
          <data>
            <name>group-value</name>
            <value>0</value>
          </data>
        </apply-macro>
      </mpls>
    </protocols>
  </configuration>
</rpc-reply>

```

When you write commit script macros, referring to the `<data>`, `<name>`, and `<value>` elements enables you to extract and manipulate the parameters contained in `apply-macro` statements. For example, in the following `select` attribute, the XPath expression extracts the text contained in the `<value>` element that is a child of a `<data>` element that also contains a `<name>` child element with the text `color`. The variable declaration assigns the text of the `<value>` element to a variable named `$color`.

```
<xsl:variable name="color" select="data[name = 'color']/value"/>
```

Expanding the Custom Syntax

In the corresponding commit script, you include one or more XSLT or SLAX programming instructions that inspect the configuration for the **apply-macro** statement at a specified hierarchy level. Optionally, you can use the **data/name** expression to select a parameter in the **apply-macro** statement:

```
<xsl:for-each select="xpath-expression/apply-macro[data/name = 'parameter-name']">
```

For example, the following XSLT programming instruction selects every **apply-macro** statement that contains the **color** parameter and that appears at the **[edit protocols mpls]** hierarchy level:

```
<xsl:for-each select="protocols/mppls/apply-macro[data/name = 'color']">
```

The SLAX equivalent is:

```
for-each (protocols/mppls/apply-macro[data/name = 'color'])
```

When expanding macros, a particularly useful programming instruction is the **<xsl:value-of>** instruction. This instruction selects a parameter value and uses it to build option values for Junos OS statements. For example, the following instruction concatenates the value of the **\$color** variable, the text **-lsp-**, and the current context node (represented by **"."**) to build a name for an LSP.

```
<label-switched-path>
  <name>
    <xsl:value-of select="concat($color, '-lsp-',.)"/>
  </name>
</label-switched-path>
```

SLAX uses the underscore (**_**) to concatenate values:

```
<label-switched-path> {
  <name> $color _ '-lsp-' _ .;
```

When the script includes instructions to find the necessary data, you can provide content for a transient change that uses the data to construct a standard Junos OS configuration.

The following transient change creates an administration group and adds the **label-switched-path** statement to the configuration. The label-switched path is assigned a name that concatenates the value of the **\$color** variable, the text **-lsp-**, and the currently selected IP address represented by the period (**"."**). The transient change also adds the **to** statement and assigns the currently selected IP address. Finally, the transient change adds the **admin-group include-any** statement and assigns the value of the **\$color** variable.

```
<transient-change>
  <protocols>
    <mppls>
      <admin-groups>
        <name><xsl:value-of select="$color"/></name>
        <group-value><xsl:value-of select="$group-value"/></group-value>
      </admin-groups>
      <xsl:for-each select="data[not(value)]/name">
        <label-switched-path>
          <name><xsl:value-of select="concat($color, '-lsp-',.)"/></name>
          <to><xsl:value-of select="."/></to>
        <admin-group>
```

```

        <include-any><xsl:value-of select="$color"/></include-any>
      </admin-group>
    </label-switched-path>
  </xsl:for-each>
</mpls>
</protocols>
</transient-change>

```

The SLAX equivalent is:

```

<transient-change> {
  <protocols> {
    <mpls> {
      <admin-groups> {
        <name> $color;
        <group-value> $group-value;
      }
      for-each (data[not(value)]/name) {
        <label-switched-path> {
          <name> $color _ '-lsp-' _ .;
          <to> .;
          <admin-group> {
            <include-any> $color;
          }
        }
      }
    }
  }
}

```

NOTE: The example shown here is partial. For a full example, see [“Example: Creating Custom Configuration Syntax with Macros”](#) on page 208.

After committing the configuration, the script runs, and the resulting full configuration looks like this:

```

[edit]
protocols {
  mpls {
    label-switched-path blue-lsp-10.1.1.1 {
      to 10.1.1.1;
      admin-group include-any blue;
    }
    label-switched-path blue-lsp-10.2.2.2 {
      to 10.2.2.2;
      admin-group include-any blue;
    }
    label-switched-path blue-lsp-10.3.3.3 {
      to 10.3.3.3;
      admin-group include-any blue;
    }
    label-switched-path blue-lsp-10.4.4.4 {
      to 10.4.4.4;
      admin-group include-any blue;
    }
  }
}

```

```
}  
}
```

The previous example demonstrates how you can use a simplified custom syntax to configure label-switched paths (LSPs). If your network design requires a large number of LSPs to be configured, using a commit script macro can save time, ensure consistency, and prevent configuration errors.

Other Ways to Use Macros

The example discussed in [“Creating a Custom Syntax” on page 159](#) shows a macro that uses transient changes to create the intended operational impact. Alternatively, you can create a commit script that uses persistent changes to add the standard Junos OS statements to the candidate configuration and delete your custom syntax entirely. This way, a network operator who might be unfamiliar with your custom syntax can view the configuration file and see the full configuration rendered as standard Junos OS statements. Still, because the commit script macro remains in effect, you can quickly and easily create a complex configuration using your custom syntax.

In addition to the type of application discussed in [“Creating a Custom Syntax” on page 159](#), you can also use macros to prevent a commit script from performing a task. For example, a basic commit script that automatically adds MPLS configuration to interfaces can make an exception for interfaces you explicitly tag as not requiring MPLS, by testing for the presence of an **apply-macro** statement named **no-mpls**. For an example of this use of macros, see [“Example: Controlling LDP Configuration” on page 255](#).

You can use the **apply-macro** statement as a place to store external data. The commit script does not inspect the **apply-macro** statement, so the **apply-macro** statement has no operational impact on the device, but the data can be carried in the configuration file to be used by external applications.

Avoiding Potential Conflicts When Using Multiple Commit Scripts

When you use multiple commit scripts, each script evaluates the original candidate configuration file. Changes made by one script are not evaluated by the other scripts. This means that conflicts between scripts might not be resolved when the scripts are first applied to the configuration. The commit scripts are executed in the order they are listed at the `[edit system scripts commit]` hierarchy level, as illustrated in [Figure 7 on page 165](#).

Figure 7: Configuration Evaluation by Multiple Commit Scripts

As an example of a conflict between commit scripts, suppose that commit script **A.xsl** is created to ensure that the device uses the domain name server with IP address **192.168.0.255**. Later, the DNS server's address is changed to **192.168.255.255** and a second script, **B.xsl**, is added to check that the device uses the DNS server with that address. However, script **A.xsl** is not removed or disabled.

Because each commit script evaluates the original candidate configuration, the final result of executing both scripts **A.xsl** and **B.xsl** depends on which DNS server address is configured in the original candidate configuration. If the now outdated address of **192.168.0.255** is configured, script **B.xsl** changes it to **192.168.255.255**. However, if the

correct address of **192.168.255.255** is configured, script **A.xsl** changes it to the incorrect value **192.168.0.255**.

As another example of a potential conflict between commit scripts, suppose that a commit script protects a hierarchy using the **protect** attribute. If a second commit script attempts to modify or delete the hierarchy or the statements within the hierarchy, Junos OS issues a warning during the commit process and prevents the configuration change.

Exercise care to ensure that you do not introduce conflicts between scripts like those described in the examples. As a method of checking for conflicts with persistent changes, you can issue two separate **commit** commands.

Related Documentation

- [How Commit Scripts Work on page 148](#)

Required Boilerplate for Commit Scripts

When you write commit scripts, you use Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) tools provided with Junos OS. These tools include basic boilerplate that you must include in all commit scripts, optional extension functions that accomplish scripting tasks more easily, and named templates that make commit scripts easier to read and write, which you import from a file called **junos.xsl**. For more information about the extension functions and templates, see [“Junos Script Automation: Extension Functions in the jcs Namespace Overview” on page 8](#) and [“Junos Script Automation: Named Templates in the jcs Namespace Overview” on page 28](#).

Commit scripts are based on Junos XML and Junos XML protocol tag elements. Like all XML elements, angle brackets enclose the name of a Junos XML or Junos XML protocol tag element in its opening and closing tags. This is an XML convention, and the brackets are a required part of the complete tag element name. They are not to be confused with the angle brackets used in the documentation to indicate optional parts of Junos OS CLI command strings.

You must include either XSLT or SLAX boilerplate as the starting point for all commit scripts that you create. The XSLT boilerplate follows:

XSLT Boilerplate for Commit Scripts

```

1  <?xml version="1.0" standalone="yes"?>
2  <xsl:stylesheet version="1.0"
3    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4    xmlns:junos="http://xml.juniper.net/junos/*/junos"
5    xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6    xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
7    <xsl:import href="../../import/junos.xsl"/>

8    <xsl:template match="configuration">
9      <!-- ... Insert your code here ... -->
10     </xsl:template>
11  </xsl:stylesheet>
```

Line 1 is the Extensible Markup Language (XML) processing instruction (PI). This PI specifies that the code is written in XML using version 1.0. The XML PI, if present, must be the first noncomment token in the script file.

```
1 <?xml version="1.0"?>
```

Lines 2 through 6 set the style sheet element and the associated namespaces. Line 2 sets the style sheet version as 1.0. Lines 3 through 6 list all the namespace mappings commonly used in commit scripts. Not all of these prefixes are used in this example, but it is not an error to list namespace mappings that are not referenced. Listing all namespace mappings prevents errors if the mappings are used in later versions of the script.

```
2 <xsl:stylesheet version="1.0"
3   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4   xmlns:junos="http://xml.juniper.net/junos/*/junos"
5   xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6   xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
```

Line 7 is an XSLT import statement. It loads the templates and variables from the file referenced as `../import/junos.xsl`, which ships as part of the Junos OS. The `junos.xsl` file contains a set of named templates you can call in your scripts. These named templates are discussed in [“Junos Script Automation: Named Templates in the jcs Namespace Overview” on page 28](#) and [“Junos Named Templates in the jcs Namespace Summary” on page 30](#).

```
7 <xsl:import href="../import/junos.xsl"/>
```

Line 8 defines a template that matches the `<configuration>` element, which is the node selected by the `<xsl:template match="/">` template, contained in the `junos.xsl` import file. The `<xsl:template match="configuration">` element allows you to exclude the `/configuration/` root element from all XML Path Language (XPath) expressions in the script and begin XPath expressions with the top Junos OS hierarchy level. For more information, see [“XPath Overview” on page 50](#).

```
8 <xsl:template match="configuration">
```

Add your code between Lines 8 and 9.

Line 9 closes the template.

```
9 </xsl:template>
```

Line 10 closes the style sheet and the commit script.

```
10 </xsl:stylesheet>
```

SLAX Boilerplate for Commit Scripts

The corresponding SLAX boilerplate is as follows:

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  /*
  * Insert your code here
  */
}
```

XML Syntax for Common Commit Script Tasks

A commit script can perform common configuration tasks by adding the appropriate attribute to a specific XML tag. [Table 14 on page 168](#) summarizes the tasks and the syntax for each task.

Table 14: XML Syntax for Common Commit Script Tasks

Action	Syntax	Example
Add a data element	normal XML	<pre><address> <name>192.168.1.1</name> </address></pre>
Remove the inactive tag from a statement	active="active"	<pre><address active="active"> <name>192.168.1.1/30</name> </address></pre>
Delete a data element	delete="delete"	<pre><address delete="delete"> <name>192.168.1.1/30</name> </address></pre>
Add the inactive tag to a statement	inactive="inactive"	<pre><address inactive="inactive"> <name>192.168.1.1/30</name> </address></pre>
Insert a new ordered data element	insert="(before after)" name="reference-value"	<pre><address insert="before" name="192.168.1.5/30"> <name>192.168.1.1/30</name> </address></pre>
Add the protect tag to a statement or node to prevent configuration changes to that element	protect="protect"	<pre><address protect="protect"> <name>192.168.1.1/30</name> </address></pre>
Rename a statement	rename="rename" name="new-name"	<pre><address rename="rename" name="192.168.1.1/30"> <name>192.168.1.5/30</name> </address></pre>
Replace a node or statement in the hierarchy	replace="replace"	<pre><system> <services replace="replace"> [...] </services> </system></pre>
Unprotect a statement or node in the hierarchy	unprotect="unprotect"	<pre><address unprotect="unprotect"> <name>192.168.1.1/30</name> </address></pre>

Table 14: XML Syntax for Common Commit Script Tasks (*continued*)

Action	Syntax	Example
Annotate a configuration statement with a comment	<code><junos:comment></code>	<pre> <system> <junos:comment> /* added by username */ </junos:comment> <services> [...] </services> </system> </pre>

Design Considerations for Commit Scripts

After you have an understanding of XSLT and some experience looking at Junos OS configuration data in XML, creating commit scripts is fairly straightforward. This section provides some advice and common patterns for developing commit scripts.

XSLT is an interpreted language, making performance an important consideration. For best performance, minimize node traversals and testing performed on each node. When possible, use the **select** attribute on a recursive `<xsl:apply-templates>` invocation to limit the portion of the document hierarchy being visited.

For example, the following **select** attribute limits the nodes to be evaluated by specifying SONET/SDH interfaces that have the **inet** (IPv4) protocol family enabled:

```
<xsl:apply-templates select="interfaces/interface[starts-with(name, 'so-') and
unit/family/inet]"/>
```

The following example contains two `<xsl:apply-templates>` instructions that limit the scope of the script to the **import** statements configured at the **[edit protocols ospf]** and **[edit protocols isis]** hierarchy levels:

```

<xsl:template match="configuration">
  <xsl:apply-templates select="protocols/ospf/import"/>
  <xsl:apply-templates select="protocols/isis/import"/>
  <!-- ... body of template ... -->
</xsl:template>

```

In an interpreted language, doing anything more than once can affect performance. If the script needs to reference a node or node set repeatedly, make a variable that holds the node set, and then make multiple references to the variable. For example, the following variable declaration creates a variable called **mpls** that resolves to the **[edit protocols mpls]** hierarchy level. This allows the script to traverse the **/protocols/** hierarchy searching for the **mpls/** node only once.

```

<xsl:variable name="mpls" select="/protocols/mpls"/>
<xsl:choose>
  <xsl:when test="$mpls/path-mtu/allow-fragmentation">
    <!-- ... -->
  </xsl:when>
  <xsl:when test="$mpls/hop-limit > 40">
    <!-- ... -->
  </xsl:when>
</xsl:choose>

```

Variables are also important when using `<xsl:for-each>` instructions, because the current context node examines each node selected by the `<xsl:for-each>` instruction. For example, the following script uses multiple variables to store and refer to values as the `<xsl:for-each>` instruction evaluates the E1 interfaces that are configured on all channelized STM1 (`cstm1-`) interfaces:

```
<xsl:param name="limit" select="16"/>
<xsl:template match="configuration">
  <xsl:variable name="interfaces" select="interfaces"/>
  <xsl:for-each select="$interfaces/interface[starts-with(name, 'cstm1-')]">
    <xsl:variable name="triple" select="substring-after(name, 'cstm1-')"/>
    <xsl:variable name="e1name" select="concat('e1-', $triple)"/>
    <xsl:variable name="count"
      select="count($interfaces/interface[starts-with(name, $e1name)])"/>
    <xsl:if test="$count > $limit">
      <xnm:error>
        <edit-path>[edit interfaces]</edit-path>
        <statement><xsl:value-of select="name"/></statement>
        <message>
          <xsl:text>E1 interface limit exceeded on CSTM1 IQ PIC. </xsl:text>
          <xsl:value-of select="$count"/>
          <xsl:text> E1 interfaces are configured, but only </xsl:text>
          <xsl:value-of select="$limit"/>
          <xsl:text> are allowed.</xsl:text>
        </message>
      </xnm:error>
    </xsl:if>
  </xsl:for-each>
</xsl:template>
```

If you channelize a `cstm1-0/1/0` interface into 17 E1 interfaces, the script causes the following error message to appear when you issue the `commit` command. (For more information about this example, see [“Example: Limiting the Number of E1 Interfaces” on page 272.](#))

```
[edit]
user@host# commit
[edit interfaces]
'cstm1-0/1/0'
E1 interface limit exceeded on CSTM1 IQ PIC.
17 E1 interfaces are configured, but only 16 are allowed.
error: 1 error reported by commit scripts
error: commit script failure
```

- [Applying a Change to SONET/SDH Interfaces on page 171](#)
- [Applying a Change to ISO-Enabled Interfaces on page 172](#)

Applying a Change to SONET/SDH Interfaces

The following commit script applies a transient change to each interface whose name begins with **so-**, setting the encapsulation to **ppp**. For information about transient changes, see [“Overview of Generating Persistent or Transient Configuration Changes” on page 154](#). For a SLAX version of this example, see [“Example: Generating a Transient Change” on page 202](#).

```

1  <?xml version="1.0"?>
2  <xsl:stylesheet version="1.0"
3    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4    xmlns:junos="http://xml.juniper.net/junos/*/junos"
5    xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6    xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
7    <xsl:import href="../../import/junos.xsl"/>

8    <xsl:template match="configuration">
9      <xsl:for-each select="interfaces/interface[starts-with(name, 'so-') \
        and unit/family/inet]">
10        <transient-change>
11          <interfaces>
12            <interface>
13              <name><xsl:value-of select="name"/></name>
14              <encapsulation>ppp</encapsulation>
15            </interface>
16          </interfaces>
17        </transient-change>
18      </xsl:for-each>
19    </xsl:template>
20  </xsl:stylesheet>

```

Lines 1 through 8 are boilerplate as described in [“Required Boilerplate for Commit Scripts” on page 166](#) and are omitted here for brevity.

Line 9 is an **<xsl:for-each>** programming instruction that examines each interface node whose names starts with **so-** and that has **family inet** enabled on any logical unit. (It appears here on two lines only for brevity.)

```

9    <xsl:for-each select="interfaces/interface[starts-with(name, 'so-') \
        and unit/family/inet]">

```

Line 10 is the open tag for a transient change. The possible contents of the **<transient-change>** element are the same as the contents of the **<configuration>** tag element in the Junos XML protocol operation **<load-configuration>**.

```

10    <transient-change>

```

Lines 11 through 16 represent the content of the transient change. The encapsulation is set to **ppp**.

```

11    <interfaces>
12      <interface>
13        <name><xsl:value-of select="name"/></name>
14        <encapsulation>ppp</encapsulation>
15      </interface>
16    </interfaces>

```

Lines 17 through 19 close all open tags in this template.

```

17     </transient-change>
18   </xsl:for-each>
19 </xsl:template>

```

Line 20 closes the style sheet and the commit script.

```

20 </xsl:stylesheet>

```

Applying a Change to ISO-Enabled Interfaces

The following sample script ensures that interfaces that are enabled for an International Organization for Standardization (ISO) protocol also have MPLS enabled and are included at the **[edit protocols mpls interface]** hierarchy level. For a SLAX version of this example, see [“Example: Controlling IS-IS and MPLS Interfaces” on page 251](#).

```

5    xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6    xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
7    <xsl:import href="../../../import/junos.xsl"/>

8    <xsl:template match="configuration">
9      <xsl:variable name="mpls" select="protocols/mpls"/>
10     <xsl:for-each select="interfaces/interface/unit[family/iso]">
11       <xsl:variable name="ifname" select="concat(..name, ':', name)"/>
12       <xsl:if test="not(family/mpls)">
13         <xsl:call-template name="jcs:emit-change">
14           <xsl:with-param name="message">
15             <xsl:text>
16               Adding 'family mpls' to ISO-enabled interface
17             </xsl:text>
18           </xsl:with-param>
19           <xsl:with-param name="content">
20             <family>
21               <mpls/>
22             </family>
23           </xsl:with-param>
24         </xsl:call-template>
25       </xsl:if>
26       <xsl:if test="$mpls and not($mpls/interface[name = $ifname])">
27         <xsl:call-template name="jcs:emit-change">
28           <xsl:with-param name="message">
29             <xsl:text>Adding ISO-enabled interface </xsl:text>
30             <xsl:value-of select="$ifname"/>
31             <xsl:text> to [protocols mpls]</xsl:text>
32           </xsl:with-param>
33           <xsl:with-param name="dot" select="$mpls"/>
34           <xsl:with-param name="content">
35             <interface>
36               <name>
37                 <xsl:value-of select="$ifname"/>
38               </name>
39             </interface>

```

```

40         </xsl:with-param>
41     </xsl:call-template>
42 </xsl:if>
43 </xsl:for-each>
44 </xsl:template>
45 </xsl:stylesheet>

```

Lines 1 through 8 are boilerplate as described in [“Required Boilerplate for Commit Scripts” on page 166](#) and are omitted here for brevity.

Line 9 saves a reference to the **[edit protocols mpls]** hierarchy level so that it can be referenced in the following **for-each** loop.

```

9     <xsl:variable name="mpls" select="protocols/mpls"/>

```

Line 10 examines each interface unit (logical interface) on which ISO is enabled. The **select** stops at the **unit**, but the predicate limits the selection to only those units that contain an **<iso>** element nested under a **<family>** element.

```

10    <xsl:for-each select="interfaces/interface/unit[family/iso]">

```

Line 11 builds the interface name in a variable. First, the **name** attribute of the variable declaration is set to **ifname**. In Junos OS, an interface name is the concatenation of the device name, a period, and the unit number. At this point in the script, the context node is the unit number, because Line 10 changes the context to **interfaces/interface/unit**. The **../name** refers to the **<name>** element of the parent node of the context node, which is the device name (**type-fpc/pic/port**). The **"name"** token in the XPath expression refers to the **<name>** element of the context node, which is the unit number (**unit-number**). After the concatenation is performed, the XPath expression in Line 11 resolves to **type-fpc/pic/port.unit-number**. As the **<xsl:for-each>** instruction in Line 10 traverses the hierarchy and locates ISO-enabled interfaces, the interface names are recursively stored in the **ifname** variable.

```

11    <xsl:variable name="ifname" select="concat(../name, '.', name)"/>

```

Line 12 evaluates as true for each ISO-enabled interface that does not have MPLS enabled.

```

12    <xsl:if test="not(family/mpls)">

```

Line 13 calls the **jcs:emit-change** template, which is a helper or convenience template in the **junos.xml** file. This template is discussed in [jcs:emit-change Template](#).

```

13    <xsl:call-template name="jcs:emit-change">

```

Lines 14 through 18 use the **message** parameter from the **jcs:emit-change** template. The message parameter is a shortcut you can use instead of explicitly including the **<warning>**, **<edit-path>**, and **<statement>** elements.

```

14        <xsl:with-param name="message">
15            <xsl:text>
16                Adding 'family mpls' to ISO-enabled interface
17            </xsl:text>
18        </xsl:with-param>

```

Lines 19 through 23 use the **content** parameter from the **jcs:emit-change** template. The **content** parameter specifies the change to make, relative to the current context node.

```

19        <xsl:with-param name="content">
20            <family>
21            <mpls/>

```

```

22         </family>
23     </xsl:with-param>

```

Lines 24 and 25 close the tags opened in Lines 13 and 12, respectively.

```

24     </xsl:call-template>
25 </xsl:if>

```

Line 26 tests whether MPLS is already enabled and if this interface is not configured at the **[edit protocols mpls interface]** hierarchy level.

```

26     <xsl:if test="$mpls and not($mpls/interface[name = $ifname])">

```

Lines 27 through 41 contain another invocation of the **jcs:emit-change** template. In this invocation, the interface is added at the **[edit protocols mpls interface]** hierarchy level.

```

27         <xsl:call-template name="jcs:emit-change">
28             <xsl:with-param name="message">
29                 <xsl:text>Adding ISO-enabled interface </xsl:text>
30                 <xsl:value-of select="$ifname"/>
31                 <xsl:text> to [edit protocols mpls]</xsl:text>
32             </xsl:with-param>
33             <xsl:with-param name="dot" select="$mpls"/>
34             <xsl:with-param name="content">
35                 <interface>
36                     <name>
37                         <xsl:value-of select="$ifname"/>
38                     </name>
39                 </interface>
40             </xsl:with-param>
41         </xsl:call-template>

```

Lines 42 through 45 close all open elements.

```

42     </xsl:if>
43 </xsl:for-each>
44 </xsl:template>
45 </xsl:stylesheet>

```

Controlling Execution of Commit Scripts During Commit Operations

Commit scripts are stored on a device's hard drive in the **/var/db/scripts/commit** directory or on the flash drive in the **/config/scripts/commit** directory. Only users in the Junos OS superuser login class can access and edit files in these directories. For information about setting the storage location for scripts, see ["Storing and Enabling Scripts" on page 86](#) and ["Storing Scripts in Flash Memory" on page 87](#). A commit script is not actually executed during commit operations unless its filename is included at the **[edit system scripts commit file]** hierarchy level. To prevent execution of a commit script, delete the commit script's filename at that hierarchy level.

By default, the commit operation fails unless all scripts included at the **[edit system scripts commit file]** hierarchy level actually exist in the commit script directory. To enable the commit operation to succeed even if a script is missing, include the **optional** statement at the **[edit system scripts commit file filename]** hierarchy level. For example, you might

want to mark a script as optional if you anticipate the need to quickly remove it from operation by deleting it from the commit script directory, but do not want to remove the commit script filename at the **[edit system scripts commit file]** hierarchy level. To enable use of the script again later, you simply replace the file in the commit script directory.

CAUTION: When you include the **optional** statement at the **[edit system scripts commit file *filename*]** hierarchy level, no error message is generated during the commit operation if the file does not exist. As a result, you might not be aware that a script is not executed as you expect.

You can also deactivate and reactivate commit scripts by issuing the **deactivate** and **activate** configuration mode commands. When a commit script is deactivated, the script is marked as inactive in the configuration and does not execute during the commit operation. When a commit script is reactivated, the script is again executed during the commit operation.

To determine which commit scripts are currently enabled on the device, use the **show** command to display the files included at the **[edit system scripts commit]** hierarchy level. To ensure that the enabled files are on the device, list the contents of the **/var/run/scripts/commit/** directory using the **file list /var/run/scripts/commit** operational mode command.

The filename of a commit script written in SLAX must include the **.slax** extension for the script to be executed. No filename extension is required for commit scripts written in XSLT, but we strongly recommend that you append the **.xsl** extension.

See the following sections:

- [Enabling Commit Scripts to Execute During Commit Operations on page 175](#)
- [Preventing Commit Scripts from Executing During Commit Operations on page 176](#)
- [Deactivating Commit Scripts on page 176](#)
- [Activating Commit Scripts on page 177](#)

Enabling Commit Scripts to Execute During Commit Operations

To configure a commit script to execute during a commit operation, follow these steps:

1. Ensure that the commit script is located in the correct directory: the **/var/db/scripts/commit** directory on the hard drive or the **/config/scripts/commit** directory on the flash drive. For more information about script storage location, see [“Storing Scripts in Flash Memory” on page 87](#).
2. Enable the commit script by including the **file *filename*** statement at the **[edit system scripts commit]** hierarchy level. Only users who belong to the Junos OS **super-user** login class can enable commit scripts.

```
[edit system scripts commit]
user@host# set file filename <optional>
```

- **filename**—Name of the commit script.

- **optional**—Enable the commit operation to succeed when the script file does not exist in the script directory. If this statement is omitted, the commit operation fails if the script does not exist.

3. Commit the configuration:

```
[edit]
user@host# commit
```

The commit script does not execute during this commit operation, but executes automatically during each subsequent commit operation.

Preventing Commit Scripts from Executing During Commit Operations

To prevent a commit script from executing during a commit operation, follow these steps:

1. Delete the commit script filename at the **[edit system scripts commit]** hierarchy level:

```
[edit system scripts commit]
user@host# delete file filename
```

filename—Name of the commit script.

2. Remove the commit script from the commit script directory. Although removing the commit script from the commit script directory is not necessary, it is always a good policy to delete unused files from the system.

3. Commit your changes:

```
[edit]
user@host# commit
```

Deactivating Commit Scripts

To deactivate a commit script, follow these steps:

1. Issue the **deactivate** command:

```
[edit]
user@host# deactivate system scripts commit file filename
```

2. Commit your changes:

```
[edit]
user@host# commit
```

A deactivated commit script is marked as **inactive** and ignored during a commit operation.

In this example, the script **mycommit.slax** is deactivated:

```
[edit]
user@host# deactivate system scripts commit file mycommit.slax
[edit]
user@host# show system scripts commit
inactive: file mycommit.slax
```

Activating Commit Scripts

To activate an inactive commit script, follow these steps:

1. Issue the **activate** command:

```
[edit]
user@host# activate system scripts commit file filename
```

2. Commit your changes:

```
[edit]
user@host# commit
```

The commit script does not execute during this commit operation, but executes automatically during each subsequent commit operation.

Configuring Checksum Hashes for a Commit Script

You can configure one or more checksum hashes that can be used to verify the integrity of a commit script before the script runs on the switch, router, or security device.

To configure a checksum hash:

1. Create the script.
2. Place the script in the `/var/db/scripts/commit` directory on the device.
3. Run the script through one or more hash functions to calculate hash values.

Junos OS supports MD5, SHA-1, and SHA-256 hash functions.

```
user@host> file checksum md5 /var/db/scripts/commit/script1.slax
MD5 (/var/db/scripts/commit/script1.slax) = 3af7884eb56e2d4489c2e49b26a39a97
user@host> file checksum sha1 /var/db/scripts/commit/script1.slax
SHA1 (/var/db/scripts/commit/script1.slax) =
00dc690fb08fb049577d012486c9a6dad34212c0
user@host> file checksum sha-256 /var/db/scripts/commit/script1.slax
SHA256 (/var/db/scripts/commit/script1.slax) =
150bf53383769f3bfedd41fe73320777f208d4fda81230cb27b8738
```

4. Configure the script.

```
[edit system scripts commit]
user@host# set file script1.slax checksum md5 3af7884eb56e2d4489c2e49b26a39a97
[edit system scripts commit]
user@host# set file script1.slax checksum
sha-1 00dc690fb08fb049577d012486c9a6dad34212c0
[edit system scripts commit]
user@host# set file script1.slax checksum
sha-256 150bf53383769f3bfedd41fe73320777f208d4fda81230cb27b8738
```

During the execution of the script, Junos OS recalculates the checksum value using the configured hash and verifies that the calculated value matches the configured value. If the values differ, the execution of the script fails. When you configure multiple checksum values with different hash algorithms, all the configured values must match the calculated values; otherwise, the script execution fails. The commit operation also fails.

Executing Large Commit Scripts

When you use large commit scripts, the standard commit model can have trouble reading these scripts. When this occurs, you can include the **direct-access** statement at the **[edit system scripts commit]** hierarchy level. When the **direct-access** statement is included, the script driver retrieves the candidate configuration directly from the configuration database. Once the candidate configuration is retrieved, the script driver processes this configuration file against the commit scripts and returns any generated actions to the management (mgd) process.

Directly accessing the configuration data and processing non-XML converted data are processor-intensive compared to the standard commit model. You should only use this feature to handle large files, because system performance is affected.

To set the script driver to directly access the candidate configuration, include the **direct-access** statement at the **[edit system scripts commit]** hierarchy level.

```
[edit system scripts commit]
direct-access;
```

Generating a Custom Warning, Error, or System Log Message

- [Generating a Custom Warning, Error, or System Log Message on page 178](#)
- [Tag Elements to Use When Generating Messages on page 181](#)
- [Example: Generating a Custom Warning Message on page 183](#)
- [Example: Generating a Custom Error Message on page 186](#)
- [Example: Generating a Custom System Log Message on page 190](#)

Generating a Custom Warning, Error, or System Log Message

To generate a custom warning, error, or system log message, follow these steps:

1. At the start of the script, include the Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) boilerplate from “[Required Boilerplate for Commit Scripts](#)” on page 166. It is reproduced here for convenience:

XSLT Boilerplate

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
```

```

<xsl:import href="../../import/junos.xsl"/>

<xsl:template match="configuration">
  <!-- ... insert your code here ... -->
</xsl:template>
</xsl:stylesheet>

```

SLAX Boilerplate

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xsl";

match configuration {
  /*
  * insert your code here
  */
}

```

- At the position indicated by the comment *“insert your code here,”* include one or more XSLT programming instructions or their SLAX equivalents. Commonly used XSLT constructs include the following:

- **<xsl:choose>** **<xsl:when>** **<xsl:otherwise>**—Conditional construct that causes different instructions to be processed in different circumstances. The **<xsl:choose>** instruction contains one or more **<xsl:when>** elements, each of which tests an XPath expression. If the test evaluates as true, the XSLT processor executes the instructions in the **<xsl:when>** element. The XSLT processor processes only the instructions contained in the first **<xsl:when>** element whose **test** attribute evaluates as true. If none of the **<xsl:when>** elements’ **test** attributes evaluate as true, the content of the **<xsl:otherwise>** element, if there is one, is processed.
- **<xsl:for-each select="xpath-expression">**—Programming instruction that tells the XSLT processor to gather together a set of nodes and process them one by one. The nodes are selected by the Extensible Markup Language (XML) Path Language (XPath) expression in the **select** attribute. Each of the nodes is then processed according to the instructions contained in the **<xsl:for-each>** instruction. Code inside an **<xsl:for-each>** instruction is evaluated recursively for each node that matches the XPath expression. The context is moved to the node during each pass.
- **<xsl:if test="xpath-expression">**—Conditional construct that causes instructions to be processed if the XPath expression in the **test** attribute evaluates to **true**.

For example, the following programming instruction evaluates as true when the **source-route** statement is not included at the **[edit chassis]** hierarchy level:

```
<xsl:if test="not(chassis/source-route)">
```

In SLAX, the **if** construct looks like this:

```
if (not(chassis/source-route))
```

For more information about how to use programming instructions, including examples and pseudocode, see [“XSLT Programming Instructions Overview” on page 59](#). For

information about writing scripts in SLAX instead of XSLT, see [“SLAX Overview” on page 63](#).

3. Include a `<xnm:warning>`, `<xnm:error>`, or `<syslog>` element with a `<message>` child element that specifies the content of the message.

For warning and error messages, you can include several other child elements, such as the `jcs:edit-path` and `jcs:statement` templates, which cause the warning or error message to include the relevant configuration hierarchy and statement information, as shown in the following examples.

This `<xnm:warning>` element:

```
<xnm:warning>
  <xsl:call-template name="jcs:edit-path">
    <xsl:with-param name="dot" select="chassis"/>
  </xsl:call-template>
  <message>IP source-route processing is not enabled.</message>
</xnm:warning>
```

emits this output when you issue the `commit` command:

```
[edit]
user@host# commit

[edit chassis]
warning: IP source-route processing is not enabled.
commit complete
```

This `<xnm:error>` element:

```
<xnm:error>
  <xsl:call-template name="jcs:edit-path"/>
  <xsl:call-template name="jcs:statement"/>
  <message>Missing a description for this T1 interface.</message>
</xnm:error>
```

emits this output when you issue the `commit` command:

```
[edit]
user@host# commit

[edit interfaces interface t1-0/0/0]
'interface t1-0/0/0;'
Missing a description for this T1 interface.
error: 1 error reported by commit scripts
error: commit script failure
```

NOTE: If you are including a warning message in conjunction with a script-generated configuration change, you can generate the warning by including the `message` parameter with the `jcs:emit-change` template. The `message` parameter causes the `jcs:emit-change` template to call the `<xnm:warning>` template, which sends a warning notification to the CLI. (For more information, see [“Overview of Generating Persistent or Transient Configuration Changes” on page 154](#).)

For system log messages, the only supported child element is `<message>`:

```
<syslog>
  <message>syslog-string</message>
</syslog>
```

For a description of all the XSLT tags and attributes you can include, see [“Tag Elements to Use When Generating Messages” on page 181](#).

For SLAX versions of these constructs, see [“Example: Generating a Custom Warning Message” on page 183](#), [“Example: Generating a Custom Error Message” on page 186](#), and [“Example: Generating a Custom System Log Message” on page 190](#).

4. Save the script with a meaningful name.
5. Copy the script to either the `/var/db/scripts/commit` directory on the hard drive or the `/config/scripts/commit` directory on the flash drive. For information about setting the storage location for commit scripts, see [“Storing Scripts in Flash Memory” on page 87](#).

If the device has dual Routing Engines and you want the script to take effect on both of them, you must copy the script to the `/var/db/scripts/commit` or the `/config/scripts/commit` directory on both Routing Engines. The `commit synchronize` command does not copy scripts between Routing Engines.

6. Enable the script by including the `file` statement at the `[edit system scripts commit]` hierarchy level:

```
[edit system scripts commit]
file filename;
```

where *filename* is the name of the script.

Tag Elements to Use When Generating Messages

Table 15 on page 181 summarizes the tag elements that you can include in a custom warning, error, or system log message. For examples, see [“Example: Generating a Custom Warning Message” on page 183](#), [“Example: Generating a Custom Error Message” on page 186](#), and [“Example: Generating a Custom System Log Message” on page 190](#).

Table 15: Tags and Attributes for Creating Custom Warning, Error, and System Log Messages

Data Item, XML Element, or Attribute	Required or Supported	Description
Container Tags and Attributes		
<code><syslog></code>	Required for system log messages	Indicates that a system log message is going to be recorded.

Table 15: Tags and Attributes for Creating Custom Warning, Error, and System Log Messages (*continued*)

Data Item, XML Element, or Attribute	Required or Supported	Description
<code><xnm:error></code>	Required for error messages	Indicates that the server has encountered a problem while processing the client application's request.
<code><xnm:warning></code>	Required for warning messages	Indicates that the server has encountered a problem while processing the client application's request.
<code>xmlns url</code>	Supported in warning and error messages	Names the XML namespace for the contents of the tag element. The value is a URL of the form <code>http://xml.juniper.net/xnm/version/xnm</code> , where version is a string such as 1.1.
<code>xmlns:xnm url</code>	Required for warning and error messages. The <code>xmlns:xnm</code> element is included in the script boilerplate, which sets the namespace globally.	Names the XML namespace for child tag elements that have the <code>xnm:</code> prefix on their names. The value is a URL of the form <code>http://xml.juniper.net/xnm/version/xnm</code> , where version is a string such as 1.1.
Content Tags		
<code><column></code>	Supported in warning and error messages only	Identifies the element that caused the error by specifying its position as the number of characters after the first character in the line specified by the <code><line-number></code> tag element in the configuration file that was being loaded (which is named in the <code><filename></code> tag element). We recommend combining the <code><column></code> tag with the <code><line-number></code> and <code><filename></code> tags.
<code><database-status-information></code>	Supported in error messages only	Provides information about the users currently editing the configuration.
<code><edit-path></code>	Supported in warning and error messages only	Specifies the level in the configuration hierarchy where the problem occurred, using the CLI configuration mode banner. We recommend combining the <code><edit-path></code> tag with the <code><statement></code> tag.
<code><filename></code>	Supported in warning and error messages only	Names the configuration file that was being loaded.
<code><line-number></code>	Supported in warning and error messages only	Specifies the line number where the error occurred in the configuration file that was being loaded, which is named by the <code><filename></code> tag element. We recommend combining the <code><line-number></code> tag with the <code><column></code> and <code><filename></code> tags.
<code><message></code>	Required in warning, error, and system log messages	Describes the warning, error, or system log message in a natural-language text string.
<code><parse/></code>	Supported in error messages only	Indicates that there was a syntactic error in the request submitted by the client application.

Table 15: Tags and Attributes for Creating Custom Warning, Error, and System Log Messages (*continued*)

Data Item, XML Element, or Attribute	Required or Supported	Description
<code><reason></code>	Supported in warning and error messages only	Describes the reason for the warning or error message.
<code><re-name></code>	Supported in warning and error messages only	Names the Routing Engine on which the process named by the <code><source-daemon></code> tag element is running.
<code><source-daemon></code>	Supported in warning and error messages only	Names the Junos OS module that was processing the request in which the warning or error message occurred.
<code><statement></code>	Supported in warning and error messages only	Specifies the configuration statement in effect when the problem occurred. We recommend combining the <code><statement></code> tag with the <code><edit-path></code> tag.
<code><token></code>	Supported in warning and error messages only	Names the element in the request that caused the warning or error message.
<code><xsl:call-template name="jcs:edit-path"></code>	Supported in warning and error messages only	<p>Emits an <code><edit-path></code> element, which specifies the CLI configuration mode edit path in effect when the warning or error was generated.</p> <p>If the problem is not at the current position in the XML hierarchy, you can alter the edit path by passing the <code>dot</code> parameter. For example, <code><xsl:param name="dot" select="system/ports/console"/></code> changes the edit path to <code>[edit system ports console]</code>.</p>
<code><xsl:call-template name="jcs:statement"></code>	Supported in warning and error messages only	<p>Emits a <code><statement></code> element, which describes the configuration statement in effect when the warning or error was generated.</p> <p>If the problem is not at the current position in the XML hierarchy, you can alter the statement by passing the <code>dot</code> parameter. For example, <code><xsl:with-param name="dot" select="system/ports/console/type"/></code> changes the statement to <code>type</code>.</p>

Example: Generating a Custom Warning Message

This example commit script generates a custom warning message when a specific statement is not included in the device configuration. The commit process is not affected by warnings.

- [Requirements on page 183](#)
- [Overview and Commit Script on page 184](#)
- [Configuration on page 185](#)
- [Verification on page 185](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

Using a commit script, write a custom warning message that appears when the **source-route** statement is not included at the **[edit chassis]** hierarchy level. (This example is the complete script for the sample `<xnm:warning>` element used in [“Generating a Custom Warning, Error, or System Log Message”](#) on page 178.)

The script is shown in both XSLT and SLAX syntax.

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../import/junos.xsl"/>

  <xsl:template match="configuration">
    <xsl:if test="not(chassis/source-route)">
      <xnm:warning>
        <xsl:call-template name="jcs:edit-path">
          <xsl:with-param name="dot" select="chassis"/>
        </xsl:call-template>
        <message>IP source-route processing is not enabled.</message>
      </xnm:warning>
    </xsl:if>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  if (not(chassis/source-route)) {
    <xnm:warning> {
      call jcs:edit-path($dot = chassis);
      <message> "IP source-route processing is not enabled.";
    }
  }
}
```

Configuration

Step-by-Step Procedure Download, enable, and test the script. To test that a commit script generates a warning message correctly, make sure that the candidate configuration contains the condition that elicits the warning. For this example, ensure that the **source-route** statement is not included at the **[edit chassis]** hierarchy level.

To test the example in this topic, perform the following steps:

1. Copy the XSLT or SLAX script into a text file, name the file **source-route.xml** or **source-route.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts commit]** hierarchy level and **source-route.xml** or **source-route.slax** as appropriate.

```
[edit]
user@host# set system scripts commit file source-route.xml
```

3. If the **source-route** statement is included at the **[edit chassis]** hierarchy level, issue the **delete chassis source-route** configuration mode command:

```
[edit]
user@host# delete chassis source-route
```

4. Issue the **commit and-quit** command.

```
[edit]
user@host# commit and-quit
```

Verification

Verifying Script Execution

Purpose Verify the warning message generated by the commit script.

Action Review the output of the **commit** command. The commit script generates a warning message when the **source-route** statement is not included at the **[edit chassis]** hierarchy level of the configuration. The warning does not affect the commit process.

```
[edit]
user@host# commit
[edit chassis]
warning: IP source-route processing is not enabled.
commit complete
```

To display the XML-formatted version of the warning message, issue the **commit check | display xml** command:

```
[edit]
user@host# commit check | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <commit-results>
    <routing-engine junos:style="normal">
      <name>re0</name>
      <xnm:warning>
        <edit-path>
```

```

        [edit chassis]
      </edit-path>
    <message>
      IP source-route processing is not enabled.
    </message>
  </xnm:warning>
<commit-check-success/>
</routing-engine>
</commit-results>
</rpc-reply>

```

To display a detailed trace of commit script processing, issue the **commit check | display detail** command:

```

Example: Generating a Custom Error Message

This example commit script generates a custom error message when a specific statement is not included in the device configuration, thereby halting the commit operation.

- [Requirements on page 187](#)
- [Overview and Commit Script on page 187](#)
- [Configuration on page 188](#)
- [Verification on page 188](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

Using a commit script, write a custom error message that appears when the **description** statement is not included at the **[edit interfaces t1-fpc/pic/port]** hierarchy level:

The script is shown in both XSLT and SLAX syntax.

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../import/junos.xsl"/>

  <xsl:template match="configuration">
    <xsl:variable name="interface" select="interfaces/interface"/>
    <xsl:for-each select="$interface[starts-with(name, 't1-')]">
      <xsl:variable name="ifname" select="."/>
      <xsl:if test="not(description)">
        <xnm:error>
          <xsl:call-template name="jcs:edit-path"/>
          <xsl:call-template name="jcs:statement"/>
          <message>Missing a description for this T1 interface.</message>
        </xnm:error>
      </xsl:if>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  var $interface = interfaces/interface;
  for-each ($interface[starts-with(name, 't1-')]) {
    var $ifname = .;
    if (not(description)) {
      <xnm:error> {
        call jcs:edit-path();
        call jcs:statement();
        <message> "Missing a description for this T1 interface.";
      }
    }
  }
}
```

Configuration

Step-by-Step Procedure Download, enable, and test the script: To test that a commit script generates an error message correctly, make sure that the candidate configuration contains the condition that elicits the error. For this example, ensure that the configuration for a T1 interface does not include the **description** statement.

To test the example in this topic, perform the following steps:

1. Copy the XSLT or SLAX script into a text file, name the file **description.xml** or **description.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts commit]** hierarchy level and **description.xml** or **description.slax** as appropriate.

```
[edit]
user@host# set system scripts commit file description.xml
```

3. If the configuration for every T1 interface includes the **description** statement, issue the following configuration mode commands:

```
[edit]
user@host# edit interfaces t1-0/0/1
[edit interfaces t1-0/0/1]
user@host# delete description
```

4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying Script Execution

Purpose Verify the error message generated by the commit script.

Action Review the output of the **commit** command. The commit script generates an error message for each T1 interface that does not include a **description** statement. Any error causes the commit process to fail.

```
[edit]
user@host# commit
[edit interfaces interface t1-0/0/1]
'description'
Missing a description for this T1 interface.
[edit interfaces interface t1-0/0/2]
'description'
Missing a description for this T1 interface.
error: 2 errors reported by commit scripts
error: commit script failure
```

To display the XML-formatted version of the error message, issue the **commit check | display xml** command:

```
[edit interfaces t1-0/0/1]
```

```

user@host# commit check | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <commit-results>
    <routing-engine junos:style="normal">
      <name>re0</name>

Example: Generating a Custom System Log Message

This example commit script generates a custom system log message when a specific statement is not included in the device configuration.

- [Requirements on page 190](#)
- [Overview and Commit Script on page 190](#)
- [Configuration on page 191](#)
- [Verification on page 192](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

Using a commit script, write a custom system log message that appears when the **read-write** statement is not included at the **[edit snmp community *community-name* authorization]** hierarchy level.

The script is shown in both XSLT and SLAX syntax.

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xml"/>

  <xsl:template match="configuration">
    <xsl:for-each select="snmp/community">
      <xsl:if test="not(authorization/read-write)">
        <syslog>
          <message>SNMP community does not have read-write access.
        </message>
        </syslog>
      </xsl:if>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  for-each (snmp/community) {
    if (not(authorization/read-write)) {
      <syslog> {
        <message> "SNMP community does not have read-write access.";
      }
    }
  }
}

```

Configuration**Step-by-Step
Procedure**

Download, enable, and test the script. To test that a commit script generates a system log message correctly, make sure that the candidate configuration contains the condition that elicits the system log message. For this example, ensure that the **read-write** statement is not included at the **[edit snmp community *community-name* authorization]** hierarchy level.

To test the example in this topic, perform the following steps:

1. Copy the XSLT or SLAX script into a text file, name the file **read-write.xsl** or **read-write.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts commit]** hierarchy level and **read-write.xsl** or **read-write.slax** as appropriate.

```

[edit]
user@host# set system scripts commit file read-write.xsl

```

3. If the **read-write** statement is included at the **[edit snmp community *community-name* authorization]** hierarchy level, issue the following configuration mode command:

```

[edit]
user@host# delete snmp community community-name authorization read-write

```

4. Issue the following command to verify that system logging is configured to write to a file (a commonly used file name is **messages**):

```

[edit]
user@host# show system syslog

```

For information about system log configuration, see the *Junos OS System Log Messages Reference*.

5. Issue the **commit** command to commit the configuration.

```

user@host# commit

```

Verification

Verifying Script Execution

Purpose Verify the system log message generated by the commit script.

Action System log messages are generated during a commit operation but not during a commit check operation. This means you cannot use the **commit check | display xml** or **commit check | display detail** configuration mode commands to verify the output of system log messages. When the commit operation completes, inspect the system log file. The default directory for log files is **/var/log/**. View the log file by issuing the **show log filename** operational mode command. For example, if messages are logged to the **messages** file, issue the following command:

```
user@host> show log messages
```

System log entries generated by commit scripts have the following format:

```
timestamp host-name cscript: message
```

Since the **read-write** statement was not included at the **[edit snmp community community-name authorization]** hierarchy level, the commit script should generate the "SNMP community does not have read-write access" message in the system log file.

```
Jun 3 14:34:37 host-name cscript: SNMP community does not have read-write access
```

- [Example: Generating a Transient Change on page 202](#)

Generating a Persistent or Transient Change

To generate a persistent or transient change, follow these steps:

1. At the start of the script, include the Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) boilerplate from "[Required Boilerplate for Commit Scripts](#)" on page 166. It is reproduced here for convenience:

XSLT Boilerplate

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
```

```

xmlns:junos="http://xml.juniper.net/junos/*/junos"
xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
<xsl:import href="../../import/junos.xsl"/>

<xsl:template match="configuration">
  <!-- ... Insert your code here ... -->
</xsl:template>
</xsl:stylesheet>

```

SLAX Boilerplate

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xsl";

match configuration {
  /*
   * Insert your code here
   */
}

```

- At the position indicated by the comment "*Insert your code here*," include one or more XSLT programming instructions or their SLAX equivalents. Commonly used XSLT constructs include the following.

- **<xsl:choose>** **<xsl:when>** **<xsl:otherwise>**—Conditional construct that causes different instructions to be processed in different circumstances. The **<xsl:choose>** instruction contains one or more **<xsl:when>** elements, each of which tests an XPath expression. If the test evaluates as true, the XSLT processor executes the instructions in the **<xsl:when>** element. The XSLT processor processes only the instructions contained in the first **<xsl:when>** element whose **test** attribute evaluates as true. If none of the **<xsl:when>** elements' **test** attributes evaluate as true, the content of the **<xsl:otherwise>** element, if there is one, is processed.
- **<xsl:for-each select="xpath-expression">**—Programming instruction that tells the XSLT processor to gather together a set of nodes and process them one by one. The nodes are selected by the Extensible Markup Language (XML) Path Language (XPath) expression in the **select** attribute. Each of the nodes is then processed according to the instructions contained in the **<xsl:for-each>** instruction. Code inside an **<xsl:for-each>** instruction is evaluated recursively for each node that matches the XPath expression. The context is moved to the node during each pass.
- **<xsl:if test="xpath-expression">**—Conditional construct that causes instructions to be processed if the XPath expression in the **test** attribute evaluates to **true**.

For example, the following XSLT programming instructions select each SONET/SDH interface that does not have the MPLS protocol family enabled:

```

<xsl:for-each select="interfaces/interface[starts-with(name, 'so-')]/unit">
  <xsl:if test="not(family/mpls)">

```

In SLAX, the **for-each** and **if** constructs look like this:

```
for-each (interfaces/interface[starts-with(name, 'so-')]/unit) {
  if (not(family/mpls)) {
```

For more information about how to use programming instructions, including examples and pseudocode, see [“XSLT Programming Instructions Overview” on page 59](#). For information about writing scripts in SLAX instead of XSLT, see [“SLAX Overview” on page 63](#).

3. Include instructions for changing the configuration. There are two ways to generate a persistent change and two ways to generate a transient change. To generate a persistent change, you can either reference the **jcs:emit-change** template or include a **<change>** element. To generate a transient change, you can either reference the **jcs:emit-change** template and pass in the **tag** parameter with **'transient-change'** selected or include a **<transient-change>** element.

The **jcs:emit-change** template allows for more efficient, less error-prone scripting because you can define the content of the change without specifying the complete XML hierarchy for the affected statement. Instead, the XML hierarchy is defined in the XPath expression contained in the script's programming instruction.

Consider the following examples. Both of the persistent change examples have the same result, even though they place the **unit** statement in different locations in the **<xsl:for-each>** and **<xsl:if>** programming instructions. In both cases, the script searches for SONET/SDH interfaces that do not have the MPLS protocol family enabled, adds the **family mpls** statement at the **[edit interfaces so-fpc/pic/port unit logical-unit-number]** hierarchy level, and emits a warning message stating that the configuration has been changed. Likewise, both of the transient change examples have the same result. They both set Point-to-Point Protocol (PPP) encapsulation on all SONET/SDH interface that have IP version 4 (IPv4) enabled.

Persistent Change Generated with the **jcs:emit-change** Template

In this example, the content of the persistent change (contained in the **content** parameter) is specified without including the complete XML hierarchy. Instead, the XPath expression in the **<xsl:for-each>** programming instruction sets the context for the change.

The message parameter is also included. This parameter causes the **jcs:emit-change** template to call the **<xnm:warning>** template, which sends a warning notification to the CLI. The message parameter automatically includes the current hierarchy information in the warning message. (For more information about the parameters available with the **jcs:emit-change** template, see [jcs:emit-change Template](#).)

```
<xsl:for-each select="interfaces/interface[starts-with(name, 'so-')]/unit">
  <xsl:if test="not(family/mpls)">
    <xsl:call-template name="jcs:emit-change">
      <xsl:with-param name="content">
        <family>
          <mpls/>
        </family>
      </xsl:with-param>
      <xsl:with-param name="message">
        <xsl:text>Adding 'family mpls' to SONET interface.</xsl:text>
```

```

        </xsl:with-param>
      </xsl:call-template>
    </xsl:if>
  </xsl:for-each>

```

Persistent Change Generated with the <change> Element

In this example, the complete XML hierarchy leading to the affected statement must be included as child elements of the <change> element.

This example includes the current hierarchy information in the warning message by referencing the **jcs:edit-path** and **jcs:statement** templates. For more information about warning messages, see [“Overview of Generating Custom Warning, Error, and System Log Messages” on page 153](#).

```

<xsl:for-each select="interfaces/interface[starts-with(name, 'so-')] ">
  <xsl:if test="not(unit/family/mpls)">
    <change>
      <interfaces>
        <interface>
          <name><xsl:value-of select="name"/></name>
          <unit>
            <name><xsl:value-of select="unit/name"/></name>
            <family>
              <mpls/>
            </family>
          </unit>
        </interface>
      </interfaces>
    </change>
    <xnm:warning>
      <xsl:call-template name="jcs:edit-path"/>
      <xsl:call-template name="jcs:statement">
        <xsl:with-param name="dot" select="unit/name"/>
      </xsl:call-template>
      <message>Adding 'family mpls' to SONET interface.</message>
    </xnm:warning>
  </xsl:if>
</xsl:for-each>

```

Transient Change Generated with the jcs:emit-change Template

In this example, the content of the transient change (contained in the **content** parameter) is specified without including the complete XML hierarchy. Instead, the XPath expression in the <xsl:for-each> programming instruction sets the context of the change. The **and** operator in the XPath expression means both operands are **true** when converted to Booleans; the second operand is not evaluated if the first operand is **false**.

The tag parameter is included with 'transient-change' selected. Without the **tag** parameter, the **jcs:emit-change** template generates a persistent change by default. (For more information about the parameters available with the **jcs:emit-change** template, see [jcs:emit-change Template](#).)

```

<xsl:for-each select="interfaces/interface[starts-with(name, 'so-') \
  and unit/family/inet]">
  <xsl:call-template name="jcs:emit-change">

```

```

    <xsl:with-param name="tag" select="'transient-change'"/>
    <xsl:with-param name="content">
      <encapsulation>ppp</encapsulation>
    </xsl:with-param>
  </xsl:call-template>
</xsl:for-each>

```

Transient Change Generated with the <transient-change> Element

In this example, the complete XML hierarchy leading to the affected statement must be included as child elements of the <transient-change> element.

```

<xsl:for-each select="interfaces/interface[starts-with(name, 'so-')\
  and unit/family/inet]">
  <transient-change>
    <interfaces>
      <interface>
        <name><xsl:value-of select="name"/></name>
        <encapsulation>ppp</encapsulation>
      </interface>
    </interfaces>
  </transient-change>
</xsl:for-each>

```

4. Save the script with a meaningful name.
5. Copy the script to either the `/var/db/scripts/commit` directory on the device hard drive or the `/config/scripts/commit` directory on the flash drive. For information about setting the storage location for commit scripts, see [“Storing Scripts in Flash Memory” on page 87](#).

If the device has dual Routing Engines and you want the script to take effect on both of them, you must copy the script to the `/var/db/scripts/commit` or the `/config/scripts/commit` directory on both Routing Engines. The `commit synchronize` command does not copy scripts between Routing Engines.

6. Enable the script by including the `file` statement at the `[edit system scripts commit]` hierarchy level:

```

[edit system scripts commit]
  file filename;

```

where *filename* is the name you assigned in Step 4.

7. If the script makes transient changes, include the `allow-transients` statement at the `[edit system scripts commit]` hierarchy level:

```

[edit system scripts commit]
  allow-transients;

```

If all the commit scripts run without errors, any transient changes are loaded into the checkout configuration, but not to the candidate configuration. Any persistent changes are loaded into the candidate configuration. The commit process then continues by validating the configuration and propagating changes to the affected processes on the device.

To display the configuration with both persistent and transient changes applied, issue the **show | display commit-scripts** configuration mode command:

```
[edit]
user@host# show | display commit-scripts
```

To display the configuration with only persistent changes applied, issue the **show | display commit-scripts no-transients** configuration mode command:

```
[edit]
user@host# show | display commit-scripts no-transients
```

Persistent and transient changes are loaded into the configuration in the same manner that the **load replace** configuration mode command loads an incoming configuration. When generating a persistent or transient change, adding the **replace="replace"** attribute to a configuration element produces the same behavior as a **replace:** tag in a **load replace** operation. Both persistent and transient changes are loaded into the configuration with the **load replace** behavior, but persistent changes are loaded into the candidate configuration and transient changes are loaded into the checkout configuration.

Removing a Persistent or Transient Change

After a commit script changes the configuration, you can remove the change and return the configuration to its previous state.

For persistent changes only, you can undo the configuration change by issuing the **delete**, **deactivate**, or **rollback** configuration mode command and committing the configuration. For both persistent and transient changes, you must remove, delete, or deactivate the associated commit script, or else the commit script regenerates the change during a subsequent commit operation.

Deleting the **file filename** statement from the configuration effectively “unconfigures” the functionality associated with the corresponding commit script. Deactivating the statement adds the **inactive:** tag to the statement, effectively commenting out the statement from the configuration. Statements marked as inactive do not take effect when you issue the **commit** command.

To reverse the effect of a commit script and prevent the script from running again, perform the following steps:

1. For persistent changes only, delete or deactivate the statement that was added by the commit script:

```
[edit]
user@host# delete (statement | identifier)
- OR -
user@host# deactivate (statement | identifier)
```

Alternatively, you can roll back the configuration to a candidate that does not contain the statement.

```
[edit]
user@host# rollback number
```

2. Either delete or deactivate the commit script, or remove or comment out the section of code that generates the unwanted change. To delete or deactivate the script, issue one of the following commands.

```
[edit]
user@host# delete system scripts commit file filename
- OR -
user@host# deactivate system scripts commit file filename
```

3. Issue the **commit** command:

```
[edit]
user@host# commit
```

4. If you are deleting the reference to the script from the configuration, you can also remove the file from commit scripts storage directory (either `/var/db/scripts/commit` on the hard drive or `/config/scripts/commit` on the flash drive; for information about setting the storage location for commit scripts, see [“Storing Scripts in Flash Memory” on page 87](#).) To do this, exit configuration mode and issue the **file delete** operational mode command:

```
[edit]
user@host# exit

user@host> file delete /var/db/scripts/commit/filename
- OR -
user@host> file delete /config/scripts/commit/filename
```

Tag Elements to Use When Generating Persistent and Transient Changes

[Table 16 on page 198](#) describes the data that you can include in the `<change>` tag element in a commit script. To see how data values are supplied within a script, see *Examples: Generating Persistent and Transient Changes*.

Table 16: Tags and Attributes for Creating Configuration Changes

Data Item, XML Element, or Attribute	Description
Container Tags	
<code><change></code>	Request that the Junos XML protocol server load configuration data into the candidate configuration.
<code><transient-change></code>	Request that the Junos XML protocol server load configuration data into the configuration.
Content Tags	
<code><jcs:emit-change></code>	This is a template in the file <code>junos.xml</code> . This template converts the contents of the <code><xsl:with-param></code> element into a <code><change></code> request.
<code><xsl:with-param name="content"></code>	You use the <code>content</code> parameter with the <code>jcs:emit-change</code> template. It allows you to include the content of the change, relative to <code>dot</code> .

Table 16: Tags and Attributes for Creating Configuration Changes (*continued*)

Data Item, XML Element, or Attribute	Description
<code><xsl:with-param name="tag" select="'transient-change'"/></code>	<p>Convert the contents of the content parameter into a <code><transient-change></code> request.</p> <p>You use the tag parameter with the jcs:emit-change template.</p> <p>By default, the jcs:emit-change template converts the contents of the content parameter into a <code><change></code> (persistent change) request.</p>

Example: Generating a Persistent Change

If you do not explicitly configure the MPLS protocol family on an interface, the interface is not enabled for MPLS applications. This example generates a persistent change that adds the **family mpls** statement in the configuration of SONET/SDH interfaces when the statement is not already included in the configuration.

- [Requirements on page 199](#)
- [Overview and Commit Script on page 199](#)
- [Configuration on page 200](#)
- [Verification on page 202](#)

Requirements

This example uses a device running Junos OS with one or more SONET/SDH interfaces.

Overview and Commit Script

The commit script in this example finds all SONET/SDH interfaces that have a logical interface configured but that do not have the **family mpls** statement configured. For these interfaces, the script adds the **family mpls** statement to the interface configuration as a persistent change at the `[edit interfaces interface-name unit logical-unit-number]` hierarchy level.

The persistent change is generated by the **jcs:emit-change** template, which is a helper template contained in the **junos.xsl** import file. The **tag** parameter of the **jcs:emit-change** template is omitted, which directs the script to emit the change as a persistent change. The **content** parameter of the **jcs:emit-change** template includes the configuration statements to be added as a persistent change. The **message** parameter of the **jcs:emit-change** template includes the warning message to be displayed in the CLI, notifying you that the configuration has been changed.

The script is shown in both XSLT and SLAX syntax.

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos">
```

```

xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
<xsl:import href="../../import/junos.xsl"/>

<xsl:template match="configuration">
  <xsl:for-each select="interfaces/interface[starts-with(name, 'so-')]/unit">
    <xsl:if test="not(family/mpls)">
      <xsl:call-template name="jcs:emit-change">
        <xsl:with-param name="message">
          <xsl:text>Adding 'family mpls' to SONET/SDH interface.</xsl:text>
        </xsl:with-param>
        <xsl:with-param name="content">
          <family>
            <mpls/>
          </family>
        </xsl:with-param>
      </xsl:call-template>
    </xsl:if>
  </xsl:for-each>
</xsl:template>
</xsl:stylesheet>

```

SLAX Syntax

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xsl";

match configuration {
  for-each (interfaces/interface[starts-with(name, 'so-')]/unit) {
    if (not(family/mpls)) {
      call jcs:emit-change() {
        with $message = {
          expr "Adding 'family mpls' to SONET/SDH interface.";
        }
        with $content = {
          <family> {
            <mpls>;
          }
        }
      }
    }
  }
}

```

Configuration**Step-by-Step
Procedure**

Download, enable, and test the script.

1. Copy the XSLT or SLAX script into a text file, name the file **mpls.xsl** or **mpls.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts commit]** hierarchy level and **mpls.xsl** or **mpls.slax** as appropriate.

[edit]

```
user@host# set system scripts commit file mpls.xml
```

3. To test that the commit script generates the persistent change correctly, make sure that the configuration contains the condition that elicits the change. To test this script, ensure that the **family mpls** statement is not included at the **[edit interfaces so-fpc/pic/port unit logical-unit-number]** hierarchy level for at least one SONET/SDH interface.

If the **family mpls** statement is included at the **[edit interfaces so-fpc/pic/port unit logical-unit-number]** hierarchy level, issue the following configuration mode command to delete the statement:

```
[edit]
user@host# delete interfaces so-fpc/pic/port unit logical-unit-number family mpls
```

4. The **commit check** command verifies the syntax of the configuration prior to a commit, but it does not commit the changes. The commit script in this example produces a message for each change it makes. Use the **commit check** command to preview these messages to determine whether the script will update the configuration with the **family mpls** statement for the appropriate interfaces.

Issue the **commit check | display xml** command to display the XML-formatted version of the message. The sample output indicates that the script will add the **family mpls** statement to the so-2/3/4 interface configuration during the commit operation.

```
[edit]
user@host# commit check | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/11.2R1/junos">
  <commit-results>
    <routing-engine junos:style="normal">
      <name>re0</name>
      <xnm:warning xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm">
        <edit-path>
          [edit interfaces interface so-2/3/4 unit 0]
        </edit-path>
        <message>
          Adding 'family mpls' to SONET/SDH interface.
        </message>
      </xnm:warning>
      <commit-check-success/>
    </routing-engine>
  </commit-results>
</rpc-reply>
```

5. To display a detailed trace of commit script processing, issue the **commit check | display detail** command. In the sample output, there is one persistent change that will be loaded into the configuration during the commit operation.

```
[edit]
user@host# commit check | display detail
2011-06-17 14:17:35 PDT: reading commit script configuration

2011-06-17 14:17:35 PDT: copying juniper.db to juniper.data+
2011-06-17 14:17:35 PDT: finished copying juniper.db to juniper.data+
...
configuration check succeeds

```

6. After verifying that the script produces the correct changes, issue the **commit** command to start the commit operation and execute the script.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the correct changes are integrated into the configuration.

Action After executing the commit operation, view the configuration by issuing the **show interfaces** configuration mode command. If the MPLS protocol family is not enabled on one or more SONET/SDH interfaces before the script runs, the output is similar to the following:

```

[edit]
user@host# show interfaces
... other configured interface types ...
so-2/3/4 {
    unit 0 {
        family mpls; # Added by persistent change
    }
}
... other configured interface types ...

```

Requirements

This example uses a device running Junos OS with one or more SONET/SDH interfaces.

Overview and Commit Script

The commit script in this example finds all SONET/SDH interfaces with the IPv4 protocol family enabled in the configuration and adds the **encapsulation ppp** statement to the interface configuration. The transient change is generated by the **jcs:emit-change** template, which is a helper template contained in the **junos.xsl** import file. The **tag** parameter of the **jcs:emit-change** template has the value **transient-change**, which directs the script to emit the change as a transient change rather than a persistent change. The **content** parameter of the **jcs:emit-change** template includes the configuration statements to be added as a transient change.

The script is shown in both XSLT and SLAX syntax.

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xsl"/>

  <xsl:template match="configuration">
    <xsl:for-each select="interfaces/interface[starts-with(name, 'so-')
      and unit/family/inet]">
      <xsl:call-template name="jcs:emit-change">
        <xsl:with-param name="tag" select="'transient-change'"/>
        <xsl:with-param name="content">
          <encapsulation>ppp</encapsulation>
        </xsl:with-param>
      </xsl:call-template>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xsl";

match configuration {
  for-each (interfaces/interface[starts-with(name, 'so-') and unit/family/inet]) {
    call jcs:emit-change($tag = 'transient-change') {
      with $content = {
        <encapsulation> "ppp";
      }
    }
  }
}
```

```
}
}
```

Configuration

Step-by-Step Procedure Download, enable, and test the script.

1. Copy the XSLT or SLAX script into a text file, name the file **encap-ppp.xml** or **encap-ppp.slax** as appropriate, and copy it to the `/var/db/scripts/commit/` directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts commit]** hierarchy level and **encap-ppp.xml** or **encap-ppp.slax** as appropriate.

```
[edit]
user@host# set system scripts commit file encap-ppp.xml
```

3. Include the **allow-transients** statement at the **[edit system scripts commit]** hierarchy level. This enables commit scripts to load transient changes into the checkout configuration.

```
[edit]
user@host# set system scripts commit allow-transients
```

4. To test that the commit script generates the transient change correctly, make sure that the configuration contains the condition that elicits the change. Ensure that the **encapsulation ppp** statement is not included at the **[edit interfaces so-fpc/pic/port]** hierarchy level for at least one SONET/SDH interface.

If the **encapsulation ppp** statement is included at the **[edit interfaces so-fpc/pic/port]** hierarchy level, issue the following configuration mode command to delete the statement:

```
[edit]
user@host# delete interfaces so-fpc/pic/port encapsulation ppp
```

5. The **commit check** command verifies the syntax of the configuration prior to a commit, but it does not commit the changes. Issue the **commit check** command to preview a trace of commit script processing to verify that the script will add the transient change to the checkout configuration.

Issue the **commit check | display detail** command to display a detailed trace of commit script processing. In the sample output, there are two transient changes that are loaded into the checkout configuration.

```
[edit]

configuration check succeeds
```

6. After verifying that the script produces the correct changes, issue the **commit** command to start the commit operation and execute the script.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the correct changes are integrated into the checkout configuration. If there are one or more SONET/SDH interfaces with the IPv4 protocol family enabled, you should see the **encapsulation ppp** statement added as a transient change to the interface hierarchy.

Action To view the configuration with transient changes, issue the **show interfaces | display commit-scripts** configuration mode command. The **show interfaces | display commit-scripts** command displays all the statements that are in the configuration, including statements that are generated by transient changes. If there are one or more SONET/SDH interfaces with the IPv4 protocol family enabled, the output is similar to the following:

```
[edit]
user@host# show interfaces | display commit-scripts
... other configured interface types ...
so-1/2/3 {
    mtu 576;
    encapsulation ppp; /* Added by transient change. */
    unit 0 {
        family inet {
            address 10.0.0.3/32;
        }
    }
}
so-1/2/4 {
    encapsulation ppp; /* Added by transient change. */
    unit 0 {
        family inet {
            address 10.0.0.4/32;
        }
    }
}
so-2/3/4 {
    encapsulation cisco-hdlc; # Not affected by this script, because IPv4 protocol
                                # family is not configured on this interface.
    unit 0 {
        family mpls;
    }
}
... other configured interface types ...
```

Troubleshooting

Troubleshooting Commit Errors

Problem The CLI generates an invalid transient change error, and the commit fails.

```
user@host# commit check
error: invalid transient change generated by commit script: encap-ppp.xml
warning: 1 transient change was generated without [system scripts commit
allow-transients]
error: 1 error reported by commit scripts
error: commit script failure
```

Solution You must configure the **allow-transients** statement at the **[edit system scripts commit]** hierarchy level to enable commit scripts to load transient changes into the checkout configuration.

Issue the following configuration mode command to allow transient changes:

```
[edit]
user@host# set system scripts commit allow-transients
```

- [Example: Creating Custom Configuration Syntax with Macros on page 208](#)

Creating a Macro to Read the Custom Syntax and Generate Related Configuration Statements

By itself, the custom syntax in an **apply-macro** statement has no operational impact on the device. To give meaning to your syntax, there must be a corresponding commit script that uses the syntax as data for generating related standard Junos OS statements. To write such a script, follow these steps:

1. At the start of the script, include the Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) boilerplate from [“Required Boilerplate for Commit Scripts” on page 166](#). It is reproduced here for convenience:

XSLT Boilerplate

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xsl"/>

  <xsl:template match="configuration">
    <!-- ... Insert your code here ... -->
  </xsl:template>
</xsl:stylesheet>
```

SLAX Boilerplate

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xsl";

match configuration {
/*
  * Insert your code here
*/}
```

}

2. At the position indicated by the comment “*Insert your code here*,” include XSLT programming instructions (or their SLAX equivalents) that inspect the configuration for the **apply-macro** statement at a specified hierarchy level and change the configuration to include standard Junos OS CLI syntax.

For an example that uses both types of instructions and includes a line-by-line analysis of the XSLT syntax, see “[Example: Creating Custom Configuration Syntax with Macros](#)” on page 208.

3. Save the script with a meaningful name.
4. Copy the script to either the **/var/db/scripts/commit** directory on the hard drive or the **/config/scripts/commit** directory on the flash drive. For information about setting the storage location for commit scripts, see “[Storing Scripts in Flash Memory](#)” on page 87.

If the device has dual Routing Engines and you want the script to take effect on both of them, you must copy the script to the **/var/db/scripts/commit** or the **/config/scripts/commit** directory on both Routing Engines. The **commit synchronize** command does not copy scripts between Routing Engines.

5. Enable the script by including the **file** statement at the **[edit system scripts commit]** hierarchy level:

```
[edit system scripts commit]  
file filename;
```

where *filename* is the name of the script.

6. If the script makes transient changes, include the **allow-transients** statement at the **[edit system scripts commit]** hierarchy level:

```
[edit system scripts commit]  
allow-transients;
```

If all the commit scripts run without errors, any transient changes are loaded into the checkout configuration, but not to the candidate configuration. Any persistent changes are loaded into the candidate configuration. The commit process then continues by validating the configuration and propagating changes to the affected processes on the device running Junos OS.

Example: Creating Custom Configuration Syntax with Macros

This commit script example shows how to create custom configuration syntax using macros.

- [Requirements on page 209](#)
- [Overview and Commit Script on page 209](#)

- [Configuration on page 213](#)
- [Verification on page 214](#)

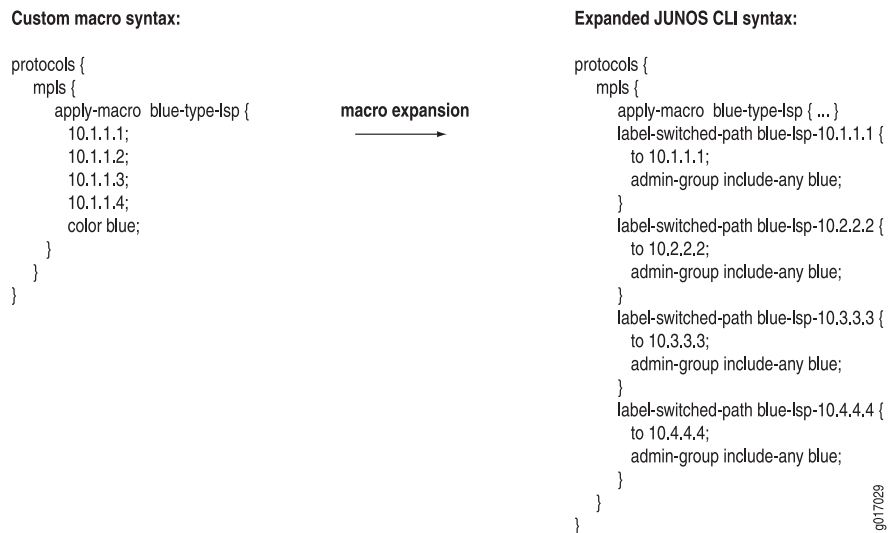

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

[Figure 8 on page 209](#) shows a macro that uses custom syntax and the corresponding expansion to standard Junos OS command-line interface (CLI) syntax.

Figure 8: Sample Macro and Corresponding Junos OS CLI Expansion

In this example, the Junos OS management (mgd) process inspects the configuration, looking for **apply-macro** statements. For each **apply-macro** statement with the **color** parameter included at the **[edit protocols mpls]** hierarchy level, the script generates a transient change, using the data provided within the **apply-macro** statement to expand the macro into a standard Junos OS administrative group for LSPs.

For this example to work, an **apply-macro** statement must be included at the **[edit protocols mpls]** hierarchy level with a set of addresses, a **color**, and a **group-value** parameter. The commit script converts each address to an LSP configuration, and the script converts the **color** parameter into an administrative group.

Following are the commit script instructions that expand the macro in [Figure 8 on page 209](#) and a line-by-line explanation of the script:

XSLT Syntax	<pre> 1 <?xml version="1.0" standalone="yes"?> 2 <xsl:stylesheet version="1.0" 3 xmlns:xsl="http://www.w3.org/1999/XSL/Transform" 4 xmlns:junos="http://xml.juniper.net/junos/*/junos" 5 xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm" 6 xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0"> 7 <xsl:import href=" ../import/junos.xml"/> 8 <xsl:template match="configuration"> </pre>
-------------	---

```

9      <xsl:variable name="mpls" select="protocols/mpls"/>
10     <xsl:for-each select="$mpls/apply-macro[data/name = 'color']">
11       <xsl:variable name="color" select="data[name = 'color']/value"/>
12       <xsl:for-each select="$mpls/apply-macro[data/name = 'group-value']">
13         <xsl:variable name="group-value" select="data[name = \
          'group-value']/value"/>
14         <transient-change>
15           <protocols>
16             <mpls>
17               <admin-groups>
18                 <name>
19                   <xsl:value-of select="$color"/>
20                 </name>
21                 <group-value>
22                   <xsl:value-of select="$group-value"/>
23                 </group-value>
24               </admin-groups>
25               <xsl:for-each select="data[not(value)]/name">
26                 <label-switched-path>
27                   <name>
28                     <xsl:value-of select="concat($color, '-lsp-',.)"/>
29                   </name>
30                   <to><xsl:value-of select="."/></to>
31                 <admin-group>
32                   <include-any>
33                     <xsl:value-of select="$color"/>
34                   </include-any>
35                 </admin-group>
36               </label-switched-path>
37             </xsl:for-each>
38           </mpls>
39         </protocols>
40       </transient-change>
41     </xsl:for-each>
42   </xsl:for-each>
43 </xsl:template>
44 </xsl:stylesheet>

```

Lines 1 through 8 (and Lines 43 and 44) are the boilerplate that you include in every commit script. For brevity, Lines 1 through 8 are omitted here.

Line 9 assigns the **[edit protocols mpls]** hierarchy level to a variable called **\$mpls**.

```
9      <xsl:variable name="mpls" select="protocols/mpls"/>
```

Line 10 selects every **apply-macro** statement at the **[edit protocols mpls]** hierarchy level that contains the **color** parameter. The sample configuration in [Figure 8 on page 209](#) contains only one **apply-macro** statement. Therefore, this **<xsl:for-each>** programming instruction takes effect only once.

```
10     <xsl:for-each select="$mpls/apply-macro[data/name = 'color']">
```

Line 11 assigns the value of the **color** parameter, in this case **blue**, to a variable called **\$color**.

```
11       <xsl:variable name="color" select="data[name = 'color']/value"/>
```

Line 12 selects every **apply-macro** statement at the **[edit protocols mpls]** hierarchy level that contains the **color** parameter. The sample configuration in [Figure 8 on page 209](#) contains only one **apply-macro** statement. Therefore, this **<xsl:for-each>** programming instruction takes effect only once.

```
12 <xsl:for-each select="$mpls/apply-macro[data/name = 'color']">
```

Line 13 assigns the value of the **group-value** parameter, in this case **0**, to a variable called **\$group-value**.

```
13 <xsl:variable name="group-value" select="data[name = 'group-value']/value"/>
```

Lines 14 through 16 generate a transient change at the **[edit protocols mpls]** hierarchy level.

```
14 <transient-change>
15 <protocols>
16 <mpls>
```

Lines 17 through 24 add the **admin-groups** statement to the configuration and assign the value of the **\$color** variable to the group name and the value of the **\$group-value** variable to the group value.

```
17 <admin-groups>
18 <name>
19 <xsl:value-of select="$color"/>
20 </name>
21 <group-value>
22 <xsl:value-of select="$group-value"/>
23 </group-value>
24 </admin-groups>
```

The resulting configuration statements are as follows:

```
admin-groups {
  blue 0;
}
```

Line 25 selects the name of every parameter that does not already have a value assigned to it, which in this case are the four IP addresses. This **<xsl:for-each>** programming instruction uses recursion through the macro and selects each IP address in turn. The **color** and **group-value** parameters each already have a value assigned (**blue** and **0**, respectively), so this line does not apply to them.

```
25 <xsl:for-each select="data[not(value)]/name">
```

Line 26 adds the **label-switched-path** statement in the configuration.

```
26 <label-switched-path>
```

Lines 27 through 29 assign the **label-switched-path** a name that concatenates the value of the **\$color** variable, the text **-lsp-**, and the current IP address currently selected by Line 25 (represented by the **."**).

```
27 <name>
28 <xsl:value-of select="concat($color, '-lsp-', .)"/>
29 </name>
```

Line 30 adds the **to** statement to the configuration and sets its value to the IP address currently selected by Line 25.

```
30          <to><xsl:value-of select="."/></to>
```

Lines 31 through 35 add the **admin-group include-any** statement to the configuration and sets its value to the value of the **\$color** variable.

```
31      <admin-group>
32          <include-any>
33              <xsl:value-of select="$color"/>
34          </include-any>
35      </admin-group>
```

The resulting configuration statements (for one pass) are as follows:

```
label-switched-path blue-lsp-10.1.1.1 {
  to 10.1.1.1;
  admin-group include-any blue;
}
```

Lines 36 through 42 are closing tags.

```
36      </label-switched-path>
37      </xsl:for-each>
38      </mpls>
39      </protocols>
40      </transient-change>
41      </xsl:for-each>
42      </xsl:for-each>
```

Lines 43 and 44 are closing tags for Lines 8 and 2, respectively.

```
43  </xsl:template>
44  </xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  var $mpls = protocols/mpls;
  for-each ($mpls/apply-macro[data/name = 'color']) {
    var $color = data[name = 'color']/value;
    for-each ($mpls/apply-macro[data/name = 'group-value']) {
      var $group-value = data[name='group-value']/value;
      <transient-change> {
        <protocols> {
          <mpls> {
            <admin-groups> {
              <name> $color;
              <group-value> $group-value;
            }
            for-each (data[not(value)]/name) {
              <label-switched-path> {
                <name> $color _ '-lsp-' _ .;
                <to> .;
              }
            }
          }
        }
      }
    }
  }
}
```

```

        <admin-group> {
            <include-any> $color;
        }
    }
}
}
}
}
}
}
}
}
}

```

For more information about this example, see [“Example: Configuring Administrative Groups for LSPs” on page 234](#).

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **lsp-admin.xml** or **lsp-admin.slax** as appropriate, and copy it to the `/var/db/scripts/commit/` directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard. If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **lsp-admin.slax**.

```

system {
  scripts {
    commit {
      allow-transients;
      file lsp-admin.xml;
    }
  }
}
protocols {
  mpls {
    apply-macro blue-type-lsp {
      10.1.1.1;
      10.2.2.2;
      10.3.3.3;
      10.4.4.4;
      color blue;
      group-value 0;
    }
  }
}
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying Script Execution

Purpose Verify that the script behaves as expected.

Action To display the configuration statements created by the script, issue the **show protocols mpls | display commit-scripts** command:

```
[edit]
user@host# show protocols mpls | display commit-scripts
apply-macro blue-type-lsp {
  10.1.1.1;
  10.2.2.2;
  10.3.3.3;
  10.4.4.4;
  color blue;
  group-value 0;
}
admin-groups {
  blue 0;
}
label-switched-path blue-lsp-10.1.1.1 {
  to 10.1.1.1;
  admin-group include-any blue;
}
label-switched-path blue-lsp-10.2.2.2 {
  to 10.2.2.2;
  admin-group include-any blue;
}
label-switched-path blue-lsp-10.3.3.3 {
  to 10.3.3.3;
  admin-group include-any blue;
}
label-switched-path blue-lsp-10.4.4.4 {
  to 10.4.4.4;
  admin-group include-any blue;
}
```

Example: Adding a Final then accept Term to a Firewall

This commit script example adds a **then accept** statement to any firewall filter that does not already end with an explicit **then accept** statement.

- [Requirements on page 215](#)
- [Overview and Commit Script on page 215](#)
- [Configuration on page 217](#)
- [Verification on page 219](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

Each firewall filter in Junos OS has an implicit discard action at the end of the filter, which is equivalent to the following explicit filter term:

```
term implicit-rule {  
    then discard;  
}
```

As a result, if a packet matches none of the terms in the filter, it is discarded. In some cases, you might want to override the default by adding a last term to accept all packets that do not match a firewall filter's series of match conditions. In this example, the commit script adds a final **then accept** statement to any firewall filter that does not already end with an explicit **then accept** statement.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xsl"/>

  <xsl:template match="configuration">
    <xsl:apply-templates select="firewall/filter | firewall/family/inet
      | firewall/family/inet6" mode="filter"/>
  </xsl:template>
  <xsl:template match="filter" mode="filter">
    <xsl:param name="last" select="term[position() = last()]" />
    <xsl:comment>

        </xsl:with-param>
      </xsl:call-template>
    </xsl:if>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
```

```

ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  apply-templates firewall/filter | firewall/family/inet | firewall/family/inet6 {
    mode "filter";
  }
}
match filter {
  mode "filter";
  param $last = term[position() = last()];
  <xsl:comment> {
    expr "Found ";
    expr name;
    expr "; last ";
    expr $last/name;
  }
  if ($last and ($last/from or $last/to or not($last/then/accept))) {
    <xnm:warning> {
      call jcs:edit-path();
      <message> "filter is missing final 'then accept' rule";
    }
    call jcs:emit-change() {
      with $content = {
        <term> {
          <name> "very-last";
          <junos:comment> "This term was added by a commit script";
          <then> {
            <accept>;
          }
        }
      }
    }
  }
}
}
}
}

```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **add-accept.xsl** or **add-accept.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **add-accept.slax**.

```

system {
  scripts {
    commit {
      file add-accept.xsl;
    }
  }
}

```

```
}
firewall {
  policer sgt-friday {
    if-exceeding {
      bandwidth-percent 10;
      burst-size-limit 250k;
    }
    then discard;
  }
  family inet {
    filter test {
      term one {
        from {
          interface t1-0/0/0;
        }
        then {
          count ten-network;
          discard;
        }
      }
      term two {
        from {
          forwarding-class assured-forwarding;
        }
        then discard;
      }
    }
  }
}
interfaces {
  t1-0/0/0 {
    unit 0 {
      family inet {
        policer output sgt-friday;
        filter input test;
      }
    }
  }
}
```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```
[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...
```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

*Verification**Verifying the Configuration*

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The script requires that all firewall filters end with an explicit **then accept** statement. The sample configuration stanzas include the **test** filter with two terms but do not include an explicit **then accept** statement. When you issue the **commit** command, the script adds the missing **then accept** statement and commits the configuration. When you issue the **commit** command, the following output appears:

```
[edit]
user@host# commit
[edit firewall family inet filter test]
warning: filter is missing final 'then accept' rule
commit complete
```

In configuration mode, issue the **show firewall** command to review the modified configuration. The following output appears:

```
[edit]
user@host# show firewall
policer sgt-friday {
  if-exceeding {
    bandwidth-percent 10;
    burst-size-limit 250k;
  }
  then discard;
}
family inet {
  filter test {
    term one {
      from {
        interface t1-0/0/0;
      }
      then {
        count ten-network;
        discard;
      }
    }
    term two {
      from {
        forwarding-class assured-forwarding;
      }
      then {
        discard;
      }
    }
    term very-last {
      then accept; /* This term was added by a commit script */
    }
  }
}
```

Example: Adding T1 Interfaces to a RIP Group

This example shows how to use commit scripts to decrease the amount of manual configuration, specifically how to add every T1 interface configured at the **[edit interfaces]** hierarchy level to the **[edit protocols rip group test]** hierarchy level.

- [Requirements on page 220](#)
- [Overview and Commit Script on page 220](#)
- [Configuration on page 221](#)
- [Verification on page 223](#)

Requirements

This example uses a device running Junos OS with T1 interfaces.

Overview and Commit Script

If you want to enable RIP on an interface, you must make changes at both the **[edit interfaces]** and **[edit protocols rip]** hierarchy levels. This example shows how to use commit scripts to add every T1 interface configured at the **[edit interfaces]** hierarchy level to the **[edit protocols rip group test]** hierarchy level. This example includes no error, warning, or system log messages. The changes to the configuration are made silently.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xsl"/>

  <xsl:template match="configuration">
    <xsl:variable name="all-t1"
      select="interfaces/interface[starts-with(name, 't1-')"]"/>
    <xsl:if test="$all-t1">
      <change>
        <protocols>
          <rip>
            <group>
              <name>test</name>
              <xsl:for-each select="$all-t1">
                <xsl:variable name="ifname" select="concat(name, '.0')"/>
                <neighbor>
                  <name><xsl:value-of select="$ifname"/></name>
                </neighbor>
              </xsl:for-each>
            </group>
          </rip>
        </protocols>
      </change>
    </xsl:if>
  </xsl:template>
```

```
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  var $all-t1 = interfaces/interface[starts-with(name, 't1-')];
  if ($all-t1) {
    <change> {
      <protocols> {
        <rip> {
          <group> {
            <name> "test";
            for-each ($all-t1) {
              var $ifname = name _ '.0';
              <neighbor> {
                <name> $ifname;
              }
            }
          }
        }
      }
    }
  }
}
```

Configuration**Step-by-Step
Procedure**

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **rip-t1.xsl** or **rip-t1.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **rip-t1.slax**.

```
system {
  scripts {
    commit {
      file rip-t1.xsl;
    }
  }
}
interfaces {
  t1-0/0/0 {
    unit 0 {
      family iso;
    }
  }
  t1-0/0/1 {
```

```
        unit 0 {  
            family iso;  
        }  
    }  
    t1-0/0/2 {  
        unit 0 {  
            family iso;  
        }  
    }  
    t1-0/0/3 {  
        unit 0 {  
            family iso;  
        }  
    }  
    t1-0/1/0 {  
        unit 0 {  
            family iso;  
        }  
    }  
    t1-0/1/1 {  
        unit 0 {  
            family iso;  
        }  
    }  
    t1-0/1/2 {  
        unit 0 {  
            family iso;  
        }  
    }  
    t1-0/1/3 {  
        unit 0 {  
            family iso;  
        }  
    }  
}
```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```
[edit]  
user@host# load merge terminal  
[Type ^D at a new line to end input]  
... Paste the contents of the clipboard here ...
```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification**Verifying the Configuration**

Purpose Verify that the script behaves as expected.

Action Issue the **show protocols rip group test** command. All T1 interfaces should now appear under the **[edit protocols rip group test]** hierarchy level.

```
[edit]
user@host# show protocols rip group test
neighbor t1-0/0/0.0;
neighbor t1-0/0/1.0;
neighbor t1-0/0/2.0;
neighbor t1-0/0/3.0;
neighbor t1-0/1/0.0;
neighbor t1-0/1/1.0;
neighbor t1-0/1/2.0;
neighbor t1-0/1/3.0;
```

Example: Assigning a Classifier

For each interface configured with the IPv4 protocol family, this commit script automatically assigns a specified classifier, which associates incoming packets with a forwarding class and loss priority as well as assigns packets to an output queue.

- [Requirements on page 223](#)
- [Overview and Commit Script on page 223](#)
- [Configuration on page 225](#)
- [Verification on page 226](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

In the Junos OS class of service (CoS), classifiers allow you to associate incoming packets with a forwarding class and loss priority and, based on the associated forwarding class, assign packets to output queues. After you configure a classifier, you must assign it to an input interface.

For each interface configured with the IPv4 protocol family, this script automatically assigns a specified classifier called **fc-q3**. The **fc-q3** classifier must be configured at the **[edit class-of-service]** hierarchy level.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
```

```

<xsl:import href="../../../import/junos.xsl"/>

<xsl:template match="configuration">
  <xsl:variable name="cos-all" select="class-of-service"/>
  <xsl:for-each
    select="interfaces/interface[contains(name, '/')]/unit[family/inet]">
    <xsl:variable name="ifname" select="../name"/>
    <xsl:variable name="unit" select="name"/>
    <xsl:variable name="cos"
      select="$cos-all/interfaces[name = $ifname]"/>
    <xsl:if test="not($cos/unit[name = $unit])">
      <xsl:call-template name="jcs:emit-change">
        <xsl:with-param name="message">
          <xsl:text>Adding CoS forwarding class for </xsl:text>
          <xsl:value-of select="concat($ifname, '.', $unit)"/>
        </xsl:with-param>
        <xsl:with-param name="dot" select="$cos-all"/>
        <xsl:with-param name="content">
          <interfaces>
            <name><xsl:value-of select="$ifname"/></name>
            <unit>
              <name><xsl:value-of select="$unit"/></name>
              <forwarding-class>fc-q3</forwarding-class>
            </unit>
          </interfaces>
        </xsl:with-param>
      </xsl:call-template>
    </xsl:if>
  </xsl:for-each>
</xsl:template>
</xsl:stylesheet>

```

SLAX Syntax

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../../import/junos.xsl";

match configuration {
  var $cos-all = class-of-service;
  for-each (interfaces/interface[contains(name, '/')]/unit[family/inet]) {
    var $ifname = ../name;
    var $unit = name;
    var $cos = $cos-all/interfaces[name = $ifname];
    if (not($cos/unit[name = $unit])) {
      call jcs:emit-change($dot = $cos-all) {
        with $message = {
          expr "Adding CoS forwarding class for ";
          expr $ifname _ '.' _ $unit;
        }
      }
      with $content = {
        <interfaces> {
          <name> $ifname;
          <unit> {
            <name> $unit;
            <forwarding-class> "fc-q3";

```

```

    }
  }
}
}
}
}
}

```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **classifier.xml** or **classifier.slax** as appropriate, and copy it to the `/var/db/scripts/commit/` directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **classifier.slax**.

```

system {
  scripts {
    commit {
      file classifier.xml;
    }
  }
}
interfaces {
  fe-0/0/0 {
    unit 0 {
      family inet {
        address 10.168.16.2/24;
      }
    }
  }
}
class-of-service {
  forwarding-classes {
    queue 3 fc-q3;
  }
  classifiers {
    inet-precedence fc-q3 {
      forwarding-class fc-q3 {
        loss-priority low code-points 010;
      }
    }
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]

```

... Paste the contents of the clipboard here ...

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. In the test configuration stanzas, the **fe-0/0/0.0** interface is configured with the **family inet** statement. Because the interface is configured with the IPv4 protocol family, the script automatically assigns the **fc-q3** classifier to the interface, which is indicated in the **commit** command output.

```
[edit]
user@host# commit
[edit interfaces interface fe-0/0/0 unit 0]
warning: Adding CoS forwarding class for fe-0/0/0.0
commit complete
```

View the configuration to verify that the script-generated changes are present. Issue the **show class-of-service** configuration mode command. The output shows that the **fe-0/0/0.0** interface has been assigned the **fc-q3** classifier:

```
[edit]
user@host# show class-of-service
classifiers {
  inet-precedence fc-q3 {
    forwarding-class fc-q3 {
      loss-priority low code-points 010;
    }
  }
}
forwarding-classes {
  queue 3 fc-q3;
}
interfaces {
  fe-0/0/0 {
    unit 0 {
      forwarding-class fc-q3; # Added by commit script
    }
  }
}
```

Example: Automatically Configuring Logical Interfaces and IP Addresses

Every interface you configure requires at least one logical unit and one IP address. Asynchronous Transfer Mode (ATM) interfaces also require a virtual circuit identifier (VCI) for each logical interface. If you need to configure multiple logical units on an interface, you can use a commit script and macro to complete the task quickly and with no errors.

- [Requirements on page 227](#)
- [Overview and Commit Script on page 227](#)
- [Configuration on page 232](#)
- [Verification on page 233](#)

Requirements

This example uses a device running Junos OS with physical ATM interfaces.

Overview and Commit Script

The following commit script expands an **apply-macro** statement that provides the name of a physical ATM interface and a set of parameters that specify how to configure a number of logical units on the interface. The units and VCI numbers are numbered sequentially from the **\$unit** variable to the **\$max** variable and are given IP addresses starting at the **\$address** variable. To loop through the logical units, Extensible Stylesheet Language Transformations (XSLT) uses recursion, which is implemented in the **<emit-interface>** template. Calculation of the next address is performed in the **<next-address>** template.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"

Configuration

Step-by-Step Procedure To download, enable, and run the script:

1. Copy the XSLT or SLAX script into a text file, name the file **atm-logical.xml** or **atm-logical.slax** as appropriate, and download it to the `/var/db/scripts/commit/` directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **atm-logical.slax**.

```
system {
  scripts {
    commit {
      allow-transients;
      file atm-logical.xml;
    }
  }
}
interfaces {
  apply-macro at-1/2/3 {
    address 10.12.13.14/20;
    max 200;
    unit 32;
  }
  at-1/2/3 {
    atm-options {
      pic-type atm2;
      vpi 0;
    }
  }
}
```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```
[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...
```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification**Verifying the Configuration**

Purpose Verify that the correct changes are integrated into the configuration.

Action Before you commit the configuration, you can verify that the commit script will produce the correct results by issuing the **show interfaces at-1/2/3 | display commit-scripts** configuration mode command. After you commit the configuration, you can review the active configuration by issuing the **show configuration interfaces at-1/2/3** operational mode command. The following output appears:

```

atm-options {
  pic-type atm2;
  vpi 0;
}
unit 32 {
  vci 32;
  family inet {
    address 10.12.13.14/20;
  }
}
unit 33 {
  vci 33;
  family inet {
    address 10.12.13.15/20;
  }
}
unit 34 {
  vci 34;
  family inet {
    address 10.12.13.16/20;
  }
}
unit 35 {
  vci 35;
  family inet {
    address 10.12.13.17/20;
  }
}
... Logical units 36 through 199 are omitted for brevity ...
unit 200 {
  vci 200 ;
  family inet {
    address 10.12.13.182/20;
  }
}

```

Meaning The **| display commit-scripts** option displays the configuration data after all commit scripts have been applied. The output includes both persistent and transient changes. If the appropriate **unit** and **vci** are configured on each ATM interface, the commit script executes successfully during a commit operation. After you commit the configuration, you can review the active configuration by issuing the **show configuration interfaces at-1/2/3** operational mode command.

Example: Configuring Administrative Groups for LSPs

Administrative groups, also known as link coloring or resource classes, are manually assigned attributes that describe the color of links. Links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based label-switched path (LSP) setups.

This commit script example searches for **apply-macro** statements with the **color** parameter included at the **[edit protocols mpls]** hierarchy level. For each **apply-macro** statement, the script uses the data provided to generate a transient change and expand the macro into a standard Junos OS administrative group for LSPs.

- [Requirements on page 234](#)
- [Overview and Commit Script on page 234](#)
- [Configuration on page 236](#)
- [Verification on page 237](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

In this example, the Junos OS management process (mgd) inspects the configuration, looking for **apply-macro** statements. For each **apply-macro** statement with the **color** parameter included at the **[edit protocols mpls]** hierarchy level, the script generates a transient change, using the data provided within the **apply-macro** statement to expand the macro into a standard Junos OS administrative group for LSPs.

For this example to work, an **apply-macro** statement must be included at the **[edit protocols mpls]** hierarchy level with a set of addresses, a **color** parameter, and a **group-value** parameter. The commit script converts each address to an LSP configuration and converts the **color** parameter into an administrative group.

For a line-by-line explanation of this script, see ["Example: Creating Custom Configuration Syntax with Macros" on page 208](#).

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```

ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xml";

match configuration {
  var $mpls = protocols/mpls;
  for-each ($mpls/apply-macro[data/name = 'color']) {
    var $color = data[name = 'color']/value;
    for-each ($mpls/apply-macro[data/name = 'group-value']) {
      var $group-value = data[name = 'group-value']/value;
      <transient-change> {
        <protocols> {
          <mpls> {
            <admin-groups> {
              <name> $color;
              <group-value> $group-value;
            }
            for-each (data[not(value)]/name) {
              <label-switched-path> {
                <name> $color _ '-lsp-' _ .;
                <to> .;

```

```

        <admin-group> {
            <include-any> $color;
        }
    }
}
}
}
}
}
}
}
}
}

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **lsp-admin.xml** or **lsp-admin.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **lsp-admin.slax**.

```

system {
  scripts {
    commit {
      allow-transients;
      file lsp-admin.xml;
    }
  }
}
protocols {
  mpls {
    apply-macro blue-type-lsp {
      10.1.1.1;
      10.2.2.2;
      10.3.3.3;
      10.4.4.4;
      color blue;
      group-value 0;
    }
  }
}
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.

- b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action Issue the **show protocols mpls | display commit-scripts** configuration mode command and review the output. Adding the **| display commit-scripts** option allows you to see the configuration statements that are generated by transient changes.

With Script-Generated Changes When you issue the **show protocols mpls | display commit-scripts** configuration mode command, the following output appears:

```
[edit]
user@host# show protocols mpls | display commit-scripts
apply-macro blue-type-lsp {
  10.1.1.1;
  10.2.2.2;
  10.3.3.3;
  10.4.4.4;
  color blue;
  group-value 0;
}
admin-groups {
  blue 0;
}
label-switched-path blue-lsp-10.1.1.1 {
  to 10.1.1.1;
  admin-group include-any blue;
}
label-switched-path blue-lsp-10.2.2.2 {
  to 10.2.2.2;
  admin-group include-any blue;
}
label-switched-path blue-lsp-10.3.3.3 {
  to 10.3.3.3;
  admin-group include-any blue;
}
label-switched-path blue-lsp-10.4.4.4 {
  to 10.4.4.4;
  admin-group include-any blue;
}
```

Without Script-Generated Changes The output of the **show protocols mpls | display commit-scripts no-transients** configuration mode command excludes the **label-switched-path** statements:

```
[edit]
user@host# show protocols mpls | display commit-scripts no-transients
```

```
apply-macro blue-type-lsp {  
  10.1.1.1;  
  10.2.2.2;  
  10.3.3.3;  
  10.4.4.4;  
  color blue;  
  group-value 0;  
}
```

When you issue the **show protocols mpls** command without the piped **display commit-scripts no-transients** command, you see the same output because this script does not generate any persistent changes:

```
[edit]  
user@host# show protocols mpls  
apply-macro blue-type-lsp {  
  10.1.1.1;  
  10.2.2.2;  
  10.3.3.3;  
  10.4.4.4;  
  color blue;  
  group-value 0;  
}
```

Example: Configuring a Default Encapsulation Type

This commit script example configures default Cisco HDLC encapsulation on SONET/SDH interfaces not configured as aggregate interfaces.

- [Requirements on page 238](#)
- [Overview and Commit Script on page 238](#)
- [Configuration on page 239](#)
- [Verification on page 240](#)

Requirements

This example uses a device running Junos OS with SONET/SDH interfaces.

Overview and Commit Script

Point-to-Point Protocol (PPP) encapsulation is the default encapsulation type for physical interfaces. You do not need to configure encapsulation for any physical interfaces that support PPP encapsulation. If you do not configure encapsulation, PPP is used by default. For physical interfaces that do not support PPP encapsulation, you must configure an encapsulation to use for packets transmitted on the interface.

This example configures default Cisco HDLC encapsulation on SONET/SDH interfaces not configured as aggregate interfaces. The **\$tag** variable is passed to the **jcs:emit-change** template as **transient-change**, so this change is not copied to the candidate configuration.

Simply including configuration groups in the configuration does not enable you to test whether the **aggregate** statement is included for an interface at the **[edit interfaces interface-name sonet-options]** hierarchy level. A commit script can perform this test and

set the encapsulation only on nonaggregated interfaces. The script written to perform this test has the following syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../import/junos.xsl"/>

  <xsl:template match="configuration">
    <xsl:for-each select="interfaces/interface[starts-with(name, 'so-')
      and not(sonet-options/aggregate)]">
      <xsl:call-template name="jcs:emit-change">
        <xsl:with-param name="tag" select="'transient-change'"/>
        <xsl:with-param name="content">
          <encapsulation>cisco-hdlc</encapsulation>
        </xsl:with-param>
      </xsl:call-template>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  for-each (interfaces/interface[starts-with(name, 'so-') and
    not(sonet-options/aggregate)]) {
    call jcs:emit-change($tag = 'transient-change') {
      with $content = {
        <encapsulation> "cisco-hdlc";
      }
    }
  }
}
```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **so-encap.xsl** or **so-encap.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **so-encap.slax**.

```
system {
```

```

scripts {
  commit {
    allow-transients;
    file so-encap.xsl;
  }
}
interfaces {
  so-1/2/2 {
    sonet-options {
      aggregate as0;
    }
  }
  so-1/2/3 {
    unit 0 {
      family inet {
        address 10.0.0.3/32;
      }
    }
  }
  so-1/2/4 {
    unit 0 {
      family inet {
        address 10.0.0.4/32;
      }
    }
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
- b. Press Enter.
- c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action When you issue the **commit** command, the commit script tests for SONET/SDH interfaces that are not configured as aggregate interfaces and sets the default encapsulation type on the nonaggregated interfaces to Cisco HDLC encapsulation. This is implemented as

a **transient-change**. Even though the transient changes are in effect, they are not, by default, displayed in the normal output of the **show interfaces** command.

```
[edit]
user@host# show interfaces
so-1/2/2 {
  sonet-options {
    aggregate as0;
  }
}
so-1/2/3 {
  unit 0 {
    family inet {
      address 10.0.0.3/32;
    }
  }
}
so-1/2/4 {
  unit 0 {
    family inet {
      address 10.0.0.4/32;
    }
  }
}
```

To view the configuration with the transient changes, issue the **show interfaces | display commit-scripts** command:

```
[edit]
user@host# show interfaces | display commit-scripts
so-1/2/2 {
  sonet-options { # The presence of these statements prevents the
    aggregate as0; # transient change from affecting this interface.
  }
}
so-1/2/3 {
  encapsulation cisco-hdlc; # Added by transient change.
  unit 0 {
    family inet {
      address 10.0.0.3/32;
    }
  }
}
so-1/2/4 {
  encapsulation cisco-hdlc; # Added by transient change.
  unit 0 {
    family inet {
      address 10.0.0.4/32;
    }
  }
}
```

Example: Configuring Dual Routing Engines

If your device has redundant (also called *dual*) Routing Engines, your Junos OS configuration can be complex. This example shows how you can use commit scripts to simplify and control the configuration of dual Routing Engine platforms.

- [Requirements on page 242](#)
- [Overview and Commit Script on page 242](#)
- [Configuration on page 245](#)
- [Verification on page 246](#)

Requirements

This example uses a device running Junos OS with dual Routing Engines.

Overview and Commit Script

Junos OS supports two special configuration groups: **re0** and **re1**. When these groups are applied using the **apply-groups [re0 re1]** statement, they take effect if the Routing Engine name matches the group name. Statements included at the **[edit groups re0]** hierarchy level are inherited only on the Routing Engine named RE0, and statements included at the **[edit groups re1]** hierarchy level are inherited only on the Routing Engine named RE1.

This example includes two commit scripts. The first script, **dual-re.xml**, generates a warning if the **system host-name** statement, any IP version 4 (IPv4) interface address, or the **fxp0** interface configuration is configured in the target configuration instead of in a configuration group.

The second script, **dual-re2.xml**, first checks whether the hostname configuration is configured and then checks whether it is configured in a configuration group. The **otherwise** construct generates an error message if the hostname is not configured at all. The first **when** construct allows the script to do nothing if the hostname is already configured in a configuration group. The second **when** construct takes effect when the hostname is configured in the target configuration. In this case, the script generates a transient change that places the hostname configuration into the **re0** and **re1** configuration groups, copies the configured hostname into those groups, concatenates each group hostname with **-RE0** and **-RE1**, and deactivates the hostname in the target configuration so the configuration group hostnames can be inherited.

The example scripts are shown in both XSLT and SLAX syntax:

XSLT Syntax:
dual-re.xml Script

}

```

Configuration

Step-by-Step Procedure

To download, enable, and run the scripts:

1. Copy the XSLT or SLAX scripts into two text files, name the files **dual-re.xsl** and **dual-re2.xsl** or **dual-re.slax** and **dual-re2.slax** as appropriate, and copy them to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filenames at the **[edit system scripts commit file]** hierarchy level to **dual-re.slax** and **dual-re2.slax**.

```

groups {
  re0 {
    interfaces {
      fxp0 {
        unit 0 {
          family inet {
            address 10.0.0.1/24;
          }
        }
      }
    }
  }
}
apply-groups re0;
system {
  host-name router1;
  scripts {
    commit {
      file dual-re.xsl;
      file dual-re2.xsl;
    }
  }
}
interfaces {
  fe-0/0/0 {
    unit 0 {
      family inet {
        address 192.168.220.1/30;
      }
    }
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```
[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...
```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Commit Script Changes

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. After the commit operation completes, the device hostname is changed to **router1-RE0**.

```
[edit]
user@host# commit
[edit system]
'host-name router1;'
warning: statement should not be in target configuration on dual RE system
[edit interfaces interface fe-0/0/0 unit 0 family inet]
'address 192.168.220.1/30;'
warning: statement should not be in target configuration on dual RE system
commit complete
```

Example: Configuring an Interior Gateway Protocol on an Interface

This commit script example uses a macro to automatically include an interface at the **[edit protocols]** hierarchy level and to configure the proper interior gateway protocol (IGP) on the interface.

- [Requirements on page 246](#)
- [Overview and Commit Script on page 247](#)
- [Configuration on page 249](#)
- [Verification on page 250](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

When you add a new interface to an OSPF or IS-IS domain, you must configure the interface at multiple hierarchy levels, including **[edit interfaces]** and **[edit protocols]**. This example uses a commit script and macro to automatically include the interface at the **[edit protocols]** hierarchy level and to configure the proper IGP on the interface, either OSPF or IS-IS, depending on the content of an **apply-macro** statement that you include in the interface configuration. This macro allows you to perform more configuration tasks at a single hierarchy level.

In this example, the Junos OS management (mgd) process inspects the configuration, looking for **apply-macro** statements. For each **apply-macro ifclass** statement included at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level, the script tests whether the **role** parameter is defined as **cpe**. If so, the script checks the **igp** parameter.

If the **igp** parameter is defined as **isis**, the script includes the relevant interface name at the **[edit protocols isis interface]** hierarchy level.

If the **igp** parameter is defined as **ospf**, the script includes the relevant interface name at the **[edit protocols ospf area address interface]** hierarchy level. For OSPF, the script references the **area** parameter to determine the correct subnet address of the area.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```

```

```

        <name> $ifname;
    }
}
}
}
}
}
}
}
}
}
}

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **if-class.xml** or **if-class.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **if-class.slax**.

```

system {
  scripts {
    commit {
      file if-class.xml;
    }
  }
}
interfaces {
  so-1/2/3 {
    unit 0 {
      apply-macro ifclass {
        area 10.4.0.0;
        igp ospf;
        role cpe;
      }
    }
  }
  t3-0/0/0 {
    unit 0 {
      apply-macro ifclass {
        igp isis;
        role cpe;
      }
    }
  }
}
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]

```

... Paste the contents of the clipboard here ...

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action View the configuration to verify that the manual changes and the script-generated changes are present.

When you issue the **show interfaces** configuration mode command, the changes added by the sample configuration stanzas should be present in the configuration.

```
[edit]
user@host# show interfaces
t3-0/0/0 {
  unit 0 {
    apply-macro ifclass {
      igp isis;
      role cpe;
    }
  }
}
so-1/2/3 {
  unit 0 {
    apply-macro ifclass {
      area 10.4.0.0;
      igp ospf;
      role cpe;
    }
  }
}
```

When you issue the **show protocols** configuration mode command, the script-generated changes should be present in the configuration.

```
[edit]
user@host# show protocols
isis {
  interface t3-0/0/0.0;
}
ospf {
  area 10.4.0.0 {
    interface so-1/2/3.0;
  }
}
```

```
}
```

Example: Controlling IS-IS and MPLS Interfaces

This example shows how to use commit scripts to decrease the amount of manual configuration.

- [Requirements on page 251](#)
- [Overview and Commit Script on page 251](#)
- [Configuration on page 253](#)
- [Verification on page 254](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

If you want to enable MPLS on an interface, you must make changes at both the **[edit interfaces]** and **[edit protocols mpls]** hierarchy levels. This example shows how to use commit scripts to decrease the amount of manual configuration.

This example performs two related tasks. If an interface has **[family iso]** configured but not **[family mpls]**, a configuration change is made (using the **jcs:emit-change** template) to enable MPLS. MPLS is not valid on loopback interfaces (**loX**), so this script ignores loopback interfaces. Secondly, if the interface is not configured at the **[edit protocols mpls]** hierarchy level, a change is made to add the interface. Both changes are accompanied by appropriate warning messages.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"

    }
  }
}
protocols {
  mpls {
    enable;
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command.

```
[edit]
user@host# commit
[edit interfaces interface so-1/2/3 unit 0]
  warning: Adding 'family mpls' to ISO-enabled interface
[edit interfaces interface so-1/2/3 unit 0]
  warning: Adding ISO-enabled interface so-1/2/3.0 to [protocols mpls]
[edit interfaces interface so-1/3/2 unit 0]
  warning: Adding 'family mpls' to ISO-enabled interface
[edit interfaces interface so-1/3/2 unit 0]
  warning: Adding ISO-enabled interface so-1/3/2.0 to [protocols mpls]
commit complete
```

Issue the **show interfaces** command. Confirm that the loopback interface is not altered and that the SONET/SDH interfaces are altered.

```
[edit]
user@host# show interfaces

    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family iso;
  }
}
```

Example: Controlling LDP Configuration

This commit script example generates a warning on LDP-enabled devices for any interfaces that are configured at either the **[edit protocols ospf]** or **[edit protocols isis]** hierarchy level but are not configured at the **[edit protocols ldp]** hierarchy level. A second test ensures that all LDP-enabled interfaces are configured for an interior gateway protocol (IGP). The example also provides instructions for excluding a particular interface from the commit script LDP test.

- [Requirements on page 255](#)
- [Overview and Commit Script on page 255](#)
- [Configuration on page 257](#)
- [Verification on page 258](#)

Requirements

This example uses a router running Junos OS.

Overview and Commit Script

If you want to enable LDP on an interface, you must configure the interface at both the **[edit protocols routing-protocol-name]** and **[edit protocols ldp]** hierarchy levels. This example shows how to use commit scripts to ensure that the interface is configured at both levels.

This example tests for interfaces that are configured at either the **[edit protocols ospf]** or **[edit protocols isis]** hierarchy level but not at the **[edit protocols ldp]** hierarchy level. If LDP is not enabled on the device, there is no problem. Otherwise, a warning is generated with the message that the interface does not have LDP enabled.

In case you want some interfaces to be exempt from the LDP test, this script allows you to tag those interfaces as not requiring LDP by including the **apply-macro no-ldp** statement at the **[edit protocols isis interface *interface-name*]** or **[edit protocols ospf area *area-id* interface *interface-name*]** hierarchy level. For example:

```
[edit]
protocols {
  isis {
    interface so-0/1/2.0 {
      apply-macro no-ldp;
    }
  }
}
```

If the **apply-macro no-ldp** statement is included, the warning is not generated.

A second test ensures that all LDP-enabled interfaces are configured for an interior gateway protocol (IGP). As for LDP, you can exempt some interfaces from the test by including the **apply-macro no-igp** statement at the **[edit protocols ldp interface *interface-name*]** hierarchy level. If that statement is not included and no IGP is configured, a warning is generated.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xsl"/>

  <xsl:template match="configuration">
    <xsl:variable name="ldp" select="protocols/ldp"/>

            <message>
              <xsl:text>ldp-enabled interface does not have </xsl:text>
              <xsl:text>an IGP configured</xsl:text>
            </message>
          </xnm:warning>
        </xsl:if>
      </xsl:for-each>
    </xsl:if>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xsl";

apply-macro no-ldp;
match configuration {
  var $ldp = protocols/ldp;
  var $isis = protocols/isis;
```

```

var $ospf = protocols/ospf;
if ($ldp) {
  for-each ($isis/interface/name | $ospf/area/interface/name) {
    var $ifname = .;
    if (not(../apply-macro[name = 'no-ldp']) and not($ldp/interface[name =
      $ifname])) {
      <xnm:warning> {
        call jcs:edit-path();
        call jcs:statement();
        <message> "ldp not enabled for this interface";
      }
    }
  }
  for-each (protocols/ldp/interface/name) {
    var $ifname = .;
    if (not(apply-macro[name = 'no-igp']) and not($isis/interface[name =
      $ifname]) and not($ospf/area/interface[name = $ifname])) {
      <xnm:warning> {
        call jcs:edit-path();
        call jcs:statement();
        <message> {
          expr "ldp-enabled interface does not have ";
          expr "an IGP configured";
        }
      }
    }
  }
}
}
}

```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **ldp.xml** or **ldp.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **ldp.slax**.

```

system {
  scripts {
    commit {
      file ldp.xml;
    }
  }
}
protocols {
  isis {
    interface so-1/2/2.0 {
      apply-macro no-ldp;
    }
    interface so-1/2/3.0;
  }
}

```

```

    }
    ospf {
        area 10.4.0.0 {
            interface ge-3/2/1.0;
            interface ge-2/2/1.0;
        }
    }
    ldp {
        interface ge-1/2/1.0;
        interface ge-2/2/1.0;
    }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```

user@host# commit

```

Verification

Verifying the Script Execution

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The sample configuration stanzas enable LDP on the device and configure the **so-1/2/2** and **so-1/2/3** interfaces at the **[edit protocols isis]** hierarchy level and the **ge-3/2/1** and **ge-2/2/1** interfaces at the **[edit protocols ospf]** hierarchy level.

Because **ge-2/2/1** is also configured at the **[edit protocols ldp]** hierarchy level, the script does not issue a warning message for this interface during the commit operation. The configuration includes the **apply-macro no-ldp** statement under the **so-1/2/2** interface, so the script does not test this interface or issue a warning message for it, even though it is not configured at the **[edit protocols ldp]** hierarchy.

Neither **so-1/2/3** nor **ge-3/2/1** is configured at the **[edit protocols ldp]** hierarchy level as required by the commit script, so a warning is issued for both interfaces. The **ge-1/2/1** interface is configured at the **[edit protocols ldp]** hierarchy. However, it is not configured for an IGP, so the commit script also issues a warning for the **ge-1/2/1** interface.

```

[edit]
user@host# commit

[edit protocols ospf area 10.4.0.0 interface so-1/2/3.0]

```

```

'interface so-1/2/3.0;'
  warning: LDP not enabled for this interface
[edit protocols ospf area 10.4.0.0 interface ge-3/2/1.0]
'interface ge-3/2/1.0;'
  warning: LDP not enabled for this interface
[edit protocols ldp interface ge-1/2/1.0]
'interface ge-1/2/1.0;'
  warning: LDP-enabled interface does not have an IGP configured
commit complete

```

Example: Creating a Complex Configuration Based on a Simple Interface Configuration

This commit script example uses a macro to automatically expand a simple interface configuration.

- [Requirements on page 259](#)
- [Overview and Commit Script on page 259](#)
- [Configuration on page 264](#)
- [Verification on page 265](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

This example uses a commit script and macro to automatically expand a simple interface configuration by generating a transient change that assigns a default encapsulation type, configures multiple routing protocols on the interface, and applies multiple configuration groups. The Junos OS management (mgd) process inspects the configuration, looking for **apply-macro params** statements included at the **[edit interfaces *interface-name*]** hierarchy level.

When the script finds an **apply-macro params** statement, it performs the following actions:

- Applies the **interface-details** configuration group to the interface.
- Includes the value of the **description** parameter at the **[edit interfaces *interface-name* description]** hierarchy level.
- Includes the value of the **encapsulation** parameter at the **[edit interfaces *interface-name* encapsulation]** hierarchy level. If the **encapsulation** parameter is not included in the **apply-macro params** statement, the script sets the encapsulation to **cisco-hdlc** as the default.
- Sets the logical unit number to **0** and tests whether the **inet-address** parameter is included in the **apply-macro params** statement. If it is, the script includes the value of the **inet-address** parameter at the **[edit interfaces *interface-name* unit 0 family inet address]** hierarchy level.
- Includes the interface name at the **[edit protocols rsvp interface]** hierarchy level.
- Includes the **level 1 enable** and **metric** statements at the **[edit protocols isis interface *interface-name*]** hierarchy level.

- Includes the **level 2 enable** and **metric** statements at the **[edit protocols isis interface *interface-name*]** hierarchy level.
- Tests whether the **isis-level-1** or **isis-level-1-metric** parameter is included in the **apply-macro params** statement. If one or both of these parameters are included, the script includes the **level 1** statement at the **[edit protocols isis interface *interface-name*]** hierarchy level. If the **isis-level-1** parameter is included, the script also includes the value of the **isis-level-1** parameter (**enable** or **disable**) at the **[edit protocols isis interface *interface-name* level 1]** hierarchy level. If the **isis-level-1-metric** parameter is included, the script also includes the value of the **isis-level-1-metric** parameter at the **[edit protocols isis interface *interface-name* level 1 metric]** hierarchy level.
- Tests whether the **isis-level-2** or **isis-level-2-metric** parameter is included in the **apply-macro params** statement. If one or both of these parameters are included, the script includes the **level 2** statement at the **[edit protocols isis interface *interface-name*]** hierarchy level. If the **isis-level-2** parameter is included, the script also includes the value of the **isis-level-2** parameter (**enable** or **disable**) at the **[edit protocols isis interface *interface-name* level 2]** hierarchy level. If the **isis-level-2-metric** parameter is included, the script also includes the value of the **isis-level-2-metric** parameter at the **[edit protocols isis interface *interface-name* level 2 metric]** hierarchy level.
- Includes the interface name at the **[edit protocols ldp interface]** hierarchy level.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```

}
}
}

```

Configuration**Step-by-Step
Procedure**

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **if-params.xml** or **if-params.slax** as appropriate, and copy it to the `/var/db/scripts/commit/` directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **if-params.slax**.

```

system {
  scripts {
    commit {
      allow-transients;
      file if-params.xml;
    }
  }
}
groups {
  interface-details {
    interfaces {
      <so-*/*/*> {
        clocking internal;
      }
    }
  }
}
interfaces {
  so-1/2/3 {
    apply-macro params {
      description "Link to Hoverville";
      encapsulation ppp;
      inet-address 10.1.2.3/28;
      isis-level-1 enable;
      isis-level-1-metric 50;
      isis-level-2-metric 85;
    }
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
- b. Press Enter.

- c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action Issue the **show interfaces | display commit-scripts | display inheritance** configuration mode command. The **| display commit-scripts** option displays all the statements that are in the configuration, including statements that are generated by transient changes. The **| display inheritance** option displays inherited configuration data and information about the source group from which the configuration has been inherited. This option also shows interface ranges configuration data in expanded format and information about the source interface-range from which the configuration has been expanded. You should see the following output:

```
[edit]
user@host# show interfaces | display commit-scripts | display inheritance
so-1/2/3 {
  apply-macro params {
    clocking internal;
    description "Link to Hoverville";
    encapsulation ppp;
    inet-address 10.1.2.3/28;
    isis-level-1 enable;
    isis-level-1-metric 50;
    isis-level-2-metric 85;
  }
  description "Link to Hoverville";
  ##
  ## 'internal' was inherited from group 'interface-details'
  ##
  clocking internal;
  encapsulation ppp;
  unit 0 {
    family inet {
      address 10.1.2.3/28;
    }
  }
}
```

Issue the **show protocols | display commit-scripts** configuration mode command. You should see the following output:

```
[edit]
user@host# show protocols | display commit-scripts
rsvp {
  interface so-1/2/3.0;
}
isis {
  interface so-1/2/3.0 {
```

```

    level 1 {
        enable;
        metric 50;
    }
    level 2 metric 85;
}
}
ldp {
    interface so-1/2/3.0;
}

```

Example: Imposing a Minimum MTU Setting

The maximum transmission unit (MTU) is the greatest amount of data or packet size (in bytes) that can be transferred in one physical frame on a network. In this example, a commit script tests the MTU of SONET/SDH interfaces. If the MTU is less than a specified minimum value, the commit script reports the error and causes the commit operation to fail.

- [Requirements on page 266](#)
- [Overview and Commit Script on page 266](#)
- [Configuration on page 267](#)
- [Verification on page 268](#)

Requirements

This example uses a device running Junos OS with SONET/SDH interfaces.

Overview and Commit Script

This example tests the MTU of SONET/SDH interfaces, reports when the MTU is less than the value of the `$min-mtu` parameter, here set to 2048, and causes the commit operation to fail. The `for` loop selects all SONET/SDH interfaces that start with `so-` and that have an MTU statement that is defined and less than the value of `$min-mtu`. For the selected interfaces, the script generates an error, which includes the location of the interface in the configuration hierarchy and the MTU configured for that interface.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```

<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xml"/>

  <xsl:param name="min-mtu" select="2048"/>
  <xsl:template match="configuration">
    <xsl:for-each select="interfaces/interface[starts-with(name, 'so-')
      and mtu and mtu < $min-mtu]">
      <xnm:error>
        <xsl:call-template name="jcs:edit-path"/>
        <xsl:call-template name="jcs:statement">

```

```

        <xsl:with-param name="dot" select="mtu"/>
    </xsl:call-template>
    <message>
        <xsl:text>SONET interfaces must have a minimum MTU of </xsl:text>
        <xsl:value-of select="$min-mtu"/>
        <xsl:text>.</xsl:text>
    </message>
</xnm:error>
</xsl:for-each>
</xsl:template>
</xsl:stylesheet>

```

SLAX Syntax

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xml";

param $min-mtu = 2048;
match configuration {
  for-each (interfaces/interface[starts-with(name, 'so-') and mtu and
    mtu < $min-mtu]) {
    <xnm:error> {
      call jcs:edit-path();
      call jcs:statement($dot = mtu);
      <message> {
        expr "SONET interfaces must have a minimum MTU of ";
        expr $min-mtu;
        expr ".";
      }
    }
  }
}

```

Configuration**Step-by-Step
Procedure**

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **so-mtu.xml** or **so-mtu.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **so-mtu.slax**.

```

system {
  scripts {
    commit {
      file so-mtu.xml;
    }
  }
}
interfaces {
  so-1/2/2 {

```

```
mtu 2048;
}
so-1/2/3 {
mtu 576;
}
}
```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```
[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...
```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Commit Script Output

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The sample configuration stanzas configure two SONET/SDH interfaces **so-1/2/2** and **so-1/2/3**. The **so-1/2/3** interface is configured with an MTU of 576, so the script generates an error message, and the commit operation fails. The following output appears after issuing a **commit** command:

```
[edit]
user@host# commit
[edit interfaces interface so-1/2/3]
'mtu 576;'
SONET interfaces must have a minimum MTU of 2048.
error: 1 error reported by commit scripts
error: commit script failure
```

Example: Limiting the Number of ATM Virtual Circuits

This commit script example limits the number of Asynchronous Transfer Mode (ATM) virtual circuits (VCs) configured on an ATM interface.

- [Requirements on page 269](#)
- [Overview and Commit Script on page 269](#)
- [Configuration on page 270](#)
- [Verification on page 272](#)

Requirements

This example uses a device running Junos OS with an ATM interface.

Overview and Commit Script

For each ATM interface, the set of corresponding VCs is selected. The number of those VCs, as determined by the built-in Extensible Stylesheet Language Transformations (XSLT) `count()` function, cannot exceed the limit set by the global variable `$limit`. If there are more ATM VCs than `$limit`, a commit error is generated, and the commit operation fails.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../import/junos.xsl"/>

  <xsl:param name="limit" select="10"/>
  <xsl:template match="configuration">
    <xsl:for-each select="interfaces/interface[starts-with(name, 'at-')] ">
      <xsl:variable name="count" select="count(unit)"/>
      <xsl:if test="$count > $limit">
        <xnm:error>
          <edit-path>[edit interfaces]</edit-path>
          <statement><xsl:value-of select="name"/></statement>
          <message>
            <xsl:text>ATM VC limit exceeded; </xsl:text>
            <xsl:value-of select="$count"/>
            <xsl:text> are configured but only </xsl:text>
            <xsl:value-of select="$limit"/>
            <xsl:text> are allowed.</xsl:text>
          </message>
        </xnm:error>
      </xsl:if>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

param $limit = 10;
match configuration {
  for-each (interfaces/interface[starts-with(name, 'at-')]) {
    var $count = count(unit);
    if ($count > $limit) {
      <xnm:error> {
        <edit-path> "[edit interfaces]";
```

```

        <statement> name;
    <message> {
        expr "ATM VC limit exceeded; ";
        expr $count;
        expr " are configured but only ";
        expr $limit;
        expr " are allowed.";
    }
}
}
}
}

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **atm-vc-limit.xml** or **atm-vc-limit.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **atm-vc-limit.slax**.

```

system {
  scripts {
    commit {
      file atm-vc-limit.xml;
    }
  }
}
interfaces {
  at-1/2/3 {
    unit 15 {
      family inet {
        address 10.12.13.15/20;
      }
    }
    unit 16 {
      family inet {
        address 10.12.13.16/20;
      }
    }
    unit 17 {
      family inet {
        address 10.12.13.17/20;
      }
    }
    unit 18 {
      family inet {
        address 10.12.13.18/20;
      }
    }
  }
}

```

```

unit 19 {
    family inet {
        address 10.12.13.19/20;
    }
}
unit 20 {
    family inet {
        address 10.12.13.20/20;
    }
}
unit 21 {
    family inet {
        address 10.12.13.21/20;
    }
}
unit 22 {
    family inet {
        address 10.12.13.22/20;
    }
}
unit 23 {
    family inet {
        address 10.12.13.23/20;
    }
}
unit 24 {
    family inet {
        address 10.12.13.24/20;
    }
}
unit 25 {
    family inet {
        address 10.12.13.25/20;
    }
}
unit 26 {
    family inet {
        address 10.12.13.26/20;
    }
}
}
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
- b. Press Enter.
- c. Press Ctrl+d.

4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Commit Script Output

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The sample configuration stanzas configure 12 virtual circuits on the ATM interface **atm-1/2/3**. Because the commit script only allows 10 ATM VCs to be configured on any ATM interface, the script generates an error, and the commit operation fails. The following output appears after issuing a **commit** command:

```
[edit]
user@host# commit
[edit interfaces]
'at-1/2/3'
ATM VC limit exceeded; 12 are configured but only 10 are allowed.
error: 1 error reported by commit scripts
error: commit script failure
```

Example: Limiting the Number of E1 Interfaces

This commit script example limits the number of E1 interfaces configured on a Channelized STM1 Intelligent Queuing (IQ) PIC to avoid contention issues with per-unit-schedulers.

- [Requirements on page 272](#)
- [Overview and Commit Script on page 272](#)
- [Configuration on page 274](#)
- [Verification on page 281](#)

Requirements

This example uses a device running Junos OS with a Channelized STM1 Intelligent Queuing (IQ) PIC.

Overview and Commit Script

The following script ensures that there are no more than 16 E1 interfaces configured on a channelized STM1 IQ interface. For each channelized STM1 interface (**cstm1-**), the set of corresponding E1 interfaces is selected. The number of those interfaces, as determined by the built-in Extensible Stylesheet Language Transformations (XSLT) **count()** function, cannot exceed the limit set by the global parameter **\$limit**. If there are more E1 interfaces than **\$limit**, a commit error is generated, and the commit operation fails.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```
[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...
```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Commit Script Execution

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The sample configuration stanzas channelize a **cstm1-0/1/0** interface into 17 **E1** interfaces, so the script generates an error, and the commit operation fails. The following output appears after issuing a **commit** command:

```
[edit]
user@host# commit
[edit interfaces]
'cstm1-0/1/0'
E1 interface limit exceeded on CSTM1 IQ PIC.
17 E1 interfaces are configured, but only 16 are allowed.
error: 1 error reported by commit scripts
error: commit script failure
```

Example: Loading a Base Configuration

This commit script example sets up a sample base configuration on a device running Junos OS.

- [Requirements on page 281](#)
- [Overview and Commit Script on page 282](#)
- [Configuration on page 294](#)
- [Verification on page 295](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

This script is a macro that sets up a device running Junos OS with a sample base configuration. With minimal manual user input, the script automatically configures:

- A device hostname
- Authentication services
- A superuser login
- System log settings
- Some SNMP settings
- System services, such as FTP and Telnet
- Static routes and a policy to redistribute the static routes
- Configuration groups **re0** and **re1**
- An address for the management Ethernet interface (**fxp0**)
- The loopback interface (**lo0**) with the device ID as the loopback address

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

    }
}
}
<policy-options> {
    <policy-statement> {
        <name> "redist";
        <from> {
            <protocol> "static";
        }
        <then> {
            <accept>;
        }
    }
}
}
<apply-groups> "re0";
<apply-groups> "re1";
<groups> {
    <name> "re0";
    <system> {

```

```

scripts {
  commit {
    allow-transients;
    file config-system.xml;
  }
}
apply-macro config-system {
  host-name test;
  mgmt-address 10.0.0.1/32;
  backup-router 10.0.0.2;
}

```

The **host-name** and **mgmt-address** statements are mandatory. The **backup-router** statement is optional. You can substitute a hostname, a management Ethernet (**fxp0**) IP address, and a backup router IP address that are appropriate for your device.

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action After committing the configuration, issue the **show | display commit-scripts** configuration mode command to view the device base configuration.

```

user@host# show | display commit-scripts
...

```

Example: Prepending a Global Policy

This commit script example ensures that a BGP global import policy is applied to all your BGP imports before any other import policies are applied.

- [Requirements on page 296](#)
- [Overview and Commit Script on page 296](#)

- [Configuration on page 298](#)
- [Verification on page 299](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

For most configuration objects, the order in which the object or its children is created is not significant, because the Junos OS configuration management software stores and displays configuration objects in predetermined positions in the configuration hierarchy. However, some configuration objects—such as routing policies and firewall filters—consist of elements that must be processed and analyzed sequentially in order to produce the intended routing behavior.

This example commit script ensures that a BGP global import policy is applied to all your BGP imports before any other import policies are applied.

This example automatically prepends the **bgp_global_import** policy in front of any other BGP import policies. If the **bgp_global_import** policy statement is not included in the configuration, an error message is generated, and the commit operation fails.

Otherwise, the commit script uses the **insert="before"** Junos XML protocol attribute and the **position()** XSLT function to control the position of the global BGP policy in relation to any other applied policies. The **insert="before"** attribute inserts the **bgp_global_import** policy in front of the first preexisting BGP import policy.

If there is no preexisting default BGP import policy, the global policy is included in the configuration.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>

import "../import/junos.xml";

match configuration {
  if (not(policy-options/policy-statement[name='bgp_global_import'])) {
    <xnm:error> {
      <message> "Policy error: Policy bgp_global_import required";
    }
  }
  for-each (protocols/bgp | protocols/bgp/group |
    protocols/bgp/group/neighbor) {
    var $first = import[position() = 1];
    if ($first) {
      call jcs:emit-change($tag = 'transient-change') {
        with $content = {
          <import insert="before" name="{ $first}"> "bgp_global_import";
        }
      }
    }
  }
  for-each (protocols/bgp) {
    if (not(import)) {
      call jcs:emit-change($tag = 'transient-change') {
        with $content = {
          <import> "bgp_global_import";
        }
      }
    }
  }
}

```

*Configuration***Step-by-Step
Procedure**

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **bgp-global-import.xsl** or **bgp-global-import.slax** as appropriate, and copy it to the `/var/db/scripts/commit/` directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **bgp-global-import.slax**.

```

system {
  scripts {
    commit {
      allow-transients;
      file bgp-global-import.xsl;
    }
  }
}
interfaces {
  fe-0/0/0 {
    unit 0 {
      family inet {
        address 192.168.16.2/24;
      }
      family inet6 {
        address 2002:18a5:e996:beef::2/64;
      }
    }
  }
}
routing-options {
  autonomous-system 65400;
}
protocols {
  bgp {
    group fish {
      neighbor 192.168.16.4 {
        import [ blue green ];
        peer-as 65401;
      }
      neighbor 192.168.16.6 {
        peer-as 65402;
      }
    }
  }
}
policy-options {
  policy-statement blue {
    from protocol bgp;
    then accept;
  }
  policy-statement green {

```

```

        then accept;
    }
    policy-statement bgp_global_import {
        then accept;
    }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```

user@host# commit

```

Verification

Verifying the Configuration

Purpose Verify that the script behaves as expected.

Action When you issue the **show protocols** configuration mode command, the **bgp_global_import** import policy is not displayed, because it is added as a transient change.

```

[edit]
user@host# show protocols
bgp {
  group fish {
    neighbor 192.168.16.4 {
      import [ blue green ];
      peer-as 65401;
    }
    neighbor 192.168.16.6 {
      peer-as 65402;
    }
  }
}

```

The commit script adds the **import bgp_global_import** statement at the **[edit protocols bgp]** hierarchy level and prepends the **bgp_global_import** policy to the **192.168.16.4** neighbor policy chain. Issue the **show protocols | display commit-scripts** to view all configuration statements including transient changes.

```

[edit]
user@host# show protocols | display commit-scripts
bgp {
  import bgp_global_import;

```

```
group fish {  
  neighbor 192.168.16.4 {  
    import [ bgp_global_import blue green ];  
    peer-as 65401;  
  }  
  neighbor 192.168.16.6 {  
    peer-as 65402;  
  }  
}
```

After you add a policy to the **192.168.16.6** neighbor, which previously had no policies applied, the **bgp_global_import** policy is prepended. Issue the **show protocols | display commit-scripts** command to view all configuration statements including transient changes.

```
[edit]  
user@host# set protocols bgp group fish neighbor 192.168.16.6 import green
```

```
[edit]  
user@host# show protocols | display commit-scripts  
bgp {  
  import bgp_global_import;  
  group fish {  
    neighbor 192.168.16.4 {  
      import [ bgp_global_import blue green ];  
      peer-as 65401;  
    }  
    neighbor 192.168.16.6 {  
      import [ bgp_global_import green ];  
      peer-as 65402;  
    }  
  }  
}
```

Example: Preventing Import of the Full Routing Table

In the Junos OS routing policy, if you configure a policy with no match conditions and a terminating action of **then accept**, and then apply the policy to a routing protocol, the protocol imports the entire routing table. This example shows how to use a commit script to prevent this scenario.

- [Requirements on page 300](#)
- [Overview and Commit Script on page 300](#)
- [Configuration on page 302](#)
- [Verification on page 303](#)

Requirements

This example uses a device running Junos OS.

Overview and Commit Script

This example inspects the **import** statements configured at the **[edit protocols ospf]** and **[edit protocols isis]** hierarchy levels to determine if any of the named policies contain a

then accept term with no match conditions. The script protects against importing the full routing table into these interior gateway protocols (IGPs).

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax	<pre> <?xml version="1.0" standalone="yes"?> <xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" xmlns:junos="http://xml.juniper.net/junos/*/junos" xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm" xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0"> <xsl:import href="../../import/junos.xsl"/> <xsl:param name="po" select="commit-script-input/configuration/policy-options"/> <xsl:template match="configuration"> <xsl:apply-templates select="protocols/ospf/import"/> <xsl:apply-templates select="protocols/isis/import"/> </xsl:template> <xsl:template match="import"> <xsl:param name="test" select="."/> <xsl:for-each select="\$po/policy-statement[name=\$test]"> <xsl:choose> <xsl:when test="then/accept and not(to) and not(from)"> <xnm:error> <xsl:call-template name="jcs:edit-path"> <xsl:with-param name="dot" select="\$test"/> </xsl:call-template> <xsl:call-template name="jcs:statement"> <xsl:with-param name="dot" select="\$test"/> </xsl:call-template> <message>policy contains bare 'then accept'</message> </xnm:error> </xsl:when> </xsl:choose> </xsl:for-each> </xsl:template> </xsl:stylesheet> </pre>
SLAX Syntax	<pre> version 1.0; ns junos = "http://xml.juniper.net/junos/*/junos"; ns xnm = "http://xml.juniper.net/xnm/1.1/xnm"; ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0"; import "../../import/junos.xsl"; param \$po = commit-script-input/configuration/policy-options; match configuration { apply-templates protocols/ospf/import; apply-templates protocols/isis/import; } match import { param \$test = .; for-each (\$po/policy-statement[name=\$test]) { if (then/accept and not(to) and not(from)) { <xnm:error> { call jcs:edit-path(\$dot = \$test); } } } } </pre>

```

        call jcs:statement($dot = $test);
        <message> "policy contains bare 'then accept'";
    }
}
}
}

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **import.xml** or **import.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **import.slax**.

```

system {
  scripts {
    commit {
      file import.xml;
    }
  }
}
protocols {
  ospf {
    import bad-news;
  }
}
policy-options {
  policy-statement bad-news {
    then accept;
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```

user@host# commit

```

Verification

Verifying the Commit Script Execution

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The sample configuration configures an **import** statement at the **[edit protocols ospf]** hierarchy level. Because the policy contains a **then accept** term with no match conditions, the script generates an error, and the commit operation fails. The following output appears after issuing a **commit** command:

```
[edit]
user@host# commit
[edit protocols ospf]
  'import bad-news;'
    policy contains bare 'then accept'
error: 1 error reported by commit scripts
error: commit script failure
```

Example: Requiring Internal Clocking on T1 Interfaces

This example shows how to use a commit script to require that T1 interfaces be configured with internal clocking.

- [Requirements on page 303](#)
- [Overview and Commit Script on page 303](#)
- [Configuration on page 304](#)
- [Verification on page 305](#)

Requirements

This example uses a device running Junos OS with T1 interfaces.

Overview and Commit Script

This commit script ensures that T1 interfaces are explicitly configured to use internal clocking. If the **clocking** statement is not included in the configuration, or if the **clocking external** statement is included, an error message is generated, and the configuration is not committed.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax	<pre><?xml version="1.0" standalone="yes"?> <xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" xmlns:junos="http://xml.juniper.net/junos/*/junos" xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm" xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0"> <xsl:import href="../../import/junos.xsl"/> <xsl:template match="configuration"> <xsl:for-each select="interfaces/interface[starts-with(name, 't1-')]"> <xsl:variable name="clock-source"> <xsl:value-of select="clocking"/> </xsl:variable></pre>
--------------------	---

```

<xsl:if test="not($clock-source = 'internal')">
<!-- or xsl:if test="$clock-source != 'internal'" -->
  <xnm:error>
    <xsl:call-template name="jcs:edit-path"/>
    <xsl:call-template name="jcs:statement">
      <xsl:with-param name="dot" select="clocking"/>
    </xsl:call-template>
    <message>
      This T1 interface should have internal clocking.
    </message>
  </xnm:error>
</xsl:if>
</xsl:for-each>
</xsl:template>
</xsl:stylesheet>

```

SLAX Syntax

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match configuration {
  for-each (interfaces/interface[starts-with(name, 't1-')]) {
    var $clock-source = {
      expr clocking;
    }
    if (not($clock-source = 'internal')) {
      <xnm:error> {
        call jcs:edit-path();
        call jcs:statement($dot = clocking);
        <message> "This T1 interface should have internal clocking.";
      }
    }
  }
}

```

Configuration**Step-by-Step
Procedure**

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **clocking-error.xsl** or **clocking-error.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **clocking-error.slax**.

```

system {
  scripts {
    commit {
      file clocking-error.xsl;
    }
  }
}

```

```

    }
  }
  interfaces {
    t1-0/0/0 {
      clocking external;
    }
    t1-0/0/1 {
      unit 0;
    }
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.
 - b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```

user@host# commit

```

Verification

Verifying Commit Script Execution

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The sample configuration stanzas configure two T1 interfaces **t1-0/0/0** and **t1-0/0/1**. Interface **t1-0/0/0** is configured with the **clocking external** statement, and interface **t1-0/0/1** does not include any **clocking** statement. The script generates an error, and the commit operation fails. The following output appears after issuing a **commit** command:

```

[edit]
user@host# commit
[edit interfaces interface t1-0/0/0]
'clocking external;'
This T1 interface should have internal clocking.
[edit interfaces interface t1-0/0/1]
','
This T1 interface should have internal clocking.
error: 2 errors reported by commit scripts
error: commit script failure

```

Example: Requiring and Restricting Configuration Statements

Junos OS commit scripts enforce custom configuration rules. When a candidate configuration is committed, it is inspected by each active commit script. This example uses a commit script to specify required and prohibited configuration statements.

- [Requirements on page 306](#)
- [Overview and Commit Script on page 306](#)
- [Configuration on page 308](#)
- [Verification on page 309](#)

Requirements

This example uses a device running Junos OS that has the Ethernet management interface **fxp0**.

Overview and Commit Script

This example shows how to use a commit script to specify required and prohibited configuration statements. The following commit script ensures that the Ethernet management interface (**fxp0**) is configured and detects when the interface is improperly disabled. The script also detects when the **bgp** statement is not included at the **[edit protocols]** hierarchy level. In all cases, the script generates an error message, and the commit operation fails.

The example script is shown in both XSLT and SLAX syntax:

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"

      <message> {
        copy-of $message;
      }
    }
  }
}
}

```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **no-nukes.xml** or **no-nukes.slax** as appropriate, and copy it to the **/var/db/scripts/commit/** directory on the device.
2. Select the following test configuration stanzas, and press Ctrl+c to copy them to the clipboard.

If you are using the SLAX version of the script, change the filename at the **[edit system scripts commit file]** hierarchy level to **no-nukes.slax**.

```

system {
  scripts {
    commit {
      file no-nukes.xml;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}

```

3. In configuration mode, issue the **load merge terminal** command to merge the stanzas into your device configuration.

```

[edit]
user@host# load merge terminal
[Type ^D at a new line to end input]
... Paste the contents of the clipboard here ...

```

- a. At the prompt, paste the contents of the clipboard by using the mouse and the paste icon.

- b. Press Enter.
 - c. Press Ctrl+d.
4. Issue the **commit** command to commit the configuration.

```
user@host# commit
```

Verification

Verifying Commit Script Execution

Purpose Verify that the script behaves as expected.

Action Review the output of the **commit** command. The script requires that the Ethernet management interface (**fxp0**) is configured and enabled and that the **bgp** statement is included at the **[edit protocols]** hierarchy level. The sample configuration stanzas include the **fxp0** interface but disable it. In addition, the **bgp** statement is not configured at the **[edit protocols]** hierarchy level. When you run the script, it generates an error, and the commit operation fails. The following output appears after issuing a **commit** command:

```
[edit]
user@host# commit
[edit interfaces interface fxp0 disable]
'disable;'
The fxp0 interface is disabled.
protocols bgp
missing mandatory configuration statement
error: 2 errors reported by commit scripts
error: commit script failure
```

Configuration Statements

allow-transients

Syntax	allow-transients;
Hierarchy Level	[edit system scripts commit]
Release Information	Statement introduced in Junos OS Release 7.4. Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	For Junos OS commit scripts, enable transient configuration changes to be committed.
Default	Transient changes are disabled by default. If you do not include the allow-transients statement, and an enabled script generates transient changes, the command-line interface (CLI) generates an error message and the commit operation fails.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Generating a Persistent or Transient Change on page 192• Creating a Macro to Read the Custom Syntax and Generate Related Configuration Statements on page 207

apply-macro

Syntax	<pre>apply-macro <i>apply-macro-name</i> { <i>parameter-name parameter-value</i>; }</pre>
Hierarchy Level	All hierarchy levels
Release Information	Statement introduced in Junos OS Release 7.4.
Description	<p>With commit script macros, use custom syntax in your configuration.</p> <p>Macros work by locating apply-macro statements that you include in the candidate configuration and using the values specified in the apply-macro statement as parameters to a set of instructions (the macro) defined in a commit script. The commit script alters your configuration from one that contains custom syntax into a full configuration containing standard Junos OS statements.</p> <p>In effect, your custom configuration syntax serves a dual purpose. The syntax allows you to simplify your configuration tasks, and it provides data (or <i>hooks</i>) that are used by a commit script macros.</p> <p>You can include the apply-macro statement at any level of the configuration hierarchy. You can include multiple apply-macro statements at each level of the configuration hierarchy; however, each must have a unique name.</p>
Options	<p><i>apply-macro-name</i>—Name of the apply-macro statement.</p> <p><i>parameter-name</i>—One or more parameters. Parameters can be any text you want to include in your configuration.</p> <p><i>parameter-value</i>—A value that corresponds to the parameter name. Parameter values can be any text you want to include in your configuration.</p>
Required Privilege Level	configure—To enter configuration mode; other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none"> • Overview of Creating Custom Configuration Syntax with Macros on page 158

checksum

Syntax	<code>checksum (md5 sha-256 sha1) hash;</code>
Hierarchy Level	[edit event-options event-script file filename], [edit system scripts commit file filename], [edit system scripts op file filename]
Release Information	Statement introduced in Junos OS Release 9.5. Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	For Junos OS commit scripts and op scripts, specify the MD5, SHA-1, or SHA-256 checksum hash. When it executes a local event, commit, or op script, Junos OS verifies the authenticity of the script by using the configured checksum hash.
Options	md5 hash —MD5 checksum of this script. sha-256 hash —SHA-256 checksum of this script. sha1 hash —SHA-1 checksum of this script.
Required Privilege Level	maintenance —To view this statement in the configuration. maintenance-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring Checksum Hashes for a Commit Script on page 177• Configuring Checksum Hashes for an Event Script on page 471• Configuring Checksum Hashes for an Op Script on page 345• Executing an Op Script from a Remote Site on page 346• <i>file checksum md5</i> command in the <i>System Basics and Services Command Reference</i>• <i>file checksum sha-256</i> command in the <i>System Basics and Services Command Reference</i>• <i>file checksum sha1</i> command in the <i>System Basics and Services Command Reference</i>

commit

Syntax	<pre> commit { allow-transients; direct-access; file <i>filename</i> { checksum (md5 sha-256 sha1) <i>hash</i>; optional; refresh; refresh-from <i>url</i>; source <i>url</i>; } refresh; refresh-from <i>url</i>; traceoptions { file <<i>filename</i>> <files <i>number</i>> <size <i>size</i>> <world-readable no-world-readable>; flag <i>flag</i>; no-remote-trace; } } </pre>
Hierarchy Level	[edit system scripts]
Release Information	<p>Statement introduced in Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 11.1 for the QFX Series.</p>
Description	For Junos OS commit scripts, configure the commit-time scripting mechanism.
Options	The statements are explained separately.
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Storing and Enabling Scripts on page 86

direct-access

Syntax	<code>direct-access;</code>
Hierarchy Level	[edit system scripts commit]
Release Information	Statement introduced in Junos OS Release 9.1. Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	Specify that commit scripts read input configurations directly from the database when inspecting these scripts for errors.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Executing Large Commit Scripts on page 178

file (Commit Scripts)

Syntax	<pre>file <i>filename</i> { checksum (md5 sha-256 sha1) <i>hash</i>; optional; refresh; refresh-from <i>url</i>; source <i>url</i>; }</pre>
Hierarchy Level	[edit system scripts commit]
Release Information	Statement introduced in Junos OS Release 7.4.
Description	For Junos OS commit scripts, enable a commit script that is located in the <code>/var/db/scripts/commit</code> directory.
Options	<p><i>filename</i>—Name of an Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) file containing a commit script.</p> <p>The remaining statements are explained separately.</p>

Hierarchy Level [edit system]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description For Junos OS commit or op scripts, configure scripting mechanisms.

Options The statements are explained separately.

Required Privilege Level maintenance—To view this statement in the configuration.
maintenance-control—To add this statement to the configuration.

Related Documentation

- [Storing and Enabling Scripts on page 86](#)

source (Commit Scripts)

Syntax `source url;`

Hierarchy Level [edit system [scripts commit file](#) *filename*]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description For Junos OS commit scripts, specify the location of the source file for an enabled script located in the `/var/db/scripts/commit` directory. When you include the **refresh** statement at the same hierarchy level and commit the configuration, the local copy is overwritten by the version stored at the specified URL.

Options *url*—The source specified as an HTTP URL, FTP URL, or scp-style remote file specification.

Required Privilege Level maintenance—To view this statement in the configuration.
maintenance-control—To add this statement to the configuration.

traceoptions (Commit and Op Scripts)

Syntax	<pre> traceoptions { file <filename> <files number> <size size> <world-readable no-world-readable>; flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit system scripts commit], [edit system scripts op]
Release Information	Statement introduced in Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Define tracing operations for commit or op scripts.
Default	If you do not include this statement, no script-specific tracing operations are performed.
Options	<p>filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory <code>/var/log</code>. By default, commit script process tracing output is placed in the file <code>cscript.log</code> and op script process tracing is placed in the file <code>op-script.log</code>. If you include the file statement, you must specify a filename. To retain the default, you can specify <code>cscript.log</code> or <code>op-script.log</code> as the filename.</p> <p>files number—(Optional) Maximum number of trace files. When a trace file named <i>trace-file</i> reaches its maximum size, it is renamed and compressed to <i>trace-file.0.gz</i>. When <i>trace-file</i> again reaches its maximum size, <i>trace-file.0.gz</i> is renamed <i>trace-file.1.gz</i> and <i>trace-file</i> is renamed and compressed to <i>trace-file.0.gz</i>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000</p> <p>Default: 10 files</p> <p>flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> • all—Log all operations • events—Log important events • input—Log script input data • offline—Generate data for offline development • output—Log script output data • rpc—Log script RPCs • xslt—Log the XSLT library

no-world-readable—Restrict file access to owner. This is the default.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named *trace-file* reaches this size, it is renamed and compressed to *trace-file.0.gz*. When *trace-file* again reaches its maximum size, *trace-file.0.gz* is renamed *trace-file.1.gz* and *trace-file* is renamed and compressed to *trace-file.0.gz*. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and a filename.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

world-readable—Enable unrestricted file access.

Required Privilege Level maintenance—To view this statement in the configuration.
maintenance-control—To add this statement to the configuration.

Junos XML and XSLT Tag Elements Used in Commit Scripts

<change> (XSLT)

Usage	<pre><change> <!-- tag elements representing configuration statements to load --> </change></pre>
Release Information	Statement introduced in Junos OS Release 7.4.
Description	Request that the Junos XML protocol server load configuration data into the candidate configuration by enclosing the configuration data within an opening <change> tag and closing </change> tag. Inside the <change> element, include the configuration data as Junos XML tag elements.
Usage Guidelines	See “ Overview of Generating Persistent or Transient Configuration Changes ” on page 154 and “ Overview of Creating Custom Configuration Syntax with Macros ” on page 158.
Related Documentation	<ul style="list-style-type: none"> • <transient-change> (XSLT) on page 321

<syslog> (Junos XML)

Usage	<pre><syslog="namespace-URL" xmlns:xnm="namespace-URL"> <message>syslog-message </message> </syslog></pre>
--------------	--

Release Information	Statement introduced in Junos OS Release 7.4.
Description	Record events that occur on a device running Junos OS.
Attributes	<p>xmlns—Names the Extensible Markup Language (XML) namespace for the contents of the tag element. The value is a URL of the form <code>http://xml.juniper.net/xnm/version/xnm</code>, where <i>version</i> is a string such as 1.1.</p> <p>xmlns:xnm—Names the XML namespace for child tag elements that have the xnm: prefix on their names. The value is a URL of the form <code>http://xml.juniper.net/xnm/version/xnm</code>, where <i>version</i> is a string such as 1.1.</p>
Contents	<message> —Specifies the content of the system log message in a natural-language text string.
Usage Guidelines	See “Generating a Custom Warning, Error, or System Log Message” on page 178.

<transient-change> (XSLT)

Usage	<pre><transient-change> <!-- tag elements representing configuration statements to load --> </transient-change></pre>
Release Information	Statement introduced in Junos OS Release 7.4.
Description	Request that the Junos XML protocol server load configuration data into the checkout configuration by enclosing the configuration data within an opening <transient-change> and closing </transient-change> tag. Inside the <transient-change> element, include the configuration data as Junos XML tag elements.

Tracing Commit Script Processing

Commit script tracing operations track all commit script operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

The default operation of commit script tracing is to log important events in a file called **cscript.log** located in the **/var/log** directory on the device. When the file **cscript.log** reaches 128 kilobytes (KB), it is renamed with a number 0 through 9 (in ascending order) appended to the end of the file and then compressed. For example, the log file is saved as **cscript.log.0.gz**, then **cscript.log.1.gz** until there are 10 trace files. Then the oldest trace

file (**cscript.log.9.gz**) is overwritten. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

This section discusses the following topics:

- [Minimum Configuration for Tracing for Commit Script Operations on page 327](#)
- [Configuring Tracing of Commit Scripts on page 328](#)

Minimum Configuration for Tracing for Commit Script Operations

If no commit script trace options are configured, the simplest way to view the trace output of a commit script is to configure the **output** trace flag and issue the **show log cscript.log | last** command. To do this, perform the following steps:

1. If you have not done so already, enable a commit script by including the **file** statement at the **[edit system scripts commit]** hierarchy level:

```
[edit system scripts commit]
user@host# set file filename
```

2. Enable trace options by including the **traceoptions flag output** statement at the **[edit system scripts commit]** hierarchy level:

```
[edit system scripts commit]
user@host# set traceoptions flag output
```

3. Issue the **commit** command:

```
[edit]
user@host# commit
```

4. Display the resulting trace messages recorded in the file **/var/log/cscript.log**. At the end of the log is the output generated by the commit script you enabled in Step 1. To display the end of the log, issue the **show log cscript.log | last** operational mode command:

```
[edit]
user@host# run show log cscript.log | last
```

[Table 18 on page 327](#) summarizes useful filtering commands that display selected portions of the **cscript.log** file.

Table 18: Commit Script Tracing Operational Mode Commands

Task	Command
Display logging data associated with all script processing.	show log cscript.log
Display script processing for only the most recent commit operation.	show log cscript.log last
Display processing for script errors.	show log cscript.log match error
Display script processing for a particular script.	show log cscript.log match filename

Example: Minimum Configuration for Enabling Traceoptions for Commit Scripts

Display the trace output for the commit script file **source-route.xml**:

```
[edit]
system {
  scripts {
    commit {
      file source-route.xml;
      traceoptions flag output;
    }
  }
}

[edit]
user@host# commit
[edit]
user@host# run show log cscript.log | last

Jun 20 10:24:15 summary: changes 0, transients 0 (allowed), syslog 0
```

Configuring Tracing of Commit Scripts

You cannot change the directory (**/var/log**) to which trace files are written. However, you can customize other trace file settings by including the following statements at the **[edit system scripts commit traceoptions]** hierarchy level:

```
[edit system scripts commit traceoptions]
file <filename> <files number> <size size> <world-readable | no-world-readable>;
flag all;
flag events;
flag input;
flag offline;
flag output;
flag rpc;
flag xslt;
no-remote-trace;
```

These statements are described in the following sections:

- [Configuring the Commit Script Log Filename on page 329](#)
- [Configuring the Number and Size of Commit Script Log Files on page 329](#)
- [Configuring Access to Commit Script Log Files on page 329](#)
- [Configuring the Commit Script Trace Operations on page 330](#)

Configuring the Commit Script Log Filename

By default, the name of the file that records trace output is **cscript.log**. You can specify a different name by including the **file** statement at the **[edit system scripts commit traceoptions]** hierarchy level:

```
[edit system scripts commit traceoptions]
file filename;
```

Configuring the Number and Size of Commit Script Log Files

By default, when the trace file reaches 128 KB in size, it is renamed and compressed to **filename.0.gz**, then **filename.1.gz**, and so on, until there are 10 trace files. Then the oldest trace file (**filename.9.gz**) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the **[edit system scripts commit traceoptions file <filename>]** hierarchy level:

```
[edit system scripts commit traceoptions file <filename>]
files number size size;
```

For example, set the maximum file size to 640 KB and the maximum number of files to 20. When the file that receives the output of the tracing operation (**filename**) reaches 640 KB, it is renamed and compressed to **filename.0.gz**, and a new file called **filename** is created. When **filename** reaches 640 KB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is renamed and compressed to **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file (**filename.19.gz**) is overwritten.

The number of files can range from 2 through 1000 files. The file size can range from 10 KB through 1 gigabyte (GB).

NOTE:

If you set either a maximum file size or a maximum number of trace files, you also must specify the other parameter and a filename.

Configuring Access to Commit Script Log Files

By default, access to the commit script log file is restricted to the owner. You can manually configure access by including the **world-readable** or **no-world-readable** statement at the **[edit system scripts commit traceoptions file <filename>]** hierarchy level.

```
[edit system scripts commit traceoptions file <filename>]
(world-readable | no-world-readable);
```

The **no-world-readable** statement restricts commit script log access to the owner. The **world-readable** statement enables unrestricted access to the commit script log file.

Configuring the Commit Script Trace Operations

By default, only important events are logged. You can configure the trace operations to be logged by including the following statements at the **[edit system scripts commit traceoptions]** hierarchy level:

```
[edit system scripts commit traceoptions]
flag all;
flag events;
flag input;
flag offline;
flag output;
flag rpc;
flag xslt;
```

Table 19 on page 330 describes the meaning of the commit script tracing flags.

Table 19: Commit Script Tracing Flags

Flag	Description	Default Setting
all	Trace all operations.	Off
events	Trace important events.	On
input	Trace commit script input data.	Off
offline	Generate data for offline development.	Off
output	Trace commit script output data.	Off
rpc	Trace commit script RPCs.	Off
xslt	Trace the Extensible Stylesheet Language Transformations (XSLT) library.	Off

Troubleshooting Commit Scripts

After you enable a commit script and issue a **commit** command, the commit script takes effect immediately.

Table 20 on page 330 describes some common problems that might occur.

Table 20: Troubleshooting Commit Scripts

Problem	Solution
The output of the commit check display detail command does not reference the expected commit scripts.	Make sure you have enabled all the scripts by including the file statement for each one at the [edit system scripts commit] hierarchy level.

Table 20: Troubleshooting Commit Scripts (*continued*)

Problem	Solution
<p>The output contains the error message:</p> <pre>error: could not open commit script: /var/db/scripts/commit/<i>filename</i>: No such file or directory</pre>	<p>Make sure the file <i>filename</i> is in the <code>/var/db/scripts/commit/</code> directory on your switch, router, or security device.</p>
<p>The following error and warning messages appear:</p> <pre>error: invalid transient change generated by commit script: <i>filename</i> warning: 1 transient change was generated without [system scripts commit allow-transients]</pre>	<p>One of your commit scripts contains instructions to generate a transient change, but you have not enabled transient changes.</p> <p>To rectify this problem, take one of the following actions:</p> <ul style="list-style-type: none"> • Remove the code that generates a transient change from the indicated script. • Remove the script. • Include the <code>allow-transients</code> statement at the <code>[edit system scripts commit]</code> hierarchy level.
<p>An expected action does not occur.</p> <p>For example, a warning message does not appear even though the configuration contains the problem that is supposed to evoke the warning message.</p>	<ol style="list-style-type: none"> 1. Make sure you have enabled the script. Scripts are ignored if they are not enabled. To enable a script, include the <code>file <i>filename</i></code> statement at the <code>[edit system scripts commit]</code> hierarchy level. 2. Make sure you have included the required boilerplate in your script. For more information, see “Required Boilerplate for Commit Scripts” on page 166. 3. Make sure that the Extensible Markup Language Path (XPath) expressions in the script contain valid Junos OS command-line interface (CLI) statements expressed as Junos XML protocol tag elements. You can verify the XML hierarchy by checking the <i>Junos XML API Configuration Developer Reference</i> or by issuing the <code>show configuration display xml</code> operational mode command. 4. Make sure that the programming instructions in the script are referencing the correct context node. If you nest one instruction inside another, the outer instruction changes the context node, so the inner instruction must be relative to the outer. In the following example, the <code><xsl:for-each></code> instruction contains an XPath expression, which changes the context node. So the nested <code><xsl:if></code> instruction uses an XPath expression that is relative to the <code>interfaces/interface[starts-with(name, 't1-')]</code> XPath expression. <pre><xsl:for-each select="interfaces/interface[starts-with(name, 't1-')]"> <xsl:if test="not(description)"></pre>

CHAPTER 3

Operations Automation Developer Guide

- [Overview on page 333](#)

Overview

- [Op Scripts Overview on page 333](#)

Op Scripts Overview

- [Op Script Overview on page 333](#)
- [How Op Scripts Work on page 334](#)

Op Script Overview

Junos OS operation (op) scripts automate network and device management and troubleshooting. Op scripts can perform any function available through the remote procedure calls (RPCs) supported by either the Junos XML management protocol or the Junos Extensible Markup Language (XML) API. Op scripts can be executed manually in the CLI or upon user login, or they can be called from another script. They are executed by the Junos OS management (mgd) process.

Op scripts enable you to do the following things:

- Create custom operational mode commands
- Execute a series of operational mode commands
- Customize the output of operational mode commands
- Shorten troubleshooting time by gathering operational information and iteratively narrowing down the cause of a network problem
- Perform controlled configuration changes
- Monitor the overall status of a device by creating a general operation script that periodically checks network warning parameters, such as high CPU usage.

Op scripts are based on the Junos XML management protocol, and the Junos XML API, which are discussed in [“Junos XML API and Junos XML Management Protocol Overview”](#)

on page 6. Op scripts can be written in either the Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) scripting language. Op scripts use XPath to locate the operational objects to be inspected and XSLT constructs to specify the actions to perform on the located operational objects. The actions can change the output or execute additional commands based on the output.

Related Documentation

- [SLAX Overview on page 63](#)
- [XPath Overview on page 50](#)
- [XSLT Overview on page 48](#)

How Op Scripts Work

Op scripts execute Junos OS operational commands and inspect the resulting output. After inspection, op scripts can automatically correct errors within the device running Junos OS based on this output.

You add op scripts to device operations by listing the filenames of one or more op script files within the **[edit system scripts op]** hierarchy level. These files must be added to the appropriate op script file directory. For more information about op script file directories, see [“Storing Scripts in Flash Memory” on page 87](#). Once added to the device, op scripts are invoked from the command line, using the **op filename** command.

You can use op scripts to generate changes to the device configuration by including the **<load-configuration>** tag element. Because the changes are loaded before the standard validation checks are performed, they are validated for correct syntax, just like statements already present in the configuration before the script is applied. If the syntax is correct, the configuration is activated and becomes the active, operational device configuration.

[Figure 9 on page 334](#) shows a high-level view of the flow of op script input and output.

Required Boilerplate for Op Scripts

When you write operation (op) scripts, you use Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) tools provided with Junos OS. These tools include basic boilerplate that you must include in all op scripts, optional extension functions that accomplish scripting tasks more easily, and named templates that make scripts easier to read and write, which you import from a file called **junos.xml**. For more information about the extension functions and templates, see [“Junos Script Automation: Extension Functions in the jcs Namespace Overview” on page 8](#) and [“Junos Script Automation: Named Templates in the jcs Namespace Overview” on page 28](#).

Op scripts are based on Junos XML and Junos XML protocol tag elements. Like all XML elements, angle brackets enclose the name of a Junos XML or Junos XML protocol tag element in its opening and closing tags. This is an XML convention, and the brackets are a required part of the complete tag element name. They are not to be confused with the angle brackets used in the documentation to indicate optional parts of Junos OS CLI command strings.

You must include either XSLT or SLAX boilerplate as the starting point for all op scripts that you create. The XSLT boilerplate follows:

XSLT Boilerplate for Op Scripts

```

1  <?xml version="1.0" standalone="yes"?>
2  <xsl:stylesheet version="1.0"
3    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4    xmlns:junos="http://xml.juniper.net/junos/*/junos"
5    xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6    xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
7    <xsl:import href=" ../import/junos.xml"/>

8    <xsl:template match="/">
9      <op-script-results>
10       <!-- ... insert your code here ... -->
11     </op-script-results>
12   </xsl:template>

  <!-- ... insert additional template definitions here ... -->

```

```
12 </xsl:stylesheet>
```

Line 1 is the Extensible Markup Language (XML) processing instruction (PI), which marks this file as XML and specifies the version of XML as 1.0. The XML PI, if present, must be the first non-comment token in the script file.

```
1 <?xml version="1.0"?>
```

Line 2 opens the style sheet and specifies the XSLT version as 1.0.

```
2 <xsl:stylesheet version="1.0"
```

Lines 3 through 6 list all the namespace mappings commonly used in operation scripts. Not all of these prefixes are used in this example, but it is not an error to list namespace mappings that are not referenced. Listing all namespace mappings prevents errors if the mappings are used in later versions of the script.

```
3 xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4 xmlns:junos="http://xml.juniper.net/junos/*/junos"
5 xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6 xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
```

Line 7 is an XSLT import statement. It loads the templates and variables from the file referenced as `../import/junos.xsl`, which ships as part of Junos OS (in the file `/usr/libdata/cscript/import/junos.xsl`). The `junos.xsl` file contains a set of named templates you can call in your scripts. These named templates are discussed in [“Junos Script Automation: Named Templates in the jcs Namespace Overview” on page 28](#) and [“Junos Named Templates in the jcs Namespace Summary” on page 30](#).

```
7 <xsl:import href="../import/junos.xsl"/>
```

Line 8 defines a template that matches the `</>` element. The `<xsl:template match="/">` element is the root element and represents the top level of the XML hierarchy. All XML Path Language (XPath) expressions in the script must start at the top level. This allows the script to access all possible Junos XML and Junos XML protocol remote procedure calls (RPCs). For more information, see [“XPath Overview” on page 50](#).

```
8 <xsl:template match="/">
```

After the `<xsl:template match="/">` tag element, the `<op-script-results>` and `</op-script-results>` container tags must be the top-level child tags, as shown in Lines 9 and 10.

```
9 <op-script-results>
  <!-- ... insert your code here ... -->
10 </op-script-results>
```

Line 11 closes the template.

```
11 </xsl:template>
```

Between Line 11 and Line 12, you can define additional XSLT templates that are called from within the `<xsl:template match="/">` template.

Line 12 closes the style sheet and the op script.

```
12 </xsl:stylesheet>
```

SLAX Boilerplate for Op Scripts

The corresponding SLAX boilerplate is as follows:

```
version 1.0;
```

```

ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xml";

match / {
  <op-script-results> {
    /*
     * Insert your code here
     */
  }
}

```

Mapping Operational Mode Commands and Output Fields to Junos XML Notation

In op scripts, you use tag elements from the Junos XML API to represent operational mode commands and output fields. For the Junos XML equivalent of commands and output fields, consult the *Junos XML API Operational Developer Reference*.

You can also display the Junos XML tag elements for operational mode command output by directing the output from the command to the **| display xml** command:

```
user@host> command-string | display xml
```

For example:

```

user@host> show interfaces terse | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <interface-information
    xmlns="http://xml.juniper.net/junos/10.0R10/junos-interface" junos:style="terse">
    <physical-interface>
      <name>dsc</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    </physical-interface>
    <physical-interface>
      <name>fxp0</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    <logical-interface>
      <name>fxp0.0</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    ...
  </interface-information>
</rpc-reply>

```

Using RPCs and Operational Mode Commands in Op Scripts

Most Junos OS operational mode commands have XML equivalents. These XML commands can be executed remotely using the remote procedure call (RPC) protocol.

All operational mode commands that have XML equivalents are listed in the *Junos XML API Operational Developer Reference*.

Use of RPC and operational mode commands in op scripts is discussed in more detail in the following sections:

- [Using RPCs in Op Scripts on page 338](#)
- [Displaying the RPC Tags for a Command on page 339](#)
- [Using Operational Mode Commands in Op Scripts on page 339](#)

Using RPCs in Op Scripts

To use an RPC in an op script, include the RPC in a variable declaration. You then invoke the RPC with the `jcs:invoke()` or `jcs:execute()` extension function and include the RPC variable as an argument. The `jcs:invoke()` function executes the RPC on the local device. You can use the `jcs:execute()` function with a connection handle to execute the RPC on a remote device.

The following snippet, which invokes an RPC on the local device, is expanded and fully described in “[Example: Customizing Output of the show interfaces terse Command Using an Op Script](#)” on page 354.

XSLT Syntax	<pre><xsl:variable name="rpc"> <get-interface-information/> # Junos RPC for the show interfaces command </xsl:variable> <xsl:variable name="out" select="jcs:invoke(\$rpc)"/> ...</pre>
SLAX Syntax	<pre>var \$rpc = <get-interface-information>; var \$out = jcs:invoke(\$rpc);</pre>

To execute an RPC on a remote device, an SSH session must be established. In order for the script to establish the connection, you must either configure the SSH host key information for the remote device on the local device where the script will be executed, or the SSH host key information for the remote device must exist in the known hosts file of the user executing the script. For each remote device where an RPC is executed, configure the SSH host key information with one of the following methods:

- To configure SSH known hosts on the local device, include the **host** statement, and specify hostname and host key options for the remote device at the **[edit security ssh-known-hosts]** hierarchy level of the configuration.
- To manually retrieve SSH host key information, issue the **set security ssh-known-hosts fetch-from-server hostname** configuration mode command to instruct Junos OS to connect to the remote device and add the key.

```
user@host# set security ssh-known-hosts fetch-from-server router2
The authenticity of host 'router2 (10.10.10.1)' can't be established.
RSA key fingerprint is 30:18:99:7a:3c:ed:40:04:0f:fd:c1:57:7e:6b:f3:90.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'router2,10.10.10.1' (RSA) to the list of known
hosts.
```

- To manually import SSH host key information from a file, use the **set security ssh-known-hosts load-key-file *filename*** configuration mode command and specify the known-hosts file.

```
user@host# set security ssh-known-hosts load-key-file /var/tmp/known_hosts
Import SSH host keys from trusted source /var/tmp/known_hosts ? [yes,no] (no)
yes
```

- Alternatively, the user executing the script can log in to the local device, SSH to the remote device, and then manually accept the host key, which is added to that user's known hosts file. In the following example, root is logged in to **router1**. In order to execute a remote RPC on **router2**, root adds the host key of **router2** by issuing the **ssh router2** operational mode command and manually accepting the key.

```
root@router1> ssh router2
The authenticity of host 'router2 (10.10.10.1)' can't be established.
RSA key fingerprint is 30:18:99:7a:3c:ed:40:04:0f:fd:c1:57:7e:6b:f3:90.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'router2,10.10.10.1' (RSA) to the list of known
hosts.
```

Displaying the RPC Tags for a Command

To display the remote procedure call (RPC) XML tags for an operational mode command, enter **display xml rpc** after the pipe symbol (|).

The following example displays the RPC tags for the **show route** command:

```
user@host> show route | display xml rpc
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.1I0/junos">
  <rpc>
    <get-route-information>
    </get-route-information>
  </rpc>
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>
```

Using Operational Mode Commands in Op Scripts

Some operational mode commands do not have XML equivalents. If a command is not listed in the *Junos XML API Operational Developer Reference*, the command does not have an XML equivalent.

Another way to determine whether a command has an XML equivalent is to issue the command followed by the **| display xml** command:

```
user@host> operational-mode-command | display xml
```

If the output includes only tag elements like **<output>**, **<cli>**, and **<banner>**, the command might not have an XML equivalent. In the following example, the output indicates that the **show host** command has no XML equivalent:

```
user@host> show host hostname | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <output>
  ...
```

```

</output>
<cli>
  <banner></banner>
</cli>
</rpc-reply>

```

NOTE: For some commands that have an XML equivalent, the output of the `pipelined | display xml` command does not include tag elements other than `<output>`, `<cli>`, and `<banner>` only because the relevant feature is not configured. For example, the `show services cos statistics forwarding-class` command has an XML equivalent that returns output in the `<service-cos-forwarding-class-statistics>` response tag, but if the configuration does not include any statements at the `[edit class-of-service]` hierarchy level then there is no actual data for the `show services cos statistics forwarding-class | display xml` command to display. The output is something like this:

```

user@host> show services cos statistics forwarding-class | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/8.3I0/junos">
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>

```

For this reason, the information in the *Junos XML API Operational Developer Reference* is normally more reliable.

An op script can include commands that have no XML equivalent. Use the `<command>`, `<xsl:value-of>`, and `<output>` elements in the script, as shown in the following code snippet. This snippet is expanded and fully described in [“Example: Displaying DNS Hostname Information Using an Op Script”](#) on page 364.

```

<xsl:variable name="query">
  <command>
    <xsl:value-of select="concat('show host ', $hostname)"/>
  </command>
</xsl:variable>
<xsl:variable name="result" select="jcs:invoke($query)"/>
<xsl:variable name="host" select="$result"/>
<output>
  <xsl:value-of select="concat('Name: ', $host)"/>
</output>
...

```

Declaring Arguments in Op Scripts

There are two ways to declare arguments to an op script: by including XSLT or SLAX instructions in the script or by including statements in the Junos configuration. *Script-generated* and *configuration-generated* arguments have the same operational impact.

To declare arguments within a script, declare a global variable named **arguments**, containing **<argument>** tag elements. Within each **<argument>** tag element, include the required **<name>** tag element and the optional **<description>** tag element:

XSLT Syntax	<pre><xsl:variable name="arguments"> <argument> <name>name</name> <description>name</description> </argument> </xsl:variable></pre>
SLAX Syntax	<pre>var \$arguments = { <argument> { <name> "name"; <description> "descriptive-text"; } }</pre>

To declare arguments in the configuration, include the **arguments** statement in the **[edit system scripts op file filename]** hierarchy level.

```
[edit system scripts op file filename]
arguments {
  argument-name {
    description descriptive-text;
  }
}
```

If you include the optional **<description>** tag element or the **description** statement, the text of the description appears in the command-line interface (CLI) as a help-text string to describe the purpose of the argument, as discussed in [“Configuring Help Text for Op Scripts” on page 343](#).

In the operation script, you must include a corresponding parameter declaration for each argument. The parameter name must match the name of the argument:

```
<xsl:param name="name"/>
```

The SLAX equivalent is:

```
param $name;
```

You can create a hidden argument by including the **<xsl:param name="name"/>** instruction without listing the argument in the **arguments** variable or in the configuration.

After you declare an argument, you can use command completion to list available arguments:

```
user@host> op filename ?
```

Possible completions:

<i>argument-name</i>	<i>description</i>
<i>argument-name</i>	<i>description</i>

For each argument you include on the command-line, you must specify a corresponding value. To do this, include an **argument-name** and an **argument-value** when you execute the script with the **op filename** command:

```
user@host> op filename argument-name argument-value
```

NOTE: If you specify an argument that the script does not recognize, the script ignores the argument.

If you configure arguments by including the **arguments** statement in the configuration, any arguments that you declare directly in the script are still available, but are not listed among the Possible completions when you issue the **op filename ?** command.

If you declare all arguments in the script (and none in the configuration), then the arguments do appear in the Possible completions list. This is because the management (mgd) process populates the Possible completions list by first checking the configuration for arguments. The mgd process looks in the script for arguments only if no arguments are found in the configuration. Thus, if arguments are declared in the configuration, the arguments declared in the script become hidden in the CLI.

Example: Declaring Arguments

Declare two arguments named **interface** and **protocol**. Execute the script, specifying the **ge-0/2/0.0** interface and the **inet** protocol as values for the arguments. For either method, you must declare corresponding script parameters:

Declaring Arguments in the Op Script (script1)

```
<xsl:param name="interface"/>
<xsl:param name="protocol"/>

<xsl:variable name="arguments">
  <argument>
    <name>interface</name>
    <description>Name of interface to display</description>
  </argument>
  <argument>
    <name>protocol</name>
    <description>Protocol to display (inet, inet6)</description>
  </argument>
</xsl:variable>
```

Declaring Arguments in the Configuration

```
[edit system scripts op]
file script1 {
  arguments {
    interface {
      description "Name of interface to display";
    }
    protocol {
      description "Protocol to display (inet, inet6)";
    }
  }
}
```

```

    }
  }
}

```

Executing the Script

```
user@host> op script1 interface ge-0/2/0.0 protocol inet
```

Configuring Help Text for Op Scripts

You can provide help text to describe an op script and its arguments when the `?` is used to list possible completions in the CLI. Include the **description** statement:

```
description descriptive-text;
```

You can include this statement at the following hierarchy levels:

- `[edit system scripts op file filename]`
- `[edit system scripts op file filename arguments argument-name]`

The following examples show the configuration and the resulting output.

Examples: Configuring Help Text for Op Scripts

Configure help text for a script and display the resulting output:

```
[edit system scripts op]
user@host# set file interface.xsl description "Test the interface"
user@host# commit
...
[edit system scripts op]
user@host# set file ?
Possible completions:
<name>      Local filename of the script file
interface.xsl  Test the interface
```

Configure help text for a script's arguments and display the resulting output:

```
[edit system scripts op file interface.xsl arguments]
user@host# set t1 description "Search for T1 interfaces"
user@host# set t3 description "Search for T3 interfaces"
user@host# commit
...
[edit system scripts op file interface.xsl arguments]
user@host# set ?
Possible completions:
<name>      Name of the argument
t1          Search for T1 interfaces
t3          Search for T3 interfaces
```

Enabling an Op Script and Defining a Script Alias

Operation (op) scripts are stored on a device's hard drive in the `/var/db/scripts/op` directory or on the flash drive in the `/config/scripts/op` directory. Only users in the Junos OS **super-user** login class can access and edit files in these directories. For information about setting the storage location for scripts, see [“Storing Scripts in Flash Memory” on page 87](#).

NOTE: If the device has dual Routing Engines and you want to enable an op script to execute on both Routing Engines, you must copy the script to the `/var/db/scripts/op` or `/config/scripts/op` directory on both Routing Engines. The `commit synchronize` command does not automatically copy scripts between Routing Engines.

You must enable an op script before it can be executed. Include the `file filename` statement at the `[edit system scripts op]` hierarchy level, specifying the name of an XSLT or SLAX file containing an op script. Only users who belong to the Junos **super-user** login class can enable op scripts.

```
[edit system scripts op]
file filename;
```

The filename of an op script written in SLAX must include the `.slax` extension for the script to be enabled and executed. No particular filename extension is required for op scripts written in XSLT, but we strongly recommend that you append the `.xsl` extension. Whether or not you choose to include the `.xsl` extension on the file, the filename that you add at the `[edit system scripts op]` hierarchy level must exactly match the filename of the script in the directory. For example, if the XSLT script filename is `script1.xsl`, then you must include `script1.xsl` in the configuration hierarchy to enable the script; likewise, if the XSLT script filename is `script1`, then you must include `script1` in the configuration hierarchy.

To determine which op scripts are currently enabled on the device, use the **show** command to display the files included at the `[edit system scripts op]` hierarchy level. To ensure that the enabled files are on the device, list the contents of the `/var/run/scripts/op/` directory using the `file list /var/run/scripts/op` operational mode command.

Optionally, you can define an alias for an op script and then specify either the filename or the alias when you execute the script. To define the alias, include the **command** statement at the `[edit system scripts op file filename]` hierarchy level:

```
[edit system scripts op]
file filename {
  command filename-alias;
}
```

Executing an Op Script

Unlike commit scripts, operation (op) scripts do not execute during a commit operation. When you issue the **commit** command, op scripts configured at the **[edit system scripts op]** hierarchy level are placed into system memory and enabled for execution. After the commit operation completes, you can execute an op script from the CLI by issuing the **op** operational mode command. You also can configure the device to execute an op script automatically when a member of a specified Junos OS login class logs in to the CLI.

Executing an Op Script by Issuing the op Command

To execute an op script from the CLI, issue the **op** operational mode command, specifying a URL, the script filename, or the alias defined by the **command** statement at the **[edit system scripts op file filename]** hierarchy level.

```
user@host> op (filename-or-alias | url url)
```

Executing an Op Script at Login

You can configure an op script to execute automatically when any user belonging to a designated Junos OS login class logs in to the CLI. To associate an op script with a login class, include the **login-script script-filename** statement at the **[edit system login class class-name]** hierarchy level:

```
[edit system login]
class class-name {
  login-script script-filename;
}
```

The following example configures the **super-user-login.slax** op script to execute when any user who belongs to the **super-user** class logs in to the CLI (provided that the script has been enabled as discussed in [“Enabling an Op Script and Defining a Script Alias” on page 344](#)).

```
[edit system login]
class super-user {
  login-script super-user-login.slax;
}
```

Configuring Checksum Hashes for an Op Script

You can configure one or more checksum hashes that can be used to verify the integrity of an op script before the script runs on the switch, router, or security device.

To configure a checksum hash:

1. Create the script.
2. Place the script in the **/var/db/scripts/op** directory on the device.
3. Run the script through one or more hash functions to calculate hash values.

Junos OS supports MD5, SHA-1, and SHA-256 hash functions.

```
user@host> file checksum md5 /var/db/scripts/commit/script1.slax
MD5 (/var/db/scripts/op/script1.slax) = 3af7884eb56e2d4489c2e49b26a39a97
user@host> file checksum sha1 /var/db/scripts/commit/script1.slax
```

```

SHA1 (/var/db/scripts/op/script1.slax) =
00dc690fb08fb049577d012486c9a6dad34212c0
user@host> file checksum sha-256 /var/db/scripts/commit/script1.slax
SHA256 (/var/db/scripts/op/script1.slax) =
150bf53383769f3bfedd41fe7332077f208d4fda81230cb27b8738

```

4. Configure the script with one or more hash values.

```

[edit system scripts op]
user@host# set file script1.slax checksum md5 3af7884eb56e2d4489c2e49b26a39a97
[edit system scripts op]
user@host# set file script1.slax checksum
sha-1 00dc690fb08fb049577d012486c9a6dad34212c0
[edit system scripts op]
user@host# set file script1.slax checksum
sha-256 150bf53383769f3bfedd41fe7332077f208d4fda81230cb27b8738

```

During the execution of the script, Junos OS recalculates the checksum value using the configured hash and verifies that the calculated value matches the configured value. If the values differ, the execution of the script fails. When you configure multiple checksum values with different hash algorithms, all the configured values must match the calculated values; otherwise, the script execution fails.

NOTE: If the `op` script is stored remotely, do not include the `checksum` statement in the configuration. You can verify the script's integrity before it runs by specifying the hash value on the command line when you run the `op` command with the `<url>` option and the `<key>` option.

Executing an Op Script from a Remote Site

As an alternative to storing operation (`op`) scripts locally on the device, you can store `op` scripts at a remote site. This allows you to execute the scripts by specifying a URL on the command line.

To execute an `op` script from a remote site:

1. Create the script.
2. (Optional) Store the script temporarily in the `/var/tmp` directory on the device, and run the script through one or more hash functions to calculate hash values.

Junos OS supports MD5, SHA-1, and SHA-256 hash functions.

```

user@host> file checksum md5 /var/tmp/script1.slax
MD5 (/var/tmp/script1.slax) = 3af7884eb56e2d4489c2e49b26a39a97
user@host> file checksum sha1 /var/tmp/script1.slax
SHA1 (/var/tmp/script1.slax) = 00dc690fb08fb049577d012486c9a6dad34212c0
user@host> file checksum sha-256 /var/tmp/script1.slax
SHA256 (/var/tmp/script1.slax) =
150bf53383769f3bfedd41fe7332077f208d4fda81230cb27b8738

```

3. Place the script on the remote server.
4. Provide the script URL and the optional hash values to the administrators who will execute the script.
5. Execute the script by running the **op** command and specifying the URL that points to the remote file.

```

user@host> op url https://www.juniper.net/scripts/2009-04-01.01.slax
key md5 3af7884eb56e2d4489c2e49b26a39a97

```

This example shows how to include the <key> option and the MD5 checksum information.

NOTE: If the **op** script is stored locally, do not include the hash key on the command line. Instead, configure the hash value by including the checksum statement at the **[edit system scripts op file *filename*]** hierarchy level. During the execution of the script, Junos OS recalculates the checksum value using the configured hash and verifies that the calculated value matches the configured value.

To prevent the execution of **op** scripts from remote sites, configure the **no-allow-url** statement at the **[edit system scripts op]** hierarchy level.

```

user@host# set system scripts op no-allow-url

```

When you configure the **no-allow-url** statement, issuing the **op url *url*** operational mode command generates an error.

Disabling an Op Script

You can disable an **op** script by deleting or deactivating the **file *filename*** statement at the **[edit system scripts op]** hierarchy in the configuration. To determine which **op** scripts are active on the device, issue the **show configuration system scripts op** operational mode command. The command output lists the enabled **op** scripts.

To delete an op script from the configuration, perform the following steps:

1. From configuration mode in the CLI, enter the following command:

```
[edit]
user@host# delete system scripts op file filename
```

2. Commit the configuration:

```
user@host# commit
```

The **file** statement is removed from the configuration for the specified op script, and the **op** operational mode command no longer lists the op script filename as a valid completion.

To deactivate an op script in the configuration, perform the following steps:

1. From configuration mode in the CLI, enter the following command:

```
[edit]
user@host# deactivate system scripts op file filename
```

2. Commit the configuration:

```
user@host# commit
```

The filename of the deactivated script remains in the configuration, but it is flagged with **inactive**. For example:

```
[edit system scripts op]
user@host# show
```

```
inactive: file script1.xsl;
file script2.xsl;
file script3.xsl;
```

NOTE: You can reactivate an op script using the **activate system scripts op file *filename*** command.

Alternatively, you can delete the script from the **/var/db/scripts/op** directory on a device's hard drive or from the **/config/scripts/op** directory on the flash drive. Only users in the Junos OS **super-user** login class can access and edit files in these directories. If you delete a script, you should also remove the **file** statement at the **[edit system scripts op]** hierarchy level in the configuration. If you delete an op script, but the **file** statement remains in the configuration, the CLI lists this script as a valid completion for the **op** command, but Junos OS issues an invalid filename error when the script is executed.

If you deactivate or delete the **file** statement for an op script in the configuration, you must enable the script again in order to execute it.

Example: Changing the Configuration Using an Op Script

This example explains how to make structured changes to the Junos OS configuration using an op script.

- [Requirements on page 349](#)
- [Overview and Op Script on page 349](#)
- [Device Configuration on page 352](#)
- [Verification on page 352](#)

Requirements

This example uses a device running Junos OS.

Overview and Op Script

Op scripts can be used to make structured changes to the Junos OS configuration using the **jcs:load-configuration** template, which is included in the import file **junos.xsl**. Experienced users, who are familiar with Junos OS, can write scripts that prompt for the relevant configuration information and modify the configuration accordingly. This allows users who have less experience with Junos OS to safely modify the configuration using the script.

When called, the **jcs:load-configuration** template performs the following actions:

1. Locks the configuration database
2. Loads the configuration changes
3. Commits the configuration
4. Unlocks the configuration database

The **jcs:load-configuration** template makes changes to the configuration in **configure exclusive** mode. In this mode, Junos OS locks the candidate *global* configuration for as long as the script accesses the shared database and makes changes to the configuration without interference from other users.

If another user is currently editing the configuration in **configure exclusive** mode or if the database is already locked when the template is called, the call fails. In addition, if there are existing, uncommitted changes to the configuration when the template is called, the commit fails. If the template call is successful but the commit fails, Junos OS discards the uncommitted changes and rolls back the configuration.

You provide arguments to the **jcs:load-configuration** template to specify how to integrate the changes into the existing configuration, how to customize the commit operation, what changes to make to the configuration, and which connection handle to use. The XSLT and SLAX syntax for the template call is:

```
<xsl:call-template name="jcs:load-configuration">
  <xsl:with-param name="action" select="(merge | override | replace)"/>
  <xsl:with-param name="commit-options" select="node-set"/>
  <xsl:with-param name="configuration" select="configuration-data"/>
  <xsl:with-param name="connection" select="connection-handle"/>
</xsl:call-template>

call jcs:load-configuration($action="(merge | override | replace)",
  $commit-options=node-set, $configuration=configuration-data,
  $connection=connection-handle);
```

The following sample SLAX script demonstrates how to use the **jcs:load-configuration** template to disable an interface on a device running Junos OS. All of the values required for the **jcs:load-configuration** template are defined as variables, which are then passed into the template as arguments.

In this example, the **\$usage** variable is initialized with a general description of the function of the script. When the script is run, the usage description is output to the CLI using a call to the **jcs:output()** function. This allows the user to verify that he is using the script for the correct purpose.

The script calls the **jcs:get-input()** function and prompts the user to enter the name of the interface that should be disabled. The interface name is stored in the **\$interface** variable. The configuration data that includes the changes to the configuration are stored in the variable **\$config-changes**. This is the value used for the **\$configuration** parameter of the **jcs:load-configuration** template. This variable includes the Junos XML API tags for the configuration statements that are to be modified. The variable **\$interface**, which is supplied by the user, designates the name of the interface to disable.

The **\$load-action** variable is initialized to **merge**, which merges the configuration changes in the **\$disable** variable with the candidate configuration. This is the equivalent of the CLI configuration mode command **load merge**. Other load options include **replace** and **override**.

The **\$options** variable uses the **:=** operator to create a node-set, which is passed to the template as the value of the **\$commit-options** parameter. This example includes the **log** tag to add the description of the commit to the commit log file for future reference.

The call to the **jcs:open()** function opens a connection with the Junos OS management process (mgd) and returns a connection handle that is stored in the **\$conn_handle** variable. All of the defined variables are passed as arguments to the **jcs:load-configuration** template at the time that it is called.

SLAX Syntax

```

version 1.0;

ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
ns ext = "http://xmlsoft.org/XSLT/namespace";

import "../import/junos.xsl";

match / {
<op-script-results> {

    var $usage = "This script disables the interface specified by the user." _
        "The script modifies the candidate configuration to disable " _
        "the interface and commits the configuration to activate it.";
    var $temp = jcs:output($usage);

    var $interface = jcs:get-input("Enter interface to disable: ");

    var $config-changes = {
        <configuration> {
            <interfaces> {
                <interface> {
                    <name> $interface;
                    <disable>;
                }
            }
        }
    }

    var $load-action = "merge";

    var $options := {
        <commit-options> {
            <log> "disabling interface " _ $interface;
        }
    }

    var $conn_handle = jcs:open();

    var $results := {
        call jcs:load-configuration( $action=$load-action, $commit-options=$options,
            $configuration=$config-changes, $connection=$conn_handle);
    }

    $close-results = jcs:close($conn_handle);
}
}

```

The `:=` operator copies the results of the `jcs:load-configuration` template call to a temporary variable and runs the **node-set** function on that variable. The resulting node-set is then stored in the `$results` variable. The `:=` operator ensures that the `$results` variable is a node-set rather than a result tree fragment so that the script can access the contents. The `jcs:close()` function closes the connection.

By default, the **jcs:load-configuration** template does not output messages to the CLI. To quickly view any issues with the commit, you should add code to the script to output any error or warning messages that are generated as a result of the **jcs:load-configuration** template call:

```
if ($results//xnm:error) {
  for-each ($results//xnm:error) {
    <output> message;
  }
}
if ($results//xnm:warning) {
  for-each ($results//xnm:warning) {
    <output> message;
  }
}
```

Device Configuration

To download, enable, and test the script:

1. Copy the script into a text file, name the file **config-change.slax**, and copy it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **config-change.slax**.

```
[edit system scripts op]
user@host# set file config-change.slax
```

3. Issue the **commit and-quit** command to commit the configuration and to return to operational mode.

```
[edit]
user@host# commit and-quit
```

4. Before running the script, issue the **show interfaces interface-name** operational mode command and record the current state of the interface that will be disabled by the script.
5. Execute the op script by issuing the **op config-change** operational mode command.

```
user@host> op config-change
This script disables the interface specified by the user. The script modifies
the candidate configuration to disable the interface and commits the
configuration to activate it.
Enter interface to disable: so-0/0/0
```

Verification

- [Verifying the Commit on page 352](#)
- [Verifying the Configuration Changes on page 353](#)

Verifying the Commit

Purpose Verify that the commit succeeded.

Action You should include code in your script that parses the node-set returned by the **jcs:load-configuration** template for any errors or warnings. This allows you to more easily

determine whether the commit succeeded. If there are no warning or error messages, you can verify the success of the commit in several ways.

- Check the commit log to verify that the commit was successful. If you included the **log** option in the **\$commit-options** parameter, the message should be visible in the commit log along with the commit information.

```
user@host> show system commit
0   2010-09-22 17:08:17 PDT by user via junoscript
    disabling interface so-0/0/0
```

- Check the syslog message file to verify that the commit operation was logged. In this case, you also see an **SNMP_TRAP_LINK_DOWN** message for the disabled interface **so-0/0/0**. Depending on your configuration settings for traceoptions, this message might or might not appear in your log file.

```
user@host> show log messages | last
Sep 22 17:08:13 host file[7319]: UI_COMMIT: User 'user' requested 'commit'
operation (comment: disabling interface so-0/0/0)
Sep 22 17:08:16 host xntpd[1386]: ntpd exiting on signal 1
Sep 22 17:08:16 host xntpd[1386]: ntpd 4.2.0-a Fri Jun 25 13:48:13 UTC 2010
(1)
Sep 22 17:08:16 host mib2d[1434]: SNMP_TRAP_LINK_DOWN: ifIndex 526,
ifAdminStatus down(2), ifOperStatus down(2), ifName so-0/0/0
```

Verifying the Configuration Changes

Purpose Verify that the correct changes are integrated into the configuration.

Action • Display the configuration and verify that the changes are visible for the specified interface:

```
user@host> show configuration interfaces so-0/0/0
disable;
```

- For this example, you also can issue the **show interfaces *interface-name* operational** mode command to check that the interface was disabled. In this case, the output captured *before* the interface was disabled shows that the interface is **Enabled**:

```
user@host> show interfaces so-0/0/0
Physical interface: so-0/0/0, Enabled, Physical link is Up
  Interface index: 128, SNMP ifIndex: 526
  Link-level type: PPP, MTU: 4474, Clocking: Internal, SONET mode, Speed: OC3,
  Loopback: None, FCS: 16,
  Payload scrambler: Enabled
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps Internal: 0x4000
  Link flags     : Keepalives
  CoS queues    : 4 supported, 4 maximum usable queues
  Last flapped  : 2010-09-14 10:33:25 PDT (1w1d 06:27 ago)
  Input rate    : 0 bps (0 pps)
  Output rate   : 0 bps (0 pps)
  SONET alarms  : None
  SONET defects : None
```

The output captured *after* running the script to disable the interface shows that the interface is now **Administratively down**:

```

user@host> show interfaces so-0/0/0
Physical interface: so-0/0/0, Administratively down, Physical link is Up
  Interface index: 128, SNMP ifIndex: 526
  Link-level type: PPP, MTU: 4474, Clocking: Internal, SONET mode, Speed: OC3,
  Loopback: None, FCS: 16,
  Payload scrambler: Enabled
  Device flags   : Present Running
  Interface flags: Down Point-To-Point SNMP-Traps Internal: 0x4000
  Link flags     : Keepalives
  CoS queues     : 4 supported, 4 maximum usable queues
  Last flapped   : 2010-09-14 10:33:25 PDT (1w1d 06:40 ago)
  Input rate     : 0 bps (0 pps)
  Output rate    : 0 bps (0 pps)
  SONET alarms   : None
  SONET defects  : None

```

Example: Customizing Output of the show interfaces terse Command Using an Op Script

This example uses an op script to customize the output of the **show interfaces terse** command. A line-by-line explanation of the XSLT script is provided.

- [Requirements on page 354](#)
- [Overview and Op Script on page 354](#)
- [Configuration on page 363](#)
- [Verification on page 363](#)

Requirements

This example uses a device running Junos OS.

Overview and Op Script

By default, the layout of the **show interfaces terse** command looks like this:

```

user@host> show interfaces terse
Interface      Admin Link Proto  Local          Remote
dsc            up   up
fxp0           up   up
fxp0.0         up   up   inet   192.168.71.246/21
fxp1           up   up
fxp1.0         up   up   inet   10.0.0.4/8
               up   up   inet6  fe80::200:ff:fe00:4/64
               up   up   inet6  fec0::10:0:0:4/64
               up   up   tnp    4
gre            up   up

```

```

ipip                up    up
lo0                 up    up
lo0.0               up    up    inet    127.0.0.1        --> 0/0
lo0.16385           up    up    inet    fe80::2a0:a5ff:fe12:2f04
lsi                 up    up
mtun                up    up
pimd                up    up
pime                up    up
tap                 up    up

```

In Junos XML, the output fields are represented as follows:

```

user@host> show interfaces terse | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <interface-information xmlns="http://xml.juniper.net/junos/10.0R1/junos-interface"
    junos:style="terse">
    <physical-interface>
      <name>dsc</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    </physical-interface>
    <physical-interface>
      <name>fxp0</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    <logical-interface>
      <name>fxp0.0</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    ... Remainder of output omitted for brevity ...

```

XSLT Syntax The following script customizes the output of the **show interfaces terse** command. A line-by-line explanation of the script is provided.

```

1  <?xml version="1.0" standalone="yes"?>

100         </xsl:when>
101         <xsl:otherwise>
102             <xsl:copy-of select="address-family"/>
103         </xsl:otherwise>
104     </xsl:choose>
105 </logical-interface>
106 </xsl:template>
107 </xsl:stylesheet>

```

Line-by-Line Explanation Lines 1 through 7, Line 20, and Lines 105 and 106 are the boilerplate that you include in every op script. For more information, see [“Required Boilerplate for Op Scripts” on page 335](#).

```

1 <?xml version="1.0" standalone="yes"?>
2 <xsl:stylesheet version="1.0"
3   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4   xmlns:junos="http://xml.juniper.net/junos/*/junos"
5   xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6   xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
7   <xsl:import href="../import/junos.xml"/>
...
20   <xsl:template match="/">
...
105 </xsl:template>
106 </xsl:stylesheet>

```

Lines 8 through 17 declare a variable called **arguments**, containing two arguments to the script: **interface** and **protocol**. This variable declaration causes **interface** and **protocol** to appear in the command-line interface (CLI) as available arguments to the script.

```

8   <xsl:variable name="arguments">
9       <argument>
10         <name>interface</name>

```

```

11      <description>Name of interface to display</description>
12    </argument>
13    <argument>
14      <name>protocol</name>
15      <description>Protocol to display (inet, inet6)</description>
16    </argument>
17  </xsl:variable>

```

Lines 18 and 19 declare two parameters to the script, corresponding to the arguments created in Lines 8 through 17. The parameter names must exactly match the argument names.

```

18    <xsl:param name="interface"/>
19    <xsl:param name="protocol"/>

```

Lines 20 through 31 declare a variable named **rpc**. The **show interfaces terse** command is assigned to the **rpc** variable. If you include the **interface** argument when you execute the script, the value of the argument (the interface name) is passed into the script.

```

20    <xsl:template match="/">
21      <op-script-results>
22        <xsl:variable name="rpc">
23          <get-interface-information>
24            <terse/>
25            <xsl:if test="$interface">
26              <interface-name>
27                <xsl:value-of select="$interface"/>
28              </interface-name>
29            </xsl:if>
30          </get-interface-information>
31        </xsl:variable>

```

Line 32 declares a variable named **out** and applies to it the execution of the **rpc** variable (**show interfaces terse** command).

```

32      <xsl:variable name="out" select="jcs:invoke($rpc)"/>

```

Line 33 specifies that the output level of the **show interfaces** command being modified is **terse** (as opposed to **extensive**, **detail**, and so on).

```

33      <interface-information junos:style="terse">

```

Lines 34 through 39 specify that if you include the **protocol** argument when you execute the script and if the protocol value that you specify is **inet**, **inet6**, **mpls**, or **tnp**, the **intf** template is applied to each instance of that protocol type in the output.

```

34      <xsl:choose>
35        <xsl:when test="$protocol='inet' or $protocol='inet6'
36          or $protocol='mpls' or $protocol='tnp'">
37          <xsl:for-each select="$out/physical-interface/
38            logical-interface[address-family/address-family-name = $protocol]">
39            <xsl:call-template name="intf"/>
38          </xsl:for-each>
39        </xsl:when>

```

Lines 40 through 47 specify that if you include the **protocol** argument when you execute the script and if the protocol value that you specify is something other than **inet**, **inet6**, **mpls**, or **tnp**, an error message is generated.

```

40      <xsl:when test="$protocol">
41      <xnm:error>
42      <message>
43      <xsl:text>invalid protocol: </xsl:text>
44      <xsl:value-of select="$protocol"/>
45      </message>
46      </xnm:error>
47      </xsl:when>

```

Lines 48 through 52 specify that if you do not include the **protocol** argument when you execute the script, the **intf** template is applied to each logical interface in the output.

```

48      <xsl:otherwise>
49      <xsl:for-each select="$out/physical-interface/logical-interface">
50      <xsl:call-template name="intf"/>
51      </xsl:for-each>
52      </xsl:otherwise>

```

Lines 53 through 56 are closing tags.

```

53      </xsl:choose>
54      </interface-information>
55      </op-script-results>
56      </xsl:template>

```

Line 57 opens the **intf** template. This template customizes the output of the **show interfaces terse** command.

```

57      <xsl:template name="intf">

```

Line 58 declares a variable called **status**, the purpose of which is to specify how the interface status is reported. Lines 59 through 78 contain a **<xsl:choose>** instruction that populates the **status** variable by considering all the possible states. As always in XSLT, the first **<xsl:when>** instruction that evaluates as TRUE is executed, and the remainder are ignored. Each **<xsl:when>** instruction is explained separately.

```

58      <xsl:variable name="status">
59      <xsl:choose>

```

Lines 60 through 62 specify that if **admin-status** is **up** and **oper-status** is **up**, no output is generated. In this case, the **status** variable remains empty.

```

60      <xsl:when test="admin-status='up' and oper-status='up'">
61      <xsl:text> </xsl:text>
62      </xsl:when>

```

Lines 63 through 65 specify that if **admin-status** is **down**, the **status** variable contains the text **offline**.

```

63      <xsl:when test="admin-status='down'">
64      <xsl:text>offline</xsl:text>
65      </xsl:when>

```

Lines 66 through 68 specify that if **oper-status** is **down** and the physical interface **admin-status** is **down**, the **status** variable contains the text **p-offline**. (../ selects the physical interface.)

```

66      <xsl:when test="oper-status='down' and ../admin-status='down'">
67      <xsl:text>p-offline</xsl:text>
68      </xsl:when>

```

Lines 69 through 71 specify that if **oper-status** is **down** and the physical interface **oper-status** is **down**, the **status** variable contains the text **p-down**. (../ selects the physical interface.)

```

69      <xsl:when test="oper-status='down' and ../oper-status='down'">
70      <xsl:text>p-down</xsl:text>
71      </xsl:when>

```

Lines 72 through 74 specify that if **oper-status** is **down**, the **status** variable contains the text **down**.

```

72      <xsl:when test="oper-status='down'">
73      <xsl:text>down</xsl:text>
74      </xsl:when>

```

Lines 75 through 77 specify that if none of the test cases are true, the **status** variable contains **oper-status** and **admin-status** concatenated with a slash as a separator.

```

75      <xsl:otherwise>
76      <xsl:value-of select="concat(oper-status, '/', admin-status)"/>
77      </xsl:otherwise>

```

Lines 78 and 79 are closing tags.

```

78      </xsl:choose>
79      </xsl:variable>

```

Lines 80 through 89 define a variable called **desc**. An **<xsl:choose>** instruction populates the variable by selecting the most specific interface description available. If a logical interface description is included in the configuration, it is used to populate the **desc** variable. If not, the physical interface description is used. If no physical interface description is included in the configuration, the variable remains empty. As always in XSLT, the first **<xsl:when>** instruction that evaluates as TRUE is executed, and the remainder are ignored.

```

80      <xsl:variable name="desc">
81      <xsl:choose>
82      <xsl:when test="description">
83      <xsl:value-of select="description"/>
84      </xsl:when>
85      <xsl:when test="../description">
86      <xsl:value-of select="../description"/>
87      </xsl:when>
88      </xsl:choose>
89      </xsl:variable>

```

The remainder of the script specifies how the operational mode output is displayed.

Lines 90 and 91 specify that the logical interface name is displayed first in the output.

```

90      <logical-interface>
91      <name><xsl:value-of select="name"/></name>

```

Lines 92 through 94 test whether the **desc** variable has a nonzero number of characters. If the number of characters is more than zero, the interface description is displayed in the standard location of the **admin-status** field. (In standard output, the **admin-status** field is displayed on the second line.)

```
92      <xsl:if test="string-length($desc)">
93          <admin-status><xsl:value-of select="$desc"/></admin-status>
94      </xsl:if>
```

Line 95 specifies that the interface status as defined in the **status** variable is displayed next.

```
95      <admin-status><xsl:value-of select="$status"/></admin-status>
```

Lines 96 through 103 specify that if you include the **protocol** argument when you execute the script, only interfaces with that protocol configured are displayed. If you do not include the **protocol** argument, all interfaces are displayed.

```
96      <xsl:choose>
97          <xsl:when test="$protocol">
98              <xsl:copy-of
99                  select="address-family[address-family-name = $protocol]"/>
100          </xsl:when>
101          <xsl:otherwise>
102              <xsl:copy-of select="address-family"/>
103          </xsl:otherwise>
104      </xsl:choose>
```

Lines 104 through 106 are closing tags.

```
104      </logical-interface>
105  </xsl:template>
106  </xsl:stylesheet>
```

SLAX Syntax The SLAX version of the script is as follows:

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

var $arguments = {

    } else {
        copy-of address-family;
    }
}
}
}

```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **interface.xml** or **interface.slax** as appropriate, and copy it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **interface.xml** or **interface.slax** as appropriate.

```

[edit system scripts op]
user@host# set file interface.(slax | xml)

```

3. Issue the **commit and-quit** command to commit the configuration and to return to operational mode.

```

[edit]
user@host# commit and-quit

```

4. Execute the op script by issuing the **op interface** operational mode command.

Verification

Verifying the Commit Script Output

Purpose Verify that the script behaves as expected.

Action Issue the **show interfaces terse** and **op interface** operational commands and compare the output. The **show interfaces terse** command displays the standard output. The **op interface** command displays the customized output.

```
user@host> show interfaces terse
Interface      Admin Link Proto  Local              Remote

pime           up    up
tap            up    up
```

```
user@host> op interface
Interface      Admin Link Proto  Local              Remote
fxp0.0         This is the Ethernet Management interface.
               inet    192.168.71.246/21
fxp1.0         inet    10.0.0.4/8
               inet6   fe80::200:ff:fe00:4/64
               fec0::10:0:0:4/64
               tnp      4
lo0.0          inet    127.0.0.1          --> 0/0
lo0.16385      inet    fe80::2a0:a5ff:fe12:2f04-->
               inet6
```

Issue the **op interface** operational command for different hierarchy levels and review the output. For example:

```
user@host> op interface interface fxp0
Interface      Admin Link Proto  Local              Remote
fxp0.0         This is the Ethernet Management interface.
               inet    192.168.71.246/21
```

```
user@host> op interface protocol inet
Interface      Admin Link Proto  Local              Remote
fxp0.0         This is the Ethernet Management interface.
               inet    192.168.71.246/21
fxp1.0         inet    10.0.0.4/8
lo0.0          inet    127.0.0.1          --> 0/0
lo0.16385      inet
```

Example: Displaying DNS Hostname Information Using an Op Script

This example uses an op script to display Domain Name System (DNS) information for a device in your network.

- [Requirements on page 365](#)
- [Overview and Op Script on page 365](#)
- [Configuration on page 367](#)
- [Verification on page 368](#)

Requirements

This example uses a device running Junos OS.

Overview and Op Script

This script displays DNS information for a device in your network. The script offers a slight improvement over the **show host *hostname*** command because you do not need to enter a hostname or IP address to view DNS information for the device you are currently using.

There is no Junos Extensible Markup Language (XML) equivalent for the **show host *hostname*** command. Therefore, this script uses the **show host *hostname*** command directly rather than using a remote procedure call (RPC).

The script is provided in two distinct versions, one using the `<xsl:choose>` element and the other using the `jcs:first-of()` function. Both versions accept the same argument and produce the same output. Each version is shown in both XSLT and SLAX syntax.

XSLT Syntax Using the <xsl:choose> Element

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xml"/>

  <xsl:variable name="arguments">
    <argument>
      <name>dns</name>
      <description>Name or IP address of a host</description>
    </argument>
  </xsl:variable>
  <xsl:param name="dns"/>
  <xsl:template match="/">
    <op-script-results>
      <xsl:variable name="query">
        <xsl:choose>
          <xsl:when test="$dns">
            <command>
              <xsl:value-of select="concat('show host ', $dns)"/>
            </command>
          </xsl:when>
          <xsl:when test="$hostname">
            <command>
              <xsl:value-of select="concat('show host ', $hostname)"/>
            </command>
          </xsl:when>
        </xsl:choose>
      </xsl:variable>
    </op-script-results>
  </xsl:template>
</xsl:stylesheet>
```

```

        </xsl:choose>
      </xsl:variable>
      <xsl:variable name="result" select="jcs:invoke($query)"/>
      <xsl:variable name="host" select="$result"/>
      <output>
        <xsl:value-of select="concat('Name: ', $host)"/>
      </output>
    </op-script-results>
  </xsl:template>
</xsl:stylesheet>

```

XSLT Syntax Using the jcs:first-of() Function

```

<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"
  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xsl"/>

  <xsl:variable name="arguments">
    <argument>
      <name>dns</name>
      <description>Name or IP address of a host</description>
    </argument>
  </xsl:variable>
  <xsl:param name="dns"/>
  <xsl:template match="/">
    <op-script-results>
      <xsl:variable name="target" select="jcs:first-of($dns, $hostname)"/>
      <xsl:variable name="query">
        <command>
          <xsl:value-of select="concat('show host ', $target)"/>
        </command>
      </xsl:variable>
      <xsl:variable name="result" select="jcs:invoke($query)"/>
      <xsl:variable name="host" select="$result"/>
      <output>
        <xsl:value-of select="concat('Name: ', $host)"/>
      </output>
    </op-script-results>
  </xsl:template>
</xsl:stylesheet>

```

SLAX Syntax Using the <xsl:choose> Element

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xsl";

var $arguments = {
  <argument> {
    <name> "dns";
    <description> "Name or IP address of a host";
  }
}

```

```

param $dns;
match / {
  <op-script-results> {
    var $query = {
      if ($dns) {
        <command> 'show host ' _ $dns;
      } else if ($hostname) {
        <command> 'show host ' _ $hostname;
      }
    }
    var $result = jcs:invoke($query);
    var $host = $result;
    <output> 'Name: ' _ $host;
  }
}

```

SLAX Syntax Using the jcs:first-of() Function

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

var $arguments = {
  <argument> {
    <name> "dns";
    <description> "Name or IP address of a host";
  }
}
param $dns;
match / {
  <op-script-results> {
    var $target = jcs:first-of($dns, $hostname);
    var $query = {
      <command> 'show host ' _ $target;
    }
    var $result = jcs:invoke($query);
    var $host = $result;
    <output> 'Name: ' _ $host;
  }
}

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **hostname.xsl** or **hostname.slax** as appropriate, and copy it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **hostname.xsl** or **hostname.slax** as appropriate.

```

[edit system scripts op]
user@host# set file hostname.(slax | xsl)

```

3. Issue the **commit and-quit** command to commit the configuration and to return to operational mode.

```
[edit]
user@host# commit and-quit
```

4. Execute the **op** script by issuing the **op hostname <dns (hostname | address)>** operational mode command.

Verification

Verifying the Commit Script Execution

Purpose Verify that the script behaves as expected.

Action When you issue the **op hostname** operational mode command without the **dns** option, DNS information is displayed for the local device:

```
user@host1> op hostname
Name:
host1 has address 10.168.71.246
```

When you issue the **op hostname dns hostname** command, DNS information is displayed for the specified device:

```
user@host1> op hostname dns router1
Name:
router1 has address 10.168.71.249
```

When you issue the **op hostname dns address** command, DNS information is displayed for the specified address:

```
user@host1> op hostname dns 10.168.71.249
Name:
249.71.168.10.IN-ADDR.ARPA domain name pointer router1
```

Example: Exporting Files Using an Op Script

The **op** script in this example uses the Junos XML protocol **file-put** operation to write to a file on a remote server and on the local device.

- [Requirements on page 368](#)
- [Overview and Op Script on page 368](#)
- [Configuration on page 373](#)
- [Verification on page 373](#)

Requirements

This example uses a device running Junos OS.

Overview and Op Script

The Junos XML protocol **file-put** operation creates a file and writes the specified contents to that file. The basic syntax for using the **file-put** command is as follows:

```
<rpc>
  <file-put>
    <delete-if-exist />
    <encoding>value</encoding>
    <filename>value</filename>
    <permission>value</permission>
    <file-contents>file</file-contents>
  </file-put>
</rpc>
```

The following tag elements are used with the **file-put** command. These tags can be placed in any order with the exception of **file-contents**. The **file-contents** tag element must be the last tag in list.

- **delete-if-exist**—(Optional) If included, any existing file is overwritten. If the tag is omitted, an error is returned if an existing file is encountered.
- **encoding**—(Mandatory) Specifies the type of encoding used. You can use **ASCII** or **base64** encoding.
- **filename**—(Mandatory) Within this tag, you include the full or relative path and filename of the file to create. When you use a relative path, the specified path is relative to the user's home directory. If the specified directory does not exist, the system returns a "directory does not exist" error.
- **permission**—(Optional) Sets the file's UNIX permission on the remote server. For example, to apply read/write access for the user, and read access to others, you would set the permission value to 0644. For a full explanation of UNIX permissions, see the **chmod** command.
- **file-contents**—(Mandatory) The **ASCII** or **base64** encoded file contents to export. This must be the last tag in the list.

XSLT Syntax The following sample script executes a Junos XML API request and exports the results to a file on a remote device and a file on the local device. The script takes three arguments: the IP address or hostname of the remote device, the filename, and the file encoding. The **arguments** variable is declared at the global level of the script so that the argument names and descriptions are visible in the command-line interface (CLI).

The script invokes the Junos XML API **<get-software-information>** request on the local device and stores the result in the **\$result** variable. The script declares the **\$fileput** variable, which contains the remote procedure call (RPC) for the **file-put** operation. The command-line arguments define the values for the **filename** and **encoding** tag elements. If the mandatory argument **myhost** is missing, the script issues an error and halts execution. Otherwise, the script prompts for the username and password that will be used to connect to the remote device.

If connection to the remote device is successful, the script executes the RPC within the context of the connection handle. The output of the **file-put** operation, which is the result of the **jcs:execute()** function, is stored in the **out** variable. If the operation encounters an error, the script prints the error to the CLI. If the **file-put** operation is successful, the contents specified by the **file-contents** tag element are exported to the specified file on the remote device. The connection to the remote host is then closed. The script also exports the contents to an identical file on the local device.

The sample script includes the optional tag elements **permission** and **delete-if-exist** for the **file-put** operation. By including the **delete-if-exist** tag, the script overwrites any existing file of the same name on the remote and local hosts. In this example, the **permission** tag is set to **0644**.

}
}

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **export.xml** or **export.slax** as appropriate, and copy it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **export.xml** or **export.slax** as appropriate.

```

[edit system scripts op]
user@host# set file export.(slax | xml)

```

3. Issue the **commit and-quit** command.

```

[edit]
user@host# commit and-quit

```

4. Execute the op script by issuing the **op export** operational mode command and include any necessary arguments.

Verification

- [Verifying the Op Script Arguments on page 373](#)
- [Verifying Op Script Execution on page 374](#)

Verifying the Op Script Arguments

Purpose Verify that the argument names and descriptions show up in the CLI.

Action Issue the **op exort ?** operational mode command. The CLI lists the possible completions for the script arguments based on the definitions within the global **arguments** variable in the script.

```
user@host> op exort ?
Possible completions:
<[Enter]>      Execute this command
<name>         Argument name
detail         Display detailed output
encoding        ascii or base64
filename        name of destination file
myhost         IP address or hostname of the remote host
|              Pipe through a command
```

Verifying Op Script Execution

Purpose Verify that the script behaves as expected.

Action Issue the **op export myhost *host* encoding *encoding* filename *file*** operational mode command, and include the appropriate username and password when prompted. If script execution is successful, the result of the **<get-software-information>** RPC request is written to the file on the remote device and also on the local device. For example:

```
root@host> op export myhost router1 encoding ascii filename /var/log/host-version.txt
Enter username: root
Enter password:
Connected to host. Exporting file...
```

```
/var/log/host-version.txt
Saving file on local host
```

```
/var/log/host-version.txt
```

If you fail to supply the IP address or hostname of the remote device in the command-line arguments, the script issues an error and halts execution.

```
root@host> op export
error: missing mandatory argument 'myhost'
```

If you omit the **delete-if-exist** child tag of the **file-put** operation, and the specified file already exists, the script reports an error.

```
root@host> op export myhost router1 encoding ascii filename /var/log/host-version.txt
Enter username: root
Enter password:
Connected to host. Exporting file...
```

```
Destination file exists
Saving file on local host
```

```
Destination file exists
```

If you execute the script and include a directory path that does not exist on either the remote or the local host, the script reports an error.

```
root@host> op export myhost router1 encoding ascii filename /var/test/host-version.txt
Enter username: root
Enter password:
Connected to host. Exporting file...
```

```
Destination directory does not exist: /var/test
Saving file on local host
```

```
Destination directory does not exist: /var/test
```

Requirements

This example uses a device running Junos OS.

Overview and Op Script

The following example script, which is shown in both XSLT and SLAX, checks for LSPs to multiple destinations. The script takes one mandatory command-line argument, the address specifying the LSP endpoint. The address argument can include an optional prefix length. If no address is specified, the script generates an error message and halts execution.

The `$get-configuration` variable stores the remote procedure call (RPC) to retrieve the `[edit protocols mpls]` hierarchy level of the device's committed configuration. This configuration is stored in the `$config` variable. The `$get-route-information` variable stores the RPC equivalent of the `show route address terse` operational mode command, where the value of the `destination` tag specifies `address`. The script sets this value to the address specified by the user on the command line. The script invokes the `$get-route-information` RPC and stores the output in the `$rpc-out` variable. If `$rpc-out` does not contain any errors, the script examines all host route entries present at the `route-table/rt/rt-destination` node.

For each host route entry, if an LSP to the destination is configured in the active configuration, the script generates a "Found" message with the destination address and corresponding LSP name in the output. If an LSP to the destination is not configured, the output generates a "Missing" message containing the destination address and hostname.

      }
    }
  }
}

```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **lsp.xsl** or **lsp.slax** as appropriate, and copy it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **lsp.xsl** or **lsp.slax** as appropriate.

```

[edit system scripts op]
user@host# set file lsp.(slax | xsl)

```
3. Issue the **commit and-quit** command to commit the configuration and to return to operational mode.

```

[edit]
user@host# commit and-quit

```
4. Execute the op script by issuing the **op lsp address address** operational mode command.

Verification

Verifying Script Execution

Purpose Verify that the script behaves as expected.

Action Issue the **op lsp address address** operational mode command to execute the script. The output varies depending on the configuration.

```
user@R4> op lsp address 10.168.215.0/24
Found: 192.168.215.1 (192.168.215.1) --> R4>R1
Found: 192.168.215.2 (192.168.215.2) --> R4>R2
Name: R3
Missing: 10.168.215.3
Name: R5
Missing: 10.168.215.4
Name: R6
Missing: 10.168.215.5
```

Example: Importing Files Using an Op Script

The op script in this example uses the Junos XML protocol **file-get** operation to read the contents of a file from a remote server.

- [Requirements on page 380](#)
- [Overview and Op Script on page 380](#)
- [Configuration on page 384](#)
- [Verification on page 384](#)

Requirements

This example uses a device running Junos OS.

Overview and Op Script

The Junos XML protocol **file-get** operation reads the contents of a file. The basic syntax for using the **file-get** command is as follows:

```
<rpc>
  <file-get>
    <filename>value</filename>
    <encoding>value</encoding>
  </file-get>
</rpc>
```

The following tag elements are used with the **file-get** command.

- **encoding**—(Mandatory) Specifies the type of encoding used. You can use **ASCII**, **base64**, or **raw** encoding.
- **filename**—(Mandatory) Within this tag, you include the full or relative path and filename of the file to import. When you use a relative path, the specified path is relative to the **/var/tmp/** directory if the **file-get** operation is executed locally. If the operation is executed remotely within the context of a connection handle, the path is relative to the user's home directory.

NOTE: When you use ASCII encoding, the **file-get** operation converts any control characters in the imported file to the Unicode character 'SECTION SIGN' (U+00A7).

XSLT Syntax The following sample script connects to a remote device and reads the contents of the specified file. The script takes three arguments: the IP address or hostname of the remote device, the filename, and the file encoding. The **arguments** variable is declared at the global level of the script so that the argument names and descriptions are visible in the command-line interface (CLI).

The script declares the **\$fileget** variable, which contains the remote procedure call (RPC) for the **file-get** operation. The command-line arguments define the values for the **filename** and **encoding** tag elements. If the mandatory argument **myhost** is missing, the script issues an error and halts execution. Otherwise, the script prompts for the username and password that will be used to connect to the remote device.

If connection to the remote device is successful, the script executes the RPC within the context of the connection handle. The output of the **file-get** operation, which is the result of the **jcs:execute()** function, is stored in the **out** variable. If the operation encounters an error, the script prints the error to the CLI. If the **file-get** operation is successful, the contents of the file are stored in the **out** variable, which is printed to the CLI. The connection to the remote host is then closed.

var $arguments = {
  <argument> {
    <name> "myhost";
    <description> "IP address or hostname of the remote host";
  }
  <argument> {
    <name> "filename";
    <description> "name of file";
  }
}

```

```

    <argument> {
      <name> "encoding";
      <description> "ascii, base64, or raw";
    }
  }

  param $myhost;
  param $filename;
  param $encoding;

  match / {
    <op-script-results> {
      var $fileget = {
        <file-get> {
          <filename>$filename;
          <encoding>$encoding;
        }
      }
    }

    if ($myhost = "") {
      <xnm:error> {
        <message> "missing mandatory argument 'myhost'";
      }
    }
    else {
      var $username = jcs:get-input("Enter username: ");
      var $pw = jcs:get-secret("Enter password: ");
      var $connect = jcs:open($myhost, $username, $pw);

      if ($connect) {
        <output> "Connected to host. Reading file... \n";
        var $out = jcs:execute($connect, $fileget);
        if ($out//xnm:error) {
          copy-of $out//xnm:error;
        }
        else {
          <output> "File contents: " _ $out;
        }
        expr jcs:close($connect);
      }
      else {
        <output> "No connection to host.";
      }
    }
  }
}

```

Configuration

Step-by-Step Procedure

To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **import.xml** or **import.slax** as appropriate, and copy it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **import.xml** or **import.slax** as appropriate.

```
[edit system scripts op]
user@host# set file import.(slax | xml)
```

3. Issue the **commit and-quit** command to commit the configuration and to return to operational mode.

```
[edit]
user@host# commit and-quit
```

4. Execute the **op script** by issuing the **op import** operational mode command and include any necessary arguments.

Verification

Verifying the Script Arguments

Purpose Verify that the argument names and descriptions show up in the CLI.

Action Issue the **op import ?** operational mode command. The CLI lists the possible completions for the script arguments based on the definitions within the global **arguments** variable in the script.

```
user@host> op import ?
Possible completions:
<[Enter]>          Execute this command
<name>             Argument name
detail             Display detailed output
encoding            ascii, base64, or raw
filename           name of file
myhost             IP address or hostname of the remote host
|                  Pipe through a command
```

Verifying Op Script Execution

Purpose Verify that the script behaves as expected.

Action Issue the `op import myhost host encoding encoding filename file` operational mode command, and include the appropriate username and password when prompted. If script execution is successful, the contents of the requested file are displayed. For example:

```
root@host> op import myhost router1 encoding ascii filename /var/db/scripts/op/test.slax
Enter username: root
Enter password:
Connected to host. Reading file...
File contents:

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xml";
...
```

If you fail to supply the IP address or hostname of the remote device in the command-line arguments, the script issues an error and halts execution.

```
root@host> op import
error: missing mandatory argument 'myhost'
```

Also, if the specified path or file does not exist, the script issues an error.

```
root@host> op import myhost router1 encoding ascii filename /var/db/scripts/op/test1.slax
Enter username: root
Enter password:
Connected to host. Reading file...
File contents:
```

```
Failed to open file (/var/db/scripts/op/test1.slax): No such file or directory
```

Example: Restarting an FPC Using an Op Script

This example uses an op script to restart a Flexible PIC Concentrator (FPC).

- [Requirements on page 385](#)
- [Overview and Op Script on page 385](#)
- [Configuration on page 387](#)
- [Verification on page 387](#)

Requirements

This example uses a device running Junos OS that contains a Flexible PIC Concentrator (FPC) or equivalent component.

Overview and Op Script

The following script, which is shown in both XSLT and SLAX formats, restarts an FPC given the slot number in which the FPC resides. The user provides the slot number in the

command-line interface (CLI) when the script is invoked. The script stores the slot number as the value of the parameter **slot** and constructs the **request chassis fpc** command string to include the slot number of the FPC to restart. There is no Junos Extensible Markup Language (XML) equivalent for the **request chassis** commands. Therefore, this script invokes the **request chassis fpc** command directly rather than using a remote procedure call (RPC).

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"

  xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
  xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
  <xsl:import href="../../import/junos.xml"/>

  <xsl:variable name="arguments">
    <argument>
      <name>slot</name>
      <description>Slot number of the FPC</description>
    </argument>
  </xsl:variable>
  <xsl:param name="slot"/>
  <xsl:template match="/">
    <op-script-results>
      <xsl:variable name="restart">
        <command>
          <xsl:value-of select="concat('request chassis fpc slot ', $slot, '
                                restart')"/>
        </command>
      </xsl:variable>
      <xsl:variable name="result" select="jcs:invoke($restart)"/>
      <output>
        <xsl:text>Restarting the FPC in slot </xsl:text>
        <xsl:value-of select="$slot"/>
        <xsl:text>. </xsl:text>
        <xsl:text>To verify, issue the "show chassis fpc" command.</xsl:text>
      </output>
    </op-script-results>
  </xsl:template>
</xsl:stylesheet>
```

SLAX Syntax

```
version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../../import/junos.xml";

var $arguments = {
  <argument> {
    <name> "slot";
    <description> "Slot number of the FPC";
  }
}
param $slot;
match / {
```

```

<op-script-results> {
  var $restart = {
    <command> 'request chassis fpc slot ' _ $slot _ ' restart';
  }
  var $result = jcs:invoke($restart);
  <output> {
    expr "Restarting the FPC in slot ";
    expr $slot;
    expr ". ";
    expr "To verify, issue the \"show chassis fpc\" command.";
  }
}
}

```

Configuration

Step-by-Step Procedure To download, enable, and test the script:

1. Copy the XSLT or SLAX script into a text file, name the file **restart-fpc.xml** or **restart-fpc.slax** as appropriate, and download it to the `/var/db/scripts/op/` directory on the device.

Only users who belong to the Junos OS **super-user** login class can access and edit files in this directory.

2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **restart-fpc.xml** or **restart-fpc.slax** as appropriate.

```

[edit system scripts op]
user@host# set file restart-fpc.(slax | xml)

```

3. Issue the **commit and-quit** command to commit the configuration and to return to operational mode.

```

[edit]
user@host# commit and-quit

```

4. Execute the op script by issuing the **op restart-fpc slot slot-number** operational mode command.

Verification

Verifying Op Script Execution

Purpose Verify that the FPC has been restarted and is currently online.

Action Execute the op script by issuing the **op filename** operational mode command. Supply the **slot** number of the FPC as an argument.

```

user@host> op restart-fpc slot 0

```

When you execute the script, you should see output similar to the following:

Restarting the FPC in slot 0. To verify, issue the "show chassis fpc" command.

Issue the **show chassis fpc detail fpc-slot** operational mode command.

```
user@host> show chassis fpc detail 0
```

```
Slot 0 information:
  State                Online
  Temperature          36 degrees C / 96 degrees F
  Total CPU DRAM        1024 MB
  Total RLDRAM          256 MB
  Total DDR DRAM        4096 MB
  Start time:          2009-08-11 21:20:30 PDT
  Uptime:               0 hours, 1 minutes, 50 seconds
  Max Power Consumption 335 Watts
```

Meaning The **show chassis fpc detail** command output displays the state, start time, uptime, and characteristics for the FPC. Verify that the FPC was restarted by checking the start time and uptime of the FPC. Verify the status of the restarted FPC by checking the state. If the status is **Present**, the FPC is coming up but is not yet online. If the status is **Online**, the FPC is online and running.

Example: Searching Files Using an Op Script

This sample script searches a file on a device running Junos OS for lines matching a given regular expression. The example uses the **jcs:grep** template in an op script.

- [Requirements on page 388](#)
- [Overview and Op Script on page 388](#)
- [Configuration on page 391](#)
- [Verification on page 391](#)

Requirements

This example uses a device running Junos OS.

Overview and Op Script

The **jcs:grep** template searches an ASCII file for lines matching a regular expression. The template resides in the **junos.xml** import file, which is included with the standard Junos OS installation available on all switches, routers, and security devices running Junos OS. To use the **jcs:grep** template in a script, you must import the **junos.xml** file into the script and map the **jcs** prefix to the namespace identified by the URI <http://xml.juniper.net/junos/commit-scripts/1.0>.

In this example, all values required for the **jcs:grep** template are defined as global parameters. The values for the parameters are passed into the script as command-line arguments. The following script defines two parameters, **\$filename** and **\$pattern**, which store the values of the input file path and the regular expression. If you omit either argument when you execute the script, the script generates an error and halts execution. Otherwise, the script calls the **jcs:grep** template and passes in the supplied arguments.

If the regular expression contains a syntax error, the **jcs:grep** template generates an **error: regex error** message for each line in the file. If the regular expression syntax is valid, the template parses the input file. For each match, the template adds a **<match>** element, which contains **<input>** and **<output>** child tags, to the result tree. The template writes the matching string to the **<output>** child element and writes the corresponding matching line to the **<input>** child element:

```
<match> {
  <input>
  <output>
}
```

In the SLAX script, the **:=** operator copies the results of the **jcs:grep** template call to a temporary variable and runs the **node-set** function on that variable. The **:=** operator ensures that the **results** variable is a node-set rather than a result tree fragment so that the script can access the contents. The XSLT script explicitly calls out the equivalent steps. The script then loops through all resulting input elements and prints each match.

XSLT Syntax

```
<?xml version="1.0" standalone="yes"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:junos="http://xml.juniper.net/junos/*/junos"

            <xsl:value-of select="."/>
        </output>
    </xsl:for-each>
    </xsl:otherwise>
</xsl:choose>
</op-script-results>

</xsl:template>
</xsl:stylesheet>

```

SLAX Syntax

```

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";

import "../import/junos.xml";

var $arguments = {
    <argument> {
        <name> "filename";
        <description> "name of file in which to search for the specified pattern";
    }
    <argument> {
        <name> "pattern";
        <description> "regular expression";
    }
}

param $filename;
param $pattern;

match / {
    <op-script-results> {

        if ($filename = "") {
            <xnm:error> {
                <message> "missing mandatory argument 'filename'";
            }
        }
        else if ($pattern = "") {
            <xnm:error> {
                <message> "missing mandatory argument 'pattern'";
            }
        }
    }
}

```

```

else {
    var $results := { call jcs:grep($filename, $pattern); }

    <output> "Search for " _ $pattern _ " in " _ $filename;
    for-each ($results//input) {
        <output> .;
    }
}
}
}

```

Configuration

Step-by-Step Procedure

To download, enable, and run the script:

1. Copy the XSLT or SLAX script into a text file, name the file **grep.xml** or **grep.slax** as appropriate, and download it to the **/var/db/scripts/op/** directory on the device.
2. In configuration mode, include the **file** statement at the **[edit system scripts op]** hierarchy level and **grep.xml** or **grep.slax** as appropriate.

```

[edit system scripts op]
user@host# set file grep.(slax | xml)

```

3. Issue the **commit and-quit** command to commit the configuration and to return to operational mode.

```

[edit]
user@host# commit and-quit

```

4. Execute the op script by issuing the **op grep filename filename pattern pattern** operational mode command.

Verification

Verifying the Script Arguments

Purpose Verify that the argument names and descriptions appear in the command-line interface (CLI) help.

Action Issue the **op grep ?** operational mode command. The CLI lists the possible completions for the script arguments based on the definitions within the global variable **arguments** in the script.

```
user@host> op grep
Possible completions:
  <[Enter]>      Execute this command
  <name>         Argument name
  detail         Display detailed output
  filename       name of file in which to search for the specified pattern

  pattern        regular expression
  |              Pipe through a command
```

Verifying Op Script Execution

Purpose Verify that the script behaves as expected.

Action If you issue the **op grep** command, but you fail to supply either the filename or the regex pattern, the script issues an error message and halts execution. For example:

```
user@host> op grep filename /var/log/messages
error: missing mandatory argument 'pattern'

user@host> op grep pattern SNMP_TRAP_LINK_DOWN
error: missing mandatory argument 'filename'
```

When you issue the **op grep filename *filename* pattern *pattern*** command, the script lists all lines from the input file that match the regular expression.

```
user@host> op grep filename /var/log/messages pattern SNMP_TRAP_LINK_DOWN
Search for SNMP_TRAP_LINK_DOWN in /var/log/messages
Feb 24 09:04:00 host mib2d[1325]: SNMP_TRAP_LINK_DOWN: ifIndex 543, ifAdminStatus
down(2), ifOperStatus down(2), ifName
1t-0/1/0.9
Feb 24 09:04:00 host mib2d[1325]: SNMP_TRAP_LINK_DOWN: ifIndex 542, ifAdminStatus
down(2), ifOperStatus down(2), ifName
1t-0/1/0.10
```

traceoptions (Commit and Op Scripts)

Syntax	<pre> traceoptions { file <filename> <files number> <size size> <world-readable no-world-readable>; flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit system scripts commit], [edit system scripts op]
Release Information	Statement introduced in Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Define tracing operations for commit or op scripts.
Default	If you do not include this statement, no script-specific tracing operations are performed.
Options	<p>filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory <code>/var/log</code>. By default, commit script process tracing output is placed in the file <code>cscript.log</code> and op script process tracing is placed in the file <code>op-script.log</code>. If you include the file statement, you must specify a filename. To retain the default, you can specify <code>cscript.log</code> or <code>op-script.log</code> as the filename.</p> <p>files number—(Optional) Maximum number of trace files. When a trace file named <i>trace-file</i> reaches its maximum size, it is renamed and compressed to <i>trace-file.0.gz</i>. When <i>trace-file</i> again reaches its maximum size, <i>trace-file.0.gz</i> is renamed <i>trace-file.1.gz</i> and <i>trace-file</i> is renamed and compressed to <i>trace-file.0.gz</i>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000</p> <p>Default: 10 files</p> <p>flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> • all—Log all operations • events—Log important events • input—Log script input data • offline—Generate data for offline development • output—Log script output data • rpc—Log script RPCs • xslt—Log the XSLT library

no-world-readable—Restrict file access to owner. This is the default.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed and compressed to **trace-file.0.gz**. When **trace-file** again reaches its maximum size, **trace-file.0.gz** is renamed **trace-file.1.gz** and **trace-file** is renamed and compressed to **trace-file.0.gz**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and a filename.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

world-readable—Enable unrestricted file access.

Required Privilege Level	maintenance—To view this statement in the configuration.
	maintenance-control—To add this statement to the configuration.

Troubleshooting

- [Troubleshooting Op Scripts on page 404](#)

Troubleshooting Op Scripts

- [Tracing Op Script Processing on page 404](#)

Tracing Op Script Processing

Op script tracing operations track all op script operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

The default operation of op script tracing is to log important events in a file called **op-script.log** located in the **/var/log** directory. When the file **op-script.log** reaches 128 kilobytes (KB), it is renamed with a number 0 through 9 (in ascending order) appended to the end of the file and then compressed. The resulting files are **op-script.log.0.gz**, then **op-script.log.1.gz**, until there are 10 trace files. Then the oldest trace file (**op-script.log.9.gz**) is overwritten. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

This section discusses the following topics:

- [Minimum Configuration for Enabling Traceoptions for Op Scripts on page 405](#)
- [Configuring Tracing of Op Scripts on page 406](#)

Minimum Configuration for Enabling Traceoptions for Op Scripts

If no op script trace options are configured, the simplest way to view the trace output of an op script is to configure the **output** trace flag and issue the **show log op-script.log | last** command. To do this, perform the following steps:

1. If you have not done so already, enable an op script by including the **file** statement at the **[edit system scripts op]** hierarchy level:

```
[edit system scripts op]
user@host# set file filename
```

2. Enable trace options by including the **traceoptions flag output** statement at the **[edit system scripts op]** hierarchy level:

```
[edit system scripts op]
user@host# set traceoptions flag output
```

3. Issue the **commit** command:

```
[edit]
user@host# commit
```

4. Display the resulting trace messages recorded in the file **/var/log/op-script.log** file. At the end of the log is the output generated by the op script you enabled in Step 1. To display the end of the log, issue the **show log op-script.log | last** operational mode command:

```
[edit]
user@host# run show log op-script.log | last
```

Table 21 on page 405 summarizes useful filtering commands that display selected portions of the **op-script.log** file.

Table 21: Op Script Tracing Operational Mode Commands

Task	Command
Display logging data associated with all op script processing.	show log op-script.log
Display processing for only the most recent operation.	show log op-script.log last
Display processing for script errors.	show log op-script.log match error
Display processing for a particular script.	show log op-script.log match filename

Example: Minimum Configuration for Enabling Traceoptions for Op Scripts

Display the trace output of the op script file **source-route.xml**:

```
[edit]
system {
  scripts {
    op {
```

```
        file source-route.xml;
        traceoptions flag output;
    }
}

[edit]
user@host# commit
[edit]
user@host# run show log op-script.log | last
```

Configuring Tracing of Op Scripts

You cannot change the directory (`/var/log`) to which trace files are written. However, you can customize other trace file settings by including the following statements at the `[edit system scripts op traceoptions]` hierarchy level:

```
[edit system scripts op traceoptions]
file <filename> <files number> <size size> <world-readable | no-world-readable>;
flag all;
flag events;
flag input;
flag offline;
flag output;
flag rpc;
flag xslt;
no-remote-trace;
```

These statements are described in the following sections:

- [Configuring the Op Script Log Filename on page 406](#)
- [Configuring the Number and Size of Op Script Log Files on page 406](#)
- [Configuring Access to Op Script Log Files on page 407](#)
- [Configuring the Op Script Trace Operations on page 407](#)

Configuring the Op Script Log Filename

By default, the name of the file that records trace output is `op-script.log`. You can specify a different name by including the `file` statement at the `[edit system scripts op traceoptions]` hierarchy level:

```
[edit system scripts op traceoptions]
file filename;
```

Configuring the Number and Size of Op Script Log Files

By default, when the trace file reaches 128 KB in size, it is renamed and compressed to `filename.0.gz`, then `filename.1.gz`, and so on, until there are 10 trace files. Then the oldest trace file (`filename.9.gz`) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the `[edit system scripts op traceoptions file <filename>]` hierarchy level:

```
[edit system scripts op traceoptions file <filename>]
files number size size;
```

For example, set the maximum file size to 640 KB and the maximum number of files to 20. When the file that receives the output of the tracing operation (`filename`) reaches

640 KB, it is renamed and compressed to **filename.0.gz**, and a new file called **filename** is created. When **filename** reaches 640 KB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is renamed and compressed to **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file (**filename.19.gz**) is overwritten.

The number of files can range from 2 through 1000 files. The file size can range from 10 KB through 1 gigabyte (GB).

NOTE:

If you set either a maximum file size or a maximum number of trace files, you also must specify the other parameter and a filename.

Configuring Access to Op Script Log Files

By default, access to the op script log file is restricted to the owner. You can manually configure access by including the **world-readable** or **no-world-readable** statement at the **[edit system scripts op traceoptions file <filename>]** hierarchy level.

```
[edit system scripts op traceoptions file <filename>]
(world-readable | no-world-readable);
```

The **no-world-readable** statement restricts op script log access to the owner. The **world-readable** statement enables unrestricted access to the op script log file.

Configuring the Op Script Trace Operations

By default, only important events are logged. You can configure the trace operations to be logged by including the following statements at the **[edit system scripts op traceoptions]** hierarchy level:

```
[edit system scripts op traceoptions]
flag all;
flag events;
flag input;
flag offline;
flag output;
flag rpc;
flag xslt;
```

[Table 22 on page 407](#) describes the meaning of the op script tracing flags.

Table 22: Op Script Tracing Flags

Flag	Description	Default Setting
all	Trace all operations.	Off
events	Trace important events.	On
input	Trace op script input data.	Off
offline	Generate data for offline development.	Off

Table 22: Op Script Tracing Flags (*continued*)

Flag	Description	Default Setting
output	Trace op script output data.	Off
rpc	Trace op script RPCs.	Off
xslt	Trace the Extensible Stylesheet Language Transformations (XSLT) library.	Off

Event Policy Overview

- [Event Notifications and Policies Overview on page 409](#)
- [How Event Policies Work on page 410](#)

Event Notifications and Policies Overview

To diagnose a fault or error condition on a device, you need relevant information about the state of the platform. You can derive state information from *event notifications*. Event notifications are system log messages and SNMP traps. A Junos OS process called the *event process* (eventd) receives event notifications—henceforth simply called *events*—from other Junos OS processes.

Timely diagnosis and intervention can correct error conditions and keep the device in operation. After the eventd process receives events, *event policies* instruct the eventd process to select specific events, correlate the events, and perform a set of actions. These actions can either help you diagnose a fault or take corrective action. For example, the eventd process can upload device files to a given destination and issue operational mode commands.

Events can originate as SNMP traps or system log messages. The event process receives event messages from other Junos OS processes, such as the routing protocol process (rpd) and the management process (mgd). Depending on the custom event policy you configure, eventd listens for specific events and in response to these events might create

a log file, invoke a Junos command, or invoke an event script. When an event script is invoked, event details are passed to the event script in the form of XML inputs.

Figure 10 on page 410 shows how the event process (eventd) interacts with other Junos OS processes.

Figure 10: Interaction of eventd Process with Other Junos OS Processes

How Event Policies Work

An event policy is an if-then-else construct. It defines actions to be executed by the event process (eventd) on receipt of an event. You can configure multiple policies to be processed for an event. The policies are executed in the order in which they appear in the configuration. For each policy, you can configure multiple actions. The actions are also executed in the order in which they appear in the configuration.

To view a list of the events that can be referenced in an event policy, issue the **help syslog ?** command:

```

user@host> help syslog ?
Possible completions:
<syslog-tag>          System log tag
ACCT_ACCOUNTING_FERROR Error occurred during file processing
ACCT_ACCOUNTING_FOPEN_ERROR Open operation failed on file
...

```

You can filter the output of a search by using the pipe (|) symbol. The following example lists the filters that can be used with the pipe symbol:

```

user@host> help syslog | ?
Possible completions:
count          Count occurrences
display        Show additional kinds of information
except         Show only text that does not match a pattern
find           Search for first occurrence of pattern
hold           Hold text without exiting the --More-- prompt
last           Display end of output only
match          Show only text that matches a pattern
no-more        Don't paginate output
request        Make system-level requests
resolve        Resolve IP addresses
save           Save output text to file
trim           Trim specified number of columns from start of line

```

For more information about using the pipe symbol, see the *CLI User Guide*.

You can also list multiple events as you configure the event policy. To view a partial list of the events that can be referenced in an event policy, issue the **set event-options policy *policy-name* events ?** configuration mode command:

```
[edit]
user@host# set event-options policy policy-name events ?
Possible completions:
<event>
[      Open a set of values
acct_accounting_ferror
acct_accounting_fopen_error
...
```

Some of the system log messages that you can reference in an event policy are not listed in the output of the **set event-options policy *policy-name* events ?** command. For information about referencing these system log messages in your event policies, see [“Using Nonstandard System Log Messages to Trigger Event Policies” on page 419](#).

In addition, you can reference internally generated events, which are discussed in [“Generating Internal Events to Trigger Event Policies” on page 419](#).

In response to events, the eventd process can correlate two or more events based on a policy, and execute the following actions:

- Ignore the event—Do not generate a system log message for this event and do not process any further policy instructions for this event.
- Upload a file—Upload a file to a specified destination. You can specify a transfer delay, so that, on receipt of an event, the upload of the file begins after the configured transfer delay. For example, to upload a core file, a transfer delay can ensure that the core file has been completely generated before the upload begins.
- Execute Junos OS operational mode commands—Execute commands on receipt of an event. The XML or text output of these commands is stored in a file, which is then uploaded to a specified URL. You can include variables in the command that allow data from the triggering event to be automatically included in the command syntax.
- Execute Junos OS configuration mode commands—Execute commands to modify the configuration on receipt of an event. Starting with Junos OS Release 12.1, you can configure an event policy to modify the configuration using Junos OS configuration mode commands and then commit the updated configuration.
- Execute Junos OS event scripts—Execute event scripts on receipt of an event. Event scripts are Extensible Stylesheet Transformation (XSLT) or Stylesheet Language Alternative Syntax (SLAX) scripts that you write to perform any function available through Junos XML or Junos XML protocol remote procedure calls (RPCs). Additionally, you can pass to an event script a set of arguments that you define. A script can build and run an operational mode command, receive the command output, inspect the output, and determine the next appropriate action. This process can be repeated until the source of the problem is determined. The output of the scripts is stored in a file, which is then uploaded to a specified URL. You can include variables in the arguments

to the scripts that allow data from the triggering event to be incorporated into the script.

- Raise an SNMP trap.

Event Scripts Overview

- [Event Scripts Overview on page 412](#)

Event Scripts Overview

- [Event Script Programming Overview on page 412](#)
- [How Event Scripts Work on page 412](#)

Event Script Programming Overview

Junos OS event scripts are triggered automatically by defined event policies in response to a system event and can instruct Junos OS to take immediate action. Event scripts automate network and device management and troubleshooting. Event scripts can perform functions available through the remote procedure calls (RPCs) supported by either Junos XML management protocol or the Junos Extensible Markup Language (XML) API. Event scripts are executed by the event process (eventd).

Event scripts allow you to do the following:

- Automatically diagnose and fix problems in the network
- Monitor the overall status of a device.
- Run automatically as part of an event policy that detects periodic error conditions
- Change the configuration in response to a problem

Event scripts are based on the Junos XML management protocol and the Junos XML API, which are discussed in “[Junos XML API and Junos XML Management Protocol Overview](#)” on page 6. Event scripts can be written in either the Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) scripting language. Event scripts use XPath to locate the operational objects to be inspected and XSLT constructs to specify the actions to perform on the located operational objects. The actions can change the output or execute additional commands based on the output. For more information about XPath and XSLT, see “[XPath Overview](#)” on page 50.

How Event Scripts Work

Event scripts initiate operational commands when triggered by an event policy. When an event policy is triggered, this policy forwards event details to the event script. You enable event scripts by listing the names of one or more event script files within the **[edit event-options event-script]** hierarchy level. These scripts contain instructions that execute operational mode commands and inspect the output automatically. Event scripts are invoked within an event policy. For information about event policies, see “[Event Notifications and Policies Overview](#)” on page 409 and “[Executing Event Scripts in an Event Policy](#)” on page 449.

You can use event scripts to generate changes to the device configuration by including the `<load-configuration>` tag element. Because the changes are loaded before the standard validation checks are performed, they are validated for correct syntax, just like statements already present in the configuration before the script is applied. If the syntax is correct, the configuration is activated and becomes the active, operational device configuration.

Triggering an Event Policy

- [Using Correlated Events to Trigger an Event Policy on page 413](#)
- [Representing the Correlating Event in an Event Policy on page 416](#)
- [Triggering an Event Policy Based on Event Count on page 417](#)
- [Using Regular Expressions to Refine the Set of Events That Trigger a Policy on page 417](#)
- [Generating Internal Events to Trigger Event Policies on page 419](#)
- [Using Nonstandard System Log Messages to Trigger Event Policies on page 419](#)

Using Correlated Events to Trigger an Event Policy

You can configure a policy that correlates two or more events. If the correlated events occur as specified, they cause particular actions to be taken. For example, you might want to issue certain operational mode commands when a `UI_CONFIGURATION_ERROR` event is generated within five minutes (300 seconds) after a `UI_COMMIT_PROGRESS` event. As another example, you might want to upload a particular file if a `DCD_INTERFACE_DOWN` event is generated two times within a 60-second interval.

To configure a policy that correlates events, include the following statements at the `[edit event-options]` hierarchy level:

```
[edit event-options]
policy policy-name {
  events [ events ];
  within seconds {
    events [ events ];
```

```

    not events [ events ];
    trigger (on | after | until) event-count;
}
attributes-match {
    event1.attribute-name equals event2.attribute-name;
    event.attribute-name matches regular-expression;
    event1.attribute-name starts-with event2.attribute-name;
}
then {
    ...
}
}

```

In the **events** statement, you can list multiple events. To view a list of the events that can be referenced in an event policy, issue the **set event-options policy *policy-name* events ?** configuration mode command:

```

user@host# set event-options policy policy-name events ?
Possible completions:
<event>
[          Open a set of values
acct_accounting_ferror
acct_accounting_fopen_error
...

```

Some of the system log messages that you can reference in an event policy are not listed in the output of the **set event-options policy *policy-name* events ?** command. For information about referencing these system log messages in your event policies, see [“Using Nonstandard System Log Messages to Trigger Event Policies” on page 419](#).

In addition, you can reference internally generated events, which are discussed in [“Generating Internal Events to Trigger Event Policies” on page 419](#).

The actions configured in the **then** statement are executed only if certain conditions are met, which you specify in the **within** and **attributes-match** statements.

You can configure a policy that is executed only if a specified event occurs within a specified time interval after another event. You do this by including the **within *seconds* events** statement. The policy is executed only if one or more of the events in the first **events** statement occur within a configured number of seconds after one or more of the events in the **within *seconds* events** statement. The number of seconds can be from 60 through 604,800. The **not** statement causes the policy to be executed only if the events do not occur within the configured time interval.

For example, the following policy is executed if **event3**, **event4**, or **event5** occurs within 60 seconds after **event1** or **event2** occurs:

```

[edit event-options]
policy 1 {
    events [ event3 event4 event5 ];
    within 60 events [ event1 event2 ];
    then {
        ...
    }
}

```

The **attributes-match** statement correlates two events as follows:

- **event1.attribute-name equals event2.attribute-name**—Execute the policy only if the specified attribute of **event1** equals the specified attribute of **event2**.
- **event.attribute-name matches regular-expression**—Execute the policy only if the specified attribute of **event** matches a regular expression. For more information, see [“Using Regular Expressions to Refine the Set of Events That Trigger a Policy”](#) on page 417.
- **event1.attribute-name starts-with event2.attribute-name**—Execute the policy only if the specified attribute of **event1** starts with the specified attribute of **event2**.

If the **attributes-match** statement includes the **equals** or **starts-with** options, or if it includes a **matches** option that includes a clause for an event that is not specified at the **[edit event-options policy policy-name events]** hierarchy level, you must include one or more **within** statements in the same policy configuration.

Starting with Junos OS Release 11.1, you can use event policy variables within the **attributes-match** statement to differentiate between a trigger event attribute and a correlated event attribute. The double dollar sign (**\$\$**) notation represents the event that is triggering a policy, and **\$\$attribute-name** resolves to the value of the attribute of the triggering event. Triggering events are those that you configure at the **[edit event-options policy policy-name events]** hierarchy level. For correlating events, the single dollar sign with the event name (**\$event**) notation represents the most recent event that matches the event name, and **\$event.attribute-name** resolves to the value of the attribute of the correlated event.

In the following example, the policy will execute the actions under the **then** statement if four or more commits are performed within a 5-minute period, and the username of one or more of the correlated events is the same as the username of the trigger event.

```
policy multiple-commits {
  events ui_commit;
  attributes-match {
    { $$user-name } equals { $ui_commit.user-name };
  }
  within 300 {
    trigger after 3;
    events ui_commit;
  }
  then ...
}
```

To view a list of all event attributes that you can reference, issue the **help syslog event** operational mode command. The output of this command shows the event attributes in angle brackets (<>). The following output shows that three attributes can be referenced for the **ACCT_ACCOUNTING_SMALL_FILE_SIZE** event: **filename**, **file-size**, and **record-size**.

```
user@host> help syslog ACCT_ACCOUNTING_SMALL_FILE_SIZE
Name:          ACCT_ACCOUNTING_SMALL_FILE_SIZE
Message:       File <filename> size (<file-size>) is smaller than record size
(<record-size>)
```

You can filter the output of a search by using the pipe (|) symbol. The following example lists the filters that can be used with the pipe symbol:

```
user@host> help syslog | ?
Possible completions:
count          Count occurrences
display        Show additional kinds of information
except         Show only text that does not match a pattern
find           Search for first occurrence of pattern
hold           Hold text without exiting the --More-- prompt
last           Display end of output only
match          Show only text that matches a pattern
no-more        Don't paginate output
request        Make system-level requests
resolve        Resolve IP addresses
save           Save output text to file
trim           Trim specified number of columns from start of line
```

For more information about using the pipe symbol, see the *CLI User Guide*.

Another way to view the attributes you can reference is by issuing the **set attributes-match event?** command at the **[edit event-options policy *policy-name*]** hierarchy level, as shown in the following example:

```
[edit event-options policy p1]
user@host# set attributes-match acct_accounting_small_file_size?
Possible completions:
<from-event-attribute> First attribute to compare
acct_accounting_small_file_size.filename
acct_accounting_small_file_size.filesize
acct_accounting_small_file_size.record-size
```

NOTE: In this **set** command, there is no space between the event name and the question mark (?).

Representing the Correlating Event in an Event Policy

As described in “Configuring an Event Policy to Execute Operational Mode Commands” on page 433, the double dollar sign (\$\$) notation represents the event that is triggering a

policy. Triggering events are those that you configure at the **[edit event-options policy *policy-name* events]** hierarchy level.

As described in “[Using Correlated Events to Trigger an Event Policy](#)” on page 413, you can configure a policy that is executed only if a specified event occurs within a specified time interval after another event. You do this by including the **within seconds events** statement at the **[edit event-options policy *policy-name*]** hierarchy level:

```
[edit event-options policy policy-name ]
  events [ events ];
  within seconds events [ events ];
```

The policy is executed only if one or more of the events at the **[edit event-options policy *policy-name* events]** hierarchy level occur within a configured number of seconds after one or more of the events in the **within seconds events** statement.

For correlating events, the single dollar sign with the event name (**\$event**) notation represents the most recent event that matches the event name. The dollar sign with the asterisk (**\$***) notation represents the most recent event that matches any of the correlating events.

For a configuration example, see “[Example: Representing the Correlating Event in an Event Policy](#)” on page 479.

Triggering an Event Policy Based on Event Count

You can configure an event policy to be triggered if an event or set of events occurs a specified number of times within a specified time period.

To do this, include the optional **trigger** statement at the **[edit event-options policy *policy-name* within seconds]** hierarchy level:

```
[edit event-options policy policy-name within seconds]
  trigger (after | on | until) event-count;
```

The software counts the number of times the triggering event occurs. A triggering event can be any event configured at the **[edit event-options policy *policy-name* events]** hierarchy level. You can configure the following options:

- **after *event-count***—The policy is executed when the number of matching events received equals *event-count* plus one.
- **on *event-count***—The policy is executed when the number of matching events received equals *event-count*.
- **until *event-count***—The policy is executed each time a matching event is received and stops being executed when the number of matching events received equals *event-count*.

For a configuration example, see “[Example: Triggering a Policy Based on Event Count](#)” on page 481.

Using Regular Expressions to Refine the Set of Events That Trigger a Policy

You can use regular expression matching to specify more exactly which events cause a policy to be executed.

To specify the text string that must appear in an event attribute for the policy to be executed, include the **matches** statement at the **[edit event-options policy policy-name attributes-match]** hierarchy level, and specify the regular expression which the event attribute must match:

```
[edit event-options policy policy-name attributes-match]
event.attribute-name matches regular-expression;
```

When you specify the regular expression, use the notation defined in POSIX Standard 1003.2 for extended (modern) UNIX regular expressions. Explaining regular expression syntax is beyond the scope of this document. [Table 23 on page 418](#) specifies which character or characters are matched by some of the regular expression operators that you can use in the **matches** statement. In the descriptions, the term *term* refers to either a single alphanumeric character or a set of characters enclosed in square brackets, parentheses, or braces.

NOTE: The **matches** statement is not case-sensitive.

Table 23: Regular Expression Operators for the matches Statement

Operator	Matches
. (period)	One instance of any character except the space.
* (asterisk)	Zero or more instances of the immediately preceding term.
+ (plus sign)	One or more instances of the immediately preceding term.
? (question mark)	Zero or one instance of the immediately preceding term.
(pipe)	One of the terms that appear on either side of the pipe operator.
! (exclamation point)	Any string except the one specified by the expression, when the exclamation point appears at the start of the expression. Use of the exclamation point is specific to Junos OS.
^ (caret)	The start of a line, when the caret appears outside square brackets. One instance of any character that does not follow it within square brackets, when the caret is the first character inside square brackets.
\$ (dollar sign)	The end of a line.
[] (paired square brackets)	One instance of one of the enclosed alphanumeric characters. To indicate a range of characters, use a hyphen (-) to separate the beginning and ending characters of the range. For example, [a-z0-9] matches any letter or number.
() (paired parentheses)	One instance of the evaluated value of the enclosed term. Parentheses are used to indicate the order of evaluation in the regular expression.

For a configuration example, see [“Example: Controlling Event Policy Using a Regular Expression” on page 475](#).

Generating Internal Events to Trigger Event Policies

Internal events are events that you create to trigger a policy to be executed. They are not generated by Junos OS processes, and they do not have any associated system log messages. You can generate an internal event based on a time interval or the time of day.

To generate an event, include the following statements at the **[edit event-options]** hierarchy level:

```
[edit event-options]
generate-event event-name {
  time-interval seconds;
  time-of-day hh:mm:ss;
}
```

In the **time-interval** statement, configure a frequency, in seconds, with which to repeatedly generate an event. The time interval can range from 60 through 2,592,000 seconds.

In the **time-of-day** statement, configure a time of day for the event to occur. Use the format **hh:mm:ss**.

NOTE: If you modify the system time by issuing the **set date** operational mode command, we recommend that you also issue the **commit full** or the **restart event-process** command. Otherwise, an internal event based on the time of day might not be generated at the configured time.

For example, if you configure an internal event to be generated at 15:55:00, and then you modify the system time from 15:47:17 to 15:53:00, the event is generated when the system time is approximately 16:00 instead of at the configured time, 15:55:00. You can correct this problem by issuing the **commit full** or the **restart event-process** command.

You can configure up to 10 internal events. If you attempt to commit a configuration with more than 10 internal events, Junos OS generates an error, and the commit fails.

For configuration examples, see [“Example: Generating an Internal Event” on page 476](#).

Using Nonstandard System Log Messages to Trigger Event Policies

Some of the system log messages that you can reference in an event policy are not listed in the output of the **set event-options policy policy-name events ?** command. These system log messages have an event ID and a **message** attribute. Event IDs are based on the origin of the message, as shown in [Table 24 on page 420](#).

Table 24: Event ID by System Log Message Origin

Event IDs	Origin
SYSTEM	Messages from Junos daemons and utilities
KERNEL	Messages from the Junos kernel
PIC	Messages from physical interface cards (PICs)
PFE	Messages from the Packet Forwarding Engine
LCC	On a TX Matrix router, messages from a line-card chassis (LCC)
SCC	On a TX Matrix router, messages from a switch-card chassis (SCC)

To base your event policy on the event types shown in [Table 24 on page 420](#), include the **events** *event-id* statement and the **attributes-match** statement with the *event-id.message matches "message"* attribute at the **[edit event-options policy *policy-name*]** hierarchy level:

```
[edit event-options policy policy-name]
events event-id;
attributes-match {
  event-id.message matches "message";
}
```

For a configuration example, see “[Example: Using Nonstandard System Log Messages to Trigger an Event Policy](#)” on page 483.

Configuring Event Policy File Archiving

- [Event Policy File Archiving Overview on page 420](#)
- [Example: Defining Destinations for File Archiving by Event Policies on page 421](#)
- [Example: Configuring an Event Policy to Upload Files on page 424](#)
- [Configuring the Delay Before Files Are Uploaded by an Event Policy on page 431](#)
- [Configuring an Event Policy to Retry the File Upload Action on page 432](#)

Event Policy File Archiving Overview

Various types of files are useful in diagnosing events. When an event policy action generates output files, you can archive the files for later analysis. Similarly, you might want to archive system files, including system log files, core files, and configuration files, from the time an event occurs.

When an event occurs, you can upload relevant files to a specified location for analysis. To archive files from an event policy, configure one or more *destinations* specifying the archive sites to which the files are uploaded. You then reference the configured destinations within event policies.

A transfer delay allows you to specify the number of seconds the event process (eventd) waits before beginning to upload a file or multiple files. A transfer delay helps ensure that a large file, such as a core file, is completely generated before the upload begins.

You can associate transfer delays with a destination and with an event policy action. If you associate a transfer delay with a destination, the transfer delay applies to all file upload actions that use that destination. You can also assign a transfer delay to a single event policy action. For example, you might have multiple event policy actions that use the same destination, and for some of these event policy actions, you want a transfer delay, and for other event policy actions you want no transfer delay. If you configure a transfer delay for a destination, and you also configure a transfer delay for the event policy action, the resulting transfer delay is the sum of the two delays.

Transient network problems can cause a file upload operation to fail. By default, if the file upload operation fails for any reason, the event policy does not retry the upload operation. However, you can configure an event policy to retry the file upload operation a specified number of times if the initial upload fails. You can also configure the time interval between each retry attempt.

Example: Defining Destinations for File Archiving by Event Policies

This example configures an archive site for event policies. Event policy actions that reference the configured destination upload specified files to that site.

- [Requirements on page 421](#)
- [Overview on page 422](#)
- [Configuration on page 423](#)
- [Verification on page 424](#)

Requirements

This example uses a device running Junos OS. No additional configuration beyond device initialization is required before configuring this example.

Overview

When an event policy action generates output files, you can archive the files for later analysis. Similarly, you might want to archive system files, including system log files, core files, and configuration files, from the time an event occurs.

When an event occurs, you can upload relevant files to a specified location for analysis. To archive files from an event policy, configure one or more *destinations* specifying the archive sites to which the files are uploaded. You then reference the configured destinations within event policies.

To define a destination archive site, include the **destinations** statement at the **[edit event-options]** hierarchy level.

```
[edit event-options]
destinations {
  destination-name {
    archive-sites {
      url <password password>;
    }
    transfer-delay seconds;
  }
}
```

The *destination-name* is a user-defined identifier, which is referenced by event policies. You can define multiple destinations with different archive sites.

For each destination, configure one or more archive site URIs, which are the actual sites to which the files are uploaded. If you specify multiple archive site URIs for a given destination, the device attempts to transfer to the first archive site in the list, moving to the next site in the list only if the transfer fails. Optionally, you can specify a plain-text password for login into an archive site.

Specify the archive site URI as a file URI, an active or passive FTP URI, or a Secure Copy (SCP) URI. Local device directories are also supported (for example, */var/tmp*). When you specify the archive site URI, do not add a forward slash (/) to the end of the URI.

```
file:<://host>/path
ftp://username@host:<port>url-path
pasvftp://username@host:<port>url-path
scp://username@host:<port>url-path
<path>/<filename>
```

The format for the destination filename is *device-name_filename_YYYYMMDD_HHMMSS*.

The **transfer-delay** statement allows you to specify the number of seconds the event process (eventd) waits before beginning to upload a file or multiple files to that destination. A transfer delay allows you to ensure that a large file, such as a core file, is completely generated before the upload begins. For more information, see [“Configuring the Delay Before Files Are Uploaded by an Event Policy” on page 431](#).

This example configures a new archive destination named `mgmt-archives`, which can be referenced in event policies for file archiving. The example configures two archive sites for this destination. The first site is the Secure Copy URI

"`scp://username@example.com/test`" for which a password is configured. The second site is a directory on the local device. The device attempts to transfer to the first archive site in the list, moving to the next site only if the transfer to the first site fails. The example configures a transfer delay of five seconds for all files uploaded to the `mgmt-archives` archive site.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set event-options destinations mgmt-archives archive-sites
  "scp://username@example.com/test" password PaSsWoRd
set event-options destinations mgmt-archives archive-sites /var/log
set event-options destinations mgmt-archives transfer-delay 5
```

Step-by-Step Procedure

Configure a new archive destination named `mgmt-archives` that can be referenced by event-policies.

1. Configure the identifier and associated archive sites for each destination. The device transfers to the first archive site in the list, moving to the next site only if the transfer to the first site fails.

```
[edit event-options destinations]
user@host# set mgmt-archives archive-sites scp://username@example.com/test
user@host# set mgmt-archives archive-sites /var/log
```

2. If authentication is required to access any of the archive sites, configure the required plain-text password for that site.

```
[edit event-options destinations]
user@host# set mgmt-archives archive-sites scp://username@example.com/test
password PaSsWoRd
```

3. (Optional) Configure the transfer delay associated with each destination. The `mgmt-archives` destination has a transfer delay of five seconds.

```
[edit event-options destinations]
user@host# set mgmt-archives transfer-delay 5
```

4. Commit the configuration.

```
user@host# commit
```

5. You can reference configured destinations in an event policy. For information about referencing destinations in event policies, see [“Example: Configuring an Event Policy to Upload Files” on page 424](#) and [“Configuring an Event Policy to Execute Operational Mode Commands” on page 433](#).

Verification

Verifying the Configuration

Purpose Issue the **show configuration event-options** operational mode command to review the resulting configuration.

Action

```
user@host> show configuration event-options
destinations {
  mgmt-archives {
    transfer-delay 5;
    archive-sites {
      "scp://username@example.com/test" password
      "$9$z3GRF9tu0lcrKO1bYoGq.OO1IEy"; ## SECRET-DATA
      /var/log;
    }
  }
}
```

Meaning In the sample output, the mgmt-archives destination has two archive sites and a transfer delay of five seconds. You can now reference this destination in event policies. When you reference the mgmt-archives destination in an event policy, specified files are uploaded to the first archive site after a five second delay. If the transfer to the first archive fails, the device attempts to upload the files to the **/var/log** archive site. For more information about referencing destinations in event policies, see [“Example: Configuring an Event Policy to Upload Files” on page 424](#).

Note that although the plain-text password is visible when you configure it, the configuration displays the encrypted password.

Example: Configuring an Event Policy to Upload Files

This example configures event policy actions that upload relevant files to a specified location for analysis.

- [Requirements on page 425](#)
- [Overview on page 425](#)
- [Configuration on page 427](#)
- [Verification on page 430](#)

Requirements

Before you begin:

- Configure the destinations that you will reference in the event policy. See [“Example: Defining Destinations for File Archiving by Event Policies”](#) on page 421.
- Configure the general event policy and triggering events.

Overview

When an event policy action generates output files, you can archive the files for later analysis. Similarly, you might want to archive system files, including system log files, core files, and configuration files, from the time an event occurs. You can configure an event policy to upload existing system files or to upload the output files generated from an invoked event-script or command at the time an event occurs. This section outlines the configuration hierarchies for uploading each of these file types using an event policy.

When you configure an event policy to upload files, you reference configured destinations within the event policy. Specify a destination name that is configured at the **[edit event-options destinations]** hierarchy level. For more information, see [“Example: Defining Destinations for File Archiving by Event Policies”](#) on page 421.

To upload system files to a configured archive site, configure the **upload** statement at the **[edit event-options policy *policy-name* then]** hierarchy level. If the configured events occur, the eventd process executes the upload action.

```
[edit event-options policy policy-name then]
upload filename (filename | committed) destination destination-name {
  retry-count number retry-interval seconds;
  transfer-delay seconds;
  user-name username;
}
```

The **upload filename committed destination *destination-name*** statement uploads the committed configuration file.

If desired, you can include multiple **upload** statements, one for each type of file to be archived. In the **filename** statement, specify a file or multiple files to be uploaded. You can specify multiple files with one **filename** configuration statement (sometimes called *filename globbing*). For example, to upload all files that are located in the **/var/log** directory and that start with the **messages** string, include the following statement:

```
upload filename /var/log/messages* destination destination-name;
```

When an event policy executes commands in response to an event, you can write the command output to a file. To configure an event policy to upload the generated output file to a configured archive site, include the following statements at the **[edit event-options policy *policy-name* then]** hierarchy level:

```
[edit event-options policy policy-name then]
execute-commands {
  destination destination-name {
    retry-count count retry-interval seconds;
    transfer-delay seconds;
  }
}
```

```

    output-filename filename;
}

```

When an event policy executes an event script in response to an event, you can write the script output to a file. To configure an event policy to upload the generated output file to a configured archive site, include the following statements at the **[edit event-options policy *policy-name* then]** hierarchy level:

```

[edit event-options policy policy-name then]
event-script filename {
  destination destination-name {
    retry-count count retry-interval seconds;
    transfer-delay seconds;
  }
  output-filename filename;
}

```

The **transfer-delay** statement listed in each hierarchy defines the time interval that the system waits before uploading the files specified by that event policy action. If you have also configured a transfer delay for the destination at the **[edit event-options destinations *destination-name*]** hierarchy level, the total transfer delay is the sum of the two delays. For more detailed information about transfer delays, see [“Configuring the Delay Before Files Are Uploaded by an Event Policy” on page 431](#).

If the first upload attempt fails, **retry-count** specifies the number of additional times the system attempts to upload the file. The **retry-interval** specifies the time interval that the system waits between upload attempts. For more information, see [“Configuring an Event Policy to Retry the File Upload Action” on page 432](#).

When an event policy uploads files, the files are named and time-stamped in the following format to ensure unique filenames:

device-name_filename_YYYYMMDD_HHMMSS

If a policy uploads multiple files within a 1-second period, the software gives each file a unique number as well, as follows:

device-name_filename_YYYYMMDD_HHMMSS_number

The number can be from 001 through 999. For example, if you have an event policy action with output filename **rpdp-messages** on **device1**, and this event policy is executed three times in 1 second, the files are named as follows:

- **device1_rpd-messages_20070623_132333**
- **device1_rpd-messages_20070623_132333_001**
- **device1_rpd-messages_20070623_132333_002**

In this example, **policy1** consists of the following statements, where **e1** is the triggering event. The example then configures the event policy to upload a log file and the committed configuration file as well as the output files generated from the **execute-commands** and **event-script** actions.

```

[edit event-options policy policy1]
events e1;
then {

```

```

execute-commands {
  commands {
    "show interfaces brief ge-*";
  }
}
event-script event-script1;
}

```

Configuration

- [Uploading System Files on page 427](#)
- [Uploading Command Output Files on page 428](#)
- [Uploading Event Script Output Files on page 429](#)
- [Results on page 430](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```

set event-options policy policy1 then upload filename /var/log/messages destination
  mgmt-archives transfer-delay 4
set event-options policy policy1 then upload filename /var/log/messages destination
  mgmt-archives retry-count 5 retry-interval 4
set event-options policy policy1 then upload filename /var/log/messages destination
  mgmt-archives user-name admin
set event-options policy policy1 then upload filename /var/log/messages destination
  mgmt-server
set event-options policy policy1 then upload filename committed destination
  mgmt-archives
set event-options policy policy1 then execute-commands output-filename ge-interfaces
set event-options policy policy1 then execute-commands destination mgmt-archives
  transfer-delay 5
set event-options policy policy1 then execute-commands destination mgmt-archives
  retry-count 5 retry-interval 4
set event-options policy policy1 then event-script event-script1 output-filename
  policy1-script-output
set event-options policy policy1 then event-script event-script1 destination mgmt-archives
  transfer-delay 5
set event-options policy policy1 then event-script event-script1 destination mgmt-archives
  retry-count 5 retry-interval 4

```

Uploading System Files

Step-by-Step Procedure

Configure the event policy **policy1** to upload the system file **/var/log/messages** to the archive sites **mgmt-archives** and **mgmt-server**. Additionally, upload the committed configuration to the archive site **mgmt-archives**. The destination archive sites should already be configured at the **[edit event-options destinations]** hierarchy level

1. Configure the **upload** statement at the **[edit event-options policy policy1 then]** hierarchy level. Include the file to archive and the destination archive site.

```

[edit event-options policy policy1 then]
bsmith@R1# set upload filename /var/log/messages destination mgmt-archives
bsmith@R1# set upload filename /var/log/messages destination mgmt-server

```

2. To upload the committed configuration file, specify the filename value as **committed**.

```
[edit event-options policy policy1 then]
bsmith@R1# set upload filename committed destination mgmt-archives
```

3. (Optional) Configure the transfer delay associated with each file and destination. The following configuration mode command sets the transfer delay for the **/var/log/messages** file to 4 seconds when uploaded to the mgmt-archives destination. If you have also configured a transfer delay for the destination, the total delay is the sum of the two delays.

```
[edit event-options policy policy1 then]
bsmith@R1# set upload filename /var/log/messages destination mgmt-archives
transfer-delay 4
```

4. (Optional) Configure the retry count and retry interval associated with a file and destination. In this example, if the **/var/log/messages** file fails to upload to the mgmt-archives site, the system attempts the upload up to 5 more times and waits 4 seconds in between each attempt.

```
[edit event-options policy policy1 then]
bsmith@R1# set upload filename /var/log/messages destination mgmt-archives
retry-count 5 retry-interval 4
```

5. (Optional) Configure the username associated with a file and destination. The system uploads the file using the privileges of the specified user.

```
[edit event-options policy policy1 then]
bsmith@R1# set upload filename /var/log/messages destination mgmt-archives
user-name admin
```

6. Commit the configuration.

```
[edit event-options policy policy1 then]
bsmith@R1# commit
```

Uploading Command Output Files

Step-by-Step Procedure Configure the event policy **policy1** to write command output to a file and upload the generated file to the destination mgmt-archives, which is already configured at the **[edit event-options destinations]** hierarchy level.

1. When the event policy invokes the **execute-commands** action, the command output can be written to a file. Configure the filename of the generated output file.

```
[edit event-options policy policy1 then]
bsmith@R1# set execute-commands output-filename ge-interfaces
```

2. Configure the **destination** statement to upload the generated file to the desired archive site.

```
[edit event-options policy policy1 then]
bsmith@R1# set execute-commands destination mgmt-archives
```

3. (Optional) Configure the transfer delay for each destination. The following command sets the transfer delay for files uploaded to the mgmt-archives destination to 5 seconds.

```
[edit event-options policy policy1 then]
```

```
bsmith@R1# set execute-commands destination mgmt-archives transfer-delay 5
```

4. (Optional) Configure the retry count and retry interval associated with each destination. In this example, if the output file fails to upload to the mgmt-archives site, the system attempts the upload up to 5 more times and waits 4 seconds in between each attempt.

```
[edit event-options policy policy1 then]
bsmith@R1# set execute-commands destination mgmt-archives retry-count 5
retry-interval 4
```

5. Commit the configuration.

```
[edit event-options policy policy1 then]
bsmith@R1# commit
```

Uploading Event Script Output Files

Step-by-Step Procedure Configure the event policy **policy1** to write event-script output to a file and upload the generated file to the destination mgmt-archives, which is already configured at the **[edit event-options destinations]** hierarchy level. In this example, the event policy invokes an event script named **event-script1**.

1. When the event policy invokes an event script, the script output can be written to a file. Configure the filename of the generated output file.

```
[edit event-options policy policy1 then]
bsmith@R1# set event-script event-script1 output-filename policy1-script-output
```

2. Configure the **destination** statement to upload the generated file to the desired archive site.

```
[edit event-options policy policy1 then]
bsmith@R1# set event-script event-script1 destination mgmt-archives
```

3. (Optional) Configure the transfer delay for each destination. The following command sets the transfer delay for files uploaded to the mgmt-archives destination to 5 seconds.

```
[edit event-options policy policy1 then]
bsmith@R1# set event-script event-script1 destination mgmt-archives
transfer-delay 5
```

4. (Optional) Configure the retry count and retry interval associated with each destination. In this example, if the output file fails to upload to the mgmt-archives site, the system attempts the upload up to 5 more times and waits 4 seconds in between each attempt.

```
[edit event-options policy policy1 then]
bsmith@R1# set event-script event-script1 destination mgmt-archives retry-count 5
retry-interval 4
```

5. Commit the configuration.

```
[edit event-options policy policy1 then]
bsmith@R1# commit
```

Results

```
[edit event-options policy policy1 then]
upload filename /var/log/messages destination mgmt-archives {
  user-name admin;
  transfer-delay 4;
  retry-count 5 retry-interval 4;
}
upload filename /var/log/messages destination mgmt-server
upload filename committed destination mgmt-archives;
execute-commands {
  commands {
    "show interfaces brief ge-*";
  }
  output-filename ge-interfaces;
  destination mgmt-archives {
    transfer-delay 5;
    retry-count 5 retry-interval 4;
  }
}
event-script event-script1 {
  output-filename policy1-script-output;
  destination mgmt-archives {
    transfer-delay 5;
    retry-count 5 retry-interval 4;
  }
}
```

Verification**Verifying the Upload**

Purpose When the configured event triggers the event policy, the system uploads the generated output files and the specified system files to the URL defined in the mgmt-archives destination. On the destination server, verify that all files have been uploaded.

Action On the destination server, verify that all uploaded files are present.

```
% ls
R1_ge-interfaces_20111209_213452
R1_juniper.conf.gz_20111209_213409
R1_messages_20111209_212941
R1_policy1-script-output_20111209_212619
```

Meaning Note that the filename format for each file includes the device name, the filename, and the date and time stamp.

If all of the uploaded files are present, the event policy and upload actions are working correctly. If none of the files are uploaded, verify that the destination is configured and that the archive site URL and any required password is entered correctly. For information about configuring destinations, see [“Example: Defining Destinations for File Archiving by Event Policies” on page 421](#). If a portion of the files are missing, configure a longer transfer delay and increase the retry count and retry interval for those files.

- Related Documentation**
- [Example: Defining Destinations for File Archiving by Event Policies on page 421](#)
 - [Configuring the Delay Before Files Are Uploaded by an Event Policy on page 431](#)
 - [Configuring an Event Policy to Retry the File Upload Action on page 432](#)

Configuring the Delay Before Files Are Uploaded by an Event Policy

A transfer delay allows you to specify the number of seconds the event process (eventd) waits before beginning to upload a file or multiple files. A transfer delay allows you to ensure that a large file, such as a core file, is completely generated before the upload begins.

As described in “[Example: Defining Destinations for File Archiving by Event Policies](#)” on [page 421](#), you can associate a transfer delay with a destination. If you associate a transfer delay with a destination, the transfer delay applies to all file upload actions that use the destination.

In the following example, the **some-dest** destination is common for both event policies, **policy1** and **policy2**. A transfer delay of 2 seconds is associated with the **some-dest** destination and applies to uploading the output files to the destination for both event policies.

```
[edit event-options]
policy policy1 {
  events e1;
  then {
    execute-commands {
      commands {
        "show version";
      }
      output-filename command-output.txt;
      destination some-dest;
    }
  }
}
policy policy2 {
  events e2;
  then {
    event-script bar.xsl {
      output-filename event-script-output.txt;
      destination some-dest;
    }
  }
}
destinations {
  some-dest {
    transfer-delay 2;
    archive-sites {
      "scp://robot@my.big.com/foo/moo" password "password";
      "scp://robot@my.little.com/foo/moo" password "password";
    }
  }
}
```

Suppose you have multiple event policy actions that use the same destination. For some of these event policy actions, you want a transfer delay, and for other event policy actions you want no transfer delay. To assign a transfer delay to a single event policy action, include the optional **transfer-delay** statement for each action:

transfer-delay *seconds*;

You can include this statement at the following hierarchy levels:

- [edit **event-options policy** *policy-name* then **event-script** *filename* **destination** *destination-name*]
- [edit **event-options policy** *policy-name* then **execute-commands** **destination** *destination-name*]
- [edit **event-options policy** *policy-name* then **upload** *filename* (*filename* | committed) **destination** *destination-name*]

If you configure a transfer delay at the [edit **event-options destinations** *destination-name*] hierarchy level, and you also configure a transfer delay for the event policy action, the resulting transfer delay is the sum of the two:

Total transfer-delay =
transfer-delay (destination) + transfer-delay (event-policy-action)

For a configuration example, see “[Example: Assigning a Transfer Delay to an Event Policy Action](#)” on page 472.

Configuring an Event Policy to Retry the File Upload Action

Transient network problems can cause a file upload operation to fail. When this happens, you might want to retry the file upload operation. By default, if the file upload operation fails for any reason, the event policy does not retry the upload operation.

To configure the policy to retry a file upload operation, include the optional **retry-count** and **retry-interval** statements:

retry-count *number* **retry-interval** *seconds*;

You can include these statements at the following hierarchy levels:

- [edit **event-options policy** *policy-name* then **event-script** *filename* **destination** *destination-name*]
- [edit **event-options policy** *policy-name* then **execute-commands** **destination** *destination-name*]
- [edit **event-options policy** *policy-name* then **upload** *filename* (*filename* | committed) **destination** *destination-name*]

The **retry-count** statement sets the number of times the policy retries the upload operation if the upload fails. The default value for the **retry-count** statement is 0 and the maximum is 10.

If you include the **retry-count** statement, you can also include the **retry-interval** statement, which sets the time interval (in seconds) between each retry.

For a configuration example, see [“Example: Retrying the File Upload Action” on page 480](#).

Configuring an Event Policy to Execute Operational Mode Commands

Operational mode commands request that the device running Junos OS perform an operation or provide diagnostic output. They allow you to view statistics and information about a device's current operating status. They also allow you to take corrective actions, such as restarting software processes, taking a PIC offline and back online, switching to redundant interfaces, and adjusting Label Switching Protocol (LSP) bandwidth. For more information about operational mode commands, see [CLI Explorer](#).

You can configure a policy that causes operational mode commands to be issued and the output of those commands to be uploaded to a specified location for analysis.

To configure such a policy, include the following statements at the **[edit event-options]** hierarchy level:

```
[edit event-options]
policy policy-name {
  events [ events ];
  then {
    execute-commands {
      commands {
        "command";
      }
      output-filename filename;
      output-format (text | xml);
      destination destination-name;
    }
  }
}
```

In the **events** statement, you can list multiple events. If one or more of the listed events occurs, the operational mode commands are issued. To view a list of the events that can be referenced in an event policy, issue the **set event-options policy policy-name events ?** configuration mode command:

```
[edit]
user@host# set event-options policy policy-name events ?
Possible completions:
<event>
[          Open a set of values
acct_accounting_error
```

```
acct_accounting_fopen_error
...
```

Some of the system log messages that you can reference in an event policy are not listed in the output of the **set event-options policy *policy-name* events ?** command. For information about referencing these system log messages in your event policies, see [“Using Nonstandard System Log Messages to Trigger Event Policies” on page 419](#).

In addition, you can reference internally generated events, which are discussed in [“Generating Internal Events to Trigger Event Policies” on page 419](#).

In the **commands** statement, you can issue multiple operational mode commands upon receipt of a specific event. Enclose each command in quotation marks (“ ”). The eventd process issues the commands in the order in which they appear in the configuration. For example, in the following configuration, the execution of **policy1** causes the **show interfaces** command to be issued first, followed by the **show chassis alarms** command:

```
[edit event-options policy policy1 then execute-commands]
user@host# show
commands {
  "show interfaces";
  "show chassis alarms";
}
```

You can include variables in the command to allow data from the triggering event to be automatically included in the command syntax. The eventd process replaces each variable with values contained in the event that triggers the policy. You can use command variables of the following forms:

- **{{*attribute-name*}}**—The double dollar sign (\$\$) notation represents the event that is triggering a policy. When combined with an attribute name, the variable is replaced by the value of the attribute name in the triggering event. For example, **{{*interface-name*}}** stands for the value of the **interface-name** attribute in the triggering event.
- **`\${*event.attribute-name*}`**—The **`\${*event.attribute-name*}`** notation represents the most recent event that matches the specified event. The variable is replaced by the value of the attribute name of the most recent event that matches **event**. For example, when a policy issues the **show interfaces** **`\${COSD_CHAS_SCHED_MAP_INVALID.interface-name}`** command, the **`\${COSD_CHAS_SCHED_MAP_INVALID.interface-name}`** variable is substituted by the **interface-name** attribute of the most recent **COSD_CHAS_SCHED_MAP_INVALID** event cached by the event process.

For a given event, you can view a list of event attributes that you can reference in an operational mode command by issuing the **help syslog *event-name*** command:

```
user@host> help syslog event-name
```

For example, in the following command output, text in angle brackets (< >) shows that **classifier-type** is an attribute of the **cosd_unknown_classifier** event:

```
user@host> help syslog cosd_unknown_classifier
Name:          COSD_UNKNOWN_CLASSIFIER
```

```
Message:      rtsock classifier type <classifier-type> is invalid
...
```

You can filter the output of a search by using the pipe (|) symbol. The following example lists the filters that can be used with the pipe symbol:

```
user@host# help syslog | ?
Possible completions:
count          Count occurrences
display        Show additional kinds of information
except         Show only text that does not match a pattern
find           Search for first occurrence of pattern
hold           Hold text without exiting the --More-- prompt
last           Display end of output only
match          Show only text that matches a pattern
no-more        Don't paginate output
request        Make system-level requests
resolve        Resolve IP addresses
save           Save output text to file
trim           Trim specified number of columns from start of line
```

For more information about using the pipe symbol, see the *CLI User Guide*.

Another way to view a list of event attributes is to issue the **set attributes-match event?** configuration mode command at the **[edit event-options policy *policy-name*]** hierarchy level:

```
[edit event-options policy policy-name]
user@host# set attributes-match event ?
```

For example, in the following command output, the **event.attribute** list shows that **classifier-type** is an attribute of the **cosd_unknown_classifier** event:

```
[edit event-options policy policy-name]
user@host# set attributes-match cosd_unknown_classifier?
Possible completions:
<from-event-attribute> First attribute to compare
cosd_unknown_classifier.classifier-type
```

NOTE: In this **set** command, there is no space between the event name and the question mark (?).

To view a list of all event attributes that you can reference, issue the **set attributes-match ?** configuration mode command at the **[edit event-options policy *policy-name*]** hierarchy level:

```
[edit event-options policy policy-name]
user@host# set attributes-match ?
Possible completions:
<from-event-attribute> First attribute to compare
acct_accounting_ferror
acct_accounting_fopen_error
...
```

In the **output-filename** statement, assign the name of the file to which to write command output for the specified commands. The filename format is *hostname_filename_YYYYMMDD_HHMMSS_index-number*.

For each uploaded file, a hostname and timestamp ensure that the uploaded files have unique filenames. If a policy is triggered multiple times in a 1-second period, an index number is added to ensure the filenames are unique. The index number range is 001 through 999.

For example, on a device named **r1**, if you configure the output filename to be **ifl-events**, and this event policy is triggered three times in 1 second, the files are named:

- **r1_ifl-events_20060623_132333**
- **r1_ifl-events_20060623_132333_001**
- **r1_ifl-events_20060623_132333_002**

By default, the command output format is Junos Extensible Markup Language (XML). To change this, include the **output-format text** statement. This causes the command output to be in formatted ASCII text.

In the **destination** statement, include the destination name that you configured at the **[edit event-options destinations]** hierarchy level. For more information, see [“Example: Defining Destinations for File Archiving by Event Policies” on page 421](#).

For a configuration example, see [“Example: Correlating Events Based on Receipt of Other Events Within a Specified Time Interval” on page 476](#).

Configuring an Event Policy to Change the Configuration

- [Configuring an Event Policy to Change the Configuration Overview on page 436](#)
- [Example: Changing the Configuration Using an Event Policy on page 437](#)
- [Example: Changing the Interface Configuration in Response to an Event on page 443](#)

Configuring an Event Policy to Change the Configuration Overview

An event policy performs actions in response to specific events. You can configure custom event policies in the Junos OS configuration that listen for a specific event or correlated events and then execute an action, which might include creating a log file, invoking Junos OS commands, or executing an event script.

At times, it might be necessary to modify the configuration in response to a particular event. Prior to Junos OS Release 12.1, an event policy invoked an event script to execute configuration changes. Starting with Junos OS Release 12.1, you can configure an event policy to modify the configuration using Junos OS configuration mode commands and then commit the updated configuration. For example, for an **SNMP_TRAP_LINK_DOWN** or **SNMP_TRAP_LINK_UP** event for a given interface, the event policy action might modify the configuration of a static route to adjust its metric or modify its next hop.

You configure event policy actions at the **[edit event-options policy policy-name then]** hierarchy level. To modify the configuration through an event policy, configure the **change-configuration** statement and specify the configuration mode commands that

are executed upon receipt of the configured event or events. Enclose each command in quotation marks (" "), and specify the complete statement path to the element, identifier, or value as you do in configuration mode when issuing commands at the **[edit]** hierarchy level.

The event process (eventd) executes the configuration commands in the order in which they appear in the event policy configuration. The commands update the candidate configuration, which is then committed, provided that no commit errors occur.

You can configure the **commit-options** child statement to customize the event policy commit operation. You can commit the changes on a single Routing Engine or configure the **synchronize** option to synchronize the commit on both Routing Engines. The Routing Engine on which you execute this command copies and loads its candidate configuration to the other Routing Engine. Both Routing Engines perform a syntax check on the candidate configuration file. If no errors are found, the configuration is activated and becomes the current operational configuration on both Routing Engines. By default, the **synchronize** option does not work if the responding Routing Engine has uncommitted configuration changes. However, you can enforce commit synchronization on the Routing Engines and ignore any warnings by configuring the **force** option.

Additionally, if you are testing or troubleshooting an event policy, you can configure the **check** commit option to verify the candidate configuration syntax without committing the changes. On dual control plane systems, when the **check synchronize** statement is configured, the candidate configuration on one control plane is copied to the other control plane, and the system verifies that both candidate configurations are syntactically correct. The **check** statement and the other **commit-options** statements are mutually exclusive.

The change configuration action might fail while acquiring a lock on the configuration. Configure the **retry** statement to have the system attempt the change configuration event policy action a specified number of times if the first attempt fails. Configure the **user-name** statement to execute the configuration changes and commit under the privileges of a specific user. If you do not specify a username, the action is executed as user **root**.

Example: Changing the Configuration Using an Event Policy

It might be necessary to modify the configuration in response to a particular event. Starting with Junos OS Release 12.1, you can configure an event policy to make and commit configuration changes when the event policy is triggered by one or more specific events.

This example simulates an SNMP_TRAP_LINK_DOWN event for a specific interface. Upon receipt of the event, the event policy modifies the configuration of a static route to use a new next-hop IP address through a different exit interface.

- [Requirements on page 438](#)
- [Overview on page 438](#)
- [Configuration on page 438](#)
- [Verification on page 441](#)
- [Troubleshooting on page 443](#)

Requirements

- Routing, switching, or security device running Junos OS Release 12.1 or later.

Overview

You can configure an event policy action to modify the configuration when the policy is triggered by a single event or correlated events. Suppose you have a static route to the 10.1.10.0/24 network with a next-hop IP address of 10.1.2.1 through the exit interface ge-0/3/1. At some point, this interface goes down, triggering an SNMP_TRAP_LINK_DOWN event.

This example creates an event policy named update-on-snmp-trap-link-down. The event policy is configured so that the eventd process listens for an SNMP_TRAP_LINK_DOWN event associated with the interface ge-0/3/1.0. If the interface goes down, the event policy executes a change configuration action. Commands are executed in the order in which they appear in the event policy. The event policy configuration commands remove the static route through the ge-0/3/1 exit interface and create a new static route to the same target network with a next-hop IP address of 10.1.3.1 through the exit interface ge-0/2/1.

The event policy change configuration commit operation is executed under the username bsmith with a commit comment specifying that the change was made through the associated event policy. The retry count is set to 5 and the retry interval is set to 4 seconds. If the initial attempt to issue the configuration change fails, the system attempts the configuration change 5 additional times and waits 4 seconds between each attempt.

Although not presented here, you might have a second, similar event policy that executes a change configuration action to update the static route when the interface comes back up. In that case the policy would trigger on the SNMP_TRAP_LINK_UP event for the same interface.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set event-options policy update-on-snmp-trap-link-down events snmp_trap_link_down
set event-options policy update-on-snmp-trap-link-down attributes-match
  snmp_trap_link_down.interface-name matches ge-0/3/1.0
set event-options policy update-on-snmp-trap-link-down then change-configuration
  retry count 5
set event-options policy update-on-snmp-trap-link-down then change-configuration
  retry interval 4
set event-options policy update-on-snmp-trap-link-down then change-configuration
  commands "delete routing-options static route 10.1.10.0/24 next-hop"
set event-options policy update-on-snmp-trap-link-down then change-configuration
  commands "set routing-options static route 10.1.10.0/24 next-hop 10.1.3.1"
set event-options policy update-on-snmp-trap-link-down then change-configuration
  user-name bsmith
```

```

set event-options policy update-on-snmp-trap-link-down then change-configuration
commit-options log "updating configuration from event policy
update-on-snmp-trap-link-down"
set routing-options static route 10.1.10.0/24 next-hop 10.1.2.1
set system syslog file syslog-event-daemon-warning daemon warning

```

Configuring the Event Policy

Step-by-Step Procedure

1. Create and name the event policy.

```

[edit]
bsmith@R1# edit event-options policy update-on-snmp-trap-link-down

```

2. Configure the **events** statement so that the event policy triggers on the SNMP_TRAP_LINK_DOWN event.

Set the **attributes-match** statement so that the policy triggers only if the SNMP_TRAP_LINK_DOWN event occurs for the ge-0/3/1.0 interface.

```

[edit event-options policy update-on-snmp-trap-link-down]
bsmith@R1# set events snmp_trap_link_down
bsmith@R1# set attributes-match snmp_trap_link_down.interface-name matches
ge-0/3/1.0

```

3. Specify the configuration mode commands that are executed if the ge-0/3/1 interface goes down.

Configure each command on a single line, enclose the command string in quotes, and specify the complete statement path.

```

[edit event-options policy update-on-snmp-trap-link-down then
change-configuration]
bsmith@R1# set commands "delete routing-options static route 10.1.10.0/24
next-hop"
bsmith@R1# set commands "set routing-options static route 10.1.10.0/24 next-hop
10.1.3.1"

```

4. Configure the commit options.

Configure the **log** option with a comment describing the configuration changes. The comment is added to the commit logs after a successful commit operation is made through the associated event policy.

```

[edit event-options policy update-on-snmp-trap-link-down then
change-configuration]
bsmith@R1# set commit-options log "updating configuration from event policy
update-on-snmp-trap-link-down"

```

If you have dual Routing Engines, configure the **synchronize** option to commit the configuration on both Routing Engines. Include the **force** option to force the commit on the other Routing Engine, ignoring any warnings. This example does not configure the **synchronize** and **force** options.

5. (Optional) Configure the retry count and retry interval.

In this example, **count** is set to 5 and the **interval** is 4 seconds.

```

[edit event-options policy update-on-snmp-trap-link-down then
change-configuration]

```

```
bsmith@R1# set retry count 5 interval 4
```

6. (Optional) Configure the username under whose privileges the configuration changes and commit are made.

If you do not specify a username, the action is executed as user **root**.

```
[edit event-options policy update-on-snmp-trap-link-down then
  change-configuration]
bsmith@R1# set user-name bsmith
```

7. Configure a new log file at the **[edit system syslog]** hierarchy level to record syslog events of facility **daemon** and severity **warning**.

This captures the SNMP_TRAP_LINK_DOWN events.

```
[edit system syslog]
bsmith@R1# set file syslog-event-daemon-warning daemon warning
```

8. To test this example, configure a static route to the 10.1.10.0/24 network with a next hop IP address of 10.1.2.1.

```
[edit]
bsmith@R1# set routing-options static route 10.1.10.0/24 next-hop 10.1.2.1
```

9. Commit the configuration.

```
bsmith@R1# commit
```

10. Review the **[edit routing-options static]** hierarchy level of the configuration before disabling the ge-0/3/1 interface, and note the next hop IP address.

```
bsmith@R1> show configuration routing-options static
...
route 10.1.10.0/24 next-hop 10.1.2.1;
...
```

11. To manually test the event policy, take the ge-0/3/1 interface temporarily offline to generate the SNMP_TRAP_LINK_DOWN event.

```
[edit]
bsmith@R1# set interfaces ge-0/3/1 disable
bsmith@R1# commit
```

Results

```
[edit]
event-options {
  policy update-on-snmp-trap-link-down {
    events snmp_trap_link_down;
    attributes-match {
      snmp_trap_link_down.interface-name matches ge-0/3/1.0;
    }
  }
  then {

```

Verification

Confirm that the configuration is working properly.

- [Verifying the Status of the Interface on page 441](#)
- [Verifying the Commit on page 441](#)
- [Verifying the Configuration Changes on page 442](#)

Verifying the Status of the Interface

Purpose Verify that the ge-0/3/1 interface is down and that it triggered the SNMP_TRAP_LINK_DOWN event.

Action Issue the **show interfaces ge-0/3/1** operational mode command. The command output shows that the interface is administratively offline.

```

bsmith@R1> show interfaces ge-0/3/1
Physical interface: ge-0/3/1, Administratively down, Physical link is Down
<output omitted>

```

Review the contents of the system log file configured in Step 7. The output shows that the ge-0/3/1.0 interface went down and generated an SNMP_TRAP_LINK_DOWN event.

```

bsmith@R1> show log syslog-event-daemon-warning
Oct 10 18:00:57 R1 mib2d[1371]: SNMP_TRAP_LINK_DOWN: ifIndex 531, ifAdminStatus
down(2), ifOperStatus down(2), ifName ge-0/3/1.0

```

Verifying the Commit

Purpose Verify that the event policy commit operation was successful by reviewing the commit log and the messages log file.

Action Issue the **show system commit** operational mode command to view the commit log. In this example, the log confirms that the configuration was committed through the event policy under the privileges of user bsmith at the given date and time.

```
bsmith@R1> show system commit
0   2011-10-10 18:01:03 PDT by bsmith via junoscript
    updating configuration from event policy update-on-snmp-trap-link-down
1   2011-09-02 14:16:44 PDT by admin via netconf
2   2011-07-08 14:33:46 PDT by root via other
```

Review the **messages** log file. Upon receipt of the SNMP_TRAP_LINK_DOWN event, Junos OS executed the configured event policy action to modify and commit the configuration. The commit operation occurred under the privileges of user bsmith.

```
bsmith@R1> show log messages | last 20
...
Oct 10 18:00:57 R1 mib2d[1371]: SNMP_TRAP_LINK_DOWN: ifIndex 531, ifAdminStatus
    down(2), ifOperStatus down(2), ifName ge-0/3/1.0
Oct 10 18:00:59 R1 file[17575]: UI_COMMIT: User 'bsmith' requested 'commit'
    operation (comment: updating configuration from event policy
    update-on-snmp-trap-link-down)
Oct 10 18:01:03 R1 eventd: EVENTD_CONFIG_CHANGE_SUCCESS: Configuration change
    successful: while executing policy update-on-snmp-trap-link-down with user bsmith
    privileges
```

NOTE: If you configure a different log file, review the file specific to your configuration.

Meaning The output from the **show system commit** operational mode command and the **messages** log file verify that the commit operation, which was made through the event policy under the privileges of the user bsmith, was successful. The **show system commit** output and **messages** log file reference the commit comment specified in the **log** statement at the **[edit event-options policy update-on-snmp-trap-link-down then change-configuration commit-options]** hierarchy level.

Verifying the Configuration Changes

Purpose Verify the configuration changes by reviewing the **[edit routing-options static]** hierarchy level of the configuration after disabling the ge-0/3/1 interface.

Action Issue the following operational mode command:

```
bsmith@R1> show configuration routing-options static
...
route 10.1.10.0/24 next-hop 10.1.3.1;
...
```

Meaning The configured next hop has been modified by the event policy to the new IP address 10.1.3.1, which has its route through the exit interface ge-0/2/1.

Troubleshooting

- [Troubleshooting Commit Errors on page 443](#)

Troubleshooting Commit Errors

Problem The triggered event policy does not make the specified configuration changes, and the logs verify that the commit was unsuccessful.

```
bsmith@R1> show log messages | last 20
...
Oct 10 17:48:59 R1 mib2d[1371]: SNMP_TRAP_LINK_DOWN: ifIndex 531, ifAdminStatus
down(2), ifOperStatus down(2), ifName ge-0/3/1.0
Oct 10 17:49:01 R1 file[17142]: UI_LOAD_EVENT: User 'bsmith' is performing a
'rollback'
Oct 10 17:49:01 R1 eventd: EVENTD_CONFIG_CHANGE_FAILED: Configuration change
failed: rpc to management daemon failed while executing policy
update-on-snmp-trap-link-down with user bsmith privileges
```

A failed commit might occur if the configuration is locked or if the configuration mode commands have the incorrect syntax or order.

Solution Check the configuration mode commands at the **[edit event-options policy update-on-snmp-trap-link-down then change-configuration commands]** hierarchy level, and verify that the syntax and the order of execution are correct.

Additionally, increase the retry count and interval options so that if the configuration is locked, the event policy attempts the configuration changes a specified number of times after the first failed instance.

Example: Changing the Interface Configuration in Response to an Event

It might be necessary to modify the configuration in response to a particular event. Starting with Junos OS Release 12.1, you can configure an event policy to make and commit configuration changes when the event policy is triggered by one or more specific events.

This example uses a real-time performance monitoring (RPM) probe to generate PING_TEST_FAILED events for a given interface. Upon receipt of the first instance of two PING_TEST_FAILED events within a 5-minute period from the configured RPM probe, the event policy executes a change configuration event policy action that modifies the configuration to administratively disable the specified interface. This type of action might be necessary if you have an unstable, flapping interface that is consistently affecting network performance.

- [Requirements on page 444](#)
- [Overview on page 444](#)
- [Configuration on page 444](#)
- [Verification on page 447](#)

Requirements

- Routing, switching, or security device running Junos OS Release 12.1 or later.

Overview

This example creates an event policy named `disable-on-ping-failure`. The event policy is configured so that the `eventd` process listens for `PING_TEST_FAILED` events generated by a specific RPM probe and associated with the `ge-0/3/1` interface. If two `PING_TEST_FAILED` events occur for the given interface within a 5-minute interval, the event policy executes a change configuration action. The event policy configuration commands administratively disable the interface.

To test the event policy, the example configures an RPM probe that pings the IP address associated with the `ge-0/3/1` interface every 60 seconds. In this example, the `ge-0/3/1.0` interface is configured with the IPv4 address `10.1.4.1/26`. If the ping fails, the RPM probe generates a `PING_TEST_FAILED` event. Because multiple RPM tests could be running simultaneously, the event policy matches the `owner-name` and `test-name` attributes of the received `PING_TEST_FAILED` events to the RPM probe owner name and test name. When the RPM probe generates two `PING_TEST_FAILED` events, it triggers the event policy, which disables the interface.

This policy also demonstrates how to restrict the execution of the same configuration change multiple times because of occurrences of the same event or correlated events. In this example, the **trigger on 1** statement specifies that only the first occurrence of two correlated `PING_TEST_FAILED` events triggers the configuration change. The `PING_TEST_FAILED` events must occur within a 5-minute interval (300 seconds) to trigger the event policy.

Configuration

Configuring the RPM Probe

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set services rpm probe icmp-ping-probe test ping-probe-test
set services rpm probe-type icmp-ping test-interval 60 target address 10.1.4.1
set system syslog file syslog-event-daemon-info daemon info
```

Step-by-Step Procedure

To configure the RPM probe, which creates the `PING_TEST_FAILED` events for this example:

1. Create an RPM probe named `ping-probe-test` at the **[edit services rpm]** hierarchy level to ping the `ge-0/3/1` interface.

```
[edit services rpm]
bsmith@R1# set probe icmp-ping-probe test ping-probe-test
```
2. Configure the RPM probe to send ICMP echo requests to the `ge-0/3/1` interface at IP address `10.1.4.1`, and set **test-interval** to 60 to issue the test every 60 seconds.

```
[edit services rpm probe icmp-ping-probe test ping-probe-test]
```

```
bsmith@R1# set probe-type icmp-ping test-interval 60 target address 10.1.4.1
```

3. Configure a new log file at the **[edit system syslog]** hierarchy level to record syslog events of facility **daemon** and severity **info**.

This captures the events sent during the probe tests.

```
[edit system syslog]
bsmith@R1# set file syslog-event-daemon-info daemon info
```

4. Commit the configuration.

```
bsmith@R1# commit
```

```
Results [edit]
services {
  rpm {
    probe icmp-ping-probe {
      test ping-probe-test {
        probe-type icmp-ping;
        target address 10.1.4.1;
        test-interval 60;
      }
    }
  }
}
system {
  syslog {
    file syslog-event-daemon-info {
      daemon info;
    }
  }
}
```

Configuring the Event Policy

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set event-options policy disable-on-ping-failure events ping_test_failed
set event-options policy disable-on-ping-failure within 300 trigger on
set event-options policy disable-on-ping-failure within 300 trigger 1
set event-options policy disable-on-ping-failure attributes-match
ping_test_failed.test-owner matches icmp-ping-probe
set event-options policy disable-on-ping-failure attributes-match
ping_test_failed.test-name matches ping-probe-test
set event-options policy disable-on-ping-failure then change-configuration retry count 5
set event-options policy disable-on-ping-failure then change-configuration retry interval
4
set event-options policy disable-on-ping-failure then change-configuration commands
"set interfaces ge-0/3/1 disable"
set event-options policy disable-on-ping-failure then change-configuration user-name
bsmith
set event-options policy disable-on-ping-failure then change-configuration
commit-options log "updating configuration from event policy disable-on-ping-failure"
```

**Step-by-Step
Procedure**

1. Create and name the event-policy.

```
[edit]
bsmith@R1# edit event-options policy disable-on-ping-failure
```

2. Configure the event policy to match on the PING_TEST_FAILED event if it occurs twice within 5 minutes (300 seconds).

The **trigger on 1** statement specifies that only the first set of correlated PING_TEST_FAILED events triggers this policy.

The **attributes-match** statement is set so that the policy triggers only on the PING_TEST_FAILED events generated by the associated RPM probe.

```
[edit event-options policy disable-on-ping-failure]
bsmith@R1# set events ping_test_failed
bsmith@R1# set within 300 trigger on 1
bsmith@R1# set attributes-match ping_test_failed.test-owner matches
icmp-ping-probe
bsmith@R1# set attributes-match ping_test_failed.test-name matches
ping-probe-test
```

3. Specify the configuration mode commands that are executed if the event policy triggers.

Configure each command on a single line, enclose the command string in quotes, and specify the complete statement path.

```
[edit event-options policy disable-on-ping-failure then change-configuration]
bsmith@R1# set commands "set interfaces ge-0/3/1 disable"
```

4. (Optional) Configure the retry count and retry interval.

In this example, **count** is set to 5, and the **interval** is 4 seconds.

```
[edit event-options policy disable-on-ping-failure then change-configuration]
bsmith@R1# set retry count 5 interval 4
```

5. Configure the commit options.

Configure the **log** option with a comment describing the configuration changes. The comment is added to the commit logs after a successful commit operation is made through the associated event policy.

```
[edit event-options policy disable-on-ping-failure then change-configuration]
bsmith@R1# set commit-options log "updating configuration from event policy
disable-on-ping-failure"
```

If you have dual Routing Engines, configure the **synchronize** option to commit the configuration on both Routing Engines. Include the **force** option to force the commit on the other Routing Engine, ignoring any warnings. This example does not configure the **synchronize** and **force** options.

6. (Optional) Configure the username under whose privileges the configuration changes and commit are made.

If you do not specify a username, the action is executed as user **root**.

```
[edit event-options policy disable-on-ping-failure then change-configuration]
bsmith@R1# set user-name bsmith
```

7. Commit the configuration.

```
bsmith@R1# commit
```

8. Review the output of the **show interfaces ge-0/3/1** operational mode command before the configuration change takes place.

The interface should be enabled.

```
bsmith@R1> show interfaces ge-0/3/1
Physical interface: ge-0/3/1, Enabled, Physical link is Up
  Interface index: 142, SNMP ifIndex: 531
...
```

Results

```
[edit event-options]
policy disable-on-ping-failure {
  events ping_test_failed;
  within 300 {
    trigger on 1;
  }
  attributes-match {
    ping_test_failed.test-owner matches icmp-ping-probe;
    ping_test_failed.test-name matches ping-probe-test;
  }
  then {
    change-configuration {
      retry count 5 interval 4;
      commands {
        "set interfaces ge-0/3/1 disable";
      }
      user-name bsmith;
      commit-options log "updating configuration from event policy
        disable-on-ping-failure";
    }
  }
}
```

Verification

Confirm that the configuration is working properly.

- [Verifying the Events on page 447](#)
- [Verifying the Commit on page 448](#)
- [Verifying the Configuration Changes on page 449](#)
- [Verifying the Status of the Interface on page 449](#)

Verifying the Events

Purpose To manually test the event policy, take the ge-0/3/1 interface offline until two PING_TEST_FAILED events are generated.

Action Review the configured syslog file. Verify that when the RPM probe ping tests fail, the probe generates a PING_TEST_FAILED event.

```
bsmith@R1> show log syslog-event-daemon-info
Oct  7 15:48:54 R1 rmopd[1345]: PING_TEST_COMPLETED: pingCtlOwnerIndex =
icmp-ping-probe, pingCtlTestName = ping-probe-test
Oct  7 15:49:54 R1 rmopd[1345]: PING_TEST_COMPLETED: pingCtlOwnerIndex =
icmp-ping-probe, pingCtlTestName = ping-probe-test
...
Oct  7 15:52:54 R1 rmopd[1345]: RMOPD_ICMP_SENDMSG_FAILURE: sendmsg(ICMP): No
route to host
Oct  7 15:52:54 R1 rmopd[1345]: PING_PROBE_FAILED: pingCtlOwnerIndex =
icmp-ping-probe, pingCtlTestName = ping-probe-test
Oct  7 15:52:54 R1 rmopd[1345]: PING_TEST_FAILED: pingCtlOwnerIndex =
icmp-ping-probe, pingCtlTestName = ping-probe-test
Oct  7 15:52:57 R1 rmopd[1345]: PING_TEST_FAILED: pingCtlOwnerIndex =
icmp-ping-probe, pingCtlTestName = ping-probe-test
```

Verifying the Commit

Purpose Verify that the event policy commit operation was successful by reviewing the commit log and the messages log file.

Action Issue the **show system commit** operational mode command to view the commit log. In this example, the log confirms that the configuration was committed through the event policy under the privileges of user bsmith at the given date and time.

```
bsmith@R1> show system commit
0   2011-10-07 15:52:58 PDT by bsmith via junoscript
    updating configuration from event policy disable-on-ping-failure
1   2011-09-02 14:16:44 PDT by admin via netconf
2   2011-07-08 14:33:46 PDT by root via other
```

Review the messages log file. Upon receipt of the PING_TEST_FAILED event, Junos OS executed the configured event policy action to modify and commit the configuration. The commit operation occurred under the privileges of user bsmith.

```
bsmith@R1> show log messages | last 20
Oct  7 15:52:54 R1 rmopd[1345]: RMOPD_ICMP_SENDMSG_FAILURE: sendmsg(ICMP): No
route to host
Oct  7 15:52:55 R1 file[9972]: UI_COMMIT: User 'bsmith' requested 'commit'
operation (comment: updating configuration from event policy
disable-on-ping-failure)
Oct  7 15:52:59 R1 eventd: EVENTD_CONFIG_CHANGE_SUCCESS: Configuration change
successful: while executing policy disable-on-ping-failure with user bsmith
privileges
```

Meaning The output from the **show system commit** operational mode command and the **messages** log file verify that the commit operation, which was made through the event policy under the privileges of the user bsmith, was successful. The **show system commit** output and **messages** log file reference the commit comment specified in the **log** statement at the **[edit event-options policy disable-on-ping-failure then change-configuration commit-options]** hierarchy level.

Verifying the Configuration Changes

Purpose Verify the configuration changes by reviewing the **[edit interfaces ge-0/3/1]** hierarchy level of the configuration.

Action bsmith@R1> **show configuration interfaces ge-0/3/1**
 disable;
 unit 0 {
 family inet {
 address 10.1.4.1/26;
 }
}

Meaning The ge-0/3/1 configuration hierarchy was modified through the event policy to add the **disable** statement.

Verifying the Status of the Interface

Purpose Review the output of the **show interfaces ge-0/3/1** operational mode command after the configuration change takes place.

Action Issue the **show interfaces ge-0/3/1** operational mode command. After the event policy configuration change action disables the interface, the output changes from "Enabled" to "Administratively down".

```
bsmith@R1> show interfaces ge-0/3/1
Physical interface: ge-0/3/1, Administratively down, Physical link is Down
Interface index: 142, SNMP ifIndex: 531
```

Executing Event Scripts in an Event Policy

Event scripts are Extensible Stylesheet Transformation (XSLT) or Stylesheet Language Alternative Syntax (SLAX) scripts that you write and that are run when triggered by an event policy. Event scripts can perform any function available through Junos XML or Junos XML protocol remote procedure calls (RPCs). Additionally, you can pass to an event script a set of arguments that you define.

A script can change the device configuration, build and run an operational mode command, receive the command output, inspect the output, and determine the next appropriate action. This process can be repeated until the source of the problem is determined. The script can then report the source of the problem to you on the CLI.

You can configure an event policy that causes event scripts to be run and the output of those scripts to be uploaded to a specified location for analysis.

To configure such a policy, include the following statements at the **[edit event-options]** hierarchy level:

```
[edit event-options]
policy policy-name {
  events [ events ];
  then {
    event-script filename {
      arguments {
        argument-name argument-value;
      }
      output-filename filename;
      output-format (text | xml);
      destination destination-name;
    }
  }
}
```

In the **events** statement, you can list multiple events. If one or more of the listed events occurs, the event script is executed. To view a list of the events that can be referenced in an event policy, issue the **set event-options policy policy-name events ?** configuration mode command:

```
[edit]
user@host# set event-options policy policy-name events ?
Possible completions:
<event>
[          Open a set of values
acct_accounting_ferror
acct_accounting_fopen_error
...
```

Some of the system log messages that you can reference in an event policy are not listed in the output of the **set event-options policy policy-name events ?** command. For information about referencing these system log messages in your event policies, see [“Using Nonstandard System Log Messages to Trigger Event Policies” on page 419](#).

In addition, you can reference internally generated events, which are discussed in [“Generating Internal Events to Trigger Event Policies” on page 419](#).

In the **event-script** statement, you can specify a script to be executed on receipt of an event. The **eventd** process runs the scripts in the order in which they appear in the configuration. The scripts that you reference in the **event-script** statement must be located in the **/var/db/scripts/event** directory on the device's hard drive or the **/config/scripts/event/** directory on the flash drive. Furthermore, the event scripts must be enabled at the **[edit event-options event-script file]** hierarchy level. For more information, see [“Storing and Enabling Scripts” on page 86](#).

You can include arguments to the script as name/value pairs. You can include variables in the argument values to allow data from the triggering event to be automatically included in the argument. The **eventd** process replaces each variable with values contained in the event that triggers the policy. You can use variables of the following forms:

- **`{{$.attribute-name}}`**—The double dollar sign (`$$`) notation represents the event that is triggering a policy. When combined with an attribute name, the variable is replaced by the value of the attribute name in the triggering event. For example, **`{{$.interface-name}}`** stands for the value of the **`interface-name`** attribute in the triggering event.
- **`{$event.attribute-name}`**—The **`{$event.attribute-name}`** notation represents the most recent event that matches the specified event. The variable is replaced by the value of the attribute name of the most recent event that matches **`event`**. For example, when you include an argument called **`interface`** and define the value as **`{$COSD_CHAS_SCHED_MAP_INVALID.interface-name}`**, the **`{$COSD_CHAS_SCHED_MAP_INVALID.interface-name}`** variable is replaced by the **`interface-name`** attribute of the most recent **`COSD_CHAS_SCHED_MAP_INVALID`** event cached by the eventd process.

For a given event, you can view a list of event attributes that you can reference by issuing the **`help syslog event`** command:

```
user@host> help syslog event-name
```

For example, in the following command output, text in angle brackets (`< >`) shows attributes of the **`COSD_CHASSIS_SCHEDULER_MAP_INVALID`** event:

```
user@host> help syslog COSD_CHASSIS_SCHEDULER_MAP_INVALID
Name:      COSD_CHASSIS_SCHEDULER_MAP_INVALID
Message:    Chassis scheduler map incorrectly applied to interface
<interface-name>: <error-message>
...
```

You can filter the output of a search by using the pipe (`|`) symbol. The following example lists the filters that can be used with the pipe symbol:

```
user@host> help syslog | ?
Possible completions:
count      Count occurrences
display    Show additional kinds of information
except     Show only text that does not match a pattern
find       Search for first occurrence of pattern
hold       Hold text without exiting the --More-- prompt
last       Display end of output only
match      Show only text that matches a pattern
no-more    Don't paginate output
request    Make system-level requests
resolve    Resolve IP addresses
save       Save output text to file
trim       Trim specified number of columns from start of line
```

For more information about using the pipe symbol, see the *CLI User Guide*.

Another way to view a list of event attributes is to issue the **`set attributes-match event ?`** configuration mode command at the **`[edit event-options policy policy-name]`** hierarchy level:

```
[edit event-options policy policy-name]
user@host# set attributes-match event ?
```

For example, in the following command output, the **event.attribute** list shows that **error-message** and **interface-name** are attributes of the **cosd_chassis_scheduler_map_invalid** event:

```
[edit event-options policy p1]
user@host# set attributes-match cosd_chassis_scheduler_map_invalid?
Possible completions:
<from-event-attribute> First attribute to compare
cosd_chassis_scheduler_map_invalid.error-message
cosd_chassis_scheduler_map_invalid.interface-name
```

In this **set** command, there is no space between the event name and the question mark (?).

To view a list of all event attributes that you can reference, issue the **set attributes-match ?** configuration mode command at the **[edit event-options policy *policy-name*]** hierarchy level:

```
[edit event-options policy policy-name]
user@host# set attributes-match ?
Possible completions:
<from-event-attribute> First attribute to compare
acct_accounting_ferror
acct_accounting_fopen_error
...
```

By default, the command output format is text. To change this, include the **output-format xml** statement.

In the optional **output-filename** statement, assign the name of the file to which to write script output for the specified script.

The filename format is **hostname_filename_YYYYMMDD_HHMMSS_index-number**.

For each uploaded file, a hostname and timestamp are automatically added to the filename to ensure that the uploaded files have unique filenames. If a policy is triggered multiple times in a 1-second period, an index number is added to ensure the filenames are unique. The index number range is 001 through 999.

For example, on a device named **r1**, if you configure the output filename to be **ifl-events**, and this event policy is triggered three times in 1 second, the files are named:

- **r1_ifl-events_20060623_132333**
- **r1_ifl-events_20060623_132333_001**
- **r1_ifl-events_20060623_132333_002**

In the optional **destination** statement, include the destination name that you configured at the **[edit event-options destinations]** hierarchy level. For more information, see [“Example: Defining Destinations for File Archiving by Event Policies” on page 421](#).

For the **output-filename** and **destination** statements, there are four configuration scenarios:

- You can omit the **output-filename** and **destination** statements. This option makes sense when the event script has no output. For example, the event script might execute only **request** commands, which have no output.
- You can include the **destination** statement in the configuration. You omit the **output-filename** statement in the configuration and specify an output filename in the event script instead. The script output is sent to the destination specified in the configuration. If you do not include the **destination** statement in the configuration, the script output is not uploaded.

In this scenario, the event policy extracts the filename from the event script. The event script writes the output filename as **STDOUT**. The XML syntax to use in the event script is:

```
<output>
  <event-script-output-filename>filename</event-script-output-filename>
</output>
```

The **<event-script-output-filename>** element must be the first child tag within the **<output>** parent tag.

On a device named **device2**, configure an event script action with a destination **host**, and omit the **output-filename** statement. Define the destination **host** as `ftp://user@device1//tmp`.

In the **script1.xml** event script, write the following output to **STDOUT**:

```
<event-script-output-filename>/var/cmd.txt</event-script-output-filename>
```

Configure the **policy1** event policy as follows:

```
[edit event-options]
policy policy1 {
  then {
    event-script script1.xml {
      destination host;
    }
  }
}
destinations {
  host {
    archive-sites {
      "ftp://user@device1//tmp" password "$9$XkJNbYg4ZDH.oJ.fQnpuSyl"; ##
      SECRET-DATA***
    }
  }
}
```

In this example, the `/var/cmd.txt` file resides on device **device2**. The event policy uses the File Transfer Protocol (FTP) to upload this file to the `/tmp` directory on device **device1**.

The event policy reads the output filename `/var/cmd.txt` from **STDOUT**. Then the event policy uploads the `/var/cmd.txt` file to the configured destination, which is the `/tmp` directory on device **device1**. The event policy renames the `/var/cmd.txt` file as `device2_cmd.txt_YYYYMMDD_HHMMSS_range`.

- You can include the **output-filename** and **destination** statements. If you include the **output-filename** statement in the configuration, you must also include the **destination** statement in the configuration. In this case, the script output is redirected to the output filename specified in the configuration and is sent to the destination specified in the configuration.
- You can include the **output-filename** and **destination** statements, and also specify an output filename directly within the event script. If you do this, the output filename specified in the configuration overrides the output filename specified in the event script.

Configuring Event Policies to Ignore an Event

You can modify a policy to cause particular events to be ignored or to cause all events to be ignored during a particular time interval, to allow for maintenance for example. To configure such a policy, include the following statements at the **[edit event-options]** hierarchy level:

```
[edit event-options]
policy policy-name {
  events [ events ];
  then {
    ignore;
  }
}
```

In the **events** statement, you can list multiple events. To view a list of the events that can be referenced in an event policy, issue the **set event-options policy policy-name events ?** configuration mode command:

```
[edit]
user@host# set event-options policy policy-name events ?
Possible completions:
<event>
[          Open a set of values
acct_accounting_ferror
acct_accounting_fopen_error
...
```

Some of the system log messages that you can reference in an event policy are not listed in the output of the **set event-options policy policy-name events ?** command. For information about referencing these system log messages in your event policies, see [“Using Nonstandard System Log Messages to Trigger Event Policies” on page 419](#).

In addition, you can reference internally generated events, which are discussed in [“Generating Internal Events to Trigger Event Policies” on page 419](#).

If one or more of the listed events occur, a system log message for the event is not generated, and no further policies associated with this event are processed. If you include the **ignore** statement in a policy configuration, you cannot configure any other actions in the policy.

Changing the User Privilege Level for an Event Policy Action

Only superusers can configure event policies. Event policy actions—such as executing event scripts, uploading files, and executing operational mode commands—are by default executed by user **root**, because the event process (eventd) runs with **root** privileges.

In some cases, you might want an event policy action to be executed with restricted privileges. For example, suppose you configure an event policy that executes a script if an interface goes down. The script includes remote procedure calls (RPCs) to change the device configuration if certain conditions are present. If you do not want the script to change the configuration, you can execute the script with a restricted user profile. When the script is executed with a user profile that disallows configuration changes, the RPCs to change the configuration fail.

You can associate a user with each action in an event policy. If a user is not associated with an event policy action, then the action is executed as user **root** by default.

To specify the user under whose privileges an action is executed, include the **user-name** statement:

```
user-name username;
```

You can include this statement at the following hierarchy levels:

- [edit **event-options policy** *policy-name* then **event-script** *filename*]
- [edit **event-options policy** *policy-name* then **execute-commands**]
- [edit **event-options policy** *policy-name* then **upload** *filename* (*filename* | committed) *destination* *destination-name*]

NOTE: The username that you specify must be configured at the [edit **system login**] hierarchy level. For more information, see the *Junos OS Administration Library for Security Devices*.

For a configuration example, see “[Example: Associating an Optional User with an Event Policy Action](#)” on page 474.

Configuring Event Policies to Raise SNMP Traps

SNMP *traps* enable an agent to notify a network management system (NMS) of significant events by way of an unsolicited SNMP message. You can configure an event policy action that raises traps for events based on system log messages. This enables notification of an SNMP trap-based application when an important system log message occurs. You can convert any system log message (for which there are no corresponding traps) into a trap. This is valuable if you use NMS traps rather than system log messages to monitor your network.

To configure a policy that raises a trap on receipt of an event, include the following statements at the [edit **event-options policy** *policy-name*] hierarchy level:

```
[edit event-options policy policy-name]
```

```
events [ events ];  
then {  
    raise-trap;  
}
```

The MIB (`jnx-syslog.mib`) supports this policy action. For more information, see [SNMP MIBs and Traps Reference](#).

For a configuration example, see “[Example: Raising an SNMP Trap in Response to an Event](#)” on page 479.

Configuring the System Log Priority of the Triggering Event in an Event Policy

- [Understanding the Event System Log Priority in an Event Policy on page 456](#)
- [Example: Configuring the Event System Log Priority in an Event Policy on page 457](#)

Understanding the Event System Log Priority in an Event Policy

Starting with Junos OS Release 12.1, you can configure an event policy to override the default system log priority of a triggering event so that the system logs the event with a different facility type, severity level, or both. To override the priority of the triggering event, configure the **priority-override** statement at the [\[edit event-options policy policy-name then\]](#) hierarchy level. To override the facility type with which the triggering event is logged, include the **facility** statement and the new facility type. To override the severity level with which the triggering event is logged, include the **severity** statement and the new severity level.

Junos OS processes generate system log messages, or event notifications, to record the events that occur on a routing, switching, or security platform. Each system log message identifies the Junos OS process that generated the message and describes the operation or error that occurred. The Junos OS event process (eventd) receives the event notifications, and configured event policies instruct the eventd process to perform a set of actions upon receipt of specific events or correlated events.

Each system log message belongs to a facility, which groups messages that either are generated by the same source (such as a software process) or concern a similar condition or activity (such as authentication attempts). Each message is also preassigned a severity level, which indicates how seriously the triggering event affects the functions of the routing, switching, or security platform. A message's facility and severity level are together referred to as its priority. For more information about facility and severity levels, see *Junos OS System Logging Facilities and Message Severity Levels*.

When you configure logging on a device for a specific facility and destination, you also specify a severity level. Messages from that facility that are rated at the configured severity level or higher are logged. To log related events with different severity levels in the same log file, you must filter events using the lowest severity level of any of the events from that facility to be logged. This can result in unwieldy log files that are difficult and time-consuming to parse.

For example, Junos OS logs the protocol UP and DOWN events with different severity levels. Both the `SNMP_TRAP_LINK_DOWN` and `SNMP_TRAP_LINK_UP` events have a facility of 'daemon', but the `SNMP_TRAP_LINK_DOWN` event has a severity level of 'warning', and the `SNMP_TRAP_LINK_UP` event has a severity level of 'info'. Normally,

when you configure a system log file, you must filter events to that file using the lower severity level of 'info' in order to log both of the events.

The event policy **priority-override** statement enables you to customize the priority of the triggering event so that it is logged using a different facility type and severity level. Suppose you configure a system log file to filter events of facility 'daemon' and severity 'notice', and you have event policies that trigger on the RPD_ISIS_ADJDOWN and RPD_ISIS_ADJUP events. When the system generates an RPD_ISIS_ADJDOWN message reporting that the IS-IS adjacency with a neighboring router was terminated, this message is logged. However, if the system subsequently generates an RPD_ISIS_ADJUP event notification reporting that the IS-IS adjacency has been restored, by default, the message is not logged, because it has a lower severity level of 'info'. In the event policy that triggers on the RPD_ISIS_ADJUP event, you can configure the associated priority so that the triggering RPD_ISIS_ADJUP event is logged with a severity level of 'notice' and is captured in the configured log file.

NOTE: Event policies are executed in the order in which they appear in the configuration. When you configure multiple event policies to override the priority of the same event, the event is logged based on the priority set by the last executed event policy to change it.

Example: Configuring the Event System Log Priority in an Event Policy

It is necessary to log events when monitoring, managing, and troubleshooting routing, switching, and security devices. Starting with Junos OS Release 12.1, you can configure an event policy to override the priority of its triggering event so that it is logged based on a different facility type and severity level. This enables the event to be logged even if the system filters events to the destination log file using a different facility type or a higher severity level.

This example simulates an SNMP_TRAP_LINK_UP event for a specific interface. Upon receipt of the event, the event policy overrides the severity level of the event so that it is captured in the configured log file.

- [Requirements on page 457](#)
- [Overview on page 457](#)
- [Configuration on page 458](#)
- [Verification on page 460](#)

Requirements

- Routing, switching, or security device running Junos OS Release 12.1 or later.
- Interface is configured and active. This example uses the ge-0/3/1.0 interface.

Overview

This example configures two log files to capture events of facility 'daemon'. One log file is configured to filter for events of severity 'warning' or higher, and the second log file is configured to filter for events of severity 'info' or higher.

The configured event policy triggers on the `SNMP_TRAP_LINK_UP` event for interface `ge-0/3/1.0`. The example generates an `SNMP_TRAP_LINK_DOWN` event followed by an `SNMP_TRAP_LINK_UP` event for the `ge-0/3/1.0` interface. The `SNMP_TRAP_LINK_DOWN` event, which has a severity level of 'warning' is captured in both configured log files. Upon receipt of the `SNMP_TRAP_LINK_UP` event, the event policy overrides the severity level of the event to 'warning' so that it is also captured in the log file that filters for events of severity 'warning'. By default, if the event policy does not override the severity level of this event, it is only captured in the log file that filters for the severity level 'info'.

Configuration

- [Configuring the Log Files on page 458](#)
- [Verifying the Default System Log Priority of the Events on page 459](#)
- [Configuring the Event Policy on page 459](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set system syslog file syslog-event-daemon-info daemon info
set system syslog file syslog-event-daemon-warning daemon warning
set event-options policy log-on-snmp-trap-link-up events snmp_trap_link_up
set event-options policy log-on-snmp-trap-link-up attributes-match
  snmp_trap_link_down.interface-name matches ge-0/3/1.0
set event-options policy log-on-snmp-trap-link-up then priority-override severity warning
```

Configuring the Log Files

Step-by-Step Procedure

1. Configure two log files at the **[edit system syslog]** hierarchy level to record events of facility `daemon`.

Configure one log to record events of severity 'info' or higher and one log file to record events of severity 'warning' or higher.

```
[edit system syslog]
bsmith@R1# set file syslog-event-daemon-info daemon info
bsmith@R1# set file syslog-event-daemon-warning daemon warning
```

2. Commit the configuration.

```
bsmith@R1# commit
```

3. To manually test the logging of the events, take the `ge-0/3/1.0` logical interface temporarily offline, and then bring it back up.

This generates an `SNMP_TRAP_LINK_DOWN` event followed by an `SNMP_TRAP_LINK_UP` event.

```
[edit]
bsmith@R1# set interfaces ge-0/3/1 unit 0 disable
bsmith@R1# commit
bsmith@R1# delete interfaces ge-0/3/1 unit 0 disable
bsmith@R1# commit
```

Results **[edit]**

```

system {
  syslog {
    file syslog-event-daemon-info {
      daemon info;
    }
    file syslog-event-daemon-warning {
      daemon warning;
    }
  }
}

```

Verifying the Default System Log Priority of the Events

Purpose Verify that the system generated the SNMP_TRAP_LINK_DOWN and SNMP_TRAP_LINK_UP events for the ge-0/3/1.0 interface, and note where each event is logged.

Action Review the contents of the **syslog-event-daemon-info** file configured in Step 1 of the previous procedure. The output shows that the ge-0/3/1.0 interface was brought down and back up and generated an SNMP_TRAP_LINK_DOWN event followed by an SNMP_TRAP_LINK_UP event.

```

bsmith@R1> show log syslog-event-daemon-info
Oct 24 13:22:17 R1 mib2d[1394]: SNMP_TRAP_LINK_DOWN: ifIndex 539, ifAdminStatus
down(2), ifOperStatus down(2), ifName ge-0/3/1.0
...
Oct 24 13:22:29 R1 mib2d[1394]: SNMP_TRAP_LINK_UP: ifIndex 539, ifAdminStatus
up(1), ifOperStatus up(1), ifName ge-0/3/1.0

```

Review the contents of the **syslog-event-daemon-warning** file configured in Step 1 of the previous procedure. Because the severity level of the SNMP_TRAP_LINK_UP event is 'info', it does not appear in a log file that is configured to only record events of severity 'warning' or higher. By default, this system log file captures the SNMP_TRAP_LINK_DOWN events, but does not capture the SNMP_TRAP_LINK_UP events.

```

bsmith@R1> show log syslog-event-daemon-warning
Oct 24 13:22:17 R1 mib2d[1394]: SNMP_TRAP_LINK_DOWN: ifIndex 539, ifAdminStatus
down(2), ifOperStatus down(2), ifName ge-0/3/1.0

```

Meaning Because the SNMP_TRAP_LINK_UP event has a default severity of 'info', it is not forwarded to log files that are configured to capture events of higher severity.

Configuring the Event Policy

Step-by-Step Procedure

1. Create and name the event-policy.

```

[edit]
bsmith@R1# edit event-options policy log-on-snmp-trap-link-up

```

2. Configure the **events** statement.

For this example, the event policy triggers on the SNMP_TRAP_LINK_UP event. Set the **attributes-match** statement so that the policy triggers only if the SNMP_TRAP_LINK_UP event occurs for the ge-0/3/1.0 interface.

```
[edit event-options policy log-on-snmp-trap-link-up]
bsmith@R1# set events snmp_trap_link_up
bsmith@R1# set attributes-match snmp_trap_link_down.interface-name matches
ge-0/3/1.0
```

3. Configure the **priority-override** event policy action, and include the **severity** statement with a value of **warning**.

```
[edit event-options policy log-on-snmp-trap-link-up]
bsmith@R1# set then priority-override severity warning
```

4. Commit the configuration.

```
bsmith@R1# commit
```

5. To manually test the event policy, take the ge-0/3/1.0 logical interface temporarily offline, and then bring it back up. This generates an SNMP_TRAP_LINK_DOWN event followed by an SNMP_TRAP_LINK_UP event.

```
[edit]
bsmith@R1# set interfaces ge-0/3/1 unit 0 disable
bsmith@R1# commit
bsmith@R1# delete interfaces ge-0/3/1 unit 0 disable
bsmith@R1# commit
```

Results

```
[edit]
event-options {
  policy log-on-snmp-trap-link-up {
    events snmp_trap_link_up;
    attributes-match {
      snmp_trap_link_up.interface-name matches ge-0/3/1.0;
    }
    then {
      priority-override {
        severity warning;
      }
    }
  }
}
```

Verification

Confirm that the configuration is working properly.

Verifying the Configured System Log Priority of the Events

Purpose Verify that the system generated the SNMP_TRAP_LINK_DOWN and SNMP_TRAP_LINK_UP events for the ge-0/3/1.0 interface, and note where each event is logged.

Action Review the contents of the `syslog-event-daemon-warning` file. Because the event policy overrides the severity level of the `SNMP_TRAP_LINK_UP` event, it now appears in the log file that is configured to only record events of severity 'warning' or higher. By default, this system log file captures the `SNMP_TRAP_LINK_DOWN` events, but does not capture the `SNMP_TRAP_LINK_UP` events.

```
bsmith@R1> show log syslog-event-daemon-warning
Oct 24 13:29:48 R1 mib2d[1394]: SNMP_TRAP_LINK_DOWN: ifIndex 539, ifAdminStatus
down(2), ifOperStatus down(2), ifName ge-0/3/1.0
Oct 24 13:30:02 R1 mib2d[1394]: SNMP_TRAP_LINK_UP: ifIndex 539, ifAdminStatus
up(1), ifOperStatus up(1), ifName ge-0/3/1.0
```

Meaning Although the `SNMP_TRAP_LINK_UP` event has a severity of 'info', configuring the **priority-override** statement with a severity of 'warning' causes the event to be forwarded to the system logs with the configured severity level. The event can be captured in logs that filter for a different facility type and a higher severity level.

Configuring Event Policy Privileges

- [Changing the User Privilege Level for an Event Policy Action on page 461](#)

Changing the User Privilege Level for an Event Policy Action

Only superusers can configure event policies. Event policy actions—such as executing event scripts, uploading files, and executing operational mode commands—are by default executed by user **root**, because the event process (eventd) runs with **root** privileges.

In some cases, you might want an event policy action to be executed with restricted privileges. For example, suppose you configure an event policy that executes a script if an interface goes down. The script includes remote procedure calls (RPCs) to change the device configuration if certain conditions are present. If you do not want the script to change the configuration, you can execute the script with a restricted user profile. When the script is executed with a user profile that disallows configuration changes, the RPCs to change the configuration fail.

You can associate a user with each action in an event policy. If a user is not associated with an event policy action, then the action is executed as user **root** by default.

To specify the user under whose privileges an action is executed, include the **user-name** statement:

```
user-name username;
```

You can include this statement at the following hierarchy levels:

- `[edit event-options policy policy-name then event-script filename]`
- `[edit event-options policy policy-name then execute-commands]`
- `[edit event-options policy policy-name then upload filename (filename | committed) destination destination-name]`

NOTE: The username that you specify must be configured at the `[edit system login]` hierarchy level. For more information, see the *Junos OS Administration Library for Security Devices*.

For a configuration example, see “[Example: Associating an Optional User with an Event Policy Action](#)” on page 474.

Creating and Executing Event Scripts

- [Required Boilerplate for Event Scripts on page 462](#)
- [Capturing and Using Event Details and Remote Execution Details in Event Scripts on page 464](#)
- [Mapping Operational Mode Commands and Output Fields to Junos XML Notation on page 465](#)
- [Using RPCs and Operational Mode Commands in Event Scripts on page 466](#)

- [Executing an Event Script on page 470](#)
- [Replacing an Event Script on page 470](#)
- [Configuring Checksum Hashes for an Event Script on page 471](#)

Required Boilerplate for Event Scripts

When you write event scripts, you use Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) tools provided with Junos OS. These tools include basic boilerplate that you must include in all event scripts, optional extension functions that accomplish scripting tasks more easily, and named templates that make scripts easier to read and write, which you import from a file called `junos.xsl`. For more information about the extension functions and templates, see “[Junos Script Automation: Extension Functions in the jcs Namespace Overview](#)” on page 8 and “[Junos Script Automation: Named Templates in the jcs Namespace Overview](#)” on page 28.

Event scripts are based on Junos XML and Junos XML protocol tag elements. Like all XML elements, angle brackets enclose the name of a Junos XML or Junos XML protocol tag element in its opening and closing tags. This is an XML convention, and the brackets are a required part of the complete tag element name. They are not to be confused with the angle brackets used in the documentation to indicate optional parts of Junos OS CLI command strings.

You must include either XSLT or SLAX boilerplate as the starting point for all event scripts that you create. The XSLT boilerplate follows:

XSLT Boilerplate for Event Scripts

```

1  <?xml version="1.0" standalone="yes"?>
2  <xsl:stylesheet version="1.0"
3    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4    xmlns:junos="http://xml.juniper.net/junos/*/junos"
5    xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6    xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
7    <xsl:import href="../../import/junos.xsl"/>

8    <xsl:template match="configuration">
9      <event-script-results>
10       <!-- ... Insert your code here ... -->
11     </event-script-results>
12   </xsl:template>
13   <!-- ... insert additional template definitions here ... -->
14 </xsl:stylesheet>

```

Line 1 is the Extensible Markup Language (XML) processing instruction (PI). This PI specifies that the code is written in XML using version 1.0. The XML PI, if present, must be the first noncomment token in the script file.

```
1  <?xml version="1.0"?>
```

Line 2 opens the style sheet and specifies the XSLT version as 1.0.

```
2  <xsl:stylesheet version="1.0"
```

Lines 3 through 6 list all the namespace mappings commonly used in event scripts. Not all of these prefixes are used in this example, but it is not an error to list namespace mappings that are not referenced. Listing all namespace mappings prevents errors if the mappings are used in later versions of the script.

```

3    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
4    xmlns:junos="http://xml.juniper.net/junos/*/junos"
5    xmlns:xnm="http://xml.juniper.net/xnm/1.1/xnm"
6    xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">

```

Line 7 is an XSLT import statement. It loads the templates and variables from the file referenced as `../import/junos.xsl`, which ships as part of Junos OS (in the file `/usr/libdata/cscript/import/junos.xsl`). The `junos.xsl` file contains a set of named templates you can call in your scripts. These named templates are discussed in [“Junos Script Automation: Named Templates in the jcs Namespace Overview” on page 28](#) and [“Junos Named Templates in the jcs Namespace Summary” on page 30](#).

```
7    <xsl:import href="../../import/junos.xsl"/>
```

Line 8 defines a template that matches the `</>` element. The `<xsl:template match="/">` element is the root element and represents the top level of the XML hierarchy. All XML Path Language (XPath) expressions in the script must start at the top level. This allows the script to access all possible Junos XML and Junos XML protocol remote procedure calls (RPCs). For more information, see [“XPath Overview” on page 50](#) and `xsl:template match="/" Template`.

```
8    <xsl:template match="/">
```

After the `<xsl:template match="/">` tag element, the `<event-script-results>` and `</event-script-results>` container tags must be the top-level child tags, as shown in Lines 9 and 10.

```

9      <event-script-results>
      <!-- ... insert your code here ... -->
10     </event-script-results>

```

Line 11 closes the template.

```
11    </xsl:template>
```

Between Line 11 and Line 12, you can define additional XSLT templates that are called from within the `<xsl:template match="/">` template.

Line 12 closes the style sheet and the event script.

SLAX Boilerplate for Event Scripts

```

12  </xsl:stylesheet>

version 1.0;
ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
import "../import/junos.xsl";

match / {
  <event-script-results> {
    /*
     * Insert your code here
     */
  }
}

```

Capturing and Using Event Details and Remote Execution Details in Event Scripts

When an event script is triggered by an event policy, the initiating event policy forwards a set of event details to the triggered event script. These event details can be captured, evaluated, and sent to log files as required. In addition, any configured remote execution details are also forwarded to the event script. The remote execution details allow the event script to invoke remote procedure calls as detailed in [“Using RPCs and Operational Mode Commands in Event Scripts” on page 466](#).

Two types of event details are returned: triggered events and received events. *Triggered events* record the details of the event that triggered the policy. *Received events* record the details of events that happened before the triggering event. Event details and remote execution details are forwarded to the event script as XML in the following format:

```

<event-script-input>
  <junos-context>
    ...
  </junos-context>
  <trigger-event>
    <id>event-id</id>
    <type>event-type</type>
    <generation-time>timestamp</generation-time>
    <process>
      <name>process-name</name>
    </process>
  </trigger-event>

```

For information about the `<junos-context>` element, see [“Junos Script Automation: Global Parameters and Variables in the junos.xml File” on page 39](#).

For information about one method for using event details, see [“Example: Limiting Event Script Output Based on a Specific Event Type” on page 478](#).

Mapping Operational Mode Commands and Output Fields to Junos XML Notation

In event scripts, you use tag elements from the Junos XML API to represent operational mode commands and output fields. For the Junos XML equivalent of commands and output fields, consult the *Junos XML API Operational Developer Reference*.

You can also display Junos XML by directing the output from the **show** command to the **| display xml** command:

```
user@host> operational-mode-command | display xml
```

For example:

```
user@host> show interfaces terse | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <interface-information
    xmlns="http://xml.juniper.net/junos/10.0R10/junos-interface" junos:style="terse">
    <physical-interface>
      <name>dsc</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    </physical-interface>
    <physical-interface>
      <name>fxp0</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    <logical-interface>
      <name>fxp0.0</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
    ...
```

Using RPCs and Operational Mode Commands in Event Scripts

Most Junos operational mode commands have XML equivalents. These XML commands can be executed remotely using the *remote procedure call* (RPC) protocol. All operational mode commands that have XML equivalents are listed in the *Junos XML API Operational Developer Reference*.

RPC and operational mode command use in event scripts is discussed in more detail in the following sections:

- [Using RPCs in Event Scripts on page 466](#)
- [Displaying the RPC Tags for a Command on page 468](#)
- [Using Operational Mode Commands in Event Scripts on page 468](#)

Using RPCs in Event Scripts

You can invoke remote procedure calls (RPCs) in event scripts. For each event script that invokes RPCs, you must include the **remote-execution** statement at the **[edit event-options event-script file filename]** hierarchy level. For each remote device where an RPC is executed, you must configure the SSH host key information for the that device on the local device where the event script is executed.

For each remote device where an RPC is executed, specify the device hostname and the corresponding username and passphrase at the **remote-execution** level of the configuration hierarchy.

```
[edit event-options event-script file filename]
remote-execution {
  remote-hostname {
    username username;
    passphrase passphrase;
  }
}
```

The remote hostnames and their corresponding username and passphrase, in addition to the event details, are passed as input to the event script when it is triggered by an event policy. For more information about the details that are forwarded to the event script, see [“Capturing and Using Event Details and Remote Execution Details in Event Scripts” on page 464](#). A connection handle to the remote host is generated with the `jcs:open()` function using *remote-hostname*, *username*, and *passphrase* as arguments; for more information about this function, see [jcs:open\(\) Function](#). The following code obtains a connection handle for each remote host included in the configuration:

XSLT Syntax	<pre><xsl:for-each select="event-script-input/remote-execution-details"> <xsl:variable name="d" select="remote-execution-detail"/> <xsl:variable name="connection" select="jcs:open(\$d/remote-hostname,\$d/username,\$d/passphrase)"/> ... </xsl:for-each></pre>
SLAX Syntax	<pre>for-each (event-script-input/remote-execution-details) { var \$d = remote-execution-detail; var \$connection = jcs:open(\$d/remote-hostname,\$d/username,\$d/passphrase); ... }</pre>

To execute an RPC on a remote device, an SSH session must be established. In order for the script to establish the connection, you must either configure the SSH host key information for the remote device on the local device where the script will be executed, or the SSH host key information for the remote device must exist in the known hosts file of the user executing the script. For each remote device where the RPC is executed, configure the SSH host key information with one of the following methods:

- To configure SSH known hosts on the local device, include the **host** statement, and specify hostname and host key options for the remote device at the **[edit security ssh-known-hosts]** hierarchy level of the configuration.
- To manually retrieve SSH host key information, issue the **set security ssh-known-hosts fetch-from-server hostname** configuration mode command to instruct Junos OS to connect to the remote device and add the key.

```
user@host# set security ssh-known-hosts fetch-from-server router2
The authenticity of host 'router2 (10.10.10.1)' can't be established.
RSA key fingerprint is 30:18:99:7a:3c:ed:40:04:0f:fd:c1:57:7e:6b:f3:90.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'router2,10.10.10.1' (RSA) to the list of known
hosts.
```

- To manually import SSH host key information from a file, use the **set security ssh-known-hosts load-key-file filename** configuration mode command and specify the known-hosts file.

```
user@host# set security ssh-known-hosts load-key-file /var/tmp/known_hosts
Import SSH host keys from trusted source /var/tmp/known_hosts ? [yes,no] (no)
yes
```

- Alternatively, the user executing the script can log in to the local device, SSH to the remote device, and then manually accept the host key, which is added to that user's known hosts file. In the following example, root is logged in to **router1**. In order to execute

a remote RPC on **router2**, root adds the host key of **router2** by issuing the **ssh router2** operational mode command and manually accepting the key.

```
root@router1> ssh router2
The authenticity of host 'router2 (10.10.10.1)' can't be established.
RSA key fingerprint is 30:18:99:7a:3c:ed:40:04:0f:fd:c1:57:7e:6b:f3:90.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'router2,10.10.10.1' (RSA) to the list of known
hosts.
```

After configuring the required SSH host key and obtaining a connection handle to the remote device, the event script can execute RPCs with the **jcs:execute()** extension function on that remote device. This function is described in [jcs:execute\(\) Function](#). To use an RPC in the event script, include the RPC in a variable declaration and execute it with the **jcs:execute()** function; the connection handle and RPC variable declaration are provided as arguments to the **jcs:execute()** function.

XSLT Syntax	<pre><xsl:variable name="rpc"> <get-interface-information/> # Junos RPC for the show interfaces command </xsl:variable> <xsl:variable name="out" select="jcs:execute(\$connection, \$rpc)"/></pre>
SLAX Syntax	<pre>var \$rpc = <get-interface-information>; var \$out = jcs:execute(\$connection, \$rpc);</pre>

where **\$connection** is the connection handle to the remote host. Any number of RPCs can be executed within the context of this connection handle until it is closed with the **jcs:close()** function.

Displaying the RPC Tags for a Command

To display the remote procedure call (RPC) XML tags for an operational mode command, enter **display xml rpc** after the pipe symbol (|).

The following example displays the RPC tags for the **show route** command:

```
user@host> show route | display xml rpc
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.1I0/junos">
  <rpc>
    <get-route-information>
      </get-route-information>
    </rpc>
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>
```

Using Operational Mode Commands in Event Scripts

Some operational mode commands do not have XML equivalents. If a command is not listed in the *Junos XML API Operational Developer Reference*, it does not have an XML equivalent.

Another way to determine whether a command has an XML equivalent is to issue the command followed by the | **display xml** command:

```
user@host> operational-mode-command | display xml
```

If the output includes only tag elements like `<output>`, `<cli>`, and `<banner>`, the command might not have an XML equivalent. In the following example, the output indicates that the `show host` command has no XML equivalent:

```
user@host> show host hostname | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.0R1/junos">
  <output>
    ...
  </output>
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>
```

NOTE: For some commands that have an XML equivalent, the output of the piped `| display xml` command does not include tag elements other than `<output>`, `<cli>`, and `<banner>` only because the relevant feature is not configured. For example, the `show services cos statistics forwarding-class` command has an XML equivalent that returns output in the `<service-cos-forwarding-class-statistics>` response tag, but if the configuration does not include any statements at the `[edit class-of-service]` hierarchy level then there is no actual data for the `show services cos statistics forwarding-class | display xml` command to display. The output is something like this:

```
user@host> show services cos statistics forwarding-class | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/8.3I0/junos">
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>
```

For this reason, the information in the *Junos XML API Operational Developer Reference* is normally more reliable.

An event script can include commands that have no XML equivalent. Use the `<command>`, `<xsl:value-of>`, and `<output>` elements in the script, as shown in the following code snippet. This snippet is expanded and fully described in [“Example: Displaying DNS Hostname Information Using an Op Script”](#) on page 364.

```
<xsl:variable name="query">
  <command>
    <xsl:value-of select="concat('show host ', $hostname)"/>
  </command>
</xsl:variable>
<xsl:variable name="result" select="jcs:invoke($query)"/>
<xsl:variable name="host" select="$result"/>
<output>
  <xsl:value-of select="concat('Name: ', $host)"/>
</output>
...
```

Enabling an Event Script

Event scripts are stored on a device's hard drive in the `/var/db/scripts/event` directory or on the flash drive in the `/config/scripts/event` directory. Only users in the Junos OS **super-user** login class can access and edit files in these directories. For information about setting the storage location for scripts, see [“Storing Scripts in Flash Memory” on page 87](#).

NOTE: If the device has dual Routing Engines and you want to enable an event script to execute on both Routing Engines, you must copy the script to the `/var/db/scripts/event` or `/config/scripts/event` directory on both Routing Engines. The `commit synchronize` command does not automatically copy scripts between Routing Engines.

You must enable an event op script before it can be executed. Include the **file filename** statement at the `[edit event-options events-script]` hierarchy level, specifying the name of an Extensible Stylesheet Language Transformations (XSLT) or Stylesheet Language Alternative Syntax (SLAX) file containing an event script. Only users who belong to the Junos **super-user** login class can enable event scripts.

```
[edit event-options event-script]
file filename;
```

The filename of an event script written in SLAX must include the `.slax` extension for the script to be enabled and executed. No particular filename extension is required for event scripts written in XSLT, but we strongly recommend that you append the `.xsl` extension.

To determine which event scripts are currently enabled on the device, use the **show** command to display the files included at the `[edit event-options event-script]` hierarchy level. To ensure that the enabled files are on the device, list the contents of the `/var/run/scripts/event/` directory using the **file list /var/run/scripts/event** operational mode command.

Executing an Event Script

When you issue the **commit** command, event scripts enabled at the `[edit event-options event-script]` hierarchy level are placed into system memory and enabled for execution. After the commit operation completes, an event script is executed in response to an event notification within an event policy. For more information, see [“Executing Event Scripts in an Event Policy” on page 449](#).

Replacing an Event Script

You can update or replace an existing event script without changing the device's configuration or disrupting operations. Follow these steps:

1. Edit or write the new event script.
2. Copy the script to the `/var/db/scripts/event` directory on the hard drive or the `/config/scripts/event` directory on the flash drive; for information about setting the storage location for scripts, see [“Storing Scripts in Flash Memory” on page 87](#). Only users who belong to the Junos **super-user** login class can alter files in these directories.

NOTE: If the device has dual Routing Engines, remember to copy the script to the `/var/db/scripts/event` or `/config/scripts/event` directory on both Routing Engines. The `commit synchronize` command does not automatically copy scripts between Routing Engines.

3. Issue the `request system scripts event-scripts reload` operational mode command.

```
user@host> request system scripts event-scripts reload
```

All event scripts are reloaded into the eventd process' memory.

Configuring Checksum Hashes for an Event Script

You can configure one or more checksum hashes that can be used to verify the integrity of an event script before the script runs on the switch, router, or security device.

To configure a checksum hash:

1. Create the script.
2. Place the script in the `/var/db/scripts/event` directory on the device.
3. Run the script through one or more hash functions to calculate hash values.

Junos OS supports MD5, SHA-1, and SHA-256 hash functions.

```
user@host> file checksum md5 /var/db/scripts/commit/script1.slax
MD5 (/var/db/scripts/event/script1.slax) = 3af7884eb56e2d4489c2e49b26a39a97
user@host> file checksum sha1 /var/db/scripts/commit/script1.slax
SHA1 (/var/db/scripts/event/script1.slax) =
00dc690fb08fb049577d012486c9a6dad34212c0
user@host> file checksum sha-256 /var/db/scripts/commit/script1.slax
SHA256 (/var/db/scripts/event/script1.slax) =
150bf53383769f3bfedd41fe73320777f208d4fda81230cb27b8738
```

4. Configure the script.

```
[edit event-options event-script]
user@host# set file script1.slax checksum
md5 3af7884eb56e2d4489c2e49b26a39a97
[edit event-options event-script]
user@host# set file script1.slax checksum
sha-1 00dc690fb08fb049577d012486c9a6dad34212c0
[edit event-options event-script]
user@host# set file script1.slax checksum
sha-256 150bf53383769f3bfedd41fe73320777f208d4fda81230cb27b8738
```

During the execution of the script, Junos OS recalculates the checksum value using the configured hash and verifies that the calculated value matches the configured value. If the values differ, the execution of the script fails. When you configure multiple checksum values with different hash algorithms, all the configured values must match the calculated values; otherwise, the script execution fails and the event policy fails.

Example: Assigning a Transfer Delay to an Event Policy Action

This section discusses three examples.

- Example 1** Configure two event policies, **policy1** and **policy2**. The **policy1** event policy has a 5-second transfer-delay when uploading the **process.core** file to the **some-dest** destination. The **policy2** event policy has no transfer delay when uploading the **process.core** file to the same destination.

```
[edit event-options]
policy policy1 {
  events e1;
  then {
    upload filename process.core destination some-dest {
      transfer-delay 5;
    }
  }
}
policy policy2 {
  events e2;
  then {
    upload filename process.core destination some-dest;
  }
}
destinations {
  some-dest {
```

```

        archive-sites {
            "scp://robot@my.little.com/foo/moo" password "password";
            "scp://robot@my.big.com/foo/moo" password "password";
        }
    }
}

```

Example 2 The **policy1** event policy has a 7-second (5 seconds + 2 seconds) transfer delay when uploading the **process.core** file to the destination. The **policy2** event policy has a 2-second transfer delay when uploading the **process.core** file to the destination.

```

[edit event-options]
policy policy1 {
    events e1;
    then {
        upload filename process.core destination some-dest {
            transfer-delay 5;
        }
    }
}
policy policy2 {
    events e2;
    then {
        upload filename process.core destination some-dest;
    }
}
destinations {
    some-dest {
        transfer-delay 2;
        archive-sites {
            "scp://robot@my.little.com/foo/moo" password "password";
            "scp://robot@my.big.com/foo/moo" password "password";
        }
    }
}
}

```

Example 3 The **policy1** event-policy is executed with **user1** privileges and uploads the **process.core** file after a transfer delay of 7 seconds (5 seconds + 2 seconds). The **policy2** event policy is executed with **root** privileges and uploads the **process.core** file after a transfer delay of 6 seconds (4 seconds + 2 seconds).

```

[edit event-options]
policy policy1 {
    events e1;
    then {
        upload filename process.core destination some-dest {
            transfer-delay 5;
            user-name user1;
        }
    }
}
policy policy2 {
    events e2;
    then {
        upload filename process.core destination some-dest {
            transfer-delay 4;

```

```
    }  
  }  
}  
destinations {  
  some-dest {  
    transfer-delay 2;  
    archive-sites {  
      "scp://robot@my.little.com/foo/moo" password "password";  
      "scp://robot@my.big.com/foo/moo" password "password";  
    }  
  }  
}
```

Example: Associating an Optional User with an Event Policy Action

Configure two event policies, **policy1** and **policy2**.

In **policy1**, associate user **user1** with the **execute-commands** action. The **execute-commands** action is executed with **user1** privileges.

In **policy2**, do not explicitly associate a user with the **event-script** action. The **event-script** action is executed with **root** privileges.

```
[edit system]  
login {  
  user user1 {  
    class operator;  
  }  
}  
[edit event-options]  
policy p1 {  
  events e1;  
  then {  
    execute-commands {  
      commands {  
        "show version";  
      }  
      user-name user1;  
      output-filename command-output.txt;  
      destination some-dest;  
    }  
  }  
}  
policy p2 {  
  events e2;  
  then {  
    event-script script.xml {  
      output-filename event-script-output.txt;  
      destination some-dest;  
    }  
  }  
}
```

Example: Controlling Event Policy Using a Regular Expression

The following policy is executed only if the **interface-name** attribute in both traps (**SNMP_TRAP_LINK_DOWN** and **SNMP_TRAP_LINK_UP**) match each other and the **interface-name** attribute in the **SNMP_TRAP_LINK_DOWN** trap starts with letter *t*. This means the policy is executed only for T1 (**t1-**) and T3 (**t3-**) interfaces. The policy is not executed when the **eventd** process receives traps from other interfaces.

NOTE: In system log files, the message tags appear in all uppercase letters. In the command-line interface (CLI), the message tags appear in all lowercase letters.

```
[edit event-options]
policy pol6 {
  events snmp_trap_link_down;
  within 120 events snmp_trap_link_up;
  attributes-match {
    snmp_trap_link_up.interface-name equals snmp_trap_link_down.interface-name;
    snmp_trap_link_down.interface-name matches "^t";
  }
  then {
    execute-commands {
      commands {
        "show interfaces {${$.interface-name}";
        "show configuration interfaces {${$.interface-name}";
      }
      output-filename config.txt;
      destination bsd2;
      output-format text;
    }
  }
}
```

Example: Correlating Events Based on Event Attributes

In the following policy, the two events are correlated only if two of their parameter values match. Matching on attributes of both events ensures that the two events are related. In this case, the interface addresses must match and the physical interface (**ifd**) names must match.

The **RPD_KRT_IFDCHANGE** error occurs when the routing protocol process (**rpd**) sends a request to the kernel to change the state of an interface and the request fails. The **RPD_RDISC_NOMULTI** error occurs when an interface is configured for router discovery but the interface does not support IP multicast operations as required.

In this example, **RPD_RDISC_NOMULTI.interface-name** might be **so-0/0/0.0**, and **RPD_KRT_IFDCHANGE.ifd-index** might be **so-0/0/0**.

```
[edit event-options]
policy 1 {
  events rpd_rdisc_nomulti;
  within 500 events rpd_krt_ifdchange;
  attributes-match {
```

```

        rpd_rdisc_nomulti.interface-address equals rpd_krt_ifdchange.address;
        rpd_rdisc_nomulti.interface-name starts-with rpd_krt_ifdchange.ifd-index;
    }
    then {
        ... actions ...
    }
}

```

Example: Correlating Events Based on Receipt of Other Events Within a Specified Time Interval

In the following policy, a set of commands is issued and the output is logged and saved to a given location. The policy is executed if **event3**, **event4**, or **event5** occurs within 60 seconds after **event1** or **event2** occurs. The pseudocode for the policy is as follows:

```

if this event is (event3 or event4 or event5)
and
(event1 or event2 has been received within the last 60 seconds)
then {
    run a set of commands;
    log the output of these commands to a location;
}

```

Specify two archive sites in the configuration. The device attempts to transfer to the first archive site in the list, moving to the next site only if the transfer fails.

```

[edit event-options]
policy 1 {
    events [ event3 event4 event5 ];
    within 60 events [ event1 event2 ];
    then {
        execute-commands {
            commands {
                "command";
            }
            output-filename my_cmd_out;
            destination policy-1-command-dest;
        }
    }
}
destinations {
    policy-1-command-dest {
        archive-sites {
            scp://robot@my.big.com/a/b;
            scp://robot@my.little.com/a/b;
        }
    }
}

```

Example: Generating an Internal Event

The following two examples generate an internal event. In the first example, the configuration generates an internal event every hour. In the second example, the configuration generates an event every night at midnight.

In the following example, the internal event called **EVERY-ONE-HOUR** is generated every hour (3600 seconds). If 3601 seconds pass and the event has not been generated, certain actions are taken.

```
[edit event-options]
generate-event every-one-hour time-interval 3600;
policy check-heartbeat {
  events every-one-hour;
  within 3601 not events every-one-hour;
  then {
    ... actions ...
  }
}
```

In the following example, the internal event called **IT-IS-MIDNIGHT** is generated at 12:00 AM every night (00:00:00). When the eventd process receives the **IT-IS-MIDNIGHT** event, certain actions are taken.

```
[edit event-options]
generate-event it-is-midnight time-of-day 00:00:00;
policy midnight-chores {
  events it-is-midnight;
  then {
    ... actions ...
  }
}
```

Example: Ignoring Events Based on Receipt of Other Events

In the following policy, if any of **event1**, **event2**, or **event3** has occurred, and either **event4** or **event5** has occurred within the last 600 seconds, and **event6** has not occurred within the last 800 seconds, then the event that triggered the policy (**event1**, **event2**, or **event3**) is ignored, meaning system log messages are not created.

```
[edit event-options]
policy 1 {
  events [ event1 event2 event3 ];
  within 600 events [ event4 event5 ];
  within 800 not events event6;
  then {
    ignore;
  }
}
```

Sometimes events are generated repeatedly within a short period of time. In this case, it is redundant to execute a policy multiple times, once for each instance of the event. Event dampening allows you to slow down the execution of policies by ignoring instances of an event that occur within a specified time after another instance of the same event.

In the following example, an action is taken only if the eventd process has not received another instance of the event within the past 60 seconds. If an instance of the event has been received within the last 5 seconds, the policy is not executed and a system log message for the event is not created again.

```
[edit event-options]
policy dampen-policy {
  events event1;
  within 60 events event1;
```

```

    then {
        ignore;
    }
}
policy policy {
    events event1;
    then {
        ... actions ...
    }
}

```

Example: Limiting Event Script Output Based on a Specific Event Type

In situations where an event policy is triggered by multiple event types, you can limit the number of events that trigger the event script. For example, the following event policy triggers the **event-details.slax** event script whenever a **ui_login_event** or **ui_logout_event** occurs.

```

event-options {
    policy event-detail {
        events [ ui_login_event ui_logout_event ];
        then {
            event-script event-details.slax {
                output-filename systemlog;
                destination /tmp;
            }
        }
    }
}

```

The **event-details.slax** event script writes a log file only when the **ui_login_event** event occurs.

```

version 1.0;

    <event-options> {
        <policy> {
            <namex> "event-detail";
            <eventsx> "ui_login_event";
            <thenx> {
                <event-scriptx> {
                    <namex> "event_detail.slax";
                    <output-filenamex> "foo";
                    <destinationx> {
                        <namex> "foo";
                    }
                }
            }
        }
    }
}

```

```

match / {
  <event-script-resultsx> {
    <event-triggered-this-policyx> {
      expr event-script-input/trigger-event/id;
    }
    <type-of-eventx> {
      expr event-script-input/trigger-event/type;
    }
    <process-namex> {
      expr event-script-input/trigger-event/attribute-list/attribute/name;
    }
  }
}

```

Example: Raising an SNMP Trap in Response to an Event

Raise a trap and execute an associated event script in response to an event:

```

[edit event-options]
policy p1 {
  events ui_mgd_terminate;
  then {
    raise-trap;
    event-script bgp.xml {
      arguments {
        destination {${ui_mgd_terminate.destination};
        code 2;
      }
      output-filename bgp-out;
      destination bsd3;
    }
  }
}

```

Example: Representing the Correlating Event in an Event Policy

```

[edit event-options]
policy p1 {
  events [ e1 e2 e3 ];
  within 60 events [ e4 e5 e6 ];
  then {
    execute-commands {
      commands {
        "show interfaces {${$.interface-name}";
        "show interfaces {e4.interface-name}";
        "show interfaces {${*.interface-name}";
      }
      output-filename command-output.txt;
      destination some-dest;
    }
  }
}

```

In the `show interfaces {${$.interface-name}` command, the value of the `interface-name` attribute of event `e1`, `e2`, or `e3` is substituted for the `{${$.interface-name}` variable.

In the **show interfaces** `{${e4.interface-name}}` command, the value of the **interface-name** attribute of the most recent **e4** event is substituted for the `{${e4.interface-name}}` variable.

In the **show interfaces** `{${*:interface-name}}` command, the value of the **interface-name** attribute of the most recent **e4**, **e5**, or **e6** event is substituted for the `{${*:interface-name}}` variable. If one of **e4**, **e5**, or **e6** occurs within 60 seconds of **e1**, **e2**, or **e3**, the value of the **interface-name** attribute for that correlating event (**e4**, **e5**, or **e6**) is substituted for the `{${*:interface-name}}` variable. If the correlating event does not have an **interface-name** attribute, the software does not execute the **show interfaces** `{${*:interface-name}}` command.

If both **e4** and **e5** occur within 60 seconds of **e1**, then the value of the **interface-name** attribute for **e4** is substituted for the `{${*:interface-name}}` variable. This is because the event process (eventd) searches for correlating events in sequential order as configured in the **within** statement. In this case, the order is **e4** > **e5** > **e6**.

Example: Retrying the File Upload Action

This section discusses two examples.

- Example 1** Configure a policy that retries the file upload operation two times with a time interval of 5 seconds between retries:

```
event-options {
  policy p1 {
    events e1;
    then {
      execute-commands {
        commands {
          command1;
        }
        output-filename command-output.txt;
        destination some-dest {
          retry-count 2 retry-interval 5;
        }
      }
    }
  }
}
```

- Example 2** Configure a transfer delay of 10 seconds and retry the file upload operation two times with a time interval of 5 seconds between retries:

```
event-options {
  policy p2 {
    events e1;
    then {
      execute-commands {
        commands {
          command1;
        }
        output-filename command-output.txt;
        destination some-dest {
          retry-count 2 retry-interval 5;
          transfer-delay 10;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

The transfer delay is in operation for the first upload attempt only. The policy uploads the **command-output.txt** file after a 10-second transfer delay. If the event process (eventd) detects failure of the upload operation, eventd retries the upload operation after 5 seconds. The failure detection time can be in the range from 60 to 90 seconds, depending on the transmission protocol, such as FTP.

The following sequence describes the file upload operation with two failed retransmissions:

1. Policy triggers upload operation.
2. Transmission delay of 10 seconds.
3. Policy tries to upload the output file.
4. Policy detects transmission failure.
5. Retry interval of 5 seconds.
6. Policy tries to upload the output file.
7. Policy detects transmission failure.
8. Retry interval of 5 seconds.
9. Policy tries to upload the output file.
10. Policy detects transmission failure.
11. Policy declares the failure of the file upload operation.

Example: Triggering a Policy Based on Event Count

This section discusses two examples.

NOTE: The **RADIUS_LOGIN_FAIL**, **TELNET_LOGIN_FAIL**, and **SSH_LOGIN_FAIL** events are not actual Junos OS events. They are illustrative for these examples.

Example 1 Configure an event policy called **login**. The **login** policy is executed if five login failure events (**RADIUS_LOGIN_FAIL**, **TELNET_LOGIN_FAIL**, or **SSH_LOGIN_FAIL**) are generated within 120 seconds. Take action by executing the **login-fail.xml** event script, which disables the user account.

```

[edit event-options]
policy login {
  events [ RADIUS_LOGIN_FAIL TELNET_LOGIN_FAIL SSH_LOGIN_FAIL ];
  within 120 {
    trigger after 4;
  }
}

```

```

    then {
      event-script login-fail.xml {
        destination some-dest;
      }
    }
  }
}

```

Table 25 on page 482 shows how events add to the count.

Table 25: Event Count Triggers Policy

Event Number	Event	Time	Count	Order
1	RADIUS_LOGIN_FAIL	00:00:00	1	[1]
2	TELNET_LOGIN_FAIL	00:00:20	2	[1 2]
3	RADIUS_LOGIN_FAIL	00:02:05	2	[2 3]
4	SSH_LOGIN_FAIL	00:02:40	2	[3 4]
5	TELNET_LOGIN_FAIL	00:02:55	3	[3 4 5]
6	TELNET_LOGIN_FAIL	00:03:01	4	[3 4 5 6]
7	RADIUS_LOGIN_FAIL	00:03:55	5	[3 4 5 6 7]

The columns in Table 25 on page 482 mean the following:

- Event number—Event sequence number.
- Event—Policy login events received by the event process (eventd).
- Time—Time (in *hh:mm:ss* format) when eventd receives the event.
- Count—The number of events received by eventd within the last 120 seconds.
- Order—Order of events as received by eventd within the last 120 seconds.

At time 00:03:55, the value of count is more than 4; therefore, the **login** policy executes the **login-fail.xml** script.

Example 2 Configure an event policy called **login**. The **login** policy is executed if five login failure events (**RADIUS_LOGIN_FAIL**, **TELNET_LOGIN_FAIL**, or **SSH_LOGIN_FAIL**) are generated within 120 seconds from username **roger**. Take action by executing the **login-fail.xml** event script, which disables the **roger** user account.

```

[edit event-options]
policy p2 {
  events [ RADIUS_LOGIN_FAIL TELNET_LOGIN_FAIL SSH_LOGIN_FAIL ];
  within 120 {
    trigger after 4;
  }
  attributes-match {
    RADIUS_LOGIN_FAIL.username matches roger;
    TELNET_LOGIN_FAIL.username matches roger;
  }
}

```

```
    }  
    then {  
        event-script login-fail.xsl {  
            destination some-dest;  
        }  
    }  
}
```

Example: Using Nonstandard System Log Messages to Trigger an Event Policy

Reference a **KERNEL** system log message in an event policy. The **raise-trap** action in the **then** statement is executed only if a **KERNEL** event containing a message that matches "exited on signal 11" occurs.

```
[edit event-options]  
policy kernel-policy {  
    events KERNEL;  
    attributes-match {  
        KERNEL.message matches "exited on signal 11";  
    }  
    then {  
        raise-trap;  
    }  
}
```

Summary of Event Policy Configuration Statements

archive-sites

Syntax	<pre>archive-sites { url <password password>; }</pre>
Hierarchy Level	[edit event-options destinations destination-name]
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Specify an archive site to which files are transferred. If you specify more than one archive site, the device attempts to transfer to the first archive site in the list, moving to the next site only if the transfer fails.
Options	<p>url—The archive destination specified as a file URI, an active or passive FTP URI, or a Secure Copy (SCP) URI. Local device directories are also supported (for example, <code>/var/tmp/</code>).</p> <pre>file:<host>/path ftp://username@host:<port>url-path pasvftp://username@host:<port>url-path scp://username@host:<port>url-path <path>/<filename></pre> <p>password password—A plain-text password required for login into the archive site.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Example: Defining Destinations for File Archiving by Event Policies on page 421• destinations on page 492

arguments

Syntax	<pre>arguments { <i>argument-name</i> <i>argument-value</i>; }</pre>
Hierarchy Level	[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>]
Release Information	Statement introduced in Junos OS Release 7.6. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Define command-line arguments for an event script that is invoked from an event policy.
Options	<i>argument-name</i> —Name of the argument. <i>argument-value</i> —Value of the argument.
Required Privilege Level	<i>maintenance</i> —To view this statement in the configuration. <i>maintenance-control</i> —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Executing Event Scripts in an Event Policy on page 449• event-script on page 496• policy on page 503

attributes-match

Syntax	<pre> attributes-match { event1.attribute-name equals event2.attribute-name; event.attribute-name matches regular-expression; event1.attribute-name starts-with event2.attribute-name; } </pre>
Hierarchy Level	[edit event-options policy <i>policy-name</i>]
Release Information	<p>Statement introduced in Junos OS Release 7.5.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	<p>Execute the policy only if the attributes of two events are correlated or if the attribute of one event matches a regular expression.</p> <p>If the attributes-match statement includes the equals or starts-with options, or if it includes a matches option that includes a clause for an event that is not specified at the [edit event-options policy <i>policy-name events</i>] hierarchy level, you must include one or more within statements in the same policy configuration.</p> <p>Starting with Junos OS Release 11.1, you can include event policy variables within the statement to differentiate between a trigger event attribute and a correlated event attribute. You can use variables of the following forms:</p> <ul style="list-style-type: none"> • `\${attribute-name}—The double dollar sign (\$\$) notation represents the event that is triggering a policy. When combined with an attribute name, the variable is replaced by the value of the attribute of the triggering event. • `\${event.attribute-name}—The dollar sign with the event name (`\${event}`) notation represents the most recent event that matches the specified event. The variable is replaced by the value of the attribute of the most recent event that matches event. <p>The statements are explained separately.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Using Correlated Events to Trigger an Event Policy on page 413 • Using Regular Expressions to Refine the Set of Events That Trigger a Policy on page 417 • equals on page 493 • matches on page 500 • starts-with on page 509 • within on page 517

change-configuration

Syntax	<pre> change-configuration { commands { "command"; } commit-options { check <synchronize>; force; log "comment-string"; synchronize; } retry count <i>number</i> interval <i>seconds</i>; user-name <i>username</i>; } </pre>
Hierarchy Level	[edit event-options policy policy-name then]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	<p>When the associated event policy is invoked, update the candidate configuration using Junos OS configuration mode commands, and commit the changes.</p> <p>The statements are explained separately.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring an Event Policy to Change the Configuration on page 436 • commands (Event Policy Change Configuration) on page 488 • commit-options on page 490 • retry on page 506 • user-name on page 519

commands (Event Policy Change Configuration)

Syntax	<pre>commands { "command"; }</pre>
Hierarchy Level	[edit event-options policy <i>policy-name</i> then change-configuration]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Specify the configuration mode commands to be issued on receipt of an event. Within an event policy, on receipt of the specified event or events, the event process (eventd) invokes the configured commands to update the candidate configuration, which is then committed, provided that no commit errors occur. The eventd process executes the configuration commands in the order in which they appear in the event policy configuration.
Options	command —Configuration mode command to be executed. Enclose each command in quotation marks (" "), and specify the complete statement path to the element, identifier, or value as you do in configuration mode when issuing commands at the [edit] hierarchy level.
Required Privilege Level	maintenance —To view this statement in the configuration. maintenance-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring an Event Policy to Change the Configuration on page 436• change-configuration on page 487• commit-options on page 490• retry on page 506• user-name on page 519

commands (Event Policy Execute Commands)

Syntax	<pre>commands { "command"; }</pre>
Hierarchy Level	[edit event-options policy policy-name then execute-commands]
Release Information	<p>Statement introduced in Junos OS Release 7.5.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	Specify an operational mode command to be issued on receipt of an event.
Options	<p>command—Command to be issued. Enclose each command in quotation marks (“ ”). The event process (eventd) issues the commands in the order in which they appear in the configuration.</p> <p>You can include variables in commands. The eventd process replaces each variable with values contained in the event that triggers the policy. You can use command variables of the following forms:</p> <ul style="list-style-type: none"> • {{\$.attribute-name}}—The double dollar sign (\$\$) notation represents the event that is triggering a policy. When combined with an attribute name, the command variable is replaced by the value of the attribute name of the triggering event. • {\$event.attribute-name}—The dollar sign with the event name (<i>\$event</i>) notation represents the most recent event that matches the specified event. The variable is replaced by the value of the attribute name of the most recent event that matches <i>event</i>. • {\$*.attribute-name}—The dollar sign with the asterisk (\$*) notation represents the most recent event that matches any of the correlating events. The variable is replaced by the value of the attribute name of the most recent event that matches any of the events specified in the policy configuration.
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring an Event Policy to Execute Operational Mode Commands on page 433 • Representing the Correlating Event in an Event Policy on page 416

commit-options

Syntax	<pre>commit-options { check <synchronize>; force; log "comment-string"; synchronize; }</pre>
Hierarchy Level	[edit event-options policy policy-name then change-configuration]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Customize the commit options for configuration updates made through an event policy. The check statement and the other commit-options statements are mutually exclusive.
Options	<p>check <synchronize>—Verify that the candidate configuration is syntactically correct, but do not commit the changes. On dual control plane systems, when the check synchronize statement is configured, the candidate configuration on one control plane is copied to the other control plane, and the system verifies that both candidate configurations are syntactically correct. The check statement and the other commit-options statements are mutually exclusive.</p> <p>force—Force the commit on the other Routing Engine, ignoring any warnings. By default, the synchronize command does not work if the responding Routing Engine has uncommitted configuration changes. However, you can enforce commit synchronization on the Routing Engines by using the force option.</p> <p>log "comment-string"—Include a comment describing changes to the committed configuration. Enclose the comment in quotation marks and include it on a single line. To view commit comments, issue the show system commit operational mode command.</p> <p>synchronize—Synchronize the commit on both Routing Engines. The Routing Engine on which you execute this command copies and loads its candidate configuration to the other Routing Engine. Both Routing Engines perform a syntax check on the candidate configuration file. If no errors are found, the configuration is activated and becomes the current operational configuration on both Routing Engines.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring an Event Policy to Change the Configuration on page 436 • change-configuration on page 487 • commands (Event Policy Change Configuration) on page 488 • retry on page 506 • user-name on page 519

destination

Syntax	<pre>destination <i>destination-name</i> { retry-count <i>count</i> retry-interval <i>seconds</i>; transfer-delay <i>seconds</i>; }</pre>
Hierarchy Level	<pre>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>], [edit event-options policy <i>policy-name</i> then execute-commands]</pre>
Release Information	<p>Statement introduced in Junos OS Release 7.5.</p> <p>Support extended to the <code>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>]</code> hierarchy level in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	Assign a location to which to upload command or script output for the specified policy.
Options	<p><i>destination-name</i>—Name of a destination defined in the destinations statement at the <code>[edit event-options]</code> hierarchy level.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring an Event Policy to Execute Operational Mode Commands on page 433 • Executing Event Scripts in an Event Policy on page 449 • destinations on page 492

destinations

Syntax	<pre>destinations { <i>destination-name</i> { archive-sites { url <password <i>password</i>>; } transfer-delay <i>seconds</i>; } }</pre>
Hierarchy Level	[edit event-options]
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Define one or more destinations, each with a unique name and other attributes. You can use the destination as a storage location for command output and for various files, such as system log files and core files.
Options	<p><i>destination-name</i>—Name of a destination.</p> <p>The remaining statements are explained separately.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>

Hierarchy Level [edit]

Release Information Statement introduced in Junos OS Release 7.5.
Statement introduced in Junos OS Release 9.0 for EX Series switches.

Description	Configure event policies. The statements are explained separately.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.

event-script

Syntax	<pre>event-script filename { arguments { argument-name argument-value; } destination destination-name { retry-count count retry-interval seconds; transfer-delay seconds; } output-filename filename; output-format (text xml); user-name username; }</pre>
Hierarchy Level	[edit event-options policy policy-name then]
Release Information	Statement introduced in Junos OS Release 7.6. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	On receipt of an event, specify operational mode commands to be issued, the format of the command output, and a name and destination for the output file. The statements are explained separately.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Executing Event Scripts in an Event Policy on page 449

events (Associating Events with a Policy)

Syntax	<code>events [<i>events</i>];</code>
Hierarchy Level	<code>[edit event-options policy <i>policy-name</i>]</code>
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Create a list of events that trigger this policy. If one or more of the listed events occurs, the policy is executed.
Options	<code>[<i>events</i>]</code> —List of events. Events can be internally generated, or they can be generated by Junos OS processes.
Required Privilege Level	<code>maintenance</code> —To view this statement in the configuration. <code>maintenance-control</code> —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Using Correlated Events to Trigger an Event Policy on page 413 • Example: Correlating Events Based on Event Attributes on page 475

events (Correlating Events with Each Other)

Syntax	<code>events [<i>events</i>];</code>
Hierarchy Level	<code>[edit event-options policy <i>policy-name</i> within <i>seconds</i>]</code>
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Create a list of events that must occur within a specified time interval for the policy to be triggered.
Options	<code>[<i>events</i>]</code> —List of events. Events can be internally generated, or they can be generated by Junos OS processes.
Required Privilege Level	<code>maintenance</code> —To view this statement in the configuration. <code>maintenance-control</code> —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Using Correlated Events to Trigger an Event Policy on page 413

execute-commands

Syntax	<pre>execute-commands { commands { "command"; } destination destination-name { retry-count count retry-interval seconds; transfer-delay seconds; } output-filename filename; output-format (text xml); user-name username; }</pre>
Hierarchy Level	[edit event-options policy policy-name then]
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	On receipt of an event, specify operational mode commands to be issued, the format of the command output, and a name and destination for the output file. The statements are explained separately.

facility

Syntax	<pre>facility facility-type;</pre>
Hierarchy Level	[edit event-options policy policy-name then priority-override]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Within an event policy, override the default facility type of the triggering event so that the event is logged based on the configured facility type.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring the System Log Priority of the Triggering Event in an Event Policy on page 456• Junos OS System Logging Facilities and Message Severity Levels• priority-override on page 505• severity on page 508

generate-event

Syntax	<code>generate-event event-name { time-interval seconds; time-of-day hh:mm:ss; }</code>
Hierarchy Level	[edit event-options]
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Generate an internal event, based on a time interval or the time of day. You can configure up to 10 internal events.
Options	event-name —Name of an internally generated event. The statements are explained separately.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Generating Internal Events to Trigger Event Policies on page 419 • time-interval on page 511 • time-of-day on page 512

ignore

Syntax	<code>ignore;</code>
Hierarchy Level	[edit event-options policy policy-name then]
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Define a policy that ignores particular events. If one or more of the listed events occur, a system log message for the event is not generated, and no further policies associated with this event are processed. If you include the ignore statement in a policy configuration, you cannot configure any other actions in the policy.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Event Policies to Ignore an Event on page 454

matches

Syntax	<i>event.attribute-name matches regular-expression;</i>
Hierarchy Level	[edit event-options policy policy-name attributes-match]
Release Information	Statement introduced in Junos OS Release 7.5.
Description	Execute the policy only if the specified attribute of event matches a regular expression.
Options	event.attribute-name —Event attribute to compare to a regular expression. regular-expression —Regular expression to compare.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Using Correlated Events to Trigger an Event Policy on page 413• Using Regular Expressions to Refine the Set of Events That Trigger a Policy on page 417

not

Syntax	not events [<i>events</i>];
Hierarchy Level	[edit event-options policy policy-name within seconds]
Release Information	Statement introduced in Junos OS Release 7.5. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Create a list of events that must not occur within the specified time interval for the policy to be triggered.
Options	[<i>events</i>]—List of events. Events can be internally generated, or they can be generated by Junos OS processes.
Required Privilege Level	maintenance—To view this statement in the configuration. maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Using Correlated Events to Trigger an Event Policy on page 413

output-filename

Syntax	<code>output-filename <i>filename</i>;</code>
Hierarchy Level	<code>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>],</code> <code>[edit event-options policy <i>policy-name</i> then execute-commands]</code>
Release Information	Statement introduced in Junos OS Release 7.5. Support at the <code>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>]</code> hierarchy level introduced in Junos OS Release 7.6.
Description	Assign a filename to which to write command or script output for the specified commands or script. For op scripts, this statement is optional.
Options	<i>filename</i> —Name of a file in which to write command or script output.
Required Privilege Level	<code>maintenance</code> —To view this statement in the configuration. <code>maintenance-control</code> —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring an Event Policy to Execute Operational Mode Commands on page 433• Executing Event Scripts in an Event Policy on page 449

output-format

Syntax	<code>output-format (text xml);</code>
Hierarchy Level	<code>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>],</code> <code>[edit event-options policy <i>policy-name</i> then execute-commands]</code>
Release Information	Statement introduced in Junos OS Release 7.5. Support at the <code>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>]</code> hierarchy level introduced in Junos OS Release 8.3. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Specify the format (ASCII text or XML) for the output of the specified commands or script.
Options	text —Formatted ASCII text. xml —Junos Extensible Markup Language (XML) tags. Default: xml at the <code>[edit event-options policy <i>policy-name</i> then execute-commands]</code> hierarchy level and text at the <code>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i>]</code> hierarchy level.
Required Privilege Level	maintenance —To view this statement in the configuration. maintenance-control —To add this statement to the configuration.

}

```

Hierarchy Level [edit *event-options*]

Release Information Statement introduced in Junos OS Release 7.5.
Statement introduced in Junos OS Release 9.0 for EX Series switches.

Description Define an event policy to be processed by the eventd process. If you configure a policy, the **events** and **then** statements are mandatory.

You can configure multiple policies to be processed for an event. The policies are executed in the order in which they appear in the configuration. If you configure more than one policy for an event, and if one of the policies is to ignore the event, no policies that follow the **ignore** statement are executed.

Default If you do not configure a policy for an event, the event is recorded in the system log.

Options *policy-name*—Name of an event policy.

The statements are explained separately.

Required Privilege Level maintenance—To view this statement in the configuration.
maintenance-control—To add this statement to the configuration.

priority-override

Syntax	<pre>priority-override { facility facility-type; severity severity-level; }</pre>
Hierarchy Level	[edit event-options policy policy-name then]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	<p>Within an event policy, override the default system log priority of the triggering event so that the system logs the event with a different facility type, severity level, or both. If you configure multiple event policies to override the priority of the same event, the event is logged based on the priority set by the last executed event policy to change it.</p> <p>The statements are explained separately.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring the System Log Priority of the Triggering Event in an Event Policy on page 456 • <i>Junos OS System Logging Facilities and Message Severity Levels</i> • facility on page 498 • severity on page 508

raise-trap

Syntax	raise-trap;
Hierarchy Level	[edit event-options policy policy-name then]
Release Information	<p>Statement introduced in Junos OS Release 8.1.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	<p>Define a policy that raises an SNMP trap in response to an event. If one or more of the listed events occur, the system log message for the event is converted into a trap. This enables an agent to notify a trap-based network management system (NMS) of significant events.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring Event Policies to Raise SNMP Traps on page 455

retry

Syntax	<code>retry count <i>number</i> interval <i>seconds</i>;</code>
Hierarchy Level	[edit event-options policy <i>policy-name</i> then change-configuration]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Specify the number of times that Junos OS attempts the change-configuration event policy action if the initial attempt fails while acquiring a lock on the configuration database. If you include the retry statement, you must configure both the count and interval statements.
Default	If you do not include the retry statement, and the change-configuration event policy action fails, the configuration changes specified in the event policy are not implemented or committed.
Options	count <i>number</i> —The number of attempts to retry the change-configuration event policy action upon failure of the initial attempt. Range: 0 through 10 Default: 0 interval <i>seconds</i> —The time interval specified in seconds between retry attempts.
Required Privilege Level	maintenance —To view this statement in the configuration. maintenance-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring an Event Policy to Change the Configuration on page 436• change-configuration on page 487• commands (Event Policy Change Configuration) on page 488• commit-options on page 490• user-name on page 519

retry-count

Syntax	<code>retry-count <i>number</i> retry-interval <i>seconds</i>;</code>
Hierarchy Level	<pre>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i> destination <i>destination-name</i>], [edit event-options policy <i>policy-name</i> then execute-commands destination <i>destination-name</i>], [edit event-options policy <i>policy-name</i> then upload <i>filename</i> (<i>filename</i> committed) destination <i>destination-name</i>]</pre>
Release Information	<p>Statement introduced in Junos OS Release 8.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	Configure an event policy to retry a file upload operation if the first attempt fails.
Default	If you do not include this statement, the file upload operation is attempted one time only.
Options	<p><i>number</i>—Number of retries.</p> <p><i>retry-interval seconds</i>—Length of time to wait between retries.</p>
Required Privilege Level	<p><i>maintenance</i>—To view this statement in the configuration.</p> <p><i>maintenance-control</i>—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring an Event Policy to Retry the File Upload Action on page 432

severity

Syntax `severity severity-level;`

Hierarchy Level `[edit event-options policy policy-name then priority-override]`

Release Information Statement introduced in Junos OS Release 12.1.

Description Within an event policy, override the preassigned severity level of a triggering event so that the event is logged based on the configured severity level. [Table 26 on page 508](#) lists the possible severity levels.

Table 26: System Log Message Severity Levels

Severity Level	Description
emergency	System panic or other conditions that cause the routing platform to stop functioning
alert	Conditions that require immediate correction, such as a corrupted system database
critical	Critical conditions, such as hard drive errors
error	Error conditions that generally have less serious consequences than errors in the emergency, alert, and critical levels
warning	Conditions that warrant monitoring
notice	Conditions that are not errors but might warrant special handling
info	Events or non-error conditions of interest

Required Privilege Level maintenance—To view this statement in the configuration.
maintenance-control—To add this statement to the configuration.

traceoptions

Syntax	<pre> traceoptions { file <filename> <files number> <match regular-expression> <size size> <world-readable no-world-readable>; flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit event-options]
Release Information	<p>Statement introduced in Junos OS Release 7.5.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	Define tracing operations for event policies.
Default	If you do not include this statement, no event-policy-specific tracing operations are performed.
Options	<p>filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory <code>/var/log</code>. By default, commit script process tracing output is placed in the file eventtd. If you include the file statement, you must specify a filename. To retain the default, you can specify eventtd as the filename.</p> <p>files number—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed and compressed to trace-file.0.gz. When trace-file again reaches its maximum size, trace-file.0.gz is renamed trace-file.1.gz and trace-file is renamed and compressed to trace-file.0.gz. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000</p> <p>Default: 3 files</p> <p>flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> • all—Log all operations • configuration—Log reading of configuration at the [edit event-options] hierarchy level • events—Log eventtd processing • database—Log events involving storage and retrieval in events database • server—Log communication with processes that are generating events • timer-events—Log internally generated events

match *regular-expression*—(Optional) Refine the output to include lines that contain the regular expression.

no-world-readable—Restrict file access to owner. This is the default.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed and compressed to ***trace-file.0.gz***. When the ***trace-file*** again reaches its maximum size, ***trace-file.0.gz*** is renamed ***trace-file.1.gz*** and ***trace-file*** is renamed and compressed to ***trace-file.0.gz***. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and filename.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

world-readable—(Optional) Enable unrestricted file access.

Required Privilege Level	maintenance—To view this statement in the configuration.
	maintenance-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Tracing Event Policy Processing on page 529

transfer-delay

Syntax	<code>transfer-delay <i>seconds</i>;</code>
Hierarchy Level	<code>[edit event-options destinations <i>destination-name</i>],</code> <code>[edit event-options policy <i>policy-name</i> then event-script <i>filename</i></code> <code> <i>destination destination-name</i>],</code> <code>[edit event-options policy <i>policy-name</i> then execute-commands</code> <code> <i>destination destination-name</i>],</code> <code>[edit event-options policy <i>policy-name</i> then upload <i>filename</i> (<i>filename</i> committed)</code> <code> <i>destination destination-name</i>]</code>
Release Information	<p>Statement introduced in Junos OS Release 7.5.</p> <p>Support at the <code>[edit event-options policy <i>policy-name</i> then ...]</code> hierarchy levels introduced in Junos OS Release 8.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	<p>Configure a delay before transferring files. This allows the files to be completely generated before the upload starts. If you configure a transfer delay at the <code>[edit event-options destination <i>destination-name</i>]</code> hierarchy level and at one of the <code>[edit event-options policy <i>policy-name</i> then ...]</code> hierarchy levels, the resulting delay is the sum of the two delays.</p>
Default	If you do not include this statement, there is no transfer delay.
Options	<i>seconds</i> —Duration of the delay before files are uploaded.
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Defining Destinations for File Archiving by Event Policies on page 421 • Configuring the Delay Before Files Are Uploaded by an Event Policy on page 431

trigger

Syntax	<code>trigger (on after until) <i>event-count</i>;</code>
Hierarchy Level	[edit event-options policy <i>policy-name</i> within seconds]
Release Information	Statement introduced in Junos OS Release 8.4. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Configure an event policy to be triggered if an event or set of events occurs <i>event-count</i> times within a specified time period.
Default	If you do not include this statement, the policy is executed on receipt of the first configured event.
Options	<p>after <i>event-count</i>—The policy is executed when the number of matching events received equals <i>event-count</i> + 1.</p> <p>on <i>event-count</i>—The policy is executed when the number of matching events received equals <i>event-count</i>.</p> <p>until <i>event-count</i>—The policy is executed each time a matching event is received and stops being executed when the number of matching events received equals <i>event-count</i>.</p>
Required Privilege Level	<p>maintenance—To view this statement in the configuration.</p> <p>maintenance-control—To add this statement to the configuration.</p>

traceoptions (Event Scripts)

Syntax	<pre> traceoptions { file <filename> <files number> <size size> <world-readable no-world-readable>; flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit event-options event-script]
Release Information	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>
Description	Define tracing operations for event scripts.
Default	If you do not include this statement, no event script–specific tracing operations are performed.
Options	<p>filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory <code>/var/log</code>. By default, event script process tracing output is placed in the file escript.log. If you include the file statement, you must specify a filename. To retain the default, you can specify escript.log as the filename.</p> <p>files number—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed and compressed to trace-file.0.gz. When trace-file again reaches its maximum size, trace-file.0.gz is renamed trace-file.1.gz and trace-file is renamed and compressed to trace-file.0.gz. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000</p> <p>Default: 10 files</p> <p>flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> • all—Log all operations • events—Log important events • input—Log event script input data • offline—Generate data for offline development • output—Log event script output data • rpc—Log event script RPCs • xslt—Log the XSLT library <p>no-world-readable—Restrict file access to owner. This is the default.</p>

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named *trace-file* reaches this size, it is renamed and compressed to *trace-file.0.gz*. When *trace-file* again reaches its maximum size, *trace-file.0.gz* is renamed *trace-file.1.gz* and *trace-file* is renamed and compressed to *trace-file.0.gz*. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and a filename.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

world-readable—Enable unrestricted file access.

Required Privilege	maintenance—To view this statement in the configuration.
Level	maintenance-control—To add this statement to the configuration.

Troubleshooting Event Policy and Event Scripts

- [Tracing Event Policy Processing on page 529](#)
- [Tracing Event Script Processing on page 532](#)

Tracing Event Policy Processing

Event policy tracing operations track all event policy operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

By default, no events are traced. If you include the **traceoptions** statement at the **[edit event-options]** hierarchy level, the default tracing behavior is the following:

- Important events are logged in a file called **eventd** located in the **/var/log** directory.
- When the file **eventd** reaches 128 kilobytes (KB), it is renamed and compressed to **eventd.0.gz**, then **eventd.1.gz**, and so on, until there are three trace files. Then the oldest trace file (**eventd.2.gz**) is overwritten. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)
- Log files can be accessed only by the user who configures the tracing operation.

You cannot change the directory (**/var/log**) to which trace files are written. However, you can customize the other trace file settings by including the following statements at the **[edit event-options traceoptions]** hierarchy level:

```
[edit event-options traceoptions]
file <filename> <files number> <match regular-expression> <size size> <world-readable |
  no-world-readable>;
flag all;
flag configuration;
flag database;
flag events;
flag policy;
flag server;
flag syslog;
flag timer-events;
no-remote-trace;
```

These statements are described in the following sections:

- [Configuring the Event Policy Log Filename on page 530](#)
- [Configuring the Number and Size of Event Policy Log Files on page 530](#)
- [Configuring Access to the Log File on page 531](#)
- [Configuring a Regular Expression for Lines to Be Logged on page 531](#)
- [Configuring the Trace Operations on page 531](#)

Configuring the Event Policy Log Filename

By default, the name of the file that records trace output is **eventd**. You can specify a different name by including the **file** statement at the **[edit event-options traceoptions]** hierarchy level:

```
[edit event-options traceoptions]
file filename;
```

Configuring the Number and Size of Event Policy Log Files

By default, when the trace file reaches 128 kilobytes (KB) in size, it is renamed **filename.0**, then **filename.1**, and so on, until there are three trace files. Then the oldest trace file (**filename.2**) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the **[edit event-options traceoptions file <filename>]** hierarchy level:

```
[edit event-options traceoptions file <filename>]
files number size size;
```

For example, set the maximum file size to 2 MB and the maximum number of files to 20. When the file that receives the output of the tracing operation (*filename*) reaches 2 MB, *filename* is renamed and compressed to *filename.0.gz* and a new file called *filename* is created.

When *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is renamed and compressed to *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file (*filename.19.gz*) is overwritten.

The number of files can range from 2 through 1000 files. The file size can range from 10 KB through 1 gigabyte (GB).

Configuring Access to the Log File

By default, log files can be accessed only by the user who configures the tracing operation.

To specify that any user can read all log files, include the **world-readable** statement at the **[edit event-options traceoptions file <filename>]** hierarchy level:

```
[edit event-options traceoptions file <filename>]
world-readable;
```

To explicitly set the default behavior, include the **no-world-readable** statement at the **[edit event-options traceoptions file <filename>]** hierarchy level:

```
[edit event-options traceoptions file <filename>]
no-world-readable;
```

Configuring a Regular Expression for Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged events.

You can refine the output by including the **match** statement at the **[edit event-options traceoptions file <filename>]** hierarchy level and specifying a regular expression to be matched:

```
[edit event-options traceoptions file <filename>]
match regular-expression;
```

Configuring the Trace Operations

By default, only important events are logged. You can configure the trace operations to be logged by including the following statements at the **[edit event-options traceoptions]** hierarchy level:

```
[edit event-options traceoptions]
flag all;
flag configuration;
flag database;
flag events;
flag policy;
flag server;
flag syslog;
flag timer-events;
```

[Table 27 on page 532](#) describes the meaning of the event policy tracing flags.

Table 27: Event Policy Tracing Flags

Flag	Description	Default Setting
all	Trace all operations.	Off
configuration	Log reading of configuration at the [edit event-options] hierarchy level.	Off
events	Trace important events.	Off
database	Log events involving storage and retrieval in events database.	Off
policy	Log policy processing.	Off
server	Log communication with processes that are generating events.	Off
syslogd	Log syslog related traces	Off
timer-events	Log internally generated events.	Off

To display the end of the log, issue the **show log eventd | last** operational mode command:

```
[edit]
user@host# run show log eventd | last
```

Related Documentation

- [Configuring the System Log Priority of the Triggering Event in an Event Policy on page 456](#)

Tracing Event Script Processing

Event script tracing operations track all event script operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

The default operation of event script tracing is to log important events in a file called **escript.log** located in the **/var/log** directory. When the file **escript.log** reaches 128 kilobytes (KB), it is renamed with a number 0 through 9 (in ascending order) appended to the end of the file and then compressed. The resulting files are **escript.log.0.gz**, then **escript.log.1.gz**, until there are 10 trace files. Then the oldest trace file (**escript.log.9.gz**) is overwritten. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

This section discusses the following topics:

- [Minimum Configuration for Enabling Traceoptions for Event Scripts on page 533](#)
- [Configuring Tracing of Event Scripts on page 534](#)

Minimum Configuration for Enabling Traceoptions for Event Scripts

If no event script trace options are configured, the simplest way to view the trace output of an event script is to configure the **output** trace flag and issue the **show log escript.log | last** command. To do this, perform the following steps:

1. If you have not done so already, enable an event script by including the **file** statement at the **[edit event-options event-script]** hierarchy level:

```
[edit event-options event-script]
user@host# set file filename
```

2. Enable trace options by including the **traceoptions flag output** statement at the **[edit event-options event-script]** hierarchy level:

```
[edit event-options event-script]
user@host# set traceoptions flag output
```

3. Issue the **commit** command:

```
[edit]
user@host# commit
```

4. Display the resulting trace messages recorded in the **/var/log/escript.log** file. At the end of the log is the output generated by the event script you enabled in Step 1 after a configured event policy is triggered and invokes the script. To display the end of the log, issue the **show log escript.log | last** operational mode command:

```
[edit]
user@host# run show log escript.log | last
```

[Table 28 on page 533](#) summarizes useful filtering commands that display selected portions of the **escript.log** file.

Table 28: Event Script Tracing Operational Mode Commands

Task	Command
Display logging data associated with all event script processing.	show log escript.log
Display processing for only the most recent operation.	show log escript.log last
Display processing for script errors.	show log escript.log match error
Display processing for a particular script.	show log escript.log match filename

Example: Minimum Configuration for Enabling Traceoptions for Event Scripts

Display the trace output of the event script file **source-route.xml**:

```
[edit]
event-options {
  event-script {
    file source-route.xml;
```

```
        traceoptions flag output;
    }
}

[edit]
user@host# commit
[edit]
user@host# run show log escript.log | last
```

Configuring Tracing of Event Scripts

You cannot change the directory (**/var/log**) to which trace files are written. However, you can customize other trace file settings by including the following statements at the **[edit event-options event-script traceoptions]** hierarchy level:

```
[edit event-options event-script traceoptions]
file <filename> <files number> <size size> <world-readable | no-world-readable>;
flag all;
flag events;
flag input;
flag offline;
flag output;
flag rpc;
flag xslt;
no-remote-trace;
```

These statements are described in the following sections:

- [Configuring the Event Script Log Filename on page 534](#)
- [Configuring the Number and Size of Event Script Log Files on page 534](#)
- [Configuring Access to Event Script Log Files on page 535](#)
- [Configuring the Event Script Trace Operations on page 535](#)

Configuring the Event Script Log Filename

By default, the name of the file that records trace output is **escript.log**. You can specify a different name by including the **file** statement at the **[edit event-options event-script traceoptions]** hierarchy level:

```
[edit event-options event-script traceoptions]
file filename;
```

Configuring the Number and Size of Event Script Log Files

By default, when the trace file reaches 128 KB in size, it is renamed and compressed to **filename.0.gz**, then **filename.1.gz**, and so on, until there are 10 trace files. Then the oldest trace file (**filename.9.gz**) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the **[edit event-options event-script traceoptions file <filename>]** hierarchy level:

```
[edit event-options event-script traceoptions file <filename>]
files number size size;
```

For example, set the maximum file size to 640 KB and the maximum number of files to 20. When the file that receives the output of the tracing operation (**filename**) reaches

640 KB, it is renamed and compressed to **filename.0.gz**, and a new file called **filename** is created. When **filename** reaches 640 KB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is renamed and compressed to **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file (**filename.19.gz**) is overwritten.

The number of files can range from 2 through 1000 files. The file size can range from 10 KB through 1 gigabyte (GB).

NOTE:

If you set either a maximum file size or a maximum number of trace files, you also must specify the other parameter and a filename.

Configuring Access to Event Script Log Files

By default, access to the event script log file is restricted to the owner. You can manually configure access by including the **world-readable** or **no-world-readable** statement at the **[edit event-options event-script traceoptions file <filename>]** hierarchy level.

```
[edit event-options event-script traceoptions file <filename>]
(world-readable | no-world-readable);
```

The **no-world-readable** statement restricts event script log access to the owner. The **world-readable** statement enables unrestricted access to the event script log file.

Configuring the Event Script Trace Operations

By default, only important events are logged. You can configure the trace operations to be logged by including the following statements at the **[edit event-options event-script traceoptions]** hierarchy level:

```
[edit event-options event-script traceoptions]
flag all;
flag events;
flag input;
flag offline;
flag output;
flag rpc;
flag xslt;
```

[Table 29 on page 535](#) describes the meaning of the event script tracing flags.

Table 29: Event Script Tracing Flags

Flag	Description	Default Setting
all	Trace all operations.	Off
events	Trace important events.	On
input	Trace event script input data.	Off
offline	Generate data for offline development.	Off

Table 29: Event Script Tracing Flags (*continued*)

Flag	Description	Default Setting
output	Trace event script output data.	Off
rpc	Trace event script RPCs.	Off
xslt	Trace the Extensible Stylesheet Language Transformations (XSLT) library.	Off

CHAPTER 5

Introduction to the NETCONF XML Management Protocol and Junos XML API

This chapter discusses the following:

- [XML and Junos OS on page 539](#)
- [NETCONF XML Management Protocol and Junos XML API Overview on page 541](#)
- [XML Overview on page 542](#)
- [Advantages of Using the NETCONF XML Management Protocol and Junos XML API on page 543](#)
- [Overview of a NETCONF XML Management Protocol Session on page 544](#)

XML and Junos OS

Extensible Markup Language (XML) is a standard for representing and communicating information. It is a metalanguage for defining customized tags that are applied to a data set or document to describe the function of individual elements and codify the hierarchical relationships between them. Junos OS natively supports XML for the operation and configuration of devices running Junos OS.

The Junos OS command-line interface (CLI) and the Junos OS infrastructure communicate using XML. When you issue an operational mode command in the CLI, the CLI converts the command into XML format for processing. After processing, Junos OS returns the output in the form of an XML document, which the CLI converts back into a readable format for display. Remote client applications also use XML-based data encoding for operational and configuration requests on devices running Junos OS.

The Junos XML API is an XML representation of Junos configuration statements and operational mode commands. It defines an XML equivalent for all statements in the Junos configuration hierarchy and many of the commands that you issue in CLI operational mode. Each operational mode command with a Junos XML counterpart maps to a request tag element and, if necessary, a response tag element.

You can view the XML-formatted output of any operational mode command by issuing the command in the CLI and adding the **| display xml** option. The following example shows the text-formatted and XML-formatted output for the **show chassis alarms** operational mode command:

```
user@host> show chassis alarms
No alarms currently active
```

```
user@host> show chassis alarms | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.4B1/junos">
  <alarm-information xmlns="http://xml.juniper.net/junos/10.4B1/junos-alarm">
    <alarm-summary>
      <no-active-alarms/>
    </alarm-summary>
  </alarm-information>
</cli>
  <banner></banner>
</cli>
</rpc-reply>
```

You can view the Junos XML API representation of any operational mode command by issuing the command in the CLI and adding the **| display xml rpc** option. The following example shows the Junos XML API tag element for the **show chassis alarms** command.

```
user@host> show chassis alarms | display xml rpc
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.4B1/junos">
  <rpc>
    <get-alarm-information>
  </get-alarm-information>
  </rpc>
</cli>
  <banner></banner>
</cli>
</rpc-reply>
```

As shown in the previous example, the **| display xml rpc** option displays the command's corresponding Junos XML API request tag element that is sent to Junos OS for processing whenever the command is issued. In contrast, the **| display xml** option displays the actual output of the processed command in XML format.

When you issue the **show chassis alarms** operational mode command, the CLI converts the command into its equivalent Junos XML API request tag **<get-alarm-information>** and sends the XML request to the Junos infrastructure for processing. Junos OS processes the request and returns the **<alarm-information>** response tag element to the CLI. The CLI then converts the XML output into the "No alarms currently active" message that is displayed to the user.

Junos automation scripts use XML to communicate with the host device. Junos OS provides XML-formatted input to a script. The script processes the input source tree and then returns XML-formatted output to Junos OS. The script type determines the XML input document that is sent to the script as well as the output document that is returned to Junos OS for processing. Commit script input consists of an XML representation of the post-inheritance candidate configuration file. Event scripts receive an XML document containing the description of the triggering event. All script input documents contain a common node-set with information pertaining to the Junos OS environment.

NETCONF XML Management Protocol and Junos XML API Overview

The NETCONF XML management protocol is an XML-based protocol that client applications use to request and change configuration information on routing, switching, and security devices. The NETCONF XML management protocol uses an Extensible Markup Language (XML)-based data encoding for the configuration data and remote procedure calls. The NETCONF protocol defines basic operations that are equivalent to configuration mode commands in the command-line interface (CLI). Applications use the protocol operations to display, edit, and commit configuration statements (among other operations), just as administrators use CLI configuration mode commands to perform those operations.

The Junos XML API is an XML representation of Junos OS configuration statements and operational mode commands. When the client application manages a device running Junos OS, Junos XML configuration tag elements are the content to which the NETCONF XML protocol operations apply. Junos XML operational tag elements are equivalent in function to operational mode commands in the CLI, which administrators use to retrieve status information for a routing platform running Junos OS.

The NETCONF XML management protocol is described in RFC 4741, *NETCONF Configuration Protocol*, which is available at <http://www.ietf.org/rfc/rfc4741.txt>.

Client applications request or change information on a switch, router, or security device by encoding the request with tag elements from the NETCONF XML management protocol and Junos XML API and then sending it to the NETCONF server on the device. On devices running Junos OS, the NETCONF server is integrated into Junos OS and does not appear as a separate entry in process listings. The NETCONF server directs the request to the appropriate software modules within the device, encodes the response in NETCONF and Junos XML API tag elements, and returns the result to the client application. For example, to request information about the status of a device's interfaces, a client application sends the **<get-interface-information>** tag element from the Junos XML API. The NETCONF server gathers the information from the interface process and returns it in the **<interface-information>** tag element.

You can use the NETCONF XML management protocol and Junos XML API to configure devices running Junos OS or to request information about the device configuration or operation. You can write client applications to interact with the NETCONF server, but you can also use the NETCONF XML management protocol to build custom end-user interfaces for configuration and information retrieval and display, such as a Web browser-based interface.

XML Overview

XML is a language for defining a set of markers, called *tags*, that are applied to a data set or document to describe the function of individual elements and codify the hierarchical relationships between them. Tags look much like Hypertext Markup Language (HTML) tags, but XML is actually a metalanguage used to define tags that best suit the kind of data being marked.

For more details about XML, see *A Technical Introduction to XML* at <http://www.xml.com/pub/a/98/10/guide0.html> and the additional reference material at the <http://www.xml.com> site. The official XML specification from the World Wide Web Consortium (W3C), *Extensible Markup Language (XML) 1.0*, is available at <http://www.w3.org/TR/REC-xml>.

The following sections discuss Junos XML and NETCONF XML management protocol tag elements:

- [Junos XML and NETCONF XML Management Protocol Tag Elements on page 542](#)
- [Document Type Definition on page 543](#)

Junos XML and NETCONF XML Management Protocol Tag Elements

Items in an XML-compliant document or data set are always enclosed in paired opening and closing tags. XML is stricter in this respect than HTML, which sometimes uses only opening tags. The following examples show paired opening and closing tags enclosing a value:

```
<interface-state>enabled</interface-state>  
<input-bytes>25378</input-bytes>
```

The term *tag element* refers to a three-part set: opening tag, contents, and closing tag. The content can be an alphanumeric character string as in the preceding examples, or can itself be a *container* tag element, which contains other tag elements. For simplicity, the term *tag* is often used interchangeably with *tag element* or *element*.

If a tag element is *empty*—has no contents—it can be represented either as paired opening and closing tags with nothing between them, or as a single tag with a forward slash after the tag name. For example, the notation **<snmp-trap-flag/>** is equivalent to **<snmp-trap-flag></snmp-trap-flag>**.

As the preceding examples show, angle brackets enclose the name of a Junos XML tag element or NETCONF tag element in its opening and closing tags. This is an XML convention, and the brackets are a required part of the complete tag element name. They are not to be confused with the angle brackets used in Juniper Networks documentation to indicate optional parts of CLI command strings.

NETCONF and Junos XML tag elements obey the XML convention that the tag element name indicates the kind of information enclosed by the tag element. For example, the name of the Junos XML **<interface-state>** tag element indicates that it contains a description of the current status of an interface on the routing platform, whereas the

name of the `<input-bytes>` tag element indicates that its contents specify the number of bytes received.

When discussing tag elements in text, this documentation conventionally uses just the name of the opening tag to represent the complete tag element (opening tag, contents, and closing tag). For example, the documentation refers to the `<input-bytes>` tag to indicate the entire `<input-bytes>number-of-bytes</input-bytes>` tag element.

Document Type Definition

An XML-tagged document or data set is *structured*, because a set of rules specifies the ordering and interrelationships of the items in it. The rules define the contexts in which each tagged item can—and in some cases must—occur. A file called a *document type definition*, or *DTD*, lists every tag element that can appear in the document or data set, defines the parent-child relationships between the tags, and specifies other tag characteristics. The same DTD can apply to many XML documents or data sets.

Advantages of Using the NETCONF XML Management Protocol and Junos XML API

The NETCONF XML management protocol and Junos XML API fully document all options for every supported Junos operational request and all elements in every Junos configuration statement. The tag names clearly indicate the function of an element in an operational request or configuration statement.

The combination of meaningful tag names and the structural rules in a DTD makes it easy to understand the content and structure of an XML-tagged data set or document. NETCONF and Junos XML tag elements make it straightforward for client applications that request information from a device to parse the output and find specific information.

The following example illustrates how the Junos XML API makes it easier to parse device output and extract the needed information. It compares formatted ASCII and XML-tagged versions of output from a device running the Junos OS. The formatted ASCII follows:

```
Physical interface: fxp0, Enabled, Physical link is Up
Interface index: 4, SNMP ifIndex: 3
```

The corresponding XML-tagged version is:

```
<interface>
  <name>fxp0</name>
  <admin-status>enabled</admin-status>
  <operational-status>up</operational-status>
  <index>4</index>
  <snmp-index>3</snmp-index>
</interface>
```

When a client application needs to extract a specific value from formatted ASCII output, it must rely on the value's location, expressed either absolutely or with respect to labels or values in adjacent fields. Suppose that the client application wants to extract the interface index. It can use a regular-expression matching utility to locate specific strings, but one difficulty is that the number of digits in the interface index is not necessarily predictable. The client application cannot simply read a certain number of characters after the **Interface index:** label, but must instead extract everything between the label and the subsequent label, which is

, SNMP ifIndex

A problem arises if the format or ordering of output changes in a later version of the Junos OS, for example, if a **Logical index** field is added following the interface index number:

Physical interface: fxp0, Enabled, Physical link is Up
Interface index: 4, Logical index: 12, SNMP ifIndex: 3

An application that extracts the interface index number delimited by the **Interface index:** and **SNMP ifIndex** labels now obtains an incorrect result. The application must be updated manually to search for the following label instead:

, Logical index

In contrast, the structured nature of XML-tagged output enables a client application to retrieve the interface index by extracting everything within the opening **<index>** tag and closing **</index>** tag. The application does not have to rely on an element's position in the output string, so the NETCONF server can emit the child tag elements in any order within the **<interface>** tag element. Adding a new **<logical-index>** tag element in a future release does not affect an application's ability to locate the **<index>** tag element and extract its contents.

Tagged output is also easier to transform into different display formats. For instance, you might want to display different amounts of detail about a given device component at different times. When a device returns formatted ASCII output, you have to design and write special routines and data structures in your display program to extract and store the information needed for a given detail level. In contrast, the inherent structure of XML output is an ideal basis for a display program's own structures. It is also easy to use the same extraction routine for several levels of detail, simply ignoring the tag elements you do not need when creating a less detailed display.

Overview of a NETCONF XML Management Protocol Session

Communication between the NETCONF server and a client application is session based. The two parties explicitly establish a connection before exchanging data and close the connection when they are finished. Each request from the client application and each response from the NETCONF server constitutes a *well-formed* XML document, because the tag streams obey the structural rules defined in the NETCONF and Junos XML DTDs for the kind of information they encode. Client applications must produce a well-formed XML document for each request by emitting tag elements in the required order and only in the legal contexts.

The following list outlines the basic structure of a NETCONF session.

1. The client application establishes a connection to the NETCONF server and opens the NETCONF session.
2. The NETCONF server and client application exchange initialization information, which is used to determine if they are using compatible versions of the Junos OS and the NETCONF XML management protocol.
3. The client application sends one or more requests to the NETCONF server and parses its responses.
4. The client application closes the NETCONF session and the connection to the NETCONF server.

CHAPTER 6

Using NETCONF XML Management Protocol and Junos XML Tag Elements

This chapter describes the syntactic and notational conventions used by the NETCONF server and client applications, including the mappings between statements and commands in the Junos OS command-line interface (CLI) and the tag elements in the Junos Extensible Markup Language (XML) application programming interface (API).

For more information about the syntax of CLI commands and configuration statements, see the *CLI User Guide*. For information about specific configuration statements, see the Junos OS configuration guides. For information about specific operational mode commands, see the Junos OS command references.

This chapter discusses the following topics:

- [XML and NETCONF XML Management Protocol Conventions Overview on page 547](#)
- [Mapping Commands to Junos XML Tag Elements on page 551](#)
- [Mapping Configuration Statements to Junos XML Tag Elements on page 552](#)
- [Using the Same Configuration Tag Elements in Requests and Responses on page 558](#)

XML and NETCONF XML Management Protocol Conventions Overview

A client application must comply with XML and NETCONF XML management protocol conventions. Each request from the client application must be a *well-formed* XML document; that is, it must obey the structural rules defined in the NETCONF and Junos XML DTDs for the kind of information encoded in the request. The client application must emit tag elements in the required order and only in the legal contexts. Compliant applications are easier to maintain in the event of changes to the Junos OS or NETCONF XML management protocol.

Similarly, each response from the NETCONF server constitutes a well-formed XML document (the NETCONF server obeys XML and NETCONF conventions).

The following sections describe NETCONF XML management protocol conventions:

- [Request and Response Tag Elements on page 548](#)
- [Child Tag Elements of a Request Tag Element on page 548](#)
- [Child Tag Elements of a Response Tag Element on page 549](#)

- [Spaces, Newline Characters, and Other White Space](#) on page 549
- [XML Comments](#) on page 550
- [Predefined Entity References](#) on page 550

Request and Response Tag Elements

A *request* tag element is one generated by a client application to request information about a device's current status or configuration, or to change the configuration. A request tag element corresponds to a CLI operational or configuration command. It can occur only within an `<rpc>` tag element. For information about the `<rpc>` tag element, see [“Sending a Request to the NETCONF Server”](#) on page 577.

A *response* tag element represents the NETCONF server's reply to a request tag element and occurs only within an `<rpc-reply>` tag element. For information about the `<rpc-reply>` tag element, see [“Parsing the NETCONF Server Response”](#) on page 580.

The following example represents an exchange in which a client application emits the `<get-interface-information>` request tag element with the `<extensive/>` flag and the NETCONF server returns the `<interface-information>` response tag element.

Client Application

```
<rpc>
  <get-interface-information>
    <extensive/>
  </get-interface-information>
</rpc>
]]>]]>
```

NETCONF Server

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <interface-information xmlns="URL">
    <!-- children of <interface-information> -->
  </interface-information>
</rpc-reply>
]]>]]>
```

T2100

NOTE: This example, like all others in this guide, shows each tag element on a separate line, in the tag streams emitted by both the client application and NETCONF server. In practice, a client application does not need to include newline characters between tag elements, because the server automatically discards such white space. For further discussion, see [“Spaces, Newline Characters, and Other White Space”](#) on page 549.

For information about the attributes in the opening `<rpc-reply>` tag, see [“Parsing the NETCONF Server Response”](#) on page 580. For information about the `xmlns` attribute in the opening `<interface-information>` tag, see [“Requesting Operational Information”](#) on page 594. For information about the `]]>]]>` character sequence, see [“Generating Well-Formed XML Documents”](#) on page 562.

Child Tag Elements of a Request Tag Element

Some request tag elements contain child tag elements. For configuration requests, each child tag element represents a configuration element (hierarchy level or configuration

object). For operational requests, each child tag element represents one of the options you provide on the command line when issuing the equivalent CLI command.

Some requests have mandatory child tag elements. To make a request successfully, a client application must emit the mandatory tag elements within the request tag element's opening and closing tags. If any of the children are themselves container tag elements, the opening tag for each must occur before any of the tag elements it contains, and the closing tag must occur before the opening tag for another tag element at its hierarchy level.

In most cases, the client application can emit children that occur at the same level within a container tag element in any order. The important exception is a configuration element that has an *identifier tag element*, which distinguishes the configuration element from other elements of its type. The identifier tag element must be the first child tag element in the container tag element. Most frequently, the identifier tag element specifies the name of the configuration element and is called **<name>**. For more information, see [“Mapping for Objects That Have an Identifier” on page 552](#).

Child Tag Elements of a Response Tag Element

The child tag elements of a response tag element represent the individual data items returned by the NETCONF server for a particular request. The children can be either individual tag elements (empty tags or tag element triples) or container tag elements that enclose their own child tag elements. For some container tag elements, the NETCONF server returns the children in alphabetical order. For other elements, the children appear in the order in which they were created in the configuration.

The set of child tag elements that can occur in a response or within a container tag element is subject to change in later releases of the Junos XML API. Client applications must not rely on the presence or absence of a particular tag element in the NETCONF server's output, nor on the ordering of child tag elements within a response tag element. For the most robust operation, include logic in the client application that handles the absence of expected tag elements or the presence of unexpected ones as gracefully as possible.

Spaces, Newline Characters, and Other White Space

As dictated by the XML specification, the NETCONF server ignores white space (spaces, tabs, newline characters, and other characters that represent white space) that occurs between tag elements in the tag stream generated by a client application. Client applications can, but do not need to, include white space between tag elements. However, they must not insert white space within an opening or closing tag. If they include white space in the contents of a tag element that they are submitting as a change to the candidate configuration, the NETCONF server preserves the white space in the configuration database.

In its responses, the NETCONF server includes white space between tag elements to enhance the readability of responses that are saved to a file: it uses newline characters to put each tag element on its own line, and spaces to indent child tag elements to the right compared to their parents. A client application can ignore or discard the white space, particularly if it does not store responses for later review by human users. However, it

must not depend on the presence or absence of white space in any particular location when parsing the tag stream.

For more information about white space in XML documents, see the XML specification from the World Wide Web Consortium (W3C), *Extensible Markup Language (XML) 1.0*, at <http://www.w3.org/TR/REC-xml/>.

XML Comments

Client applications and the NETCONF server can insert XML comments at any point between tag elements in the tag stream they generate, but not within tag elements. Client applications must handle comments in output from the NETCONF server gracefully but must not depend on their content. Client applications also cannot use comments to convey information to the NETCONF server, because the server automatically discards any comments it receives.

XML comments are enclosed within the strings `<!--` and `-->`, and cannot contain the string `--` (two hyphens). For more details about comments, see the XML specification at <http://www.w3.org/TR/REC-xml/>.

The following is an example of an XML comment:

```
<!-- This is a comment. Please ignore it. -->
```

Predefined Entity References

By XML convention, there are two contexts in which certain characters cannot appear in their regular form:

- In the string that appears between opening and closing tags (the contents of the tag element)
- In the string value assigned to an attribute of an opening tag

When including a disallowed character in either context, client applications must substitute the equivalent *predefined entity reference*, which is a string of characters that represents the disallowed character. Because the NETCONF server uses the same predefined entity references in its response tag elements, the client application must be able to convert them to actual characters when processing response tag elements.

[Table 30 on page 550](#) summarizes the mapping between disallowed characters and predefined entity references for strings that appear between the opening and closing tags of a tag element.

Table 30: Predefined Entity Reference Substitutions for Tag Content Values

Disallowed Character	Predefined Entity Reference
& (ampersand)	&
> (greater-than sign)	>

Table 30: Predefined Entity Reference Substitutions for Tag Content Values (*continued*)

Disallowed Character	Predefined Entity Reference
< (less-than sign)	<

Table 31 on page 551 summarizes the mapping between disallowed characters and predefined entity references for attribute values.

Table 31: Predefined Entity Reference Substitutions for Attribute Values

Disallowed Character	Predefined Entity Reference
& (ampersand)	&
' (apostrophe)	'
> (greater-than sign)	>
< (less-than sign)	<
" (quotation mark)	"

As an example, suppose that the following string is the value contained by the **<condition>** tag element:

```
if (a<b && b>c) return "Peer's not responding"
```

The **<condition>** tag element looks like this (it appears on two lines for legibility only):

```
<condition>if (a&lt;b &amp;&amp; b&gt;c) return "Peer's not \
    responding"</condition>
```

Similarly, if the value for the **<example>** tag element's **heading** attribute is **Peer's "age" <> 40**, the opening tag looks like this:

```
<example heading="Peer&apos;s &quot;age&quot; &lt;&gt; 40">
```

Mapping Commands to Junos XML Tag Elements

The Junos XML API defines tag-element equivalents for many commands in CLI operational mode. For example, the **<get-interface-information>** tag element corresponds to the **show interfaces** command.

Information about the available command equivalents in the current release of the Junos OS can be found in the *Junos XML API Operational Developer Reference*. For the mapping between commands and Junos XML tag elements, see the *Junos XML API Operational Developer Reference* "Mapping Between Operational Tag Elements, Perl Methods, and CLI Commands" chapter. For detailed information about a specific operation, see the

Junos XML API Operational Developer Reference “Summary of Operational Request Tags” chapter.

The following sections describe the tag elements that map to command options:

- [Mapping for Command Options with Variable Values on page 552](#)
- [Mapping for Fixed-Form Command Options on page 552](#)

Mapping for Command Options with Variable Values

Many CLI commands have options that identify the object that the command affects or reports about, distinguishing the object from other objects of the same type. In some cases, the CLI does not precede the identifier with a fixed-form keyword, but XML convention requires that the Junos XML API define a tag element for every option. To learn the names for each identifier (and any other child tag elements) for an operational request tag element, consult the tag element’s entry in the appropriate DTD or in the *Junos XML API Operational Developer Reference*.

The following example shows the Junos XML tag elements for two CLI operational commands that have variable-form options. In the **show interfaces** command, **t3-5/1/0:0** is the name of the interface. In the **show bgp neighbor** command, **10.168.1.122** is the IP address for the BGP peer of interest.

CLI Command	JUNOS XML Tags
show interfaces t3-5/1/0:0	<pre><rpc> <get-interface-information> <interface-name>t3-5/1/0:0</interface-name> </get-interface-information> </rpc></pre>
show bgp neighbor 10.168.1.122	<pre><rpc> <get-bgp-neighbor-information> <neighbor-address>10.168.1.122</neighbor-address> </get-bgp-neighbor-information> </rpc></pre>

T1500

Mapping for Fixed-Form Command Options

Some CLI commands include options that have a fixed form, such as the **brief** and **detail** strings, which specify the amount of detail to include in the output. The Junos XML API usually maps such an option to an empty tag whose name matches the option name.

The following example shows the Junos XML tag elements for the **show isis adjacency** command, which has a fixed-form option called **detail**.

CLI Command	JUNOS XML Tags
show isis adjacency detail	<pre><rpc> <get-isis-adjacency-information> <detail/> </get-isis-adjacency-information> </rpc></pre>

T1501

Mapping Configuration Statements to Junos XML Tag Elements

The Junos XML API defines a tag element for every container and leaf statement in the configuration hierarchy. At the top levels of the configuration hierarchy, there is almost

always a one-to-one mapping between tag elements and statements, and most tag names match the configuration statement name. At deeper levels of the hierarchy, the mapping is sometimes less direct, because some CLI notational conventions do not map directly to XML-compliant tagging syntax.

NOTE: For some configuration statements, the notation used when you type the statement at the CLI configuration-mode prompt differs from the notation used in a configuration file. The same Junos XML tag element maps to both notational styles.

The following sections describe the mapping between configuration statements and Junos XML tag elements:

- [Mapping for Hierarchy Levels and Container Statements on page 553](#)
- [Mapping for Objects That Have an Identifier on page 554](#)
- [Mapping for Single-Value and Fixed-Form Leaf Statements on page 555](#)
- [Mapping for Leaf Statements with Multiple Values on page 556](#)
- [Mapping for Multiple Options on One or More Lines on page 556](#)
- [Mapping for Comments About Configuration Statements on page 557](#)

Mapping for Hierarchy Levels and Container Statements

The **<configuration>** tag element is the top-level Junos XML container tag element for configuration statements. It corresponds to the **[edit]** hierarchy level in CLI configuration mode. Most statements at the next few levels of the configuration hierarchy are container statements. The Junos XML container tag element that corresponds to a container statement almost always has the same name as the statement.

The following example shows the Junos XML tag elements for two statements at the top level of the configuration hierarchy. Note that a closing brace in a CLI configuration statement corresponds to a closing Junos XML tag.

CLI Configuration Statements	JUNOS XML Tags
system {	<configuration>
login {	<system>
...child statements...	<login>
}	<!-- tags for child statements -->
}	</login>
	</system>
protocols {	<protocols>
ospf {	<ospf>
...child statements...	<!-- tags for child statements -->
}	</ospf>
}	</protocols>
	</configuration>

T1502

Mapping for Objects That Have an Identifier

At some hierarchy levels, the same kind of configuration object can occur multiple times. Each instance of the object has a unique identifier to distinguish it from the other instances. In the CLI notation, the parent statement for such an object consists of a keyword and identifier of the following form:

```
keyword identifier {
... configuration statements for individual characteristics ...
}
```

keyword is a fixed string that indicates the type of object being defined, and **identifier** is the unique name for this instance of the type. In the Junos XML API, the tag element corresponding to the keyword is a container tag element for child tag elements that represent the object's characteristics. The container tag element's name generally matches the **keyword** string.

The Junos XML API differs from the CLI in its treatment of the identifier. Because the Junos XML API does not allow container tag elements to contain both other tag elements and untagged character data such as an identifier name, the identifier must be enclosed in a tag element of its own. Most frequently, identifier tag elements for configuration objects are called **<name>**. Some objects have multiple identifiers, which usually have names other than **<name>**. To verify the name of each identifier tag element for a configuration object, consult the entry for the object in the *Junos XML API Configuration Developer Reference*.

NOTE: The Junos OS reserves the prefix **junos-** for the identifiers of configuration groups defined within the **junos-defaults** configuration group. User-defined identifiers cannot start with the string **junos-**.

Identifier tag elements also constitute an exception to the general XML convention that tag elements at the same level of hierarchy can appear in any order; the identifier tag element always occurs first within the container tag element.

The configuration for most objects that have identifiers includes additional leaf statements, which represent other characteristics of the object. For example, each BGP group configured at the **[edit protocols bgp group]** hierarchy level has an associated name (the identifier) and can have leaf statements for other characteristics such as type, peer autonomous system (AS) number, and neighbor address. For information about the Junos XML mapping for leaf statements, see [“Mapping for Single-Value and Fixed-Form Leaf Statements” on page 555](#), [“Mapping for Leaf Statements with Multiple Values” on page 556](#), and [“Mapping for Multiple Options on One or More Lines” on page 556](#).

The following example shows the Junos XML tag elements for configuration statements that define two BGP groups called **G1** and **G2**. Notice that the Junos XML **<name>** tag element that encloses the identifier of each group (and the identifier of the neighbor within a group) does not have a counterpart in the CLI statements. For complete information about changing routing platform configuration, see [“Changing Configuration Information” on page 623](#).

CLI Configuration Statements	JUNOS XML Tags
<pre> protocols { bgp { group G1 { type external; peer-as 56; neighbor 10.0.0.1; } group G2 { type external; peer-as 57; neighbor 10.0.10.1; } } } </pre>	<pre> <configuration> <protocols> <bgp> <group> <name>G1</name> <type>external</type> <peer-as>56</peer-as> <neighbor> <name>10.0.0.1</name> </neighbor> </group> <group> <name>G2</name> <type>external</type> <peer-as>57</peer-as> <neighbor> <name>10.0.10.1</name> </neighbor> </group> </bgp> </protocols> </configuration> </pre>

T1503

Mapping for Single-Value and Fixed-Form Leaf Statements

A *leaf statement* is a CLI configuration statement that does not contain any other statements. Most leaf statements define a value for one characteristic of a configuration object and have the following form:

keyword *value*;

In general, the name of the Junos XML tag element corresponding to a leaf statement is the same as the **keyword** string. The string between the opening and closing Junos XML tags is the same as the *value* string.

The following example shows the Junos XML tag elements for two leaf statements that have a keyword and a value: the **message** statement at the [edit system login] hierarchy level and the **preference** statement at the [edit protocols ospf] hierarchy level.

CLI Configuration Statements	JUNOS XML Tags
<pre> system { login { message "Authorized users only"; ...other statements under login... } } protocols { ospf { preference 15; ...other statements under ospf... } } </pre>	<pre> <configuration> <system> <login> <message>Authorized users only</message> <!-- tags for other child statements --> </login> </system> <protocols> <ospf> <preference>15</preference> <!-- tags for other child statements --> </ospf> </protocols> </configuration> </pre>

T1504

Some leaf statements consist of a fixed-form keyword only, without an associated variable-form value. The Junos XML API represents such statements with an empty tag. The following example shows the Junos XML tag elements for the **disable** statement at the [edit forwarding-options sampling] hierarchy level.

CLI Configuration Statement	JUNOS XML Tags	
forwarding-options { sampling { disable; ...other statements under sampling ... } }	<configuration> <forwarding-options> <sampling> <disable/> <!-- tags for other child statements --> </sampling> </forwarding-options> </configuration>	T1505

Mapping for Leaf Statements with Multiple Values

Some Junos leaf statements accept multiple values, which can be either user-defined or drawn from a set of predefined values. CLI notation uses square brackets to enclose all values in a single statement, as in the following:

statement [*value1 value2 value3* ...];

The Junos XML API instead encloses each value in its own tag element. The following example shows the Junos XML tag elements for a CLI statement with multiple user-defined values. The **import** statement imports two routing policies defined elsewhere in the configuration. For complete information about changing routing platform configuration, see [“Changing Configuration Information” on page 623](#).

CLI Configuration Statements	JUNOS XML Tags	
protocols { bgp { group 23 { import [policy1 policy2]; } } }	<configuration> <protocols> <bgp> <group> <name>23</name> <import>policy1</import> <import>policy2</import> </group> </bgp> </protocols> </configuration>	T1506

The following example shows the Junos XML tag elements for a CLI statement with multiple predefined values. The **permissions** statement grants three predefined permissions to members of the **user-accounts** login class.

CLI Configuration Statements	JUNOS XML Tags	
system { login { class user-accounts { permissions [configure admin control]; } } }	<configuration> <system> <login> <class> <name>user-accounts</name> <permissions>configure</permissions> <permissions>admin</permissions> <permissions>control</permissions> </class> </login> </system> </configuration>	T1507

Mapping for Multiple Options on One or More Lines

For some Junos configuration objects, the standard CLI syntax places multiple options on a single line, usually for greater legibility and conciseness. In most such cases, the first

option identifies the object and does not have a keyword, but later options are paired keywords and values. The Junos XML API encloses each option in its own tag element. Because the first option has no keyword in the CLI statement, the Junos XML API assigns a name to its tag element.

The following example shows the Junos XML tag elements for a CLI configuration statement with multiple options on a single line. The Junos XML API defines a tag element for both options and assigns a name to the tag element for the first option (**10.0.0.1**), which has no CLI keyword.

CLI Configuration Statements

```
system {
  backup-router 10.0.0.1 destination 10.0.0.2;
}
```

JUNOS XML Tags

```
<configuration>
  <system>
    <backup-router>
      <address>10.0.0.1</address>
      <destination>10.0.0.2</destination>
    </backup-router>
  </system>
</configuration>
```

T1508

The syntax for some configuration objects includes more than one multioption line. Again, the Junos XML API defines a separate tag element for each option. The following example shows Junos XML tag elements for a **traceoptions** statement at the **[edit protocols isis]** hierarchy level. The statement has three child statements, each with multiple options.

CLI Configuration Statements

```
protocols {
  isis {
    traceoptions {
      file trace-file size 3m files 10 world-readable;

      flag route detail;

      flag state receive;
    }
  }
}
```

JUNOS XML Tags

```
<configuration>
  <protocols>
    <isis>
      <traceoptions>
        <file>
          <filename>trace-file</filename>
          <size>3m</size>
          <files>10</files>
          <world-readable/>
        </file>
        <flag>
          <name>route</name>
          <detail/>
        </flag>
        <flag>
          <name>state</name>
          <receive/>
        </flag>
      </traceoptions>
    </isis>
  </protocols>
</configuration>
```

T1509

Mapping for Comments About Configuration Statements

A Junos configuration can include comments that describe statements in the configuration. In CLI configuration mode, the **annotate** command specifies the comment to associate with a statement at the current hierarchy level. You can also use a text editor to insert comments directly into a configuration file. For more information, see the *CLI User Guide*.

The Junos XML API encloses comments about configuration statements in the **<junos:comment>** tag element. (These comments are different from the comments that are enclosed in the strings **<!--** and **-->** and are automatically discarded by the protocol server.)

In the Junos XML API, the `<junos:comment>` tag element immediately precedes the tag element for the associated configuration statement. (If the tag element for the associated statement is omitted, the comment is not recorded in the configuration database.) The comment text string can include one of the two delimiters that indicate a comment in the configuration database: either the `#` character before the comment or the paired strings `/*` before the comment and `*/` after it. If the client application does not include the delimiter, the protocol server adds the appropriate one when it adds the comment to the configuration. The protocol server also preserves any white space included in the comment.

The following example shows the Junos XML tag elements that associate comments with two statements in a sample configuration statement. The first comment illustrates how including newline characters in the contents of the `<junos:comment>` tag element (`/* New backbone area */`) results in the comment appearing on its own line in the configuration file. There are no newline characters in the contents of the second `<junos:comment>` tag element, so in the configuration file the comment directly follows the associated statement on the same line.

CLI Configuration Statements	JUNOS XML Tags
protocols {	<code><configuration></code>
ospf {	<code><protocols></code>
/* New backbone area */	<code><ospf></code>
area 0.0.0.0 {	<code><junos:comment></code>
interface so-0/0/0 { # From jnpr1 to jnpr2	<code>/* New backbone area */</code>
hello-interval 5;	<code></junos:comment></code>
}	<code><area></code>
}	<code><name>0.0.0.0</name></code>
}	<code><junos:comment> # From jnpr1 to jnpr2</junos:comment></code>
}	<code><interface></code>
	<code><name>so-0/0/0</name></code>
	<code><hello-interval>5</hello-interval></code>
	<code></interface></code>
	<code></area></code>
	<code></ospf></code>
	<code></protocols></code>
	<code></configuration></code>

T1510

Using the Same Configuration Tag Elements in Requests and Responses

The NETCONF server encloses its response to each configuration request in `<rpc-reply>` and `<configuration>` tag elements. Enclosing each configuration response within a `<configuration>` tag element contrasts with how the server encloses each different operational response in a tag element named for that type of response—for example, the `<chassis-inventory>` tag element for chassis information or the `<interface-information>` tag element for interface information.

The Junos XML tag elements within the `<configuration>` tag element represent configuration hierarchy levels, configuration objects, and object characteristics, always ordered from higher to deeper levels of the hierarchy. When a client application loads a configuration, it can emit the same tag elements in the same order as the NETCONF server uses when returning configuration information. This consistent representation makes handling configuration information more straightforward. For instance, the client application can request the current configuration, store the NETCONF server's response in a local memory buffer, make changes or apply transformations to the buffered data, and submit the altered configuration as a change to the candidate configuration. Because

the altered configuration is based on the NETCONF server's response, it is certain to be syntactically correct. For more information about changing routing platform configuration, see [“Changing Configuration Information” on page 623](#).

Similarly, when a client application requests information about a configuration element (hierarchy level or configuration object), it uses the same tag elements that the NETCONF server will return in response. To represent the element, the client application sends a complete stream of tag elements from the top of the configuration hierarchy (represented by the **<configuration>** tag element) down to the requested element. The innermost tag element, which represents the level or object, is either empty or includes the identifier tag element only. The NETCONF server's response includes the same stream of parent tag elements, but the tag element for the requested configuration element contains all the tag elements that represent the element's characteristics or child levels. For more information, see [“Requesting Configuration Information” on page 598](#).

The tag streams emitted by the NETCONF server and by a client application can differ in the use of white space, as described in [“XML and NETCONF XML Management Protocol Conventions Overview” on page 547](#).

CHAPTER 7

Controlling the NETCONF Session

This chapter explains how to start and terminate a session with the NETCONF server, and describes the Extensible Markup Language (XML) tag elements from the NETCONF XML management protocol that client applications and the NETCONF server use to coordinate information exchange during the session. It discusses the following topics:

- [Client Application's Role in a NETCONF Session on page 561](#)
- [Establishing a NETCONF Session on page 562](#)
- [Exchanging Information with the NETCONF Server on page 577](#)
- [Locking and Unlocking the Candidate Configuration on page 584](#)
- [Terminating Another NETCONF Session on page 586](#)
- [Ending a NETCONF Session and Closing the Connection on page 587](#)
- [Displaying CLI Output as XML Tag Elements on page 587](#)
- [Displaying the RPC Tags for a Command on page 588](#)
- [Example of a NETCONF Session on page 589](#)

Client Application's Role in a NETCONF Session

To create a session and communicate with the NETCONF server, a client application performs the following procedures, which are described in the indicated sections:

1. Establishes a connection to the NETCONF server on the routing platform, as described in ["Connecting to the NETCONF Server" on page 573](#).
2. Opens a NETCONF session, as described in ["Starting the NETCONF Session" on page 574](#).
3. (Optional) Locks the candidate configuration, as described in ["Locking the Candidate Configuration" on page 584](#). Locking the configuration prevents other users or applications from changing it at the same time.
4. Requests operational or configuration information, or changes configuration information, as described in ["Requesting Information" on page 593](#) and ["Changing Configuration Information" on page 623](#).
5. (Optional) Verifies the syntactic correctness of a configuration before attempting to commit it, as described in ["Verifying a Configuration Before Committing It" on page 647](#).

6. Commits changes made to the configuration, as described in [“Committing a Configuration” on page 648](#).
7. Unlocks the candidate configuration if it is locked, as described in [“Unlocking the Candidate Configuration” on page 585](#).
8. Ends the NETCONF session and closes the connection to the device, as described in [“Ending a NETCONF Session and Closing the Connection” on page 587](#).

Establishing a NETCONF Session

The NETCONF server communicates with client applications within the context of a NETCONF *session*. The server and client explicitly establish a connection and session before exchanging data and close the session and connection when they are finished.

The streams of NETCONF and Junos XML tag elements emitted by the NETCONF server and the client application must each constitute well-formed XML by obeying the structural rules defined in the document type definition (DTD) for the kind of information they are exchanging. The client application must emit tag elements in the required order and only in the allowed contexts.

Client applications access the NETCONF server using the SSH protocol and use the standard SSH authentication mechanism. After authentication, the NETCONF server uses the Junos login usernames and classes already configured on the device to determine whether a client application is authorized to make each request.

For information about establishing a connection and NETCONF session, see the following sections:

- [Generating Well-Formed XML Documents on page 562](#)
- [Prerequisites for Establishing an SSH Connection on page 563](#)
- [Connecting to the NETCONF Server on page 573](#)
- [Starting the NETCONF Session on page 574](#)

For an example of a complete NETCONF session, see [“Example of a NETCONF Session” on page 589](#).

Generating Well-Formed XML Documents

Each set of NETCONF and Junos XML tag elements emitted by the NETCONF server and a client application within a `<hello>`, `<rpc>`, or `<rpc-reply>` tag element must constitute a well-formed XML document by obeying the structural rules defined in the document type definition (DTD) for the kind of information being sent. The client application must emit tag elements in the required order and only in the allowed contexts.

The NETCONF server and client applications must also comply with RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*, available at <http://www.ietf.org/rfc/rfc4742.txt>. In particular, the server and applications must send the character sequence `]]>]]>` after each XML document. Because this sequence is not legal within an XML document, it unambiguously signals the end of a document. In practice, the client application sends the sequence after the closing `</hello>` tag and

each closing `</rpc>` tag, and the NETCONF server sends it after the closing `</hello>` tag and each closing `</rpc-reply>` tag.

NOTE: In the following example (and in all examples in this document of tag elements emitted by a client application), bold font is used to highlight the part of the tag sequence that is discussed in the text.

```
<!-- generated by a client application -->
<hello | rpc>
  <!-- contents of top-level tag element -->
</hello | /rpc>
]]>]]>

<!-- generated by the NETCONF server -->
<hello | rpc-reply attributes>
  <!-- contents of top-level tag element -->
</hello | /rpc-reply>
]]>]]>
```

Prerequisites for Establishing an SSH Connection

You use the SSH protocol to establish connections between a *configuration management server* and a device running Junos OS. A configuration management server, as the name implies, is used to configure the device running Junos OS remotely. This server typically manages the configurations using Perl scripts.

There are two options available when establishing a connection between the configuration management server and a device running Junos OS: SSH and outbound SSH. With SSH, the configuration management server initiates an SSH session with the device running Junos OS. Outbound SSH is used when the configuration management server cannot initiate an SSH connection because of network restrictions (such as a firewall). In this situation, the device running Junos OS is configured to initiate, establish, and maintain an SSH connection with a predefined set of configuration management servers. For a complete discussion of outbound SSH, see “Configuring Outbound SSH Service” in the *Junos OS System Basics Configuration Guide*.

- [Establishing an SSH Connection on page 563](#)
- [Establishing an Outbound SSH Connection on page 568](#)

Establishing an SSH Connection

Before the configuration management server establishes an SSH connection with a device running Junos OS, you must satisfy the requirements discussed in the following sections.

- [SSH Software Is Installed on the Configuration Management Server on page 564](#)
- [Client Application Can Log In on Devices Running Junos OS on page 564](#)
- [Junos Login Account Has Public/Private Key Pair or Password on page 565](#)

- [Client Application Can Access the Keys or Password on page 566](#)
- [NETCONF Service over SSH Is Enabled on page 567](#)

SSH Software Is Installed on the Configuration Management Server

The configuration management server handles the SSH connection between the configuration management server and the device running Junos OS. Therefore, the SSH software must be installed locally on the configuration management server. If the client application accessing the NETCONF server uses the NETCONF Perl module provided by Juniper Networks, no further action is necessary. As part of the installation procedure for the Perl module, you install a prerequisites package that includes the necessary SSH software. If the client application does not use the NETCONF Perl module, obtain the SSH software and install it on the configuration management server where the client application runs. For information about obtaining and installing SSH software, see <http://www.ssh.com/> and <http://www.openssh.com/>.

Client Application Can Log In on Devices Running Junos OS

When establishing a NETCONF session, the configuration management server must log in to the device running the Junos OS. Thus, each configuration management server needs a user account on each device where a NETCONF session will be established. The following instructions explain how to create a Junos OS login account on devices running the Junos OS. Alternatively, you can skip this section and enable authentication through RADIUS or TACACS+; for instructions, see the chapter about system authentication in the *Junos OS System Basics Configuration Guide*.

To determine whether a login account exists on a device running Junos OS, enter CLI configuration mode on the device and issue the following commands:

```
[edit]
user@host# edit system login
[edit system login]
user@host# show user account-name
```

If the appropriate account does not exist, perform the following steps to create one:

1. Include the **user** statement at the **[edit system login]** hierarchy level and specify a username. Also include the **class** statement at the **[edit system login user username]** hierarchy level, and specify a login class that has the permissions required for all actions to be performed by the application. Optionally, include the **full-name** and **uid** statements.

```
[edit system login]
user@host# set user user-name class class-name
```

NOTE: For detailed information about creating user accounts, see the chapter about configuring user access in the *Junos OS System Basics Configuration Guide*.

2. Commit the configuration to activate the user account on the device. If you are going to make more changes to the configuration file, you can wait to commit the file until

you have completed making all of the changes to the file. However, the user account is not activated on the device until you commit the configuration.

```
[edit system login]
user@host# commit
```

3. Repeat the preceding steps on each device where the client application will establish a NETCONF session.

Junos Login Account Has Public/Private Key Pair or Password

The configuration management server needs an SSH public/private key pair, a text-based password, or both before it can authenticate with the NETCONF server. A public/private key pair is sufficient if the account is used only to connect to the NETCONF server through SSH. If the account is also used to access the device in other ways (for login on the console, for example), it must have a text-based password. The password is also used (the SSH server prompts for it) if key-based authentication is configured but fails.

NOTE: You can skip this section if you have chosen to enable authentication through RADIUS or TACACS+, as described in the chapter about system authentication in the *Junos OS System Basics Configuration Guide*.

Follow the instructions in the appropriate section:

- [Creating a Text-Based Password on page 565](#)
- [Creating a Public/Private Key Pair on page 566](#)

Creating a Text-Based Password

To create a text-based password, perform the following steps:

1. Include either the **plain-text-password** or **encrypted-password** statement at the **[edit system login user account-name authentication]** hierarchy level. First, move to that hierarchy level:

```
[edit system login]
user@host# edit user account-name authentication
```

To enter a password as text, issue the following command. You are prompted for the password, which is encrypted before being stored.

```
[edit system login user account-name authentication]
user@host# set plain-text-password
New password: password
Retype new password: password
```

To store a password that you have previously created and hashed using Message Digest 5 (MD5) or Secure Hash Algorithm 1 (SHA-1), issue the following command:

```
[edit system login user account-name authentication]
user@host# set encrypted-password "password"
```

2. (Optional) Commit the configuration. Alternatively, you can wait until you have added the statements that satisfy all prerequisites (see [“NETCONF Service over SSH Is Enabled” on page 567](#)).

```
[edit system login user account-name authentication]
user@host# commit
```

3. Repeat the preceding steps on each device running Junos OS where the client application establishes NETCONF sessions.

Creating a Public/Private Key Pair

To create an SSH public/private key pair, perform the following steps:

1. Issue the **ssh-keygen** command in the standard command shell (not the Junos OS CLI) on the configuration management server where the client application runs. By providing the appropriate arguments, you encode the public key with either RSA (supported by SSH versions 1 and 2) or the Digital Signature Algorithm (DSA, supported by SSH version 2). For more information, see the manual page for the **ssh-keygen** command. The Junos OS uses SSH version 2 by default, but also supports version 1.

```
% ssh-keygen options
```

2. Associate the public key with the Junos login account by including the **load-key-file** statement at the **[edit system login user *account-name* authentication]** hierarchy level. The Junos OS copies the contents of the specified file onto the device running Junos OS.

```
[edit system login user account-name authentication]
user@host# set load-key-file URL
```

URL is the path to the file that contains one or more public keys. The **ssh-keygen** command by default stores each public key in a file in the **.ssh** subdirectory of the user home directory; the filename depends on the encoding (DSA or RSA) and SSH version. For information about specifying URLs, see the *CLI User Guide*.

Alternatively, you can include one or both of the **ssh-dsa** and **ssh-rsa** statements at the **[edit system login user *account-name* authentication]** hierarchy level. We recommend using the **load-key-file** statement, however, because it eliminates the need to type or cut-and-paste the public key on the command line. For more information about the **ssh-dsa** and **ssh-rsa** statements, see the *Junos OS System Basics Configuration Guide*.

3. (Optional) Commit the configuration. Alternatively, you can wait until you have added the statements that satisfy all prerequisites (see [“NETCONF Service over SSH Is Enabled” on page 567](#)).

```
[edit system login user account-name authentication]
user@host# commit
```

4. Repeat Step 2 and Step 3 on each device running Junos OS where the client application establishes NETCONF sessions.

Client Application Can Access the Keys or Password

The client application must be able to access the public/private keys or password you created in [“Junos Login Account Has Public/Private Key Pair or Password” on page 565](#) and provide it when the NETCONF server prompts for it.

There are several methods for enabling the application to access the key or password:

- If public/private keys are used, the **ssh-agent** program runs on the computer where the client application runs, and handles the private key.
- When a user starts the application, the application prompts the user for the password and stores it temporarily in a secure manner.
- The password is stored in encrypted form in a secure local-disk location or in a secured database.

NETCONF Service over SSH Is Enabled

RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*, requires that the NETCONF server, by default, provide the client device with access to the NETCONF SSH subsystem when the SSH session is established over a dedicated IANA-assigned TCP port. Use of a dedicated port makes it easy to identify and filter NETCONF traffic. The IANA-assigned port for NETCONF-over-SSH sessions is 830.

You also can configure the server to allow access to the NETCONF SSH subsystem either over the default SSH port (22) or over a port number that is explicitly configured. An explicitly configured port accepts only NETCONF-over-SSH sessions and rejects regular SSH session requests. If SSH services are enabled on the server, the default SSH port (22) continues to accept NETCONF sessions even when an alternate NETCONF-over-SSH port is configured. For added security, you can configure event policies that utilize **UI_LOGIN_EVENT** information to effectively disable the default port or further restrict NETCONF server access on a port.

To enable NETCONF service over SSH on a device running the Junos OS, perform the following steps:

1. Include one of the following statements at the indicated configuration hierarchy level:
 - To enable access to the NETCONF SSH subsystem using the default IANA-assigned port (830) as specified by RFC 4742, include the **ssh** statement at the **[edit system services netconf]** hierarchy level:

```
[edit system services]
user@host# set netconf ssh
```

- To enable access to the NETCONF SSH subsystem using a specified port number, configure the **port** statement with the desired port number at the **[edit system services netconf ssh]** hierarchy level.

```
[edit system services]
user@host# set netconf ssh port port-number
```

The **port-number** can range from 1 through 65535. The configured port accepts only NETCONF-over-SSH sessions and rejects regular SSH session requests.

NOTE: Although NETCONF-over-SSH can be configured on any port from 1 through 65535, you should avoid configuring access on a port that is normally assigned for another service. This practice avoids potential resource conflicts. If you configure NETCONF-over-SSH on a port assigned for another service, such as FTP, and that service is enabled, a commit check does not reveal a resource conflict or issue any warning message to that effect.

- To enable access to the NETCONF SSH subsystem using the default SSH port (22), include the **ssh** statement at the **[edit system services]** hierarchy level. This configuration enables SSH access to the device for all users and applications. The **ssh** statement can be included in the configuration in addition to the configuration statements listed previously.

```
[edit system services]
user@host# set ssh
```

2. Commit the configuration:

```
[edit]
user@host# commit
```

3. Repeat the preceding steps on each device running Junos OS where the client application will establish NETCONF sessions.

Establishing an Outbound SSH Connection

To enable a configuration management server to establish an outbound SSH connection to the NETCONF server, you must satisfy the requirements discussed in the following sections:

- [Configuring the Device Running Junos OS for Outbound SSH on page 568](#)
- [Installing SSH Software on the Client on page 571](#)
- [Receiving and Managing the Outbound SSH Initiation Sequence on the Client on page 571](#)
- [Enabling NETCONF Service over SSH on page 572](#)

Configuring the Device Running Junos OS for Outbound SSH

To configure the device running Junos OS for outbound SSH:

1. At the **[edit system services ssh]** hierarchy level, set the SSH **protocol-version** to v2:

```
[edit system services ssh]
user@host# set protocol-version v2
```

2. Generate or obtain a public/private key pair for the device running Junos OS. This key pair will be used to encrypt the data transferred across the SSH connection. For more information on generating key pairs, see the *Junos OS System Basics Configuration Guide*.
3. If the public key will be installed on the configuration management server manually, transfer the public key to the configuration management server.

4. Add the following **outbound-ssh** statement at the **[edit system services]** hierarchy level:

```
[edit system services]
outbound-ssh {
  client client-id {
    device-id device-id;
    secret secret;
    keep-alive {
      retry number
      timeout number;
    }
    reconnect-strategy (sticky | in-order);
    services netconf;
    [ address ] {
      port destination-port;
      retry number;
      timeout number;
    }
  }
  traceoptions {
    file filename {
      files files;
      size size;
      match match;
      (world-readable | no-world-readable);
    }
    flag (all | configuration | connectivity);
    no-remote-trace;
  }
}
```

The attributes are as follows:

- **client *client-id***—**outbound-ssh** configuration stanza on the device. Each **outbound-ssh** stanza represents a single outbound SSH connection. This attribute is not sent to the client.
- **device-id *device-id***—Unique ID identifying the device running Junos OS to the configuration management server during the initiation process.
- **secret *secret***—(Optional) Public SSH host key of the device. If this statement is added to the **outbound-ssh** configuration hierarchy, the device will pass its public key to the configuration management server during the initialization of the outbound SSH service. This is the recommended method of maintaining a current copy of the device's public key on the configuration management server.
- **keep-alive**—(Optional) Specify that keepalive messages be sent from the device running Junos OS to the configuration management server. To configure the keepalive message, you must set both the **timeout** and **retry** attributes.
- **retry *number***—Number of keepalive messages the device running Junos OS sends without receiving a response from the configuration management server before the current SSH connection is terminated. The default is three tries.

- **timeout seconds**—Amount of time, in seconds, that the server waits for data before sending a keepalive signal. The default is 15 seconds.
- **reconnect-strategy (sticky | in-order)**—(Optional) Method that the device running Junos OS uses to reestablish a disconnected outbound SSH connection. Two methods are available:
 - **sticky**—The device attempts to reconnect to the configuration management server to which it was last connected. If the connection is unavailable, the device attempts to establish a connection with the next configuration management server on the list and so forth until a connection is established.
 - **in-order**—The device attempts to reestablish an outbound SSH session based on the configuration management server address list. The device attempts to establish a session with the first server on the list. If this connection is not available, the device attempts to establish a session with the next server, and so on down the list until a connection is established.

When reconnecting to a client, the device running Junos OS attempts to reconnect to the client based on the **retry** and **timeout** values for each client listed in the configuration management server list.

- **services netconf**—(Required) Specifies the services available for the session. Currently, NETCONF is the only service available.
- **address**—(Required) The host name or the IPv4 address of the configuration management server. You can list multiple clients by adding each client's IP address or host name along with the connection parameters listed below:
 - **port destination-port**—Outbound SSH port for the client. The default is port 22.
 - **retry number**—Number of times the device running Junos OS attempts to establish an outbound SSH connection before giving up. The default is three tries.
 - **timeout seconds**—Amount of time, in seconds, that the device running Junos OS attempts to establish an outbound SSH connection before giving up. The default is 15 seconds.
- **file filename**—(Optional) Filename of the log file used to record the trace options. By default it is the name of the traced process (for example **mib2d** or **snmpd**). Use this option to override the default value.
- **files files**—(Optional) Maximum number of trace files generated. By default, the maximum number of trace files is 10. Use this option to override the default value.

When a trace file reaches its maximum size, the system archives the file and starts a new file. The system archives trace files by appending a number to the filename in sequential order from 1 to the maximum value (specified by the default value or the options value set here). Once the maximum value is reached, the numbering sequence is restarted at 1, overwriting the older file.

- **size size**—(Optional) The maximum size of the trace file in kilobytes (KB). Once the maximum file size is reached, the system will archive the file. The default value is 1 MB. Use this option to override the default value.

- **match *match***—(Optional) Add lines to the trace file that match the the regular expression specified. For example, if the match value is set to **=error**, the system will only record lines to the trace file that include the string **error**.
- **(world-readable | no-world-readable)**—(Optional) This option specifies whether the files are accessible by the originator of the trace operation only or by any user. By default, log files are only accessible by the user that started the trace operation (**no-world-readable**). Use this option to override the default value.
- **(all | configuration | connectivity)**—(Optional) Flag specifying the type of tracing operation to perform.
 - **all**—Log all events.
 - **configuration**—Log all events pertaining to the configuration of the device running Junos OS.
 - **connectivity**—Log all events pertaining to the establishment of a connection between the client server and the device running Junos OS.
- **no-remote-trace**—(Optional) Disables remote tracing.

5. Commit the configuration:

```
[edit]
user@host# commit
```

Installing SSH Software on the Client

Once the device establishes the SSH connection to the configuration management server, the configuration management server takes control of the SSH session. Therefore, the SSH client software must be installed locally on the configuration management server.

If the client application accessing the NETCONF server uses the NETCONF Perl module provided by Juniper Networks, no further action is necessary. As part of the installation procedure for the Perl module, you install a prerequisites package that includes the necessary SSH software. If the client application does not use the NETCONF Perl module, obtain the SSH client software and install it on the configuration management server where the application runs. For information about obtaining and installing SSH software, see <http://www.ssh.com/> and <http://www.openssh.com/>.

Receiving and Managing the Outbound SSH Initiation Sequence on the Client

When configured for outbound SSH, the device running Junos OS attempts to maintain a constant connection with a configuration management server. Whenever an outbound SSH session is not established, the device sends an outbound SSH initiation sequence to a configuration management server listed within the device's configuration management server list. Prior to establishing a connection with the device, each configuration management server must be set up to receive this initiation sequence, establish a TCP connection with the device, and transmit the device identity back to the device.

The initiation sequence takes one of two forms, depending on how you chose to handle the Junos server's public key.

If the public key is installed manually on the configuration management server, the initiation sequence takes the following form:

```
MSG-ID: DEVICE-CONN-INFO\r\n
MSG-VER: V1\r\n
DEVICE-ID: <device-id>\r\n
```

If the public key is forwarded to the configuration management server by the device during the initialization sequence, the sequence takes the following form:

```
MSG-ID: DEVICE-CONN-INFO\r\n
MSG-VER: V1\r\n
DEVICE-ID: : <device-id>\r\n
HOST-KEY: <pub-host-key>\r\n
HMAC: <HMAC(pub-SSH-host-key,<secret>)>\r\n
```

Enabling NETCONF Service over SSH

RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*, requires that the NETCONF server, by default, provide the client device with access to the NETCONF SSH subsystem when the SSH session is established over a dedicated IANA-assigned TCP port. Use of a dedicated port makes it easy to identify and filter NETCONF traffic. The IANA-assigned port for NETCONF-over-SSH sessions is 830.

You also can configure the server to allow access to the NETCONF SSH subsystem either over the default SSH port (22) or over a port number that is explicitly configured. An explicitly configured port accepts only NETCONF-over-SSH sessions and rejects regular SSH session requests. If SSH services are enabled on the server, the default SSH port (22) continues to accept NETCONF sessions even when an alternate NETCONF-over-SSH port is configured. For added security, you can configure event policies that utilize **UI_LOGIN_EVENT** information to effectively disable the default port or further restrict NETCONF server access on a port.

To enable NETCONF service over SSH on a device running the Junos OS, perform the following steps:

1. Include one of the following statements at the indicated hierarchy level:
 - To enable access to the NETCONF SSH subsystem using the default IANA-assigned port (830) as specified by RFC 4742, include the **ssh** statement at the **[edit system services netconf]** hierarchy level:

```
[edit system services]
user@host# set netconf ssh
```

- To enable access to the NETCONF SSH subsystem using a specified port number, configure the **port** statement with the desired port number at the **[edit system services netconf ssh]** hierarchy level.

```
[edit system services]
user@host# set netconf ssh port port-number
```

The ***port-number*** can range from 1 through 65535. The configured port accepts only NETCONF-over-SSH sessions and rejects regular SSH session requests.

NOTE: Although NETCONF-over-SSH can be configured on any port from 1 through 65535, you should avoid configuring access on a port that is normally assigned for another service. This practice avoids potential resource conflicts. If you configure NETCONF-over-SSH on a port assigned for another service, such as FTP, and that service is enabled, a commit check does not reveal a resource conflict or issue any warning message to that effect.

- To enable access to the NETCONF SSH subsystem using the default SSH port (22), include the **ssh** statement at the **[edit system services]** hierarchy level. This configuration enables SSH access to the device for all users and applications. The **ssh** statement can be included in the configuration in addition to the configuration statements listed previously.

```
[edit system services]
user@host# set ssh
```

2. Commit the configuration:

```
[edit]
user@host# commit
```

3. Repeat the preceding steps on each device where the client application will establish a NETCONF session.

Connecting to the NETCONF Server

Before a client application can connect to the NETCONF server, you must satisfy the requirements described in [“Prerequisites for Establishing an SSH Connection” on page 563](#).

When the prerequisites are satisfied, applications written in Perl use the NETCONF Perl module to connect to the NETCONF server. A client application that does not use the NETCONF Perl module uses one of two methods:

- It uses SSH library routines to establish an SSH connection to the NETCONF server, provide the username and password or passphrase, and create a channel that acts as an SSH subsystem for the NETCONF session. Providing instructions for using library routines is beyond the scope of this document.
- It issues the following **ssh** command to create a NETCONF session as an SSH subsystem:

```
ssh -p 830 -s user@hostname netconf
```

The **-p** option defines the port number on which the NETCONF server listens. This option can be omitted if you enabled access to SSH over the default port in [“Enabling NETCONF Service over SSH” on page 572](#).

The **-s** option establishes the NETCONF session as an SSH subsystem.

The application must include code to intercept the NETCONF server’s prompt for the password or passphrase. Perhaps the most straightforward method is for the application

to use a utility such as the **expect** command. The NETCONF Perl client uses this method, for example.

Starting the NETCONF Session

Each NETCONF session begins with a handshake in which the NETCONF server and the client application specify the NETCONF capabilities they support. The following sections describe how to start a NETCONF session:

- [Exchanging <hello> Tag Elements on page 574](#)
- [Verifying Compatibility on page 576](#)

Exchanging <hello> Tag Elements

The NETCONF server and client application each begin by emitting a **<hello>** tag element to specify which operations, or *capabilities*, they support from among those defined in the NETCONF specification. The **<hello>** tag element encloses the **<capabilities>** tag element and the **<session-id>** tag element, which specifies the UNIX process ID (PID) of the NETCONF server for the session. Within the **<capabilities>** tag element, a **<capability>** tag element specifies each supported function.

The client application must emit the **<hello>** tag element before any other tag element during the NETCONF session, and must not emit it more than once.

Each capability defined in the NETCONF specification is represented in a **<capability>** tag element by a uniform resource name (URN). Capabilities defined by individual vendors are represented by uniform resource identifiers (URIs), which can be URNs or URLs. The NETCONF XML management protocol for Junos OS Release 12.1 emits the following **<hello>** tag element (each **<capability>** tag element appears on three lines for legibility only):

```
<hello>
  <capabilities>
    <capability>urn:ietf:params:xml:ns:netconf:base:1.0</capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:candidate:1.0
    </capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:confirmed-commit:1.0
    </capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:validate:1.0
    </capability>
    <capability>
      urn:ietf:params:xml:ns:netconf:capability:url:1.0?protocol=http,ftp,file
    </capability>
    <capability>http://xml.juniper.net/netconf/junos/1.0</capability>
  </capabilities>
  <session-id>3911</session-id>
</hello>
]]>]]>
```

(For information about the `]]>]]>` character sequence, see [“Generating Well-Formed XML Documents” on page 562.](#))

The URIs in the `<hello>` tag element indicate the following supported capabilities:

- **urn:ietf:params:xml:ns:netconf:base:1.0**—The NETCONF server supports the basic NETCONF operations and tag elements defined in this namespace.
- **urn:ietf:params:xml:ns:netconf:capability:candidate:1.0**—The NETCONF server supports operations on a candidate configuration. For more information, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#) and [“Committing Configurations” on page 647.](#)
- **urn:ietf:params:xml:ns:netconf:capability:confirmed-commit:1.0**—The NETCONF server supports confirmed commit operations. For more information, see [“Committing the Candidate Configuration Only After Confirmation” on page 648.](#)
- **urn:ietf:params:xml:ns:netconf:capability:validate:1.0**—The NETCONF server supports the validation operation, which verifies the syntactic correctness of a configuration without actually committing it. For more information, see [“Verifying a Configuration Before Committing It” on page 647.](#)
- **urn:ietf:params:xml:ns:netconf:capability:url:1.0?protocol=http,ftp,file**—The NETCONF server accepts configuration data stored in a file. It can retrieve files both from its local filesystem (indicated by the `file` option in the URN) and from remote machines by using Hypertext Transfer Protocol (HTTP) or FTP (indicated by the `http` and `ftp` options in the URN). For more information, see [“Referencing Configuration Data Files” on page 625.](#)
- **http://xml.juniper.net/netconf/junos/1.0**—The NETCONF server supports the operations defined in the Junos XML API for requesting and changing operational information (the tag elements in the *Junos XML API Operational Developer Reference*). The NETCONF server also supports operations in the Junos XML management protocol for requesting or changing configuration information.

NETCONF client applications should use only native NETCONF XML management protocol operations and the extensions available in the Junos XML management protocol as documented in

[“Summary of Junos XML Protocol Tag Elements Supported in NETCONF Sessions” on page 667](#) for configuration functions. The semantics of corresponding Junos XML protocol operations and NETCONF XML protocol operations are not necessarily identical, so using Junos XML protocol configuration operations other than the extensions documented in

[“Summary of Junos XML Protocol Tag Elements Supported in NETCONF Sessions” on page 667](#) can lead to unexpected results.

To comply with the NETCONF specification, the client application also emits a `<hello>` tag element to define the capabilities it supports. It does not include the `<session-id>` tag element:

```
<hello>
<capabilities>
  <capability>first-capability</capability>
  <!-- tag elements for additional capabilities -->
```

```

</capabilities>
</hello>
]]>]]>

```

Verifying Compatibility

Exchanging **<hello>** tag elements enables a client application and the NETCONF server to determine if they support the same capabilities. In addition, we recommend that the client application determine the version of the Junos OS running on the NETCONF server. After emitting its **<hello>** tag, the client application emits the **<get-software-information>** tag element in an **<rpc>** tag element:

```

<rpc>
  <get-software-information/>
</rpc>
]]>]]>

```

The NETCONF server returns the **<software-information>** tag element, which encloses the **<host-name>** and **<product-name>** tag elements plus a **<package-information>** tag element for each Junos OS module. (For information about the **<rpc-reply>** tag element, see [“Parsing the NETCONF Server Response” on page 580](#).) The **<comment>** tag element within the **<package-information>** tag element specifies the Junos OS Release number (in the following example, 8.2 for Junos OS Release 8.2) and the build date in the form **YYYYMMDD** (year, month, day—12 January 2007 in the following example). Some tag elements appear on multiple lines, for legibility only:

```

<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" \
  xmlns:junos="http://xml.juniper.net/junos/8.2R1/junos">
  <software-information>
    <host-name>router1</host-name>
    <product-name>m20</product-name>
    <package-information>
      <name>junos</name>
      <comment>JUNOS Base OS boot [8.2-20070112.0]</comment>
    </package-information>
    <package-information>
      <name>jbase</name>
      <comment>JUNOS Base OS Software Suite \
        [8.2-20070112.0]</comment>
    </package-information>
    <!-- <package-information> tag elements for additional modules -->
  </software-information>
</capabilities>
</rpc-reply>
]]>]]>

```

Normally, the version is the same for all Junos OS modules running on the device (we recommend this configuration for predictable routing performance). Therefore, verifying the version number of just one module is usually sufficient.

The client application is responsible for determining how to handle any differences in version or capabilities. For fully automated performance, include code in the client application that determines whether it supports the same capabilities and Junos OS

version as the NETCONF server. Decide which of the following options is appropriate when there are differences, and implement the corresponding response:

- Ignore differences in capabilities and Junos version, and do not alter the client application's behavior to accommodate the NETCONF server. A difference in Junos versions does not necessarily make the server and client incompatible, so this is often a valid approach. Similarly, it is a valid approach if the capabilities that the client application does not support are operations that are always initiated by a client, such as validation of a configuration and confirmed commit. In that case, the client maintains compatibility by not initiating the operation.
- Alter standard behavior to be compatible with the NETCONF server. If the client application is running a later version of the Junos OS, for example, it can choose to emit only NETCONF and Junos XML tag elements that represent the software features available in the NETCONF server's version of the Junos OS.
- End the NETCONF session and terminate the connection. This is appropriate if you decide that it is not practical to accommodate the NETCONF server's version or capabilities. For instructions, see [“Ending a NETCONF Session and Closing the Connection” on page 587](#).

Exchanging Information with the NETCONF Server

The session continues when the client application sends a request to the NETCONF server. The NETCONF server does not emit any tag elements after session initialization except in response to the client application's requests. The following sections describe the exchange of tagged data:

- [Sending a Request to the NETCONF Server on page 577](#)
- [Parsing the NETCONF Server Response on page 580](#)
- [Handling an Error or Warning on page 583](#)

Sending a Request to the NETCONF Server

To initiate a request to the NETCONF server, a client application emits the opening `<rpc>` tag, followed by one or more tag elements that represent the particular request, and the closing `</rpc>` tag, in that order:

```
<rpc>
  <!-- tag elements representing a request -->
</rpc>
]]>]]>
```

Each request is enclosed in its own separate pair of opening `<rpc>` and closing `</rpc>` tags and must constitute a well-formed XML document by including only compliant and correctly ordered tag elements. For information about the `]]>]]>` character sequence, see [“Generating Well-Formed XML Documents” on page 562](#). For an example of emitting an `<rpc>` tag element in the context of a complete NETCONF session, see [“Example of a NETCONF Session” on page 589](#).

The NETCONF server ignores any newline characters, spaces, or other white space characters that occur between tag elements in the tag stream, but it preserves white

space within tag elements. For more information, see [“XML and NETCONF XML Management Protocol Conventions Overview” on page 547](#).

See the following sections for further information:

- [Request Classes on page 578](#)
- [Including Attributes in the Opening <rpc> Tag on page 580](#)

Request Classes

A client application can make three classes of requests:

- [Operational Requests on page 578](#)
- [Configuration Information Requests on page 578](#)
- [Configuration Change Requests on page 579](#)

NOTE: Although operational and configuration requests conceptually belong to separate classes, a NETCONF session does not have distinct modes that correspond to CLI operational and configuration modes. Each request tag element is enclosed within its own <rpc> tag element, so a client application can freely alternate operational and configuration requests.

Operational Requests

Operational requests are requests for information about the status of a device running Junos OS. Operational requests correspond to the CLI operational mode commands listed in the Junos OS command references. The Junos XML API defines a request tag element for many CLI commands. For example, the <get-interface-information> tag element corresponds to the **show interfaces** command, and the <get-chassis-inventory> tag element requests the same information as the **show chassis hardware** command.

The following sample request is for detailed information about the interface **ge-2/3/0**:

```
<rpc>
  <get-interface-information>
    <interface-name>ge-2/3/0</interface-name>
    <detail/>
  </get-interface-information>
</rpc>
]]>]]>
```

For more information, see [“Requesting Operational Information” on page 594](#). For information about the Junos XML request tag elements available in the current Junos OS Release, see the *Junos XML API Operational Developer Reference*.

Configuration Information Requests

Configuration information requests are requests for information about the device's candidate configuration, a private configuration, or the committed configuration (the one currently in active use on the switching, routing, or security platform). The candidate and committed configurations diverge when there are uncommitted changes to the candidate configuration.

The NETCONF protocol defines the `<get-config>` operation for retrieving configuration information. The Junos XML API defines a tag element for every container and leaf statement in the configuration hierarchy.

The following example shows how to request information from the `[edit system login]` hierarchy level of the candidate configuration:

```
<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
    <filter type="subtree">
      <configuration>
        <system>
          <login/>
        </system>
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>
```

For more information, see [“Requesting Configuration Information” on page 598](#). For a summary of the available configuration tag elements, see the *Junos XML API Configuration Developer Reference*.

Configuration Change Requests

Configuration change requests are requests to change the candidate configuration, or to commit those changes to put them into active use on the device running Junos OS. The NETCONF protocol defines the `<edit-config>` and `<copy-config>` operations for changing configuration information. The Junos XML API defines a tag element for every CLI configuration statement described in the Junos OS configuration guides.

The following example shows how to create a new Junos OS user account called **admin** at the `[edit system login]` hierarchy level in the candidate configuration:

```
<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <config>
      <configuration>
        <system>
          <login>
            <user>
              <name>admin</name>
              <full-name>Administrator</full-name>
              <class>superuser</class>
            </user>
          </login>
        </system>
      </configuration>
    </config>
  </edit-config>
</rpc>
```

```

        </configuration>
      </config>
    </edit-config>
  </rpc>
}>]]>

```

For more information, see [“Changing Configuration Information” on page 623](#). For a summary of Junos XML configuration tag elements, see the *Junos XML API Configuration Developer Reference*.

Including Attributes in the Opening <rpc> Tag

Optionally, a client application can include one or more attributes of the form **attribute-name="value"** in the opening <rpc> tag for each request. The NETCONF server echoes each attribute, unchanged, in the opening <rpc-reply> tag in which it encloses its response.

A client application can use this feature to associate requests and responses by including an attribute in each opening <rpc> request tag that assigns a unique identifier. The NETCONF server echoes the attribute in its opening <rpc-reply> tag, making it easy to map the response to the initiating request. The NETCONF specification specifies the name **message-id** for this attribute.

Parsing the NETCONF Server Response

The NETCONF server encloses its response to each client request in a separate pair of opening <rpc-reply> and closing </rpc-reply> tags. Each response constitutes a well-formed XML document. The opening <rpc-reply> tag includes the **xmlns** and **xmlns:junos** attributes (the opening tag appears here on multiple lines for legibility only):

```

<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" \
  xmlns:junos="http://xml.juniper.net/junos/release/junos" \
  [echoed attributes]>
  <!-- tag elements representing a response -->
</rpc-reply>
]]>]]>

```

The **xmlns** attribute defines the namespace for enclosed tag elements that do not have the **junos:** prefix on their names and that are not enclosed in a child container tag that has the **xmlns** attribute with a different value.

The **xmlns:junos** attribute defines the namespace for enclosed Junos XML tag elements that have the **junos:** prefix on their names. The variable **release** is replaced by a code such as **12.1R1** for the initial version of Junos OS Release 12.1.

For information about the **]]>]]>** character sequence, see [“Generating Well-Formed XML Documents” on page 562](#). For information about echoed attributes, see [“Including Attributes in the Opening <rpc> Tag” on page 580](#).

Client applications must include code for parsing the stream of response tag elements coming from the NETCONF server, either processing them as they arrive or storing them until the response is complete. See the following sections for further information:

- [NETCONF Server Response Classes on page 581](#)
- [Using a Standard API to Parse Response Tag Elements on page 582](#)

NETCONF Server Response Classes

The NETCONF server returns three classes of responses:

- [Operational Responses on page 581](#)
- [Configuration Information Responses on page 582](#)
- [Configuration Change Responses on page 582](#)

Operational Responses

Operational responses are responses to requests for information about the status of a switching, routing, or security platform. They correspond to the output from CLI operational commands as described in the Junos OS command references.

The Junos XML API defines response tag elements for all defined operational request tag elements. For example, the NETCONF server returns the information requested by the `<get-interface-information>` tag element in a response tag element called `<interface-information>` and returns the information requested by the `<get-chassis-inventory>` tag element in a response tag element called `<chassis-inventory>`. Operational responses also can be returned in formatted ASCII, which is enclosed in an `output` tag element. For more information about formatting operational responses see [“Specifying the Output Format for Operational Information Requests in a NETCONF Session” on page 596](#).

The following sample response includes information about the interface `ge-2/3/0`. The namespace indicated by the `xmlns` attribute in the opening `<interface-information>` tag is for interface information in the initial version of Junos OS Release 12.1. The opening tags appear on two lines here for legibility only:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" \
  xmlns:junos="http://xml.juniper.net/junos/12.1R1/junos">
  <interface-information \
    xmlns="http://xml.juniper.net/junos/12.1R1/junos-interface">
    <physical-interface>
      <name>ge-2/3/0</name>
      <!-- other data tag elements for the ge-2/3/0 interface - ->
    </physical-interface>
  </interface-information>
</rpc-reply>
]]>]]>
```

For more information about the `xmlns` attribute and the contents of operational response tag elements, see [“Requesting Operational Information” on page 594](#). For a summary of operational response tag elements, see the *Junos XML API Operational Developer Reference*.

Configuration Information Responses

Configuration information responses are responses to requests for information about the device's current configuration. The Junos XML API defines a tag element for every container and leaf statement in the configuration hierarchy.

The following sample response includes the information at the **[edit system login]** hierarchy level in the configuration hierarchy. For brevity, the sample shows only one user defined at this level. The opening **<rpc-reply>** tag appears on two lines for legibility only. For information about the attributes in the opening **<configuration>** tag, see ["Requesting Information from the Committed or Candidate Configuration" on page 599](#).

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:junos="http://xml.juniper.net/junos/12.1R1/junos">
  <data>
    <configuration attributes>
      <system>
        <login>
          <user>
            <name>admin</name>
            <full-name>Administrator</full-name>
            <!-- other data tag elements for the admin user -->
          </user>
        </login>
      </system>
    </configuration>
  </data>
</rpc-reply>
]]>]]>
```

Configuration Change Responses

Configuration change responses are responses to requests that change the state or contents of the device configuration. The NETCONF server indicates successful execution of a request by returning the **<ok/>** tag within the **<rpc-reply>** tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

If the operation fails, the **<rpc-reply>** tag element instead encloses an **<rpc-error>** tag element that describes the cause of the failure. For information about handling errors, see ["Handling an Error or Warning" on page 583](#).

For information about changing the device configuration, see ["Changing Configuration Information" on page 623](#). For a summary of the available configuration tag elements, see the *Junos XML API Configuration Developer Reference*.

Using a Standard API to Parse Response Tag Elements

Client applications can handle incoming XML tag elements by feeding them to a parser that is based on a standard API such as the Document Object Model (DOM) or Simple API for XML (SAX). Describing how to implement and use a parser is beyond the scope of this document.

Routines in the DOM accept incoming XML and build a tag hierarchy in the client application's memory. There are also DOM routines for manipulating an existing hierarchy. DOM implementations are available for several programming languages, including C, C++, Perl, and Java. For detailed information, see the *Document Object Model (DOM) Level 1 Specification* from the World Wide Web Consortium (W3C) at <http://www.w3.org/TR/REC-DOM-Level-1/>. Additional information is available from the Comprehensive Perl Archive Network (CPAN) at <http://search.cpan.org/~tjmath/XML-DOM/lib/XML/DOM.pm>.

One potential drawback with DOM is that it always builds a hierarchy of tag elements, which can become very large. If a client application needs to handle only one subhierarchy at a time, it can use a parser that implements SAX instead. SAX accepts XML and feeds the tag elements directly to the client application, which must build its own tag hierarchy. For more information, see the official SAX website at <http://sax.sourceforge.net/>.

Handling an Error or Warning

If the NETCONF server encounters an error condition, it emits an **<rpc-error>** tag element containing tag elements that describe the error:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rpc-error>
    <error-severity>error-severity</error-severity>
    <error-path>error-path</error-path>
    <error-message>error-message</error-message>
    <error-info>
      <bad-element>command-or-statement</bad-element>
    </error-info>
  </rpc-error>
</rpc-reply>
]]>]]>
```

<bad-element> identifies the command or configuration statement that was being processed when the error or warning occurred. For a configuration statement, the **<error-path>** tag element enclosed in the **<rpc-error>** tag element specifies the statement's parent hierarchy level.

<error-message> describes the error or warning in a natural-language text string.

<error-path> specifies the path to the Junos OS configuration hierarchy level at which the error or warning occurred, in the form of the CLI configuration mode banner.

<error-severity> indicates the severity of the event that caused the NETCONF server to return the **<rpc-error>** tag element. The two possible values are **error** and **warning**.

An error can occur while the server is performing any of the following operations, and the server can send a different combination of child tag elements in each case:

- Processing an operational request submitted by a client application
- Locking, changing, committing, or closing a configuration as requested by a client application

- Parsing configuration data submitted by a client application in an **<edit-config>** tag element

Client applications must be prepared to receive and handle an **<rpc-error>** tag element at any time. The information in any response tag elements already received and related to the current request might be incomplete. The client application can include logic for deciding whether to discard or retain the information.

When the **<error-severity>** tag element has the value **error**, the usual response is for the client application to discard the information and terminate. When the **<error-severity>** tag element has the value **warning**, indicating that the problem is less serious, the usual response is for the client application to log the warning or pass it to the user and to continue parsing the server's response.

Locking and Unlocking the Candidate Configuration

When a client application is requesting or changing configuration information, it can use one of two methods to access the configuration:

- Lock the candidate configuration, which prevents other users or applications from changing it until the application releases the lock (equivalent to the CLI **configure exclusive** command).
- Change the candidate configuration without locking it. We do not recommend this method, because of the potential for conflicts with changes made by other applications or users that are editing the configuration at the same time.

If an application is simply requesting configuration information and not changing it, locking the configuration is not required. The application can begin requesting information immediately, as described in [“Requesting Configuration Information” on page 598](#). However, it is appropriate to lock the configuration if it is important that the information being returned not change during the session.

For more information about locking and unlocking the candidate configuration, see the following sections:

- [Locking the Candidate Configuration on page 584](#)
- [Unlocking the Candidate Configuration on page 585](#)

Locking the Candidate Configuration

To lock the candidate configuration, a client application emits the **<lock>** and **<target>** tag elements and the **<candidate/>** tag in the **<rpc>** tag element:

```
<rpc>
  <lock>
    <target>
      <candidate/>
    </target>
  </lock>
</rpc>
]]>]]>
```

Locking the candidate configuration prevents other users or applications from changing the candidate configuration until the lock is released (equivalent to the CLI **configure exclusive** command). Locking the configuration before making changes is recommended, particularly on devices where multiple users are authorized to change the configuration. A commit operation applies to all changes in the candidate configuration, not just those made by the user or application that requests the commit. Allowing multiple users or applications to make changes simultaneously can lead to unexpected results.

The NETCONF server confirms that it has locked the candidate by returning the **<ok/>** tag in the **<rpc-reply>** tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

If the NETCONF server cannot lock the configuration, the **<rpc-reply>** tag element instead encloses an **<rpc-error>** tag element explaining the reason for the failure. Reasons for the failure can include the following:

- Another user or application has already locked the candidate configuration. The error message reports the NETCONF session identifier of the user or application. If the client application has the necessary Junos access privilege, it can terminate the session that holds the lock. For more information, see [“Terminating Another NETCONF Session” on page 586](#).
- The candidate configuration already includes changes that have not yet been committed. To commit the changes, see [“Committing a Configuration” on page 648](#). To discard uncommitted changes, see [“Rolling Back a Configuration” on page 635](#).

Only one application can hold the lock on the candidate configuration at a time. Other users and applications can read the candidate configuration while it is locked. The lock persists until either the NETCONF session ends or the client application unlocks the configuration by emitting the **<unlock>** tag element, as described in [“Unlocking the Candidate Configuration” on page 585](#).

If the candidate configuration is not committed before the client application unlocks it, or if the NETCONF session ends for any reason before the changes are committed, the changes are automatically discarded. The candidate and committed configurations remain unchanged.

Unlocking the Candidate Configuration

As long as a client application holds a lock on the candidate configuration, other applications and users cannot change the candidate. To unlock the candidate configuration, the client application includes the **<unlock>** and **<target>** tag elements and the **<candidate/>** tag in an **<rpc>** tag element:

```
<rpc>
  <unlock>
    <target>
      <candidate/>
```

```
    </target>
  </unlock>
</rpc>
]]>]]>
```

The NETCONF server confirms that it has unlocked the candidate by returning the `<ok/>` tag in the `<rpc-reply>` tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

If the NETCONF server cannot unlock the configuration, the `<rpc-reply>` tag element instead encloses an `<rpc-error>` tag element explaining the reason for the failure.

Terminating Another NETCONF Session

A client application's attempt to lock the candidate configuration can fail because another user or application already holds the lock, as mentioned in [“Locking the Candidate Configuration” on page 584](#). In this case, the NETCONF server returns an error message that includes the username and process ID (PID) for the entity that holds the existing lock:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rpc-error>
    <error-severity>error</error-severity>
    <error-message>
      configuration database locked by:
      user terminal (pid PID) on since YYYY-MM-DD hh:mm:ss TZ, idle hh:mm:ss
      exclusive
    </error-message>
  </rpc-error>
</rpc-reply>
]]>]]>
```

If the client application has the Junos **maintenance** permission, it can end the session that holds the lock by emitting the `<kill-session>` and `<session-id>` tag elements in an `<rpc>` tag element. The `<session-id>` tag element specifies the PID obtained from the error message:

```
<rpc>
  <kill-session>
    <session-id>PID</session-id>
  </kill-session>
</rpc>
]]>]]>
```

The NETCONF server confirms that it has terminated the other session by returning the `<ok/>` tag in the `<rpc-reply>` tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

We recommend that the application include logic for determining whether it is appropriate to terminate another session, based on factors such as the identity of the user or application that holds the lock, or the length of idle time.

When a session is terminated, the NETCONF server that is servicing the session rolls back all uncommitted changes that have been made during the session. If a confirmed commit is pending (changes have been committed but not yet confirmed), the NETCONF server restores the configuration to its state before the confirmed commit instruction was issued. (For information about the confirmed commit operation, see [“Committing the Candidate Configuration Only After Confirmation” on page 648.](#))

The following example shows how to terminate another session:

Client Application	NETCONF Server
<pre><rpc> <kill-session> <session-id>3250</session-id> </kill-session> </rpc>]]>]]></pre>	<pre><rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]></pre>

T2101

Ending a NETCONF Session and Closing the Connection

When a client application is finished making requests, it ends the NETCONF session by emitting the empty `<close-session/>` tag within an `<rpc>` tag element:

```
<rpc>
  <close-session/>
</rpc>
]]>]]>
```

In response, the NETCONF server emits the `<ok/>` tag enclosed in an `<rpc-reply>` tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

For an example of the exchange of closing tag elements, see [“Closing the NETCONF Session” on page 592.](#)

Because the connection to the NETCONF server is an SSH subsystem, it closes automatically when the NETCONF session ends.

Displaying CLI Output as XML Tag Elements

To display the output from a CLI command as NETCONF and Junos XML tag elements instead of as the default formatted ASCII, pipe the command to the `display xml` command. Infrastructure tag elements in the response belong to the Junos XML management

protocol instead of the NETCONF XML management protocol. The tag elements that describe Junos OS configuration or operational data belong to the Junos XML API, which defines the Junos content that can be retrieved and manipulated by both the Junos XML management protocol and the NETCONF XML management protocol operations.

The following example shows the output from the **show chassis hardware** command issued on an M20 router that is running the initial version of Junos OS Release 12.1 (the opening **<chassis-inventory>** tag appears on two lines for legibility only):

```
user@host> show chassis hardware | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/12.1R1/junos">
  <chassis-inventory \
    xmlns="http://xml.juniper.net/junos/12.1R1/junos-chassis">
    <chassis junos:style="inventory">
      <name>Chassis</name>
      <serial-number>00118</serial-number>
      <description>M20</description>
      <chassis-module>
        <name>Backplane</name>
        <version>REV 06</version>
        <part-number>710-001517</part-number>
        <serial-number>AB5911</serial-number>
      </chassis-module>
      <chassis-module>
        <name>Power Supply A</name>
        <!-- other child tags of <chassis-module> -->
      </chassis-module>
      <!-- other child tags of <chassis> -->
    </chassis>
  </chassis-inventory>
</rpc-reply>
]]>]]>
```

Displaying the RPC Tags for a Command

To display the remote procedure call (RPC) XML tags for an operational mode command, enter **display xml rpc** after the pipe symbol (|).

The following example displays the RPC tags for the **show route** command:

```
user@host> show route | display xml rpc
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.1I0/junos">
  <rpc>
    <get-route-information>
      </get-route-information>
    </rpc>
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>
```

Example of a NETCONF Session

This section describes the sequence of tag elements in a sample NETCONF session. The client application begins by establishing a connection to a NETCONF server. See the following sections:

- [Exchanging Initialization Tag Elements on page 589](#)
- [Sending an Operational Request on page 590](#)
- [Locking the Configuration on page 590](#)
- [Changing the Configuration on page 591](#)
- [Committing the Configuration on page 591](#)
- [Unlocking the Configuration on page 592](#)
- [Closing the NETCONF Session on page 592](#)

Exchanging Initialization Tag Elements

After the client application establishes a connection to a NETCONF server, the two exchange **<hello>** tag elements, as shown in the following example. For legibility, the example places the client application's **<hello>** tag element below the NETCONF server's. The two parties can actually emit their **<hello>** tag elements at the same time. For information about the **]]>]]>** character sequence used in this and the following examples, see [“Generating Well-Formed XML Documents” on page 562](#). For a detailed discussion of the **<hello>** tag element, see [“Exchanging <hello> Tag Elements” on page 574](#).

NETCONF Client Application Server

```
<hello>
  <capabilities>
    <capability>urn:ietf:params:xml:ns:netconf:base:1.0</capability>
    <capability>urn:ietf:params:xml:ns:netconf:capability:candidate:1.0</capability>
    <capability>urn:ietf:params:xml:ns:netconf:capability:confirmed-commit:1.0</capability>
    <capability>urn:ietf:params:xml:ns:netconf:capability:validate:1.0</capability>
    <capability>urn:ietf:params:xml:ns:netconf:capability:url:1.0?protocol=http,ftp,file </capability>
    <capability>http://xml.juniper.net/netconf/junos/1.0</capability>
  </capabilities>
  <session-id>3911</session-id>
</hello>
]]>]]>

  <hello>
    <capabilities>
      <capability>urn:ietf:params:xml:ns:netconf:base:1.0</capability>
      <capability>urn:ietf:params:xml:ns:netconf:capability:candidate:1.0</capability>
      <capability>urn:ietf:params:xml:ns:netconf:capability:confirmed-commit:1.0</capability>
      <capability>urn:ietf:params:xml:ns:netconf:capability:validate:1.0</capability>
      <capability>urn:ietf:params:xml:ns:netconf:capability:url:1.0?protocol=http,ftp,file</capability>
      <capability>http://xml.juniper.net/netconf/junos/1.0</capability>
    </capabilities>
  </hello>
]]>]]>
```

T2102

Sending an Operational Request

The client application now emits the `<get-chassis-inventory>` tag element to request information about the device's chassis hardware. The NETCONF server returns the requested information in the `<chassis-inventory>` tag element.

Client Application	NETCONF Server
<pre> <rpc> <get-chassis-inventory> <detail/> </get-chassis-inventory> </rpc>]]>]]> </pre>	<pre> <rpc-reply xmlns="URN" xmlns:junos="URL"> <chassis-inventory xmlns="URL"> <chassis> <name>Chassis</name> <serial-number>1122</serial-number> <description>M320</description> <chassis-module> <name>Midplane</name> <!-- other child tags for the midplane --> </chassis-module> <!-- tags for other chassis modules --> </chassis> </chassis-inventory> </rpc-reply>]]>]]> </pre>

T2103

Locking the Configuration

The client application then prepares to incorporate a change into the candidate configuration by emitting the `<lock/>` tag to prevent any other users or applications from altering the candidate configuration at the same time. To confirm that the candidate configuration is locked, the NETCONF server returns an `<ok/>` tag in an `<rpc-reply>` tag element. For more information and locking the configuration, see [“Locking the Candidate Configuration” on page 584](#).

Client Application	NETCONF Server
<pre> <rpc> <lock> <target> <candidate/> </target> </lock> </rpc>]]>]]> </pre>	<pre> <rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]> </pre>

T2104

Changing the Configuration

The client application now emits tag elements to create a new Junos login class called **network-mgmt** at the **[edit system login class]** hierarchy level in the candidate configuration. To confirm that it incorporated the changes, the NETCONF server returns an **<ok/>** tag in an **<rpc-reply>** tag element. (Understanding the meaning of these tag elements is not necessary for the purposes of this example, but for information about them, see [“Changing Configuration Information” on page 623.](#))

Client Application	NETCONF Server
<pre><rpc> <edit-config> <target> <candidate/> </target> <config> <configuration> <system> <login> <class> <name>network-mgmt</name> <permissions>configure</permissions> <permissions>snmp</permissions> <permissions>system</permissions> </class> </login> </system> </configuration> </config> </edit-config> </rpc>]]>]]></pre>	<pre><rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]></pre> <div>T2105</div>

Committing the Configuration

The client application commits the candidate configuration. To confirm that it committed the candidate configuration, the NETCONF server returns an **<ok/>** tag in an **<rpc-reply>** tag element. For more information about the commit operation, see [“Committing the Candidate Configuration” on page 648.](#)

Client Application	NETCONF Server
<pre><rpc> <commit/> </rpc>]]>]]></pre>	<pre><rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]></pre> <div>T2106</div>

Unlocking the Configuration

The client application unlocks (and by implication closes) the candidate configuration. To confirm that it unlocked the candidate configuration, the NETCONF server returns an `<ok/>` tag in an `<rpc-reply>` tag element. For more information about unlocking a configuration, see [“Unlocking the Candidate Configuration” on page 585](#).

Client Application	NETCONF Server
<pre> <rpc> <unlock> <target> <candidate/> </target> </unlock> </rpc>]]>]]> </pre>	<pre> <rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]> </pre>

T2107

Closing the NETCONF Session

The client application closes the NETCONF session. For more information about closing the session, see [“Ending a NETCONF Session and Closing the Connection” on page 587](#).

Client Application	NETCONF Server
<pre> <rpc> <close-session/> </rpc>]]>]]> </pre>	<pre> <rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]> </pre>

T2108

CHAPTER 8

Requesting Information

This chapter explains how to use the NETCONF XML management protocol and Junos XML API to request information about the status and the current configuration of a routing, switching, or security platform running Junos OS.

The tag elements for operational requests are defined in the Junos XML API and correspond to Junos OS command-line interface (CLI) operational commands, which are described in the Junos OS command references. There is a request tag element for many commands in the CLI **show** family of commands.

The tag element for configuration requests is the NETCONF **<get-config>** tag element. It corresponds to the CLI configuration mode **show** command, which is described in the *CLI User Guide*. The Junos XML tag elements that make up the content of both the client application's requests and the NETCONF server's responses correspond to CLI configuration statements, which are described in the Junos OS configuration guides.

In addition to information about the current configuration, client applications can request other configuration-related information, including an XML schema representation of the configuration hierarchy, information about previously committed (rollback) configurations, or information about the rescue configuration.

This chapter discusses the following topics:

- [Overview of the Request Procedure on page 593](#)
- [Requesting Operational Information on page 594](#)
- [Specifying the Output Format for Operational Information Requests in a NETCONF Session on page 596](#)
- [Requesting Configuration Information on page 598](#)
- [Requesting an XML Schema for the Configuration Hierarchy on page 613](#)
- [Requesting a Previous \(Rollback\) Configuration on page 617](#)
- [Comparing Two Previous \(Rollback\) Configurations on page 618](#)
- [Requesting the Rescue Configuration on page 620](#)

Overview of the Request Procedure

To request information from the NETCONF server, a client application performs the procedures described in the indicated sections:

1. Establishes a connection to the NETCONF server on the routing, switching, or security platform, as described in [“Connecting to the NETCONF Server” on page 573](#).
2. Opens a NETCONF session, as described in [“Starting the NETCONF Session” on page 574](#).
3. If making configuration requests, optionally locks the candidate configuration, as described in [“Locking the Candidate Configuration” on page 584](#).
4. Makes any number of requests one at a time, freely intermingling operational and configuration requests. See [“Requesting Operational Information” on page 594](#) and [“Requesting Configuration Information” on page 598](#).

The application can also intermix requests with configuration changes, which are described in [“Changing Configuration Information” on page 623](#).

5. Accepts the tag stream emitted by the NETCONF server in response to each request and extracts its content, as described in [“Parsing the NETCONF Server Response” on page 580](#).
6. Unlocks the candidate configuration if it is locked, as described in [“Unlocking the Candidate Configuration” on page 585](#). Other users and applications cannot change the configuration while it remains locked.
7. Ends the NETCONF session and closes the connection to the device, as described in [“Ending a NETCONF Session and Closing the Connection” on page 587](#).

Requesting Operational Information

To request information about the current status of a device running Junos OS, a client application emits the specific tag element from the Junos XML API that returns the desired information. For example, the `<get-interface-information>` tag element corresponds to the `show interfaces` command, the `<get-chassis-inventory>` tag element requests the same information as the `show chassis hardware` command, and the `<get-system-inventory>` tag element requests the same information as the `show software information` command.

For complete information about the operational request tag elements available in the current Junos OS release, see “Mapping Between Operational Tag Elements, Perl Methods, and CLI Commands” and “Summary of Operational Request Tag Elements” in the *Junos XML API Operational Developer Reference*.

The application encloses the request tag element in an `<rpc>` tag element. The syntax depends on whether the corresponding CLI command has any options:

```
<rpc>
  <!-- If the command does not have options -->
  <operational-request/>

  <!-- If the command has options -->
  <operational-request>
    <!-- tag elements representing the options -->
  </operational-request>
</rpc>
```

```
]]>]]>
```

The client application can specify the formatting of the information returned by the NETCONF server. By setting an optional attribute in the opening operational request tag, a client application can specify the format of the response as either XML-tagged format, which is the default, or formatted ASCII text.

If the client application requests the output in formatted ASCII text, the NETCONF server encloses its response in an **<output>** tag element, which is enclosed in an **<rpc-reply>** tag element.

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <output>
    operational-response
  </output>
</rpc-reply>
]]>]]>
```

If the client application requests the output in XML-tagged format, the NETCONF server encloses its response in the specific response tag element that corresponds to the request tag element, enclosed in an **<rpc-reply>** tag element.

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <operational-response xmlns="URL-for-DTD">
    <!-- tag elements for the requested information -->
  </operational-response>
</rpc-reply>
]]>]]>
```

For XML-tagged format, the opening tag for each operational response includes the **xmlns** attribute to define the XML namespace for the enclosed tag elements that do not have a prefix (such as **junos:**) in their names. The namespace indicates which Junos XML document type definition (DTD) defines the set of tag elements in the response. The Junos XML API defines separate DTDs for operational responses from different software modules. For instance, the DTD for interface information is called **junos-interface.dtd** and the DTD for chassis information is called **junos-chassis.dtd**. The division into separate DTDs and XML namespaces means that a tag element with the same name can have distinct functions depending on which DTD it is defined in.

The namespace is a URL of the following form:

```
http://xml.juniper.net/junos/release-code/junos-category
```

release-code is the standard string that represents the release of the Junos OS running on the NETCONF server device.

category specifies the DTD.

The *Junos XML API Operational Developer Reference* includes the text of the Junos XML DTDs for operational responses.

Specifying the Output Format for Operational Information Requests in a NETCONF Session

In a NETCONF session, to request information about a routing, switching, or security platform running Junos OS, a client application encloses a Junos XML request tag element in an `<rpc>` tag element. By setting the optional **format** attribute in the opening operational request tag, the client application can specify the formatting of the output returned by the NETCONF server. Information can be returned as XML-tagged format or formatted ASCII text. The basic syntax is as follows:

```
<rpc>
  <operational-request [format="(xml | text | ascii)"]>
    <!-- tag elements for options -->
  </operational-request>
</rpc>
```

XML Format By default, the NETCONF server returns operational information in XML-tagged format. If the value of the **format** attribute is set to **xml**, or if the **format** attribute is omitted, the server returns the response in XML. The following example requests information for the **ge-0/3/0** interface. The **format** attribute is omitted.

```
<rpc>
  <get-interface-information>
    <brief/>
    <interface-name>ge-0/3/0</interface-name>
  </get-interface-information>
</rpc>
]]>]]>
```

The NETCONF server returns the information in XML-tagged format, which is identical to the output displayed in the CLI when you include the **| display xml** option after the operational mode command.

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:junos="http://xml.juniper.net/junos/11.4R1/junos">
  <interface-information
    xmlns="http://xml.juniper.net/junos/11.4R1/junos-interface" junos:style="brief">

    <physical-interface>
      <name>ge-0/3/0</name>
      <admin-status junos:format="Enabled">up</admin-status>
      <oper-status>down</oper-status>
      <link-level-type>Ethernet</link-level-type>
      <mtu>1514</mtu>
      <source-filtering>disabled</source-filtering>
      <speed>1000mbps</speed>
      <bpdu-error>none</bpdu-error>
      <l2pt-error>none</l2pt-error>
      <loopback>disabled</loopback>
      <if-flow-control>enabled</if-flow-control>
      <if-auto-negotiation>enabled</if-auto-negotiation>
      <if-remote-fault>online</if-remote-fault>
      <if-device-flags>
        <ifdf-present/>
        <ifdf-running/>
        <ifdf-down/>
```

```

        </if-device-flags>
        <if-config-flags>
            <iff-hardware-down/>
            <iff-snmp-traps/>
            <internal-flags>0x4000</internal-flags>
        </if-config-flags>
        <if-media-flags>
            <ifmf-none/>
        </if-media-flags>
    </physical-interface>
</interface-information>
</rpc-reply>
]]>]]>

```

ASCII Format To request that the NETCONF server return operational information as formatted ASCII text instead of tagging it with Junos XML tag elements, the client application includes the **format="text"** or **format="ascii"** attribute in the opening request tag. The client application encloses the request in an **<rpc>** tag element.

```

<rpc>
  <get-interface-information [format="(text | ascii)]">
    <brief/>
    <interface-name>ge-0/3/0</interface-name>
  </get-interface-information>
</rpc>
]]>]]>

```

When the client application includes the **format="text"** or **format="ascii"** attribute in the request tag, the NETCONF server formats the reply as ASCII text and encloses it in an **<output>** tag element. The **format="text"** and **format="ascii"** attributes produce identical output.

```

<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:junos="http://xml.juniper.net/junos/11.4R1/junos">
  <output>
Physical interface: ge-0/3/0, Enabled, Physical link is Down
  Link-level type: Ethernet, MTU: 1514, Speed: 1000mbps, Loopback: Disabled,
  Source filtering: Disabled, Flow control: Enabled, Auto-negotiation: Enabled,
  Remote fault: Online
  Device flags   : Present Running Down
  Interface flags: Hardware-Down SNMP-Traps Internal: 0x4000
  Link flags     : None
  </output>
</rpc-reply>
]]>]]>

```

The following example shows the equivalent operational mode command executed in the CLI:

```

user@host> show interfaces ge-0/3/0 brief
Physical interface: ge-0/3/0, Enabled, Physical link is Down
  Link-level type: Ethernet, MTU: 1514, Speed: 1000mbps, Loopback: Disabled,
Source filtering: Disabled,
  Flow control: Enabled, Auto-negotiation: Enabled, Remote fault: Online
  Device flags   : Present Running Down
  Interface flags: Hardware-Down SNMP-Traps Internal: 0x4000
  Link flags     : None

```

The formatted ASCII text returned by the NETCONF server is identical to the CLI output except in cases where the output includes disallowed characters such as '<' (less-than sign), '>' (greater-than sign), and '&' (ampersand). The NETCONF server substitutes these characters with the equivalent predefined entity reference of '<', '>', and '&' respectively.

If the Junos XML API does not define a response tag element for the type of output requested by a client application, the NETCONF server returns the reply as formatted ASCII text enclosed in an **<output>** tag element, even if XML-tagged output is requested.

For information about the **<output>** tag element, see the *Junos XML API Operational Developer Reference*.

NOTE: The content and formatting of data within an **<output>** tag element are subject to change, so client applications must not depend on them.

Requesting Configuration Information

To request information about a configuration on a routing, switching, or security platform, a client application encloses the **<get-config>**, **<source>**, and **<filter>** tag elements in an **<rpc>** tag element. By including the appropriate child tag element in the **<source>** tag element, the client application requests information from either the candidate or active configuration. By including the appropriate child tag elements in the **<filter>** tag element, the application can request the entire configuration or specific portions of the configuration:

```
<rpc>
  <get-config>
    <source>
      <!-- tag specifying the source configuration -->
    </source>
    <filter type="subtree">
      <!-- tag elements representing the configuration elements to return -->
    </filter>
  </get-config>
</rpc>
]]>]]>
```

The **type="subtree"** attribute in the opening **<filter>** tag indicates that the client application is using Junos XML tag elements to represent the configuration elements about which it is requesting information. For information about the syntax used within the **<filter>** tag element to represent elements, see ["Specifying the Scope of Configuration Information to Return" on page 601](#).

NOTE: If the client application locks the candidate configuration before making requests, it needs to unlock it after making its read requests. Other users and applications cannot change the configuration while it remains locked. For more information, see [“Locking and Unlocking the Candidate Configuration” on page 584](#).

The NETCONF server encloses its reply in `<configuration>`, `<data>`, and `<rpc-reply>` tag elements. It includes attributes in the opening `<configuration>` tag that indicate the XML namespace for the enclosed tag elements and when the configuration was last changed or committed. For information about the attributes of the `<configuration>` tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration attributes>
      <!-- JUNOS XML tag elements representing configuration elements -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>
```

If a Junos XML tag element is returned within an `<undocumented>` tag element, the corresponding configuration element is not documented in the Junos OS configuration guides or officially supported by Juniper Networks. Most often, the enclosed element is used for debugging only by support personnel. In a smaller number of cases, the element is no longer supported or has been moved to another area of the configuration hierarchy, but appears in the current location for backward compatibility.

Client applications can also request other configuration-related information, including an XML schema representation of the configuration hierarchy or information about previously committed configurations. For more information, see the following sections:

- [Requesting an XML Schema for the Configuration Hierarchy on page 613](#)
- [Requesting a Previous \(Rollback\) Configuration on page 617](#)
- [Comparing Two Previous \(Rollback\) Configurations on page 618](#)
- [Requesting the Rescue Configuration on page 620](#)

The following sections describe how a client application specifies the source and scope of configuration information returned by the NETCONF server:

- [Requesting Information from the Committed or Candidate Configuration on page 599](#)
- [Specifying the Scope of Configuration Information to Return on page 601](#)

Requesting Information from the Committed or Candidate Configuration

To request information from the candidate configuration, a client application includes the `<source>` tag element and `<candidate/>` tag within the `<rpc>` and `<get-config>` tag elements:

```

<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
    <filter>
      <!-- tag elements representing the configuration elements to return -->
    </filter>
  </get-config>
</rpc>
]]>]]>

```

To request information from the active configuration—the one most recently committed on the device—a client application includes the `<source>` tag element and `<running/>` tag within the `<rpc>` and `<get-config>` tag elements:

```

<rpc>
  <get-config>
    <source>
      <running/>
    </source>
    <filter>
      <!-- tag elements representing the configuration elements to return -->
    </filter>
  </get-config>
</rpc>
]]>]]>

```

NOTE: If requesting the entire configuration, the application omits the `<filter>` tag element. For information about the `<filter>` tag element, see [“Specifying the Scope of Configuration Information to Return” on page 601](#).

The NETCONF server encloses its reply in `<rpc-reply>`, `<data>`, and `<configuration>` tag elements. In the opening `<configuration>` tag, it includes the `xmlns` attribute to specify the namespace for the enclosed tag elements.

When returning information from the candidate configuration, the NETCONF server also includes attributes that indicate when the configuration last changed (they appear on multiple lines here only for legibility):

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration xmlns="URL" junos:changed-seconds="seconds" \
      junos:changed-localtime="YYYY-MM-DD hh:mm:ss TZ">
      <!-- Junos XML tag elements representing the configuration -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

`junos:changed-localtime` represents the time of the last change as the date and time in the device's local time zone.

junos:changed-seconds represents the time of the last change as the number of seconds since midnight on 1 January 1970.

When returning information from the active configuration, the NETCONF server also includes attributes that indicate when the configuration was committed (they appear on multiple lines here only for legibility):

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration xmlns="URL" junos:commit-seconds="seconds" \
      junos:commit-localtime="YYYY-MM-DD hh:mm:ss TZ" \
      junos:commit-user="username">
      <!-- Junos XML tag elements representing the configuration -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>
```

junos:commit-localtime represents the commit time as the date and time in the device's local time zone.

junos:commit-seconds represents the commit time as the number of seconds since midnight on 1 January 1970.

junos:commit-user specifies the Junos OS username of the user who requested the commit operation.

Specifying the Scope of Configuration Information to Return

By including the appropriate child tag elements in the **<filter>** tag element within the **<rpc>** and **<get-config>** tag elements, a client application can request the entire configuration or specific portions of the configuration:

```
<rpc>
  <get-config>
    <source>
      ( <candidate/> | <running/> )
    </source>
    <filter>
      <!-- tag elements representing the configuration elements to return -->
    </filter>
  </get-config>
</rpc>
]]>]]>
```

For information about requesting different amounts of configuration information, see the following sections:

- [Requesting the Complete Configuration on page 602](#)
- [Requesting a Hierarchy Level or Container Object Without an Identifier on page 602](#)
- [Requesting All Configuration Objects of a Specified Type on page 604](#)
- [Requesting Identifiers for Configuration Objects of a Specified Type on page 606](#)
- [Requesting One Configuration Object on page 608](#)

- [Requesting Specific Child Tags for a Configuration Object on page 610](#)
- [Requesting Multiple Configuration Elements Simultaneously on page 612](#)

Requesting the Complete Configuration

To request the entire candidate configuration, a client application encloses `<get-config>` and `<source>` tag elements and the `<candidate/>` tag in an `<rpc>` tag element:

```
<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
  </get-config>
</rpc>
]]>]]>
```

To request the entire active configuration, a client application encloses `<get-config>` and `<source>` tag elements and the `<running/>` tag in an `<rpc>` tag element:

```
<rpc>
  <get-config>
    <source>
      <running/>
    </source>
  </get-config>
</rpc>
]]>]]>
```

The NETCONF server encloses its reply in `<configuration>`, `<data>`, and `<rpc-reply>` tag elements. For information about the attributes in the opening `<configuration>` tag, see ["Requesting Information from the Committed or Candidate Configuration" on page 599](#).

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration attributes>
      <!-- Junos XML tag elements representing the configuration -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>
```

Requesting a Hierarchy Level or Container Object Without an Identifier

To request complete information about all child configuration elements at a hierarchy level or in a container object that does not have an identifier, a client application emits a `<filter>` tag element that encloses the tag elements representing all levels in the configuration hierarchy from the root (represented by the `<configuration>` tag element) down to the immediate parent level of the level or container object, which is represented by an empty tag. The entire request is enclosed in an `<rpc>` tag element:

```
<rpc>
  <get-config>
    <source>
      <!-- tag specifying the source configuration -->
    </source>
```

```

<filter type="subtree">
  <configuration>
    <!-- opening tags for each parent of the requested level -->
    <level-or-container/>
    <!-- closing tags for each parent of the requested level -->
  </configuration>
</filter>
</get-config>
</rpc>
]]>]]>

```

For information about the **<source>** tag element, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

The NETCONF server returns the requested section of the configuration in **<data>** and **<rpc-reply>** tag elements. For information about the attributes in the opening **<configuration>** tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration attributes>
      <!-- opening tags for each parent of the level -->
      <level-or-container>
        <!-- child tag elements of the level or container -->
      </level-or-container>
      <!-- closing tags for each parent of the level -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

The application can also request additional configuration elements of the same or other types by including the appropriate tag elements in the same **<get-config>** tag element. For more information, see [“Requesting Multiple Configuration Elements Simultaneously” on page 612](#).

The following example shows how to request the contents of the **[edit system login]** hierarchy level in the candidate configuration.

Client Application

```

<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
    <filter>
      <configuration>
        <system>
          <login/>
        </system>
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration xmlns="URL" \
      junos:changed-seconds="seconds" \
      junos:changed-localtime="timestamp">
      <system>
        <login>
          <user>
            <name>barbara</name>
            <full-name>Barbara Anderson</full-name>
            <class>superuser</class>
            <uid>632</uid>
          </user>
          <!-- other child tag elements of <login> -->
        </login>
      </system>
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

T2128

Requesting All Configuration Objects of a Specified Type

To request complete information about all configuration objects of a specified type in a hierarchy level, a client application emits a **<filter>** tag element that encloses the tag elements representing all levels in the configuration hierarchy from the root (represented by the **<configuration>** tag element) down to the immediate parent level for the object type. An empty tag represents the requested object type. The entire request is enclosed in an **<rpc>** tag element:

```

<rpc>
  <get-config>
    <source>
      <!-- tag specifying the source configuration -->
    </source>
    <filter type="subtree">
      <configuration>
        <!-- opening tags for each parent of the requested object type -->
        <object-type/>
        <!-- closing tags for each parent of the requested object type -->
      </configuration>
    </filter>
  </get-config>
</rpc>

```

```

    </filter>
  </get-config>
</rpc>
]]>]]>

```

For information about the **<source>** tag element, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

This type of request is useful when the object’s parent hierarchy level has more than one type of child object. If the requested object is the only child type that can occur in its parent hierarchy level, then this type of request yields the same output as a request for the complete parent hierarchy, which is described in [“Requesting a Hierarchy Level or Container Object Without an Identifier” on page 602](#).

The NETCONF server returns the requested objects in **<data>** and **<rpc-reply>** tag elements. For information about the attributes in the opening **<configuration>** tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration attributes>
      <!-- opening tags for each parent of the object type -->
      <first-object>
        <!-- child tag elements for the first object -->
      </first-object>
      <second-object>
        <!-- child tag elements for the second object -->
      </second-object>
      <!-- additional instances of the object -->
      <!-- closing tags for each parent of the object type -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

The application can also request additional configuration elements of the same or other types by including the appropriate tag elements in the same **<get-config>** tag element. For more information, see [“Requesting Multiple Configuration Elements Simultaneously” on page 612](#).

The following example shows how to request complete information about all **radius-server** objects at the **[edit system]** hierarchy level in the candidate configuration.

Client Application

```

<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
  <filter>
    <configuration>
      <system>
        <radius-server/>
      </system>
    </configuration>
  </filter>
</get-config>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration xmlns="URL" \
      junos:changed-seconds="seconds" \
      junos:changed-localtime="timestamp">
      <system>
        <radius-server>
          <name>10.25.34.166</name>
          <secret>$9$Pf3900REcr/9t...</secret>
          <timeout>5</timeout>
          <retry>3</retry>
        </radius-server>
        <radius-server>
          <name>10.25.6.204</name>
          <secret>$9$K5Kvxd2gJZUi-d...</secret>
          <timeout>5</timeout>
          <retry>3</retry>
        </radius-server>
      </system>
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

T2129

Requesting Identifiers for Configuration Objects of a Specified Type

To request output that shows only the identifier for each configuration object of a specific type in a hierarchy, a client application emits a **<filter>** tag element that encloses the tag elements representing all levels of the configuration hierarchy from the root (represented by the **<configuration>** tag element) down to the immediate parent level for the object type. The object type is represented by its container tag element enclosing an empty **<name/>** tag. (The **<name>** tag element can always be used, even if the actual identifier tag element has a different name. The actual name is also valid.) The entire request is enclosed in an **<rpc>** tag element:

```

<rpc>
  <get-config>
    <source>
      <!-- tag specifying the source configuration -->
    </source>
    <filter type="subtree">

```

```

<configuration>
  <!-- opening tags for each parent of the object type -->
  <object-type>
    <name/>
  </object-type>
  <!-- closing tags for each parent of the object type -->
</configuration>
</filter>
</get-config>
</rpc>
]]>]]>

```

For information about the `<source>` tag element, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

NOTE: You cannot request only identifiers for object types that have multiple identifiers. However, for many such objects the identifiers are the only child tag elements, so requesting complete information yields the same output as requesting only identifiers. For instructions, see [“Requesting All Configuration Objects of a Specified Type” on page 604](#).

The NETCONF server returns the requested objects in `<data>` and `<rpc-reply>` tag elements (here, objects for which the identifier tag element is called `<name>`). For information about the attributes in the opening `<configuration>` tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration attributes>
      <!-- opening tags for each parent of the object type -->
      <first-object>
        <name>identifier-for-first-object</name>
      </first-object>
      <second-object>
        <name>identifier-for-second-object</name>
      </second-object>
      <!-- additional objects -->
      <!-- closing tags for each parent of the object type -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

The application can also request additional configuration elements of the same or other types by including the appropriate tag elements in the same `<get-config>` tag element. For more information, see [“Requesting Multiple Configuration Elements Simultaneously” on page 612](#).

The following example shows how to request the identifier for each BGP neighbor configured at the `[edit protocols bgp group next-door-neighbors]` hierarchy level in the candidate configuration.

Client Application

```

<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
    <filter>
      <configuration>
        <protocols>
          <bgp>
            <group>
              <name>next-door-neighbors</name>
              <neighbor>
                <name/>
              </neighbor>
            </group>
          </bgp>
        </protocols>
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration xmlns="URL" \
      junos:changed-seconds="seconds" \
      junos:changed-localtime="timestamp">
      <protocols>
        <bgp>
          <group>
            <name>next-door-neighbors</name>
            <neighbor>
              <name>10.2.35.188</name>
            </neighbor>
            <neighbor>
              <name>10.3.62.95</name>
            </neighbor>
            <neighbor>
              <name>10.4.122.9</name>
            </neighbor>
          </group>
        </bgp>
      </protocols>
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

T2130

Requesting One Configuration Object

To request complete information about a specific configuration object, a client application emits a **<filter>** tag element that encloses the tag elements representing all levels of the configuration hierarchy from the root (represented by the **<configuration>** tag element) down to the immediate parent level for the object.

To represent the requested object, the application emits its container tag element and each of its identifier tag elements, complete with identifier value. For objects with a single

identifier, the **<name>** tag element can always be used, even if the actual identifier tag element has a different name. The actual name is also valid. For objects with multiple identifiers, the actual names of the identifier tag elements must be used. To verify the name of each of the identifiers for a configuration object, see the *Junos XML API Configuration Developer Reference*. The entire request is enclosed in an **<rpc>** tag element:

```
<rpc>
  <get-config>
    <source>
      <!--tag specifying the source configuration -->
    </source>
    <filter type="subtree">
      <configuration>
        <!-- opening tags for each parent of the object -->
        <object>
          <name>identifier</name>
        </object>
        <!-- closing tags for each parent of the object -->
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>
```

For information about the **<source>** tag element, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

The NETCONF server returns the requested object in **<data>** and **<rpc-reply>** tag elements (here, an object for which the identifier tag element is called **<name>**). For information about the attributes in the opening **<configuration>** tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration attributes>
      <!-- opening tags for each parent of the object -->
      <object>
        <name>identifier</name>
        <!-- other child tag elements of the object -->
      </object>
      <!-- closing tags for each parent of the object -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>
```

The application can also request additional configuration elements of the same or other types by including the appropriate tag elements in the same **<get-config>** tag element. For more information, see [“Requesting Multiple Configuration Elements Simultaneously” on page 612](#).

The following example shows how to request the contents of one multicasting scope called **local**, which is at the **[edit routing-options multicast]** hierarchy level in the candidate configuration. To specify the desired object, the client application emits the **<name>local</name>** identifier tag element as the innermost tag element.

Client Application

```

<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
    <filter>
      <configuration>
        <routing-options>
          <multicast>
            <scope>
              <name>local</name>
            </scope>
          </multicast>
        </routing-options>
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration xmlns="URL" \
      junos:changed-seconds="seconds" \
      junos:changed-localtime="timestamp">
      <routing-options>
        <multicast>
          <scope>
            <name>local</name>
            <prefix>239.255.0.0/16</prefix>
            <interface>ip-f/p/0</interface>
          </scope>
        </multicast>
      </routing-options>
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

T2131

Requesting Specific Child Tags for a Configuration Object

To request specific child tag elements for a specific configuration object, a client application emits a **<filter>** tag element that encloses the tag elements representing all levels of the configuration hierarchy from the root (represented by the **<configuration>** tag element) down to the immediate parent level for the object. To represent the requested object, the application emits its container tag element and identifier tag element. For objects with a single identifier, the **<name>** tag element can always be used, even if the actual identifier tag element has a different name. The actual name is also valid. For objects with multiple identifiers, the actual names of the identifier tag elements must be used. To represent the child tag elements to return, it emits each one as an empty tag. The entire request is enclosed in an **<rpc>** tag element:

```

<rpc>
  <get-config>
    <source>
      <!-- tag specifying the source configuration -->
    </source>
  </get-config>
</rpc>

```

```

<filter type="subtree">
  <configuration>
    <!-- opening tags for each parent of the object -->
    <object>
      <name>identifier</name>
      <first-child/>
      <second-child/>
      <!-- empty tag for each additional child to return -->
    </object>
    <!-- closing tags for each parent of the object -->
  </configuration>
</filter>
</get-config>
</rpc>
]]>]]>

```

For information about the `<source>` tag element, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

The NETCONF server returns the requested children of the object in `<data>` and `<rpc-reply>` tag elements (here, an object for which the identifier tag element is called `<name>`). For information about the attributes in the opening `<configuration>` tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration attributes>
      <!-- opening tags for each parent of the object -->
      <object>
        <name>identifier</name>
      </object>
      <!-- closing tags for each parent of the object -->
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

The application can also request additional configuration elements of the same or other types by including the appropriate tag elements in the same `<get-config>` tag element. For more information, see [“Requesting Multiple Configuration Elements Simultaneously” on page 612](#).

The following example shows how to request only the address of the next-hop device for the `192.168.5.0/24` route at the `[edit routing-options static]` hierarchy level in the candidate configuration.

Client Application

```

<rpc>
  <get-config>
    <source>
      <candidate/>
    </source>
    <filter>
      <configuration>
        <routing-options>
          <static>
            <route>
              <name>192.168.5.0/24</name>
              <next-hop/>
            </route>
          </static>
        </routing-options>
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <data>
    <configuration xmlns="URL" \
      junos:changed-seconds="seconds" \
      junos:changed-localtime="timestamp">
      <routing-options>
        <static>
          <route>
            <name>192.168.5.0/24</name>
            <next-hop>192.168.71.254</next-hop>
          </route>
        </static>
      </routing-options>
    </configuration>
  </data>
</rpc-reply>
]]>]]>

```

T2132

Requesting Multiple Configuration Elements Simultaneously

Within a **<get-config>** tag element, a client application can request multiple configuration elements of the same type or different types. The request includes only one **<filter>** and **<configuration>** tag element (the NETCONF server returns an error if there is more than one of each).

If two requested objects have the same parent hierarchy level, the client can either include both requests within one parent tag element, or repeat the parent tag element for each request. For example, at the **[edit system]** hierarchy level the client can request the list of configured services and the identifier tag element for RADIUS servers in either of the following two ways:

```

<!-- both requests in one <system> tag element -->
<rpc>
  <get-config>
    <source>
      <!-- tag specifying the source configuration -->

```

```

    </source>
    <filter type="subtree">
      <configuration>
        <system>
          <services/>
          <radius-server>
            <name/>
          </radius-server>
        </system>
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>
<!-- separate <system> tag element for each element -->
<rpc>
  <get-config>
    <source>
      <!-- tag specifying the source configuration -->
    </source>
    <filter type="subtree">
      <configuration>
        <system>
          <services/>
        </system>
        <system>
          <radius-server>
            <name/>
          </radius-server>
        </system>
      </configuration>
    </filter>
  </get-config>
</rpc>
]]>]]>

```

The client can combine requests for any of the following types of information:

- [Requesting a Hierarchy Level or Container Object Without an Identifier on page 602](#)
- [Requesting All Configuration Objects of a Specified Type on page 604](#)
- [Requesting Identifiers for Configuration Objects of a Specified Type on page 606](#)
- [Requesting One Configuration Object on page 608](#)
- [Requesting Specific Child Tags for a Configuration Object on page 610](#)

Requesting an XML Schema for the Configuration Hierarchy

To request an XML Schema-language representation of the entire configuration hierarchy, a client application emits the Junos XML **<get-xnm-information>** tag element and its **<type>** and **<namespace>** child tag elements with the indicated values in an **<rpc>** tag element:

```
<rpc>
```

```

    <get-xnm-information>
      <type>xml-schema</type>
      <namespace>junos-configuration</namespace>
    </get-xnm-information>
  </rpc>
]>]]>

```

The NETCONF server encloses the XML schema in **<rpc-reply>** and **<xsd:schema>** tag elements:

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <xsd:schema>
    <!-- tag elements for the Junos XML schema -->
  </xsd:schema>
</rpc-reply>
]>]]>

```

The schema represents all configuration elements available in the version of the Junos OS that is running on a device. (To determine the Junos OS version, emit the **<get-software-information>** operational request tag element, which is documented in the *Junos XML API Operational Developer Reference*.)

Client applications can use the schema to validate the configuration on a device or simply to learn which configuration statements are available in the version of the Junos OS running on the device. The schema does not indicate which elements are actually configured or even that an element can be configured on that type of device (some configuration statements are available only on certain device types). To request the set of currently configured elements and their settings, emit the **<get-config>** tag element instead, as described in [“Requesting Configuration Information” on page 598](#).

Explaining the structure and notational conventions of the XML Schema language is beyond the scope of this document. For information, see *XML Schema Part 0: Primer*, available from the World Wide Web Consortium (W3C) at <http://www.w3.org/TR/xmlschema-0/>. The primer provides a basic introduction and lists the formal specifications where you can find detailed information.

For further information, see the following sections:

- [Creating the junos.xsd File on page 614](#)
- [Example: Requesting an XML Schema on page 615](#)

Creating the junos.xsd File

Most of the tag elements defined in the schema returned in the **<xsd:schema>** tag belong to the default namespace for Junos OS configuration elements. However, at least one tag, **<junos:comment>**, belongs to a different namespace:

http://xml.juniper.net/junos/Junos-version/junos. By XML convention, a schema describes only one namespace, so schema validators need to import information about any additional namespaces before they can process the schema.

Starting with Junos OS Release 6.4, the **<xsd:import>** tag element is enclosed in the **<xsd:schema>** tag element and references the file **junos.xsd**, which contains the required information about the **junos** namespace. For example, the following **<xsd:import>** tag

element specifies the file for Junos OS Release 12.1R1 (and appears on two lines for legibility only):

```
<xsd:import schemaLocation="junos.xsd" \
  namespace="http://xml.juniper.net/junos/12.1R1/junos"/>
```

To enable the schema validator to interpret the `<xsd:import>` tag element, you must manually create a file called `junos.xsd` in the directory where you place the `.xsd` file that contains the complete Junos configuration schema. Include the following text in the file. Do not use line breaks in the list of attributes in the opening `<xsd:schema>` tag. Line breaks appear in the following example for legibility only. For the *Junos-version* variable, substitute the release number of the Junos OS running on the device (for example, `12.1R1` for the first release of Junos OS 12.1).

```
<?xml version="1.0" encoding="us-ascii"?>
<xsd:schema elementFormDefault="qualified" \
  attributeFormDefault="unqualified" \
  xmlns:xsd="http://www.w3.org/2001/XMLSchema" \
  targetNamespace="http://xml.juniper.net/junos/Junos-version/junos">
  <xsd:element name="comment" type="xsd:string"/>
</xsd:schema>
```

NOTE: Schema validators might not be able to process the schema if they cannot locate or open the `junos.xsd` file.

Whenever you change the version of Junos OS running on the device, remember to update the *Junos-version* variable in the `junos.xsd` file to match.

Example: Requesting an XML Schema

The following examples show how to request the Junos configuration schema. In the NETCONF server's response, the first `<xsd:element>` statement defines the `<undocumented>` Junos XML tag element, which can be enclosed in most other container tag elements defined in the schema (container tag elements are defined as `<xsd:complexType>`).

The attributes in the opening tags of the NETCONF server's response appear on multiple lines for legibility only. The NETCONF server does not insert newline characters within tags or tag elements. Also, in actual output the *JUNOS-version* variable is replaced by a value such as `12.1R1` for the initial version of Junos OS Release 12.1.

Client Application NETCONF Server

```

<rpc>
  <get-xnm-information>
    <type>xml-schema</type>
    <namespace>junos-configuration</namespace>
  </get-xnm-information>
</rpc>
]]>]]>

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema" \
    elementFormDefault="qualified">
    <xsd:import schemaLocation="junos.xsd" \
      namespace="http://xml.juniper.net/junos/JUNOS-version/junos"/>
    <xsd:element name="undocumented">
      <xsd:complexType>
        <xsd:sequence>
          <xsd:any namespace="##any" processContents="skip"/>
        </xsd:sequence>
      </xsd:complexType>
    </xsd:element>
    <xsd:complexType name="hostname">
      <xsd:simpleContent>
        <xsd:extension base="xsd:string"/>
      </xsd:simpleContent>
    </xsd:complexType>
    .
    .
    .

```

T2114

Another `<xsd:element>` statement near the beginning of the schema defines the Junos XML `<configuration>` tag element. It encloses the `<xsd:element>` statement that defines the `<system>` tag element, which corresponds to the **[edit system]** hierarchy level. The statements corresponding to other hierarchy levels are omitted for brevity.

Client Application NETCONF Server

```

.
.
.
</xsd:element>
<xsd:element name="configuration">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:choice minOccurs="0" maxOccurs="unbounded">
        <xsd:element ref="undocumented"/>
        <xsd:element ref="comment"/>
        <xsd:element name="system" minOccurs="0">
          <xsd:complexType>
            <xsd:sequence>
              <xsd:choice minOccurs="0" maxOccurs="unbounded">
                <xsd:element ref="undocumented"/>
                <xsd:element ref="comment"/>
                <!-- child elements of <system> here -->
              </xsd:choice>
            </xsd:sequence>
          </xsd:complexType>
        </xsd:element>
        <!-- statements for other hierarchy levels here -->
      </xsd:choice>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
</xsd:schema>
</rpc-reply>
]]>]]>

```

T2115

Requesting a Previous (Rollback) Configuration

To request a previously committed (rollback) configuration, a client application emits the Junos XML `<get-rollback-information>` tag element and its child `<rollback>` tag element in an `<rpc>` tag element. This operation is equivalent to the `show system rollback` operational mode command. The `<rollback>` tag element specifies the index number of the previous configuration to display; its value can be from 0 (zero, for the most recently committed configuration) through 49.

To request Junos XML-tagged output, the application either includes the `<format>` tag element with the value `xml` or omits the `<format>` tag element (Junos XML tag elements are the default):

```
<rpc>
  <get-rollback-information>
    <rollback> index-number </rollback>
  </get-rollback-information>
</rpc>
]]>]]>
```

The NETCONF server encloses its response in `<rpc-reply>`, `<rollback-information>`, and `<configuration>` tag elements. The `<ok/>` tag is a side effect of the implementation and does not affect the results. For information about the attributes in the opening `<configuration>` tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rollback-information>
    <ok/>
    <configuration attributes>
      <!-- tag elements representing the complete previous configuration -->
    </configuration>
  </rollback-information>
</rpc-reply>
]]>]]>
```

To request formatted ASCII output, the application includes the `<format>` tag element with the value `text`:

```
<rpc>
  <get-rollback-information>
    <rollback> index-number </rollback>
    <format> text </format>
  </get-rollback-information>
</rpc>
]]>]]>
```

The NETCONF server encloses its response in `<rpc-reply>`, `<rollback-information>`, `<configuration-information>`, and `<configuration-output>` tag elements. For more information about the formatted ASCII notation used in Junos configuration statements, see the *CLI User Guide*.

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rollback-information>
```

```

    <ok/>
    <configuration-information>
      <configuration-output>
        /* formatted ASCII representing the complete previous configuration*/
      </configuration-output>
    </configuration-information>
  </rollback-information>
</rpc-reply>
]]>]]>

```

The following example shows how to request Junos XML-tagged output for the rollback configuration that has an index of 2. In actual output, the **Junos-version** variable is replaced by a value such as **12.1R1** for the initial version of Junos OS Release 12.1.

Client Application

```

<rpc>
  <get-rollback-information>
    <rollback>2</rollback>
  </get-rollback-information>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rollback-information>
    <ok/>
    <configuration xmlns="URL" \
      junos:changed-seconds="seconds" \
      junos:changed-localtime="timestamp">
      <version>JUNOS-version</version>
      <system>
        <host-name>big-router</host-name>
        <!-- other children of <system> -->
      </system>
      <!-- other children of <configuration> -->
    </configuration>
  </rollback-information>
</rpc-reply>
]]>]]>

```

T2133

Comparing Two Previous (Rollback) Configurations

To compare the contents of two previously committed (rollback) configurations, a client application emits the Junos XML **<get-rollback-information>** tag element and its child **<rollback>** and **<compare>** tag elements in an **<rpc>** tag element. This operation is equivalent to the **show system rollback** operational mode command with the **compare** option. The **<rollback>** tag element specifies the index number of the configuration that is the basis for comparison. The **<compare>** tag element specifies the index number of the configuration to compare with the base configuration. Valid values in both tag elements range from **0** (zero, for the most recently committed configuration) through **49**:

```

<rpc>
  <get-rollback-information>
    <rollback>index-number</rollback>
    <compare>index-number</compare>
  </get-rollback-information>

```

```
</rpc>
]]>]]>
```

NOTE: The output corresponds more logically to the chronological order of changes if the older configuration (the one with the higher index number) is the base configuration. Its index number is enclosed in the `<rollback>` tag element and the index of the more recent configuration is enclosed in the `<compare>` tag element.

The NETCONF server encloses its response in `<rpc-reply>`, `<rollback-information>`, `<configuration-information>`, and `<configuration-output>` tag elements. The `<ok/>` tag is a side effect of the implementation and does not affect the results.

The information in the `<configuration-output>` tag element is formatted ASCII and includes a banner line (such as `[edit interfaces]`) for each hierarchy level at which the two configurations differ. Each line between banner lines begins with either a plus sign (+) or a minus sign (–). The plus sign indicates that adding the statement to the base configuration results in the second configuration, whereas a minus sign means that removing the statement from the base configuration results in the second configuration.

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rollback-information>
    <ok/>
    <configuration-information>
      <configuration-output>
        /* formatted ASCII representing the changes */
      </configuration-output>
    </configuration-information>
  </rollback-information>
</rpc-reply>
]]>]]>
```

The following example shows how to request a comparison of the rollback configurations that have indexes of **20** and **4**.

Client Application

```

<rpc>
  <get-rollback-information>
    <rollback>20</rollback>
    <compare>4</compare>
  </get-rollback-information>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rollback-information>
    <ok/>
    <configuration-information>
      <configuration-output>
        [edit interfaces]
        - ge-0/2/0 {
        -   stacked-vlan-tagging;
        -   mac 00.01.02.03.04.05;
        -   gigether-options {
        -     loopback;
        -   }
        - }
        [edit]
        + services {
        +   l2tp {
        +     tunnel-group 12 {
        +       local-gateway;
        +     }
        +   }
        + }
      </configuration-output>
    </configuration-information>
  </rollback-information>
</rpc-reply>
]]>]]>

```

T2117

Requesting the Rescue Configuration

To request the rescue configuration, a client application emits the Junos XML **<get-rescue-information>** tag element in an **<rpc>** tag element. This operation is equivalent to the **show system configuration rescue** operational mode command.

The rescue configuration is a configuration saved in case it is necessary to restore a valid, nondefault configuration. (To create a rescue configuration, use the Junos XML **<request-save-rescue-configuration>** tag element or the **request system configuration rescue save** CLI operational mode command. For more information, see the *Junos XML API Operational Developer Reference* or the [CLI Explorer](#).)

To request Junos XML-tagged output, the application either includes the **<format>** tag element with the value **xml** or omits the **<format>** tag element (Junos XML tag elements are the default):

```

<rpc>
  <get-rescue-information/>
</rpc>
]]>]]>

```

The NETCONF server encloses its response in `<rpc-reply>`, `<rescue-information>`, and `<configuration>` tag elements. The `<ok/>` tag is a side effect of the implementation and does not affect the results. For information about the attributes in the opening `<configuration>` tag, see [“Requesting Information from the Committed or Candidate Configuration” on page 599](#).

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rescue-information>
    <ok/>
    <configuration attributes
      <!-- tag elements representing the rescue configuration -->
    </configuration>
  </rescue-information>
</rpc-reply>
]]>]]>
```

To request formatted ASCII output, the application includes the `<format>` tag element with the value `text`:

```
<rpc>
  <get-rescue-information>
    <format>text</format>
  </get-rescue-information>
</rpc>
]]>]]>
```

The NETCONF server encloses its response in `<rpc-reply>`, `<rescue-information>`, `<configuration-information>`, and `<configuration-output>` tag elements. For more information about the formatted ASCII notation used in Junos configuration statements, see the *CLI User Guide*.

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <rescue-information>
    <ok/>
    <configuration-information>
      <configuration-output>
        /* formatted ASCII for the rescue configuration */
      </configuration-output>
    </configuration-information>
  </rescue-information>
</rpc-reply>
]]>]]>
```

CHAPTER 9

Changing Configuration Information

This chapter explains how to use the NETCONF XML management protocol along with Junos XML or command-line interface (CLI) configuration statements to change the configuration on a routing, switching, or security platform. The NETCONF protocol operations `<copy-config>`, `<edit-config>`, and `<discard-changes>` offer functionality that is analogous to configuration mode commands in the Junos OS CLI. These CLI configuration mode commands, as well as the CLI configuration statements, are described in the *CLI User Guide*. The Junos XML tag elements described here correspond to configuration statements, which are described in the Junos OS configuration guides.

This chapter discusses how to use the NETCONF XML management protocol to make changes to a device's configuration. To see how this activity fits in within the overall NETCONF session, see [“Client Application's Role in a NETCONF Session” on page 561](#).

This chapter discusses the following topics:

- [Editing the Candidate Configuration on page 624](#)
- [Replacing the Candidate Configuration on page 633](#)
- [Rolling Back a Configuration on page 635](#)
- [Deleting the Candidate Configuration on page 635](#)
- [Changing Individual Configuration Elements on page 636](#)

Editing the Candidate Configuration

To change the candidate configuration on a device, a client application emits the **<copy-config>**, the **<edit-config>**, or the **<discard-changes>** tag element and the corresponding tag subelements within the **<rpc>** tag element.

The following examples shows the various tag elements available:

```
<rpc>
  <copy-config>
    <target><candidate/></target>
    <error-operation> (ignore-error | stop-on-error) </error-operation>
    <source><url>location</url></source>
  </copy-config>
</rpc>
]]>]]>

<rpc>
  <edit-config>
    <target><candidate/></target>
    <default-operation>operation</default-operation>
    <error-operation>error</error-operation>
    <(config | config-text | url)>
      <!-- configuration change file or data -->
    </(config | config-text | url)>
  </edit-config>
</rpc>
]]>]]>

<rpc>
  <discard-changes/>
</rpc>
]]>]]>
```

Notice that the three tags—**<copy-config>**, **<edit-config>**, and **<discard-changes>**—correspond to the three basic configuration tasks available to you:

- Overwriting the candidate configuration with a new configuration—Using the **<copy-config>** tag element, you can replace the current candidate configuration with a new configuration.
- Editing the candidate configuration elements—Using the **<edit-config>** tag element, you can add, change, or delete specific configuration elements within the candidate configuration.
- Rolling back changes to the current configuration—Using the **<discard-changes>** tag element, you can roll back the candidate configuration to a previously committed configuration. This tag element provides functionality analogous to the CLI command **rollback**.

Notice also that the `<copy-config>` and the `<edit-config>` tags both have additional subtags related to each tag element. These subtag elements are described in the following sections:

- [Formatting the Configuration Data on page 625](#)
- [Setting the Edit Configuration Mode on page 629](#)
- [Handling Errors on page 633](#)

Formatting the Configuration Data

A client application can use a text file or streaming data to deliver configuration data to the candidate configuration. The data delivered can be in one of two formats: Junos XML or CLI configuration statements. You can specify the delivery mechanism and the format used when delivering configuration changes to the device.

For more information on Junos XML tag elements, see “[XML Overview](#)” on page 542. For more information on CLI configuration statements, see the *CLI User Guide*.

- [Delivery Mechanism: Data Files Versus Streaming Data on page 625](#)
- [Data Format: Junos XML versus CLI Configuration Statements on page 628](#)

Delivery Mechanism: Data Files Versus Streaming Data

When formatting your configuration data output, you can choose to stream your configuration changes within your session or reference data files that include the desired configuration changes. Each method has advantages and disadvantages. Streaming data allows you to send your configuration change data in line, using your NETCONF connection. This is useful when the device is behind a firewall and you cannot establish another connection to upload a data file. With text files you can keep the edit configuration commands simple; with data files, there is no need to include the possibly complex configuration data stream.

Referencing Configuration Data Files

To reference configuration data as a file, a client application emits the file location between `<url>` tag elements within the `<rpc>` and the `<edit-config>` tag elements.

```
<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <url>
      <!-- location and name of file containing configuration data -->
    </url>
  </edit-config>
</rpc>
]]>]]>
```

The data within these files can be formatted as either Junos XML or CLI configuration statements. When the configuration data is formatted as CLI configuration statements, you set the `<url>` format attribute to **text**.

```
<rpc>
  <edit-config>
    ...
    <url format="text">
      <!-- location and name of file containing configuration data -->
    </url>
  </edit-config>
</rpc>
```

The configuration file can be placed locally or as a network resource:

- When placed locally, the configuration file path can be relative or absolute:
 - Relative file path—The file location is based on the user's home directory.
 - Absolute file path—The file location is based on the directory structure of the device, for example `<drive>:filename` or `<drive>:/path/filename`. If you are using removable media, the drive can be in the MS-DOS or UNIX (UFS) format.
- When located on the network, the configuration file can be accessed using FTP or HTTP:

- FTP example:

```
ftp://username:password@hostname/path/filename
```

NOTE: The default value for the FTP *path* variable is the user's home directory. Thus, by default the file path to the configuration file is relative to the user directory. To specify an absolute path when using FTP, start the path with the characters `%2F`; for example:
`ftp://username:password@hostname/%2Fpath/filename.`

- HTTP example:

```
http://username:password@hostname/path/filename
```

Before loading the file, the client application or an administrator saves Junos XML tag elements as the contents of the file. The file includes the tag elements representing all levels of the configuration hierarchy from the root (represented by the `<configuration>` tag element) down to each element to change. The notation is the same as that used to request configuration information, as described in [“Requesting Information” on page 593](#). For more detailed information about the Junos XML representation of Junos configuration statements, see [“Mapping Configuration Statements to Junos XML Tag Elements” on page 552](#).

The following example shows how to incorporate configuration data stored in the file `/var/tmp/configFile` on the FTP server called `ftp.myco.com`:

Client Application

```
<rpc message-id="messageID">
  <edit-config>
    <target>
      <candidate/>
    </target>
    <url>
      ftp://admin:AdminPwd@ftp.myco.com/%F2var/tmp/configFile
    </url>
  </edit-config>
</rpc>
]]>]]>
```

NETCONF Server

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

T2134

Streaming Configuration Data

To provide configuration data as a data stream, a client application emits the `<config>` or `<config-text>` tag elements within the `<rpc>` and `<edit-config>` tag elements. To specify the configuration elements to change, the application emits Junos XML or CLI configuration statements representing all levels of the configuration hierarchy from the root (represented by the `<configuration>` or `<configuration-text>` tag element) down to each element to change. The Junos XML notation is the same as that used to request configuration information, as described in [“Requesting Information” on page 593](#). For more detailed information about the mappings between Junos configuration elements and Junos XML tag elements, see [“Mapping Configuration Statements to Junos XML Tag Elements” on page 552](#). The CLI configuration statement notation are further described in the *CLI User Guide*.

```
<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <config> or <config-text>
      <configuration> or <configuration-text>
        <!-- configuration changes -->
      </configuration> or </configuration-text>
    </config> or </config-text>
  </edit-config>
</rpc>
]]>]]>
```

The following example shows how to provide Junos XML configuration data for the **messages** system log file in a data stream:

Client Application NETCONF Server

```
<rpc message-id="messageID">
  <edit-config>
    <target>
      <candidate/>
    </target>
    <config>
      <configuration>
        <system>
          <syslog>
            <file>
              <name>messages</name>
              <contents>
                <name>any</name>
                <warning/>
              </contents>
              <contents>
                <name>authorization</name>
                <info/>
              </contents>
            </file>
          </syslog>
        </system>
      </configuration>
    </config>
  </edit-config>
</rpc>
]]>]]>

<rpc-reply xmlns="URN" xmlns:junos=" URL">
  <ok/>
</rpc-reply>
]]>]]>
```

T2135

Data Format: Junos XML versus CLI Configuration Statements

You can format the configuration data using one of two formats: Junos XML or CLI configuration statements. The choice between one data format over the other is personal preference.

If you are supplying the configuration changes in the form of data files, you enclose the data filename and path within **<url>** tags. By default, these tags specify that the referenced data files are written in Junos XML. Thus, the following code declares that the data within the file is Junos XML:

```
<url>dataFile</url>
```

To specify that the data file be written as CLI configuration statements, you set the **<url>** tag's format attribute to **text**:

```
<url format="text">dataFile</url>
```

When streaming data, you specify the data format by selecting one of two tags: **<config>** for Junos XML statements and **<config-text>** for CLI configuration statements.

In the following example, Junos XML formatted configuration data is included between the `<configuration>` tag:

```
<config>
  <configuration>
    <system>
      <services>
        <ssh>
          <protocol-version>v2</protocol-version>
        </ssh>
      </services>
    </system>
  </configuration>
</config>
```

In this next example, the same data written formatted as CLI configuration statements and included within `<configuration-text>` tags:

```
<config-text>
  <configuration-text>
    system {
      services {
        ssh {
          protocol-version v2 ;
        }
      }
    }
  </configuration-text>
</config-text>
```

Setting the Edit Configuration Mode

When sending operation data to the NETCONF server, you have the option to specify how a device should handle these configuration changes. This is known as the edit configuration mode. You can set the edit configuration mode globally for the entire session. You can also set the edit mode only for specific elements within the session.

The device has the following edit configuration modes:

- **merge**—The device merges new configuration data into the current candidate configuration. This is the default.
- **replace**—The device replaces existing configuration data with the new configuration data.
- **no-change**—The device does not change the existing configuration unless the new configuration element includes an operation attribute.

To set the mode globally for the session, place a configuration mode value within `<default-operation>` tags:

```
<rpc>
  <edit-config>
    <default-operation>ConfigModeValue</default-operation>
  </edit-config>
</rpc>
```

You can also set the mode for a specific configuration statement by adding an **operation** attribute with a value of **replace** to the configuration element:

```
<rpc>
  <edit-config>
    <config>
      <configuration>
        <protocols>
          <rip>
            <message-size operation="replace">255</message-size>
          </rip>
        </protocols>
      </configuration>
    </config>
  </edit-config>
</rpc>
```

You can set a global edit configuration mode for an entire set of configuration changes and specify a different mode for individual elements that you want handled in a different manner. For example:

```
<rpc>
  <edit-config>
    <default-operation>merge</default-operation>
    <config>
      <configuration>
        <protocols>
          <rip>
            <message-size operation="replace">255</message-size>
          </rip>
        </protocols>
      </configuration>
    </config>
  </edit-config>
</rpc>
```

Specifying the merge Data Mode

By default, the NETCONF server *merges* new configuration data into the candidate configuration. Thus, if no edit-configuration mode is specified, the device will merge the new configuration elements into the existing candidate configuration. Merging configurations is performed according to the following rules:

- A configuration element (hierarchy level or configuration object) that exists in the candidate configuration but not in the new configuration remains unchanged.
- A configuration element that exists in the new configuration but not in the candidate configuration is added to the candidate configuration.
- If a configuration element exists in both configurations, the following results occur:
 - If a child statement of the configuration element (represented by a child tag element) exists in the candidate configuration but not in the new configuration, it remains unchanged.
 - If a child statement exists in the new configuration but not in the candidate, it is added to the candidate configuration.
 - If a child statement exists in both configurations, the value in the new data replaces the value in the candidate configuration.

To explicitly specify that data be merged, the application can include the `<default-operation>` tag element with the value **merge** in the `<edit-config>` tag element:

```
<rpc>
  <edit-config>
    <default-operation>merge</default-operation>
    <!-- other child tag elements of the <edit-config> tag element -->
  </edit-config>
</rpc>
]]>]]>
```

Specifying the replace Data Mode

In the *replace* edit configuration mode, the new configuration data completely replaces the candidate configuration. To specify that the data be replaced, the application can include the `<default-operation>` tag element with the value **replace** in the `<edit-config>` tag element:

```
<rpc>
  <edit-config>
    <default-operation>replace</default-operation>
  </edit-config>
</rpc>
]]>]]>
```

We recommend using the global replace mode only when you plan to completely overwrite the candidate configuration with new configuration data. Furthermore, when the edit configuration mode is set to **replace**, we do not recommend using the **operation** attribute on individual configuration elements.

You can also replace individual configuration elements while merging or creating others. See [“Replacing Configuration Elements” on page 638](#).

Specifying the no-change Data Mode

In the *no-change* mode, configuration changes to the configuration are ignored. This mode is useful when you are deleting elements, and it prevents the NETCONF server from creating parent hierarchy levels for an element that is being deleted. For more information, see [“Deleting Configuration Elements” on page 641](#):

To set the no-change edit configuration mode globally, the application can include the `<default-operation>` tag element with the value `none` in the `<edit-config>` tag element:

```
<rpc>
  <edit-config>
    <default-operation>none</default-operation>
  </edit-config>
</rpc>
```

NOTE: If the new configuration data includes a configuration element that does not exist in the candidate, the NETCONF server returns an error. We recommend using no-change mode only when removing configuration elements from the candidate configuration. When creating or modifying elements, applications need to use merge mode. For more information, see [“Deleting Configuration Elements” on page 641](#).

When the no-change edit configuration mode is set globally, using the `<default-operation>` tag, you can override this behavior by specifying a different edit configuration mode for a specific element using the `operation` attribute. For example:

```
<rpc>
  <edit-config>
    <default-operation>none</default-operation>
    <config>
      <configuration>
        <system>
          <services>
            <outbound-ssh>
              <client>
                <name>test</name>
                <device-id>test</device-id>
                <keep-alive>
                  <retry operation="merge">4</retry>
                  <timeout operation="merge">15</timeout>
                </keep-alive>
              </client>
            </outbound-ssh>
          </services>
        </system>
      </configuration>
    </config>
  </edit-config>
</rpc>
```

Handling Errors

If the NETCONF server cannot incorporate the configuration data, the `<rpc-error>` tag element is returned with information explaining the reason for the failure. By default, when the NETCONF server encounters an error while incorporating new configuration data into the candidate configuration, it halts the incorporation process. A client application can explicitly specify this response to errors by including the `<error-option>` tag element with the value `stop-on-error` in the `<edit-config>` tag element:

```
<rpc>
  <edit-config>
    <error-option>stop-on-error</error-option>
    <!-- other child tag elements of the <edit-config> tag element -->
  </edit-config>
</rpc>
]]>]]>
```

Alternatively, the application can specify that the NETCONF server continue to incorporate new configuration data when it encounters an error. The application includes the `<error-option>` tag element with the value `ignore-error` in the `<edit-config>` tag element:

```
<rpc>
  <edit-config>
    <error-option>ignore-error</error-option>
    <!-- other child tag elements of the <edit-config> tag element -->
  </edit-config>
</rpc>
]]>]]>
```

The client application can include the optional `<test-option>` tag element described in the NETCONF specification. Regardless of the value provided, the NETCONF server for the Junos OS performs a basic syntax check on the configuration data in the `<edit-config>` tag element. When the `<test-option>` tag is included, NETCONF performs a complete syntactic and semantic validation in response to the `<commit>` and `<validate>` tag elements (that is, when the configuration is committed or explicitly checked), but not in response to the `<edit-config>` tag element. For information about the `<commit>` and `<validate>` tag elements, see [“Committing Configurations” on page 647](#).

Replacing the Candidate Configuration

You can replace the candidate configuration with a new configuration file using the `<copy-config>` tag, or you can use the `<edit-config>` tag with the `<default-operation>` subtag value set to `replace`.

For information about completely replacing the candidate configuration, see the following sections:

- [Using <copy-config> on page 634](#)
- [Using <edit-config> on page 634](#)

Using <copy-config>

One method for replacing the entire candidate configuration is to include the **<copy-config>** tag element in the **<rpc>** tag element. The **<source>** tag element encloses the **<url>** tag element to specify the filename that contains the new configuration data. The **<target>** tag element encloses the **<candidate/>** tag to indicate that the new configuration data replaces the candidate configuration:

```
<rpc>
  <copy-config>
    <target>
      <candidate/>
    </target>
    <source>
      <url>
        <!-- location specifier for file containing the new configuration -->
      </url>
    </source>
  </copy-config>
</rpc>
]]>]]>
```

Using <edit-config>

The other method for replacing the entire candidate configuration is to set the edit configuration mode to **replace** as a global variable. The candidate configuration includes the **<default-operation>** tag element with the value **replace** in the **<edit-config>** tag element, as described in [“Setting the Edit Configuration Mode” on page 629](#). To specify the new configuration data, the application includes a **<config>** or **<config-text>** tag element that contains the data or a **<url>** tag element that names the file containing the data, as discussed in [“Formatting the Configuration Data” on page 625](#).

```
<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <default-operation>replace</default-operation>

    <!-- EITHER -->
    <config>
      <configuration>
        <!-- tag elements representing the configuration elements to change -->
      </configuration>
    </config>
    <!-- OR -->
    <config-text>
      <configuration-text>
        <!-- tag elements representing the configuration elements to change -->
      </configuration-text>
    </config-text>
    <!-- OR -->
    <url>
      <!-- location specifier for file containing changes -->
    </url>
  </edit-config>
</rpc>
]]>]]>
```

```

    </url>

    </edit-config>
  </rpc>
]]>]]>

```

Rolling Back a Configuration

The **<discard-changes>** tag allows you to roll back the candidate configuration to a previous configuration. To roll back the candidate to the current running configuration, insert the **<discard-changes>** tag within the **<rpc>** tag.

```

<rpc>
  <discard-changes/>
</rpc>
]]>]]>

```

This operation is equivalent to the CLI configuration mode **rollback 0** command.

The NETCONF server indicates that it discarded the changes by returning the **<load-success/>** tag after you issue the **</discard-changes>** tag.

Deleting the Candidate Configuration

You can use the **<delete-config>** tag element to delete the current candidate configuration. Exercise caution when issuing the **<delete-config>** tag element. If you commit an empty candidate configuration, the device will go offline.

```

<rpc>
  <delete-config>
    <target>
      <candidate/>
    </target>
  </delete-config>
</rpc>

```

WARNING: If you take the device offline, you will need to access the device through the console port on the device. From this console, you can access the CLI and perform a rollback to a suitable configuration. For more information on the console port, see the hardware manual for your specific device.

Changing Individual Configuration Elements

You change individual configuration elements within a candidate configuration using the `<edit-config>` tag element within the `<rpc>` tag. By default, the NETCONF server merges new configuration data into the existing candidate configuration. However, a client application can also replace, create, or delete individual configuration elements (hierarchy levels or configuration objects). The same basic tag elements are emitted for all operations: `<config>`, `<config-text>`, or `<url>` tag sub-elements within the `<edit-config>` tag element:

```
<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>

    <!-- EITHER -->
    <config>
      <configuration>
        <!-- tag elements representing the configuration elements to change -->
      </configuration>
    </config>
    <!-- OR -->
    <config-text>
      <configuration-text>
        <!-- tag elements representing the configuration elements to change -->
      </configuration-text>
    </config-text>
    <!-- OR -->
    <url>
      <!-- location specifier for file containing changes -->
    </url>

  </edit-config>
</rpc>
]]>]]>
```

Using configuration data within the `<config>` or `<config-text>` tag elements or the file specified within the `<url>` tag element, the application defines a configuration element by including the tag elements representing all levels of the configuration hierarchy from the root (represented by the `<configuration>` tag element) down to the immediate parent level for the element. To represent the element, the application includes its container tag element. The child tag elements included within the container tag element depend on the operation, and are described in the following sections:

- [Merging Configuration Elements on page 637](#)
- [Replacing Configuration Elements on page 638](#)
- [Creating New Configuration Elements on page 639](#)
- [Deleting Configuration Elements on page 641](#)

For more information about the tag elements that represent configuration statements, see “[Mapping Configuration Statements to Junos XML Tag Elements](#)” on page 552. For

information about the tag elements for a specific configuration element, see the *Junos XML API Configuration Developer Reference*.

The NETCONF server indicates that it changed the configuration in the requested way by enclosing the `<ok/>` tag in the `<rpc-reply>` tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

For more information, see the following sections:

Merging Configuration Elements

To merge configuration elements (hierarchy levels or configuration objects) into the candidate configuration, a client application emits the basic tag elements described in [“Changing Individual Configuration Elements” on page 636](#).

To represent each element to merge in (either within the `<config>` tag element or in the file named by the `<url>` tag element), the application includes the tag elements representing its parent hierarchy levels and its container tag element, as described in [“Changing Individual Configuration Elements” on page 636](#). Within the container tag, the application includes each of the element’s identifier tag elements (if it has them) and the tag element for each child to add or for which to set a different value. In the following, the identifier tag element is called `<name>`:

```
<configuration>
  <!-- opening tags for each parent of the element -->
  <element>
    <name>identifier</name>
    <!-- - child tag elements to add or change -->
  </element>
  <!-- closing tags for each parent of the element -->
</configuration>
```

The NETCONF server merges in the new configuration element according to the rules specified in [“Setting the Edit Configuration Mode” on page 629](#). As described in that section, the application can explicitly specify merge mode by including the `<default-operation>` tag element with the value `merge` in the `<edit-config>` tag element.

The following example shows how to merge information for a new interface called `so-3/0/0` into the `[edit interfaces]` hierarchy level in the candidate configuration:

Client Application

```

<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
  <config>
    <configuration>
      <interfaces>
        <interface>
          <name>so-3/0/0</name>
          <unit>
            <name>0</name>
            <family>
              <inet>
                <address>
                  <name>10.0.0.1/8</name>
                <address>
                </address>
              </inet>
            </family>
          </unit>
        </interface>
      </interfaces>
    </configuration>
  </config>
</edit-config>
</rpc>
]]>]]>

```

NETCONF Server

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>

```

T2120

Replacing Configuration Elements

To replace configuration elements (hierarchy levels or configuration objects) in the candidate configuration, a client application emits the basic tag elements described in [“Changing Individual Configuration Elements” on page 636](#).

To represent the new definition for each configuration element being replaced (either within the **<config>** tag element or in the file named by the **<url>** tag element), the application emits the tag elements representing its parent hierarchy levels and its container tag element, as described in [“Changing Individual Configuration Elements” on page 636](#). Within the container tag, the application includes each of the element’s identifier tag elements (if it has them) and all child tag elements (with values, if appropriate) that are being defined for the new version of the element. In the following, the identifier tag element is called **<name>**. The application includes the **operation="replace"** attribute in the opening container tag:

```

<configuration>
  <!-- opening tags for each parent of the element -->
  <container-tag operation="replace">
    <name>identifier</name>
    <!-- other child tag elements -->
  </container-tag>
  <!-- closing tags for each parent of the element -->

```

```
</configuration>
```

The NETCONF server removes the existing element that has the specified identifiers and inserts the new element.

The application can also replace all objects in the configuration in one operation. For instructions, see [“Replacing the Candidate Configuration” on page 633](#).

The following example shows how to grant new permissions for the object named **operator** at the **[edit system login class]** hierarchy level.

Client Application	NETCONF Server
<pre> <rpc> <edit-config> <target> <candidate/> </target> <config> <configuration> <system> <login> <class operation="replace"> <name>operator</name> <permissions>configure</permissions> <permissions>admin-control</permissions> </class> </login> </system> </configuration> </config> </edit-config> </rpc>]]>]]> </pre>	<pre> <rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]> </pre>

T2121

Creating New Configuration Elements

To create configuration elements (hierarchy levels or configuration objects) in the candidate configuration only if the elements do not already exist, a client application emits the basic tag elements described in [“Changing Individual Configuration Elements” on page 636](#).

To represent each configuration element being created (either within the **<config>** tag element or in the file named by the **<url>** tag element), the application emits the tag elements representing its parent hierarchy levels and its container tag element, as described in [“Changing Individual Configuration Elements” on page 636](#). Within the container tag, the application includes each of the element’s identifier tag elements (if it has them) and all child tag elements (with values, if appropriate) that are being defined for the element. In the following, the identifier tag element is called **<name>**. The application includes the **operation="create"** attribute in the opening container tag:

```
<configuration>
```

```

    <!-- opening tags for each parent of the element -->
    <element operation="create">
      <name>identifier</name> <!-- if the element has an identifier -->
      <!-- other child tag elements -->
    </element>
    <!-- closing tags for each parent of the element -->
  </configuration>

```

The NETCONF server adds the new element to the candidate configuration only if there is no existing element with that name (for a hierarchy level) or with the same identifiers (for a configuration object).

The following example shows how to enable OSPF on a device if it is not already configured:

Client Application

NETCONF Server

```

<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <config>
      <configuration>
        <protocols>
          <ospf operation="create">
            <area>
              <name>0</name>
              <interface>
                <name>at-0/1/0.100</name>
              </interface>
            </area>
          </ospf>
        </protocols>
      </configuration>
    </config>
  </edit-config>
</rpc>
]]>]]>

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>

```

T2122

Deleting Configuration Elements

To delete a configuration element (hierarchy level or configuration object) from the candidate configuration, a client application emits the basic tag elements described in [“Changing Individual Configuration Elements” on page 636](#). It also emits the **<default-operation>** tag element with the value **none** to change the default mode to no-change.

```
<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <default-operation>none</default-operation>

    <!-- EITHER -->
    <config>
      <configuration>
        <!-- tag elements representing the configuration elements to delete -->
      </configuration>
    </config>
    <!-- OR -->
    <url>
      <!-- location specifier for file containing elements to delete -->
    </url>

  </edit-config>
</rpc>
]]>]]>
```

In no-change mode, existing configuration elements remain unchanged unless the corresponding element in the new configuration has the **operation="delete"** attribute in its opening tag. This mode prevents the NETCONF server from creating parent hierarchy levels for an element that is being deleted. We recommend that the only operation performed in no-change mode be deletion. When merging, replacing, or creating configuration elements, client applications use merge mode.

To represent each configuration element being deleted (either within the **<config>** tag element or in the file named by the **<url>** tag element), the application emits the tag elements representing its parent hierarchy levels, as described in [“Changing Individual Configuration Elements” on page 636](#). The tag element in which the **operation="delete"** attribute is included depends on the element type, as described in the following sections:

- [Deleting a Hierarchy Level or Container Object on page 642](#)
- [Deleting a Configuration Object That Has an Identifier on page 642](#)
- [Deleting a Single-Value or Fixed-Form Option from a Configuration Object on page 643](#)
- [Deleting Values from a Multivalue Option of a Configuration Object on page 644](#)

Deleting a Hierarchy Level or Container Object

To delete a hierarchy level and all of its children (or a container object that has children but no identifier), a client application includes the **operation="delete"** attribute in the empty tag that represents the level:

```
<configuration>
  <!-- opening tags for each parent level -->
  <level-to-delete operation="delete"/>
  <!-- closing tags for each parent level -->
</configuration>
```

We recommend that the application set the default mode to no-change by including the **<default-operation>** tag element with the value **none**, as described in [“Deleting Configuration Elements” on page 641](#). For more information about hierarchy levels and container objects, see [“Mapping Configuration Statements to Junos XML Tag Elements” on page 552](#).

The following example shows how to remove the **[edit protocols ospf]** hierarchy level of the candidate configuration:

Client Application

```
<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <default-operation>none</default-operation>
    <config>
      <configuration>
        <protocols>
          <ospf operation="delete"/>
        </protocols>
      </configuration>
    </config>
  </edit-config>
</rpc>
]]>]]>
```

NETCONF Server

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

T2123

Deleting a Configuration Object That Has an Identifier

To delete a configuration object that has an identifier, a client application includes the **operation="delete"** attribute in the container tag element for the object. Inside the container tag element, it includes the identifier tag element only, not any tag elements that represent other characteristics. In the following, the identifier tag element is called **<name>**:

```
<configuration>
  <!-- opening tags for each parent of the object -->
  <object operation="delete">
    <name>identifier</name>
```

```

</object>
<!-- closing tags for each parent of the object -->
</configuration>

```

NOTE: The `delete` attribute appears in the opening container tag, not in the identifier tag element. The presence of the identifier tag element results in the removal of the specified object, not in the removal of the entire hierarchy level represented by the container tag element.

We recommend that the application set the default mode to no-change by including the `<default-operation>` tag element with the value `none`, as described in [“Deleting Configuration Elements” on page 641](#). For more information about identifiers, see [“Mapping Configuration Statements to Junos XML Tag Elements” on page 552](#).

The following example shows how to remove the user object **barbara** from the **[edit system login user]** hierarchy level in the candidate configuration:

Client Application

NETCONF Server

```

<rpc>
  <edit-config>
    <target>
      <candidate/>
    </target>
    <default-operation>none</default-operation>
  <config>
    <configuration>
      <system>
        <login>
          <user operation="delete">
            <name>barbara</name>
          </user>
        </login>
      </system>
    </configuration>
  </config>
</edit-config>
</rpc>
]]>]]>

```

```

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>

```

T2124

Deleting a Single-Value or Fixed-Form Option from a Configuration Object

To delete from a configuration object either a fixed-form option or an option that takes just one value, a client application includes the `operation="delete"` attribute in the tag element for the option. In the following, the identifier tag element for the object is called `<name>`. (For information about deleting an option that can take multiple values, see [“Deleting Values from a Multivalue Option of a Configuration Object” on page 644](#).)

```

<configuration>
  <!-- opening tags for each parent of the object -->

```

```

<object>
  <name>identifier</name> <!-- if object has an identifier -->
  <option1 operation="delete">
  <option2 operation="delete">
  <!-- tag elements for other options to delete -->
</object>
<!-- closing tags for each parent of the object -->
</configuration>

```

We recommend that the application set the default mode to no-change by including the **<default-operation>** tag element with the value **none**, as described in ["Deleting Configuration Elements" on page 641](#). For more information about options, see ["Mapping Configuration Statements to Junos XML Tag Elements" on page 552](#).

The following example shows how to remove the fixed-form **disable** option at the **[edit forwarding-options sampling]** hierarchy level:

Client Application	NETCONF Server
<pre> <rpc> <edit-config> <target> <candidate/> </target> <default-operation>none </default-operation> <config> <configuration> <forwarding-options> <sampling> <disable operation="delete"/> </sampling> </forwarding-options> </configuration> </config> </edit-config> </rpc>]]>]]> </pre>	<pre> <rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]> </pre>

T2125

Deleting Values from a Multivalue Option of a Configuration Object

As described in ["Mapping Configuration Statements to Junos XML Tag Elements" on page 552](#), some Junos OS configuration objects are leaf statements that have multiple values. In the formatted ASCII CLI representation, the values are enclosed in square brackets following the name of the object:

```
object[value1 value2 value3 ...];
```

The Junos XML representation does not use a parent tag for the object, but instead uses a separate instance of the object tag element for each value. In the following, the identifier tag element is called **<name>**:

```

<parent-object>
  <name>identifier</name>

```

```
<object>value1</object>  
<object>value2</object>  
<object>value3</object>  
</parent-object>
```

To remove one or more values for such an object, a client application includes the **operation="delete"** attribute in the opening tag for each value. It does not include tag elements that represent values to be retained. The identifier tag element in the following is called **<name>**:

```
<configuration>
  <!-- opening tags for each parent of the parent object -->
  <parent-object>
    <name>identifier</name>
    <object operation="delete">value1</object>
    <object operation="delete">value2</object>
  </parent-object>
  <!-- closing tags for each parent of the parent object -->
</configuration>
```

We recommend that the application set the default mode to no-change by including the **<default-operation>** tag element with the value **none**, as described in [“Deleting Configuration Elements” on page 641](#). For more information about leaf statements with multiple values, see [“Mapping Configuration Statements to Junos XML Tag Elements” on page 552](#).

The following example shows how to remove two of the permissions granted to the **user-accounts** login class:

Client Application	NETCONF Server
<pre><rpc> <edit-config> <target> <candidate/> </target> <default-operation>none</default-operation> <config> <configuration> <system> <login> <class> <name>user-accounts</name> <permissions operation="delete">configure</permissions> <permissions operation="delete">control</permissions> </class> </login> </system> </configuration> </config> </edit-config> </rpc>]]>]]></pre>	<pre><rpc-reply xmlns="URN" xmlns:junos="URL"> <ok/> </rpc-reply>]]>]]></pre>

T2126

CHAPTER 10

Committing Configurations

This chapter explains how to commit a candidate configuration so that it becomes the active configuration on the routing, switching, or security platform. For more detailed information about commit operations, including a discussion of the interaction among different variants of the operation, see the *CLI User Guide*

- [Verifying a Configuration Before Committing It on page 647](#)
- [Committing a Configuration on page 648](#)

Verifying a Configuration Before Committing It

During the process of committing the candidate configuration or a private copy, the NETCONF server confirms that it is syntactically correct. If the syntax check fails, the server does not commit the candidate configuration. To avoid the potential complications of such a failure, it often makes sense to confirm the candidate's correctness before actually committing it. A client application includes the `<validate>` and `<source>` tag elements and `<candidate/>` tag in an `<rpc>` tag element:

```
<rpc>
  <validate>
    <source>
      <candidate/>
    </source>
  </validate>
</rpc>
]]>]]>
```

The NETCONF server confirms that the candidate configuration is valid by returning the `<ok/>` tag in the `<rpc-reply>` tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

If the candidate configuration is not valid, the `<rpc-reply>` tag element instead encloses an `<rpc-error>` tag element explaining the reason for the failure.

Committing a Configuration

The following sections describe how to commit the candidate configuration so that it becomes the active configuration on the routing, switching, or security platform. For more detailed information about commit operations, including a discussion of the interaction among different commit operations, see the *CLI User Guide*.

- [Committing the Candidate Configuration on page 648](#)
- [Committing the Candidate Configuration Only After Confirmation on page 648](#)

Committing the Candidate Configuration

To commit the candidate configuration, a client application encloses the `<commit/>` tag in an `<rpc>` tag element:

```
<rpc>
  <commit/>
</rpc>
]]>]]>
```

The NETCONF server confirms that it committed the candidate configuration by returning the `<ok/>` tag in the `<rpc-reply>` tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

If the NETCONF server cannot commit the candidate configuration, the `<rpc-reply>` tag element instead encloses an `<rpc-error>` tag element explaining the reason for the failure. The most common causes are semantic or syntactic errors in the candidate configuration.

To avoid inadvertently committing changes made by other users or applications, a client application locks the candidate configuration before changing it and emits the `<commit/>` tag while the configuration is still locked. (For instructions on locking and changing the candidate configuration, see [“Locking the Candidate Configuration” on page 584](#) and [“Changing Configuration Information” on page 623](#).) After committing the configuration, the client application unlocks the candidate as described in [“Unlocking the Candidate Configuration” on page 585](#).

Committing the Candidate Configuration Only After Confirmation

To commit the candidate configuration but require an explicit confirmation for the commit to become permanent, a client application includes the `<confirmed/>` tag in `<commit>` and `<rpc>` tag elements:

```
<rpc>
  <commit>
    <confirmed/>
  </commit>
</rpc>
]]>]]>
```

If the commit is not confirmed within a certain amount of time (600 seconds [10 minutes] by default), the NETCONF server automatically retrieves and commits (rolls back to) the previously committed configuration. To specify a different number of minutes for the rollback deadline, the application encloses a positive integer value in the `<confirm-timeout>` tag element:

```
<rpc>
  <commit>
    <confirmed/>
    <confirm-timeout>rollback-delay</confirm-timeout>
  </commit>
</rpc>
]]>]]>
```

In either case, the NETCONF server confirms that it committed the candidate configuration temporarily by returning the `<ok/>` tag in the `<rpc-reply>` tag element:

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

If the NETCONF server cannot commit the candidate, the `<rpc-reply>` tag element instead encloses an `<rpc-error>` tag element explaining the reason for the failure. The most common causes are semantic or syntactic errors in the candidate configuration.

The confirmed commit operation is useful for verifying that a configuration change works correctly and does not prevent management access to the device. If the change prevents access or causes other errors, the automatic rollback to the previous configuration restores access after the rollback deadline passes.

To delay the rollback to a time later than the current rollback deadline, the client application emits the `<confirmed/>` tag in a `<commit>` tag element again before the deadline passes. Optionally, it includes the `<confirm-timeout>` tag element to specify how long to delay the next rollback; omit that tag element to delay the rollback by the default of 10 minutes. The client application can delay the rollback indefinitely by emitting the `<confirmed/>` tag repeatedly in this way.

To cancel the rollback completely (and commit a configuration permanently), the client application emits the `<commit/>` tag enclosed in an `<rpc>` tag element before the rollback deadline passes. The rollback is canceled and the candidate configuration is committed immediately, as described in [“Committing a Configuration” on page 648](#). If the candidate configuration is still the same as the temporarily committed configuration, this effectively recommits the temporarily committed configuration.

If another application uses the `<kill-session/>` tag element to terminate this application's session while a confirmed commit is pending (this application has committed changes but not yet confirmed them), the NETCONF server that is servicing this session restores the configuration to its state before the confirmed commit instruction was issued. For more information about session termination, see [“Terminating Another NETCONF Session” on page 586](#).

The following example shows how to commit the candidate configuration with a rollback deadline of 20 minutes.

Client Application

```
<rpc>
  <commit>
    <confirmed/>
    <confirm-timeout>20</confirm-timeout>
  </commit>
</rpc>
]]>]]>
```

NETCONF Server

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <ok/>
</rpc-reply>
]]>]]>
```

T2127

Summary of NETCONF Tag Elements

This chapter lists the tag elements that client applications and the NETCONF server use to control the NETCONF session and to exchange configuration information. It also describes the `]]>]]>` character sequence, which signals the end of each request and response. The entries are in alphabetical order. For information about the notational conventions used in this chapter, see [Table 2 on page ccxciii](#).

]]>]]>

Usage

```
<hello>
  <!-- child tag elements included by client application or NETCONF server -->
</hello>
]]>]]>

<rpc [attributes]>
  <!-- tag elements in a request from a client application -->
</rpc>
]]>]]>

<rpc-reply xmlns="URN" xmlns:junos="URL">
  <!-- tag elements in the response from the NETCONF server -->
</rpc-reply>
]]>]]>
```

Description Signal the end of each XML document sent by the NETCONF server and client applications. Client applications send the sequence after its closing `</hello>` tag and each closing `</rpc>` tag. The NETCONF server sends the sequence after its closing `</hello>` tag and each closing `</rpc-reply>` tag.

Use of this signal is required by RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*, available at <http://www.ietf.org/rfc/rfc4742.txt>.

Usage Guidelines See “Generating Well-Formed XML Documents” on page 562.

<commit>

Usage	<pre><rpc> <commit/> </rpc>]]>]]> <rpc> <commit> <confirmed/> <confirm-timeout>rollback-delay</confirm-timeout> </commit> </rpc>]]>]]></pre>
Description	<p>Request that the NETCONF server perform one of the variants of the commit operation on the candidate configuration:</p> <ul style="list-style-type: none">• To commit the configuration immediately, making it the active configuration on the device, emit the empty <commit/> tag.• To commit the candidate configuration but require an explicit confirmation for the commit to become permanent, enclose the <confirmed/> tag in the <commit> tag element. <p>By default, the NETCONF server rolls back to the previous running configuration after 10 minutes; to set a different rollback delay, also emit the optional <confirm-timeout> tag element. To delay the rollback again (past the original rollback deadline), emit the <confirmed/> tag (enclosed in the <commit> tag element) again before the deadline passes. Include the <confirm-timeout> tag element to specify how long to delay the next rollback, or omit that tag element to use the default of 10 minutes. The rollback can be delayed repeatedly in this way.</p> <p>To commit the configuration immediately and permanently after emitting the <confirmed/> tag, emit the empty <commit/> tag before the rollback deadline passes. The NETCONF server commits the candidate configuration and cancels the rollback.</p>

If the candidate configuration is still the same as the running configuration, the effect is the same as recommitting the current running configuration.

Contents **<confirmed>**—Requests a temporary commit of the candidate configuration. The device reverts to the previous active configuration after a specified time.

<confirm-timeout>—Specifies the number of minutes before the device reverts to the previously active configuration. If this tag element is omitted, the default is 10 minutes.

Usage Guidelines See “Committing a Configuration” on page 648.

]]>]]>
```

- Description** Request that the NETCONF server incorporate configuration data into the candidate configuration. Provide the data in one of three ways:
- Include the **<config>** tag element to provide a data stream of Junos XML configuration tag elements to incorporate. The tag elements are enclosed in the **<configuration>** tag element.
 - Include the **<config-text>** tag element to provide a data stream of CLI configuration statements to incorporate. The configuration statements are enclosed in the **<configuration-text>** tag element.
 - Include the **<url>** tag element to specify the location of a file that contains the Junos XML configuration tag elements to incorporate.
- Contents**
- <config>**—Encloses the **<configuration>** tag element.
- <configuration>**—Encloses the configuration data written in Junos XML. This configuration data will be incorporated into the candidate configuration and provided as a data stream. For information about the syntax for representing the elements to create, delete, or modify, see [“Mapping Configuration Statements to Junos XML Tag Elements” on page 552](#) and [“Changing Individual Configuration Elements” on page 636](#).
- <config-text>**—Encloses the **<configuration-text>** tag element.
- <configuration-text>**—Encloses the configuration data written in CLI configuration statements. This configuration data will be incorporated into the candidate configuration and provided as a data stream. For information about the CLI configuration statements, see the *CLI User Guide*.
- <default-operation>**—(Optional) Specifies how to incorporate the new configuration data into the candidate configuration, particularly when there are conflicting statements. The following are acceptable values:

- **merge**—Combines the new configuration data with the candidate configuration according to the rules defined in [“Setting the Edit Configuration Mode” on page 629](#). This is the default mode if the **<default-operation>** tag element is omitted. It applies to all elements in the new data that do not have the **operation** attribute in their opening container tag to specify a different mode (for information about the **operation** attribute, see [“Changing Individual Configuration Elements” on page 636](#)).
- **none**—Retains each configuration element in the existing candidate configuration unless the new data includes a corresponding element that has the **operation** attribute in its opening container tag to specify an incorporation mode. This mode prevents the NETCONF server from creating parent hierarchy levels for an element that is being deleted. For more information, see [“Deleting Configuration Elements” on page 641](#).
- **replace**—Discards the existing candidate configuration and replaces it with the new data. For more information, see [“Using <edit-config>” on page 634](#).

<error-option>—(Optional) Specifies how the NETCONF server handles errors encountered while it incorporates the configuration data. The following are acceptable values:

- **ignore-error**—Specifies that the NETCONF server continue to incorporate the new configuration data even if it encounters an error.
- **stop-on-error**—Specifies that the NETCONF server stop incorporating the new configuration data when it encounters an error. This is the default behavior if the **<error-option>** tag element is omitted.

<test-option>—(Optional) Specifies whether the NETCONF server validates the configuration data before incorporating it into the candidate configuration. The acceptable values defined in the NETCONF specification are **set** (no validation) and the default **test-then-set** (do not incorporate data if validation fails).

Regardless of the value provided, the NETCONF server for the Junos OS performs a basic syntax check on the configuration data in the **<edit-config>** tag element. It performs a complete syntactic and semantic validation in response to the **<validate>** and **<commit>** tag elements, but not for the **<edit-config>** tag element.

<url>—Specifies the full pathname of the file that contains the configuration data to load. When the configuration data is formatted as CLI configuration statements, you set the **<url>** format attribute to **text**. For more information, see [“Referencing Configuration Data Files” on page 625](#).

The **<target>** tag element and its contents are explained separately.

Usage Guidelines See [“Changing Configuration Information” on page 623](#).

<get-config>

Usage	<pre><rpc> <get-config> <source> <(candidate running)/> </source> </get-config> <get-config> <source> <(candidate running)/> </source> <filter type="subtree"> <configuration> <!-- tag elements for each configuration element to return --> </configuration> </filter> </get-config> </rpc>]]>]]></pre>
Description	Request configuration data from the NETCONF server. The child tag elements <source> and <filter> specify the source and scope of data to display:

- To display the entire active configuration, enclose the **<source>** tag element and **<running/>** tag in the **<get-config>** tag element.
- To display the entire candidate configuration, enclose the **<source>** tag element and **<candidate/>** tag in the **<get-config>** tag element.
- To display one or more sections of the configuration hierarchy (hierarchy levels or configuration objects), enclose the appropriate child tag elements in the **<source>** and **<filter>** tag elements.

Contents **<candidate/>**—Represents the candidate configuration.

<configuration>—Encloses tag elements that specify which configuration elements to return.

<filter>—Encloses the **<configuration>** tag element. The mandatory **type** attribute indicates the kind of syntax used to represent the requested configuration elements; the only acceptable value is **subtree**.

To specify the configuration elements to return, include within the **<filter>** tag element the Junos XML tag elements that represent all levels of the configuration hierarchy from the root (represented by the **<configuration>** tag element) down to each element to display. For information about the syntax for representing each kind of element, see [“Specifying the Scope of Configuration Information to Return” on page 601](#). For information about the configuration elements available in the current version of the Junos OS, see the *Junos XML API Configuration Developer Reference*.

<running/>—Represents the active (mostly recently committed) configuration.

<source>—Encloses the tag that specifies the source of the configuration data. To specify the candidate configuration, include the **<candidate/>** tag. To specify the active configuration, include the **<running/>** tag.

Usage Guidelines See [“Requesting Configuration Information” on page 598](#).

<hello>

Usage

```
<!-- emitted by a client application -->
<hello>
  <capabilities>
    <capability>URI</capability>
  </capabilities>
</hello>
]]>]]>
```

```
<!-- emitted by the NETCONF server -->
<hello>
  <capabilities>
    <capability>URI</capability>
  </capabilities>
  <session-id>session-identifier</session-id>
</hello>
]]>]]>
```

Description Specify which operations, or *capabilities*, the emitter supports from among those defined in the NETCONF specification. The client application must emit the **<hello>** tag element before any other tag element during the NETCONF session, and must not emit it more than once.

Contents **<capabilities>**—Encloses one or more **<capability>** tags, which together specify the set of supported NETCONF operations.

<capability>—Specifies the uniform resource identifier (URI) of a capability defined in the NETCONF specification or by a vendor. Each capability from the NETCONF specification is represented by a uniform resource name (URN). Capabilities defined by vendors are represented by URNs or URLs. For a list of the capabilities supported by the NETCONF server for the Junos OS, see [“Exchanging <hello> Tag Elements” on page 574](#).

<session-id>—(Generated by NETCONF server only) Specifies the UNIX process ID (PID) of the NETCONF server for the session.

Usage Guidelines See [“Exchanging <hello> Tag Elements” on page 574](#).

Related Documentation

<kill-session>

Usage

```
<rpc>
  <kill-session>
    <session-id>PID</session-id>
  </kill-session>
</rpc>
]]>]]>
```

Description Request that the NETCONF server terminate another CLI or NETCONF session. The usual reason to emit this tag is that the user or application for the other session holds a lock on the candidate configuration, preventing the client application from locking the configuration itself.

The client application must have the Junos **maintenance** permission to perform this operation.

Contents	<session-id> —The PID of the entity conducting the session to terminate. The PID is reported in the <rpc-error> tag element that the NETCONF server generates when it cannot lock a configuration as requested.
Usage Guidelines	See “Terminating Another NETCONF Session” on page 586 .

<rpc>

Usage	<pre><rpc [<i>attributes</i>]> <!-- tag elements in a request from a client application --> </rpc>]]>]]></pre>
Description	Enclose all tag elements in a request generated by a client application.
Attributes	(Optional) One or more attributes of the form attribute-name="value" . This feature can be used to associate requests and responses if the value assigned to an attribute by the client application is unique in each opening <rpc> tag. The NETCONF server echoes the attribute unchanged in its opening <rpc-reply> tag, making it simple to map the response to the initiating request. The NETCONF specification assigns the name message-id to this attribute.
Usage Guidelines	See “Sending a Request to the NETCONF Server” on page 577 .
Related Documentation	<ul style="list-style-type: none">•]]>]]> on page 651• <rpc-reply> on page 663

<rpc-error>

Usage	<pre><rpc-reply xmlns="URN" xmlns:junos="URL"> <rpc-error> <error-severity>error-severity</error-severity> <error-path>error-path</error-path> <error-message>error-message</error-message> <error-info>...</error-info> </rpc-error> </rpc-reply>]]>]]></pre>
Description	Indicate that the NETCONF server has experienced an error while processing the client application's request. If the server has already emitted the response tag element for the current request, the information enclosed in that response tag element might be incomplete. The client application must include code that discards or retains the information, as appropriate. The child tag elements described in the Contents section

detail the nature of the error. The NETCONF server does not necessarily emit all child tag elements; it omits tag elements that are not relevant to the current request.

- Contents**
- <error-message>**—Describes the error or warning in a natural-language text string.
 - <error-path>**— Specifies the path to the Junos configuration hierarchy level at which the error or warning occurred, in the form of the CLI configuration mode banner.
 - <error-severity>**—Indicates the severity of the event that caused the NETCONF server to return the **<rpc-error>** tag element. The two possible values are **error** and **warning**.
- The **<error-info>** tag element is described separately.

Usage Guidelines See “[Handling an Error or Warning](#)” on page 583.

<rpc-reply>

Usage

```
<rpc-reply xmlns="URN" xmlns:junos="URL">
  <!-- tag elements in a reply from the NETCONF server-->
</rpc-reply>
]]>]]>
```

- Description** Enclose all tag elements in a reply from the NETCONF server. The immediate child tag element is usually one of the following:
- The Junos XML tag element that encloses the data requested by a client application with a Junos XML operational request tag element; for example, the **<interface-information>** tag element in response to the **<get-interface-information>** tag element
 - The **<data>** tag element, to enclose the data requested by a client application with the **<get-config>** tag element
 - The **<ok/>** tag, to confirm that the NETCONF server successfully performed an operation that changes the state or contents of a configuration (such as a lock, change, or commit operation)
 - The **<output>** tag element, if the Junos XML API does not define a specific tag element for requested operational information
 - The **<rpc-error>** tag element, if the requested operation generated an error or warning

Attributes **xmlns**—Names the default XML namespace for the enclosed tag elements.

Usage Guidelines See “[Parsing the NETCONF Server Response](#)” on page 580.

Summary of Junos XML Protocol Tag Elements Supported in NETCONF Sessions

The NETCONF server supports operations in the Junos XML management protocol that client applications can use to request or change configuration information on Juniper Networks devices running the Junos OS. The additional capabilities are Juniper Networks proprietary extensions to NETCONF and are identified in the capabilities exchange with the URI <http://xml.juniper.net/netconf/junos/1.0>.

This chapter lists Junos XML protocol operations that are supported in NETCONF sessions on Juniper Networks devices running the Junos OS. The entries are in alphabetical order. For information about the notational conventions used in this chapter, see [Table 2 on page ccxciii](#).

<abort/>

Usage	<pre><rpc> <!-- child tag elements --> </rpc> <abort/></pre>
Release Information	This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI http://xml.juniper.net/netconf/junos/1.0 . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.
Description	Direct the NETCONF server to stop processing the request that is currently outstanding. The server responds by returning the <abort-acknowledgment/> tag, but might already have sent tagged data in response to the request. The client application must discard those tag elements.
Related Documentation	<ul style="list-style-type: none"> • <abort-acknowledgement/> on page 668 • <rpc> on page 662

<abort-acknowledgement/>

Usage	<pre><rpc-reply xmlns:junos="URL"> <any-child-of-rpc-reply> <abort-acknowledgement/> </any-child-of-rpc-reply> </rpc-reply></pre>
Release Information	This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI http://xml.juniper.net/netconf/junos/1.0 . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.
Description	Indicate that the NETCONF protocol server has received the <abort/> tag and has stopped processing the current request. If the client application receives any tag elements related to the request between sending the <abort/> tag and receiving this tag, it must discard them.
Related Documentation	<ul style="list-style-type: none">• <rpc-reply> on page 663• <xnm:error> on page 687

<checksum-information>

Usage	<pre><rpc-reply> <checksum-information> <file-checksum> <computation-method>MD5</computation-method> <input-file> <!-- name and path of file--> </input-file> </file-checksum> </checksum-information> </rpc-reply></pre>
Release Information	This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI http://xml.juniper.net/netconf/junos/1.0 . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.
Description	Enclose tag elements that include the file to check, the checksum algorithm used, and the checksum output.
Contents	<p><file-checksum>—Wrapper that holds the resulting <input-file>, <computation-method>, and <checksum> attributes for a particular checksum computation.</p> <p><input-file>—Name and path of the file that the checksum algorithm was run against.</p> <p><computation-method>—Checksum algorithm used. Currently, all checksum computations use the MD5 algorithm; thus, the only possible value is MD5.</p>

<checksum>—Resulting value from the checksum computation.

Usage Guidelines See the *Junos XML API Operational Developer Reference*.

Related Documentation

- [<get-checksum-information> on page 676](#)

<close-configuration/>

Usage

```
<rpc>
  <close-configuration/>
</rpc>
```

Release Information This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI <http://xml.juniper.net/netconf/junos/1.0> . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.

Description Discard a candidate configuration and any changes to it.

This tag element is normally used only to discard a private copy of the candidate configuration without committing it. The application must have previously emitted the **<open-configuration>** tag element. Closing the NETCONF session (by emitting the **<request-end-session/>** tag, for example) has the same effect as emitting this tag element.

<log>log-message</log>
</commit-configuration>

<commit-configuration>
<synchronize/>
<check/>
<log>log-message</log>
</commit-configuration>

<commit-configuration>
<synchronize/>
<confirmed/>
<confirm-timeout>rollback-delay</confirm-timeout>
<log>log-message</log>
</commit-configuration>

<commit-configuration>
<synchronize/>
<force-synchronize/>
</commit-configuration>
</rpc>
```

Release Information This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI <http://xml.juniper.net/netconf/junos/1.0> . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.

Description Request that the NETCONF server perform one of the variants of the commit operation on either the regular candidate configuration or a private copy of the candidate configuration (if the application emitted the `<open-configuration><private/></open-configuration>` tag sequence before making changes).

Some restrictions apply to the commit operation for a private copy. For example, the commit operation fails if the regular candidate configuration is locked by another user or application, or if it includes uncommitted changes made since the private copy was created. For more information, see the *CLI User Guide*.

Enclose the appropriate tag in the **<commit-configuration>** tag element to specify the type of commit operation:

- To commit the configuration immediately, making it the active configuration on the device, emit the empty **<commit-configuration/>** tag.
- To verify the syntactic correctness of the configuration without actually committing it, enclose the **<check/>** tag in the **<commit-configuration>** tag element.
- To record a message in the **/var/log/commits** file when the associated commit operation succeeds, define the log message string in the **<log>** tag element and enclose the tag element in the **<commit-configuration>** tag element. The **<log>** tag element can be combined with any other tag element. When the **<log>** tag element is emitted alone, the associated commit operation begins immediately.
- To commit the candidate configuration but roll back to the previous configuration after a short time, enclose the **<confirmed/>** tag in the **<commit-configuration>** tag element.

By default, the rollback occurs after 10 minutes; to set a different rollback delay, also emit the optional **<confirm-timeout>** tag element. To delay the rollback again (past the original rollback deadline), emit the **<confirmed/>** tag (enclosed in the **<commit-configuration>** tag element) before the deadline passes. Include the **<confirm-timeout>** tag element to specify how long to delay the next rollback, or omit that tag element to use the default of 10 minutes. The rollback can be delayed repeatedly in this way.

To commit the configuration immediately and permanently after emitting the **<confirmed/>** tag, emit the empty **<commit-configuration/>** tag before the rollback deadline passes. The NETCONF server commits the candidate configuration and cancels the rollback. If the candidate configuration is still the same as the current committed configuration, the effect is the same as recommitting the current committed configuration.

NOTE: The confirmed commit operation is not available for a private copy of the configuration.

- On a device with two Routing Engines, commit the candidate configuration stored on the local Routing Engine on both Routing Engines. Combine tag elements as indicated in the following:
 - To copy the candidate configuration stored on the local Routing Engine to the other Routing Engine, verify the candidate's syntactic correctness, and commit it immediately on both Routing Engines, enclose the **<synchronize/>** tag in the **<commit-configuration>** tag element.
 - To copy the candidate configuration stored on the local Routing Engine to the other Routing Engine, verify the candidate's syntactic correctness, and commit it on both Routing Engines at a defined future time, enclose the **<synchronize/>** or **<force-synchronize/>** tag and **<at-time>** tag element in the **<commit-configuration>**

tag element. Set the value in the **<at-time>** tag element as previously described for use of the **<at-time>** tag element alone.

- To copy the candidate configuration stored on the local Routing Engine to the other Routing Engine and verify the candidate's syntactic correctness on each Routing Engine, enclose the **<synchronize/>** or **<force-synchronize/>** and **<check/>** tag elements in the **<commit-configuration>** tag element.
- To copy the candidate configuration stored on the local Routing Engine to the other Routing Engine, verify the candidate's syntactic correctness, and commit it on both Routing Engines but require confirmation, enclose the **<synchronize/>** tag and **<confirmed/>** tag elements, and optionally the **<confirm-timeout>** tag element, in the **<commit-configuration>** tag element. Set the value in the **<confirm-timeout>** tag element as previously described for use of the **<confirmed/>** tag and **<confirm-timeout>** tag element alone.
- To force the same synchronized commit operation as invoked by the **<synchronize/>** tag to succeed, even if there are open configuration sessions or uncommitted configuration changes on the remote machine, enclose the **<force-synchronize/>** tag in the **<commit-configuration>** tag element.
- To schedule the configuration for commit at a future time, enclose the **<at-time>** tag element in the **<commit-configuration>** tag element. There are three valid types of time specifiers:
 - The string **reboot**, to commit the configuration the next time the device reboots.
 - A time value of the form **hh:mm[:ss]** (hours, minutes, and, optionally, seconds), to commit the configuration at the specified time, which must be in the future but before 11:59:59 PM on the day the **<commit-configuration>** tag element is emitted. Use 24-hour time for the **hh** value; for example, **04:30:00** means 4:30:00 AM and **20:00** means 8:00 PM. The time is interpreted with respect to the clock and time zone settings on the device.
 - A date and time value of the form **yyyy-mm-dd hh:mm[:ss]** (year, month, date, hours, minutes, and, optionally, seconds), to commit the configuration at the specified date and time, which must be after the **<commit-configuration>** tag element is emitted. Use 24-hour time for the **hh** value. For example, **2005-08-21 15:30:00** means 3:30 PM on August 21, 2005. The time is interpreted with respect to the clock and time zone settings on the device.

NOTE: The time you specify must be more than 1 minute later than the current time on the device.

The configuration is checked immediately for syntactic correctness. If the check succeeds, the configuration is scheduled for commit at the specified time. If the check fails, the commit operation is not scheduled.

Contents **<at-time>**—Schedules the commit operation for a specified future time.

<check>—Requests verification that the configuration is syntactically correct, but does not actually commit it.

<confirmed>—Requests a commit of the candidate configuration and a rollback to the previous configuration after a short time, 10 minutes by default. Use the **<confirm-timeout>** tag element to specify a different amount of time.

<confirm-timeout>—Specifies the number of minutes for which the configuration remains active when the **<confirmed/>** tag is enclosed in the **<commit-configuration>** tag element.

<log>—Records a message in the file `/var/log/commits` when the commit operation succeeds.

<synchronize>—On dual control plane systems, requests that the candidate configuration on one control plane be copied to the other control plane, checked for correct syntax, and committed on both Routing Engines.

<force-synchronize>—On dual control plane systems, forces the candidate configuration on one control plane to be copied to the other control plane.

Release Information This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI <http://xml.juniper.net/netconf/junos/1.0> . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.

Description Describe a user or NETCONF client application that is logged in to the configuration database. For simplicity, the Contents section uses the term user to refer to both human users and client applications, except where the information differs for the two.

Contents **<commit-at/>**—Indicates that the user has scheduled a commit operation for a later time.

<edit-path>—Specifies the user's current location in the configuration hierarchy, in the form of the CLI configuration mode banner.

<exclusive/>—Indicates that the user or application has an exclusive lock on the configuration database. A user enters exclusive configuration mode by issuing the **configure exclusive** command in CLI operational mode. A client application obtains the lock by emitting the **<lock-configuration/>** tag element.

<idle-time>—Specifies how much time has passed since the user last performed an operation in the database.

<pid>—Specifies the process ID of the Junos management process (mgd) that is handling the user's login session.

<start-time>—Specifies the time when the user logged in to the configuration database, in the format *YYYY-MM-DD hh:mm:ss TZ* (year, month, date, hour in 24-hour format, minute, second, time zone).

<terminal>—Identifies the UNIX terminal assigned to the user's connection.

<user>—Specifies the Junos OS login ID of the user whose login to the configuration database caused the error.

<get-configuration>

Usage

```
<rpc>
  <get-configuration
    [changed="changed"]
    [commit-scripts="view"]
    [compare="rollback" [rollback="[0-49]"]]
    [database="(candidate | committed)"]
    [format="(text | xml)"]
    [inherit="(defaults | inherit)"
      [groups="groups" [interface-ranges="interface-ranges"]]/>

    <!-- tag elements for the configuration element to display -->
  </get-configuration>
</rpc>
```

Release Information This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI

<http://xml.juniper.net/netconf/junos/1.0> . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.

Description Request configuration data from the NETCONF server. The attributes specify the source and formatting of the data to display. Either the entire configuration hierarchy or a section can be displayed:

- To display the entire configuration hierarchy, emit the empty **<get-configuration/>** tag.
- To display a configuration element (hierarchy level or configuration object), emit tag elements within the **<get-configuration>** tag element to represent all levels of the configuration hierarchy from the root (represented by the **<configuration>** tag element) down to the level or object to display. To represent a hierarchy level or a configuration object that does not have an identifier, emit it as an empty tag. To represent an object that has one or more identifiers, emit its container tag element and identifier tag elements only, not any tag elements that represent other characteristics.

Attributes For detailed information on the attributes, see the *Junos XML Management Protocol Developer Guide*

changed—Specifies that the **junos:changed="changed"** attribute should appear in the opening tag of each changed configuration element.

The attribute appears in the opening tag of every parent tag element in the path to the changed configuration element, including the top-level opening **<configuration>** tag. If the changed configuration element is represented by a single (empty) tag, the **junos:changed="changed"** attribute appears in the tag. If the changed element is represented by a container tag element, the **junos:changed="changed"** attribute appears in the opening container tag and also in each child tag element enclosed in the container tag element.

The **database** attribute can be combined with the **changed="changed"** attribute to request either the candidate or active configuration:

- When the candidate configuration is requested (the **database="changed"** attribute is included or the **database** attribute is omitted completely), elements added to the candidate configuration after the last commit operation are marked with the **junos:changed="changed"** attribute.
- When the active configuration is requested (the **database="candidate"** attribute is included), elements added to the active configuration by the most recent commit are marked with the **junos:changed="changed"** attribute.

NOTE: When a commit operation succeeds, the NETCONF server removes the **junos:changed="changed"** attribute from all tag elements. However, if warnings are generated during the commit, the attribute is not removed. In this case, the **junos:changed="changed"** attribute appears in tag elements that changed before the commit operation as well as on those that changed after it.

An example of a commit-time warning is the message explaining that a configuration element will not actually apply until the device is rebooted. The warning appears in the tag string that the NETCONF server returns to confirm the success of the commit, enclosed in an **<xnm:warning>** tag element.

To remove the **junos:changed="changed"** attribute from elements that changed before the commit, take the action necessary to eliminate the cause of the warning, and commit the configuration again.

commit-scripts—Requests that the NETCONF server display commit-script-style XML data, which displays the configuration in the XML format that is input to a commit script. The only acceptable value for the **commit-scripts** attribute is **view**. The output is equivalent to the CLI output when using the **| display commit-scripts view** option.

compare—Requests that the NETCONF server display the differences between the active or candidate configuration and a previously committed configuration. The only acceptable value for the **compare** attribute is **rollback**. The compare attribute is combined with the **rollback="rollback-number"** to specify which previously committed configuration should be used in the comparison. If the **rollback** attribute is omitted, the comparison uses rollback number 0, which is the active configuration.

The **database** attribute can be combined with the **compare="rollback"** attribute to request either the candidate or active configuration. If the **database** attribute is omitted, the candidate configuration is used. When the **compare** attribute is used, the default format for the output is text. If the client application attempts to include the **format="xml"** attribute when the **compare="rollback"** attribute is present, the protocol server will return an **<xnm:error>** element indicating an error.

database—Specifies the version of the configuration from which to display data. There are two acceptable values:

- **candidate**—The candidate configuration
- **committed**—The active configuration (the one most recently committed)

format—Specifies the format in which the NETCONF server returns the configuration data. There are two acceptable values:

- **text**—Configuration statements are formatted as ASCII text, using the newline character, tabs and other white space, braces, and square brackets to indicate the hierarchical relationships between the statements. This is the format used in configuration files stored on a device running Junos OS and displayed by the CLI **show configuration** command.
- **xml**—Configuration statements are represented by the corresponding Junos XML tag elements. This is the default value if the **format** attribute is omitted.

groups—Specifies that the **junos:group="group-name"** attribute appears in the opening tag for each configuration element that is inherited from a configuration group. The **group-name** variable specifies the name of the configuration group.

The **groups** attribute must be combined with the **inherit** attribute, and the one acceptable value for it is **groups**.

inherit—Specifies how the NETCONF server displays statements that are defined in configuration groups and interface ranges. If the **inherit** attribute is omitted, the output uses the **<groups>**, **<apply-groups>**, and **<apply-groups-except>** tag elements to represent user-defined configuration groups and uses the **<interface-range>** tag element to represent user-defined interface ranges; it does not include tag elements for statements defined in the **junos-defaults** group.

There are two acceptable values:

- **defaults**—The output does not include the **<groups>**, **<apply-groups>**, and **<apply-groups-except>** tag elements, but instead displays tag elements that are inherited from user-defined groups and from the **junos-defaults** group as children of the inheriting tag elements.
- **inherit**—The output does not include the **<groups>**, **<apply-groups>**, **<apply-groups-except>**, and **<interface-range>** tag elements, but instead displays tag elements that are inherited from user-defined groups and ranges as children of the inheriting tag elements. The output does not include tag elements for statements defined in the **junos-defaults** group.

interface-ranges—Specifies that the **junos:interface-ranges="source-interface-range"** attribute appears in the opening tag for each configuration element that is inherited from an interface-range. The **source-interface-range** variable specifies the name of the interface-range.

The **interface-ranges** attribute must be combined with the **inherit** attribute, and the one acceptable value for it is **interface-ranges**.

```
<rpc>
  <load-configuration rescue="rescue"/>

  <load-configuration rollback="index"/>

  <load-configuration url="url" [action="(merge | override | replace | update)] \
    [format="(text | xml)"]/>

  <load-configuration url="url" action="set" format="text"/>

  <load-configuration [action="(merge | override | replace | update)"]
    [format="xml"]>
    <configuration>
      <!-- tag elements for configuration elements to load -->
    </configuration>
  </load-configuration>

  <load-configuration [action="(merge | override | replace | update)"]
    format="text">
    <configuration-text>
      <!-- formatted ASCII configuration statements to load -->
    </configuration-text>
  </load-configuration>

  <load-configuration action="set" format="text">
    <configuration-set>
      <!-- set configuration mode commands to load -->
    </configuration-set>
  </load-configuration>
</rpc>
```

Release Information This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI <http://xml.juniper.net/netconf/junos/1.0> . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.

Description Request that the NETCONF server load configuration data into the candidate configuration. Provide the data to load in one of four ways:

- Set the empty `<load-configuration/>` tag's **rescue** attribute to the value **rescue**. The rescue configuration completely replaces the candidate configuration.
- Set the empty `<load-configuration/>` tag's **rollback** attribute to the numerical index of a previous configuration. The routing platform stores a copy of the most recently committed configuration and up to 49 previous configurations. The specified previous configuration completely replaces the candidate configuration.
- Set the empty `<load-configuration/>` tag's **url** attribute to the pathname of a file that contains the configuration data to load. If providing the configuration data as formatted ASCII text, set the **format** attribute to **text**. If providing the configuration data as Junos XML tag elements, either omit the **format** attribute or set the value to **xml**. If providing the configuration data as a set of configuration mode commands, set the **action** attribute to **set**, and either omit the **format** attribute or set the value to **text**.

In the following example, the **url** attribute identifies `/tmp/add.conf` as the file to load.

```
<load-configuration url="/tmp/add.conf"/>
```

- Enclose the configuration data within an opening `<load-configuration>` and closing `</load-configuration>` tag. If providing the configuration data as formatted ASCII text, enclose it in a `<configuration-text>` tag element, and set the **format** attribute to **text**. If providing the configuration data as Junos XML tag elements, enclose it in a `<configuration>` tag element, and either omit the **format** attribute or set the value to **xml**. If providing the configuration data as a set of configuration mode commands, enclose it in a `<configuration-set>` tag element, set the **action** attribute to **set**, and either omit the **format** attribute or set the value to **text**.

Attributes For detailed information on the attributes, see the *Junos XML Management Protocol Developer Guide*

- **action**—Specifies how to load the configuration data, particularly when the candidate configuration and loaded configuration contain conflicting statements. The following are acceptable values:
- **merge**—Combines the data in the loaded configuration with the candidate configuration. If statements in the loaded configuration conflict with statements in the candidate configuration, the loaded statements replace the candidate ones. This is the default behavior if the **action** attribute is omitted.
- **override**—Discards the entire candidate configuration and replaces it with the loaded configuration. When the configuration is later committed, all system processes parse the new configuration.
- **replace**—Substitutes each hierarchy level or configuration object defined in the loaded configuration for the corresponding level or object in the candidate configuration.

If providing the configuration data as formatted ASCII text (either in the file named by the **url** attribute or enclosed in a **<configuration-text>** tag element), also place the **replace:** statement on the line directly preceding the statements that represent the hierarchy level or object to replace. For more information, see the discussion of loading a file of configuration data in the *CLI User Guide*.

If providing the configuration data as Junos XML tag elements, also set the **replace** attribute to the value **replace** on the opening tag of the container tag element that represents the hierarchy level or object to replace.

- **set**—Loads a set of Junos OS configuration mode commands. This option executes the configuration instructions line by line as they are stored in a file named by the **url** attribute or enclosed in a **<configuration-set>** tag element. The instructions can contain any configuration mode command, such as **set**, **delete**, **edit**, or **deactivate**. When providing the configuration data as a set of commands, the only acceptable value for the **format** attribute is **text**. If the **action** attribute value is **set**, and the **format** attribute is omitted, the format automatically defaults to **text** rather than **xml**. This option was added in Junos OS Release 11.4.
- **update**—Compares the loaded configuration and candidate configuration. For each hierarchy level or configuration object that is different in the two configurations, the version in the loaded configuration replaces the version in the candidate configuration. When the configuration is later committed, only system processes that are affected by the changed configuration elements parse the new configuration.

format—Specifies the format used for the configuration data. There are two acceptable values:

- **text**—Indicates that configuration data is formatted as ASCII text or as a set of configuration mode commands.

ASCII text format uses the newline character, tabs and other white space, braces, and square brackets to indicate the hierarchical relationships between the statements. This is the format used in configuration files stored on a routing platform running Junos OS and is displayed by the CLI **show configuration** command. Set command format

consists of a series of Junos OS configuration mode commands and is displayed by the CLI **show configuration | display set** command. To import a set of configuration mode commands, you must set the **action** attribute to **set**.

- **xml**—Indicates that configuration statements are represented by the corresponding Junos XML tag elements. If the **format** attribute is omitted, **xml** is the default format for all values of the **action** attribute except **set**, which defaults to format **text**.

rescue—Specifies that the rescue configuration replace the current candidate configuration. The only valid value is **rescue**.

rollback—Specifies the numerical index of the previous configuration to load. Valid values are **0** (zero, for the most recently committed configuration) through one less than the number of stored previous configurations (maximum is **49**).

url—Specifies the full pathname of the file that contains the configuration data to load. The value can be a local file path, an FTP location, or a Hypertext Transfer Protocol (HTTP) URL:

- A local filename can have one of the following forms:
 - **/path/filename**—File on a mounted file system, either on the local flash disk or on hard disk.
 - **a:filename** or **a:path/filename**—File on the local drive. The default path is **/** (the root-level directory). The removable media can be in MS-DOS or UNIX (UFS) format.
- A filename on an FTP server has the following form:

```
ftp://username:password@hostname/path/filename
```
- A filename on an HTTP server has the following form:

```
http://username:password@hostname/path/filename
```

In each case, the default value for the **path** variable is the home directory for the username. To specify an absolute path, the application starts the path with the characters **%2F**; for example, **ftp://username:password@hostname/%2Fpath/filename**.

Release Information This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI <http://xml.juniper.net/netconf/junos/1.0>. This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.

Description Create a private copy of the candidate configuration.

The client application can perform the same operations on the private copy as on the regular candidate configuration, including the commit operation. There are, however, restrictions on the commit operation. For details, see “[<commit-configuration>](#)” on [page 669](#).

To discard the private copy without committing it, emit the empty [<close-configuration/>](#) tag. Changes to the private copy are also lost if the NETCONF session ends for any reason before the changes are committed. It is not possible to save changes to a private copy other than by emitting the [<commit-configuration/>](#) tag.

Release Information	This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI <code>http://xml.juniper.net/netconf/junos/1.0</code> . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.
Description	Indicate that the NETCONF server has experienced an error while processing the client application's request. If the server has already emitted the response tag element for the current request, the information enclosed in the response tag element might be incomplete. The client application must include code that discards or retains the information, as appropriate. The child tag elements described in the Contents section detail the nature of the error. The NETCONF server does not necessarily emit all child tag elements; it omits tag elements that are not relevant to the current request.
Attributes	<p>xmlns—Names the XML namespace for the contents of the tag element. The value is a URL of the form <code>http://xml.juniper.net/xnm/version/xnm</code>, where <i>version</i> is a string such as 1.1.</p> <p>xmlns:xnm—Names the XML namespace for child tag elements that have the xnm: prefix on their names. The value is a URL of the form <code>http://xml.juniper.net/xnm/version/xnm</code>, where <i>version</i> is a string such as 1.1.</p>
Contents	<p><column>—(Occurs only during loading of a configuration file) Identifies the element that caused the error by specifying its position as the number of characters after the first character in the specified line in the configuration file that was being loaded. The line and file are specified by the accompanying <line-number> and <filename> tag elements.</p> <p><edit-path>—(Occurs only during loading of configuration data) Specifies the path to the configuration hierarchy level at which the error occurred, in the form of the CLI configuration mode banner.</p> <p><filename>—(Occurs only during loading of a configuration file) Names the configuration file that was being loaded.</p> <p><line-number>—(Occurs only during loading of a configuration file) Specifies the line number where the error occurred in the configuration file that was being loaded, which is named by the accompanying <filename> tag element.</p> <p><message>—Describes the error in a natural-language text string.</p> <p><parse/>—Indicates that there was a syntactic error in the request submitted by the client application.</p> <p><re-name>—Names the Routing Engine on which the error occurred.</p> <p><source-daemon>—Names the Junos OS module that was processing the request in which the error occurred.</p>

<statement>—(Occurs only during loading of configuration data) Identifies the configuration statement that was being processed when the error occurred. The accompanying **<edit-path>** tag element specifies the statement's parent hierarchy level.

<token>—Names which element in the request caused the error.

The other tag elements are explained separately.

Release Information This is a Junos XML management protocol operation. It is a Juniper Networks proprietary extension to NETCONF and is identified in the capabilities exchange by the URI <http://xml.juniper.net/netconf/junos/1.0> . This operation is only supported in NETCONF sessions on Juniper Networks devices running the Junos OS.

Description Indicate that the server has encountered a problem while processing the client application's request. The child tag elements described in the Contents section detail the nature of the warning.

Attributes

xmlns—Names the XML namespace for the contents of the tag element. The value is a URL of the form <http://xml.juniper.net/xnm/version/xnm>, where **version** is a string such as 1.1.

xmlns:xnm—Names the XML namespace for child tag elements that have the **xnm:** prefix in their names. The value is a URL of the form <http://xml.juniper.net/xnm/version/xnm>, where **version** is a string such as 1.1.

Contents

<column>—(Occurs only during loading of a configuration file) Identifies the element that caused the problem by specifying its position as the number of characters after the first character in the specified line in the configuration file that was being loaded. The line and file are specified by the accompanying **<line-number>** and **<filename>** tag elements.

<edit-path>—(Occurs only during loading of configuration data) Specifies the path to the configuration hierarchy level at which the problem occurred, in the form of the CLI configuration mode banner.

<filename>—(Occurs only during loading of a configuration file) Names the configuration file that was being loaded.

<line-number>—(Occurs only during loading of a configuration file) Specifies the line number where the problem occurred in the configuration file that was being loaded, which is named by the accompanying **<filename>** tag element.

<message>—Describes the warning in a natural-language text string.

<source-daemon>—Names the Junos OS module that was processing the request in which the warning occurred.

<statement>—(Occurs only during loading of configuration data) Identifies the configuration statement that was being processed when the error occurred. The accompanying **<edit-path>** tag element specifies the statement's parent hierarchy level.

<token>—Names which element in the request caused the warning.

The other tag element is explained separately.

          <name>identifier</name>
          <!-- if changing element has an identifier - -->
          <!-- other child tag elements, if appropriate for the operation -->
        </changing-element>
        <!-- closing tags for each parent of the changing element -->
      </configuration>
    </config>
    <!-- other child tag elements of the <edit-config> tag element -->
  </edit-config>
</rpc>
```

]]>]]>

Description	Specify how the NETCONF server incorporates an individual configuration element into the candidate configuration. If the attribute is omitted, the element is merged into the configuration according to the rules defined in “Setting the Edit Configuration Mode” on page 629 . The following are acceptable values: <ul style="list-style-type: none"> • create—Creates the specified element in the configuration only if the element does not already exist. See “Creating New Configuration Elements” on page 639. • delete—Deletes the specified element from the candidate configuration. We recommend that the <default-operation> tag element with the value none also be included in the <edit-config> tag element. See “Deleting Configuration Elements” on page 641. • replace—Replaces the specified element in the candidate configuration with the provided new configuration data. See “Replacing Configuration Elements” on page 638.
Usage Guidelines	See “Changing Individual Configuration Elements” on page 636 .
Related Documentation	<ul style="list-style-type: none"> • <configuration> in the <i>Junos XML API Configuration Developer Reference</i> • <edit-config> on page 655 • <rpc> on page 662 • xmlns on page 694

xmlns

Usage	<pre> <rpc-reply xmlns:junos="URL"> <operational-response xmlns="URL-for-DTD"> <!-- Junos XML tag elements for the requested operational data --> </operational-response> </rpc-reply> <rpc-reply xmlns:junos="URL"> <configuration xmlns="URL" junos:(changed commit)-seconds="seconds" \ junos:(changed commit)-localtime="YYY-MM-DD hh:mm:ss TZ" \ [junos:commit-user="username"]> <!-- Junos XML tag elements for the requested configuration data --> </configuration> </rpc-reply> </pre>
Description	<p>For operational responses, define the XML namespace for the enclosed tag elements that do not have a prefix (such as junos:) in their names. The namespace indicates which Junos XML document type definition (DTD) defines the set of tag elements in the response.</p> <p>For configuration data responses, define the XML namespace for the enclosed tag elements.</p>
Usage Guidelines	See “Requesting Operational Information” on page 594 and “Requesting Information from the Committed or Candidate Configuration” on page 599 .

Writing NETCONF Perl Client Applications

Juniper Networks provides a Perl module, called **NET::Netconf::Manager**, to help you more quickly and easily develop custom NETCONF scripts for configuring and monitoring switches, routers, and security devices. The module implements a **NET::Netconf::Manager** object that client applications can use to communicate with the NETCONF server on a device. The Perl distribution includes several sample Perl scripts, which illustrate how to use the module in scripts that perform various functions.

This chapter discusses the following topics:

- [Overview of the NETCONF::Netconf::Manager Perl Module and Sample Scripts on page 697](#)
- [Downloading the NETCONF Perl Client and Prerequisites Package on page 698](#)
- [Installing the NETCONF Perl Client and Prerequisites Package on page 699](#)
- [Tutorial: Writing Perl Client Applications on page 703](#)

Overview of the NETCONF::Netconf::Manager Perl Module and Sample Scripts

The NETCONF Perl distribution uses the same directory structure for Perl modules as the Comprehensive Perl Archive Network (<http://www.cpan.org>). This includes a **lib** directory for the **NET::Netconf** module and its supporting files, and an **examples** directory for the sample scripts.

Client applications use the **NET::Netconf::Manager** object to communicate with a NETCONF server. All of the sample scripts use this object.

The sample scripts illustrate how to perform the following functions:

- **diagnose_bgp.pl**—Illustrates how to write scripts to monitor device status and diagnose problems. The sample script extracts and displays information about a device's unestablished Border Gateway Protocol (BGP) peers from the full set of BGP configuration data. The script is provided in the **examples/diagnose_bgp** directory in the NETCONF Perl distribution.
- **get_chassis_inventory.pl**—Illustrates how to use a predefined query to request information from a device. The sample script invokes the **get_chassis_inventory** query with the **detail** option to request the same information as the Junos XML `<get-chassis-inventory><detail></get-chassis-inventory>` tag sequence and the command-line interface (CLI) **show chassis hardware detail** command. The script is

provided in the **examples/get_chassis_inventory** directory in the NETCONF Perl distribution.

- **edit_configuration.pl**—Illustrates how to change the device configuration by loading a file that contains configuration data formatted with Junos XML tag elements. The distribution includes a sample configuration file, **config.xml**; however, you can specify another configuration file on the command line. The script is provided in the **examples/edit_configuration** directory in the NETCONF Perl distribution.

For instructions on running the scripts, see the **README** or **README.html** file included in the NETCONF Perl distribution.

Downloading the NETCONF Perl Client and Prerequisites Package

To download the compressed tar archives that contains the NETCONF Perl client distribution and the prerequisites package, perform the following steps:

1. Access the Juniper Networks Customer Support Center Web page at <http://www.juniper.net/customers/support/>.
2. Under Support, click the link labeled Download Software.
3. Under the Network Management section, click the link labeled NETCONF XML Management Protocol.
4. Click the link for the appropriate software release.
5. Select the Software tab.
6. Click the links labeled NETCONF API Perl client and NETCONF API Perl client prerequisites to download the client distribution and the prerequisites package.

NOTE: The NETCONF XML protocol Perl client software should be installed and run on a regular computer with a UNIX-like operating system; it is not meant to be installed on a Juniper Networks device.

Optionally, download the packages containing the document type definitions (DTDs) and the XML Schema language representation of the Junos configuration hierarchy:

1. Access the download page at <http://www.juniper.net/support/products/xmlapi/>.
2. Click the link for the appropriate software release.
3. Select the Software tab.
4. Click the links to download the desired packages.

Related Documentation

- [Installing the NETCONF Perl Client and Prerequisites Package on page 699](#)

Installing the NETCONF Perl Client and Prerequisites Package

To install the NETCONF Perl client and the prerequisites package, perform the following procedures:

- [Verifying the Installation and Version of Perl on page 699](#)
- [Extracting the NETCONF Perl Client and Sample Scripts on page 699](#)
- [Extracting and Installing the NETCONF Perl Client Prerequisites Package on page 700](#)
- [Installing the NETCONF Perl Client on page 702](#)

Verifying the Installation and Version of Perl

Perl must be installed on your system before you install the NETCONF Perl client prerequisites package or client software. The NETCONF Perl client requires Perl version 5.6.1 or later. To confirm whether Perl is installed on your system and to determine which version of Perl is currently running, issue the following commands:

```
$ which perl
$ perl -v
```

If the issued output indicates that Perl is not installed or that the version is earlier than the required version, you must download and install Perl version 5.6.1 or later in order to use the NETCONF Perl client. The Perl source packages are located at:

<http://www.cpan.org/src/> .

After installing a suitable version of Perl, extract the NETCONF Perl client, extract and install the prerequisites package, and then install the NETCONF Perl client application.

Extracting the NETCONF Perl Client and Sample Scripts

To uncompress and extract the contents of the compressed tar archive that contains the NETCONF Perl client and sample scripts:

1. Create the directory where you want to store the **NET::Netconf** Perl client application and sample scripts, move the downloaded client application file into that directory, and then make that directory the working directory.

```
$ mkdir parent-directory
$ mv netconf-perl-release.tar.gz parent-directory
$ cd parent-directory
```

2. Uncompress and extract the contents of the NETCONF Perl client package:

- On FreeBSD and Linux systems:

```
$ tar xzf netconf-perl-release.tar.gz
```

- On Solaris systems:

```
$ gzip -dc netconf-perl-release.tar.gz | tar xf
```

where *release* is the release code, for example **10.4R2.6**. The command creates a directory called **netconf-perl-*release*** and extracts the contents of the tar archive to it. For example,

a typical filename for the compressed tar archive is **netconf-perl-10.4R2.6.tar.gz**. Extracting the contents of this archive creates the directory **netconf-perl-10.4R2.6** directly under **parent-directory** and places the application files and sample scripts into this new directory.

The **netconf-perl-release/README** file contains instructions for extracting and installing the Perl prerequisite modules, creating a **Makefile**, and installing and testing the **NET::Netconf** module.

Extracting and Installing the NETCONF Perl Client Prerequisites Package

The prerequisites package consists of C libraries, executables, and Perl modules. It must be installed on the client machine in order for the NETCONF Perl client and the included examples to work correctly. The NETCONF Perl distribution includes the **install-prereqs.pl** script, which you use to install the prerequisites. Starting with Junos OS Release 11.4, you have the option to install all Perl modules that are part of the prerequisites directly from the Comprehensive Perl Archive Network (CPAN) global repository.

To uncompress and extract the contents of the compressed tar archive containing the prerequisite files:

1. Move the downloaded prerequisites package into the **parent-directory/netconf-perl-release/** directory that was created in [“Extracting the NETCONF Perl Client and Sample Scripts” on page 699](#).

The compressed tar archive containing the prerequisite files must be uncompressed, unpacked, and installed in that directory.

2. Uncompress and extract the contents of the package:

- On FreeBSD and Linux systems:

```
$ tar xzf netconf-perl-prereqs-release.tar.gz
```

- On Solaris systems:

```
$ gzip -dc netconf-perl-prereqs-release.tar.gz | tar xf
```

where *release* is the release code, for example **10.4R2.6**. This command creates a directory called **prereqs/** and extracts the contents of the tar archive to it.

By default, the prerequisite Perl modules are installed in the standard directory, which is **/usr/local/lib/**. You can opt to install the modules in a private directory.

- To install the required modules in the standard directory:

1. Log in as root.
2. Go to the **netconf-perl-release/** directory where you extracted the contents of the prerequisites package.
3. Issue the following command:

```
# perl install-prereqs.pl -used_by example -force
```

where the **-used_by example** option is invoked to install only modules used by a specific example, and the **-force** option installs the module even if an earlier version of the module exists or if the **make test** command fails.

- To install the required modules in a private directory:

1. Set the **PERL5LIB**, **MANPATH**, and **PATH** environment variables.

```
$ setenv PERL5LIB private-directory-path
$ setenv MANPATH "$MANPATH/:$PERL5LIB/./man"
$ setenv PATH "$PATH/:$PERL5LIB/./bin"
```

For sh, ksh, and bash shells, **\$PERL5LIB** can be set with **EXPORT**
PERL5LIB=private-directory-path

2. Go to the **netconf-perl-release** directory where you extracted the contents of the prerequisites package.
3. Issue the following command:

```
$ perl install-prereqs.pl -used_by example -install_directory $PERL5LIB -force
```

where the **-used_by example** option is invoked to install only modules used by a specific example, and the **-force** option installs the module even if an earlier version of the module exists or if the **make test** command fails. The **-install_directory \$PERL5LIB** option installs the prerequisite Perl modules in the private directory that you specified in Step 1.

Starting with Junos OS Release 11.4, after issuing the **perl install-prereqs.pl** command, the script provides the option to install the prerequisites from CPAN. The CPAN module is included with standard Perl installations. If you choose to install from CPAN, the script checks that the CPAN module is installed on your system and that you have connectivity to <http://www.cpan.org>. If the CPAN module is present and connectivity is verified, installation begins automatically.

1. To install from CPAN, press Enter or type 'y' when prompted.

```
# perl install-prereqs.pl
This script installs all modules required by default.
Would you like to install the pre-requisite modules from CPAN? [y]/n y
Testing MCPAN on your system...
OK
Trying to ping CPAN
OK
These modules will be installed in the system directory.

This installation takes around 15 minutes

Begin automatic installation:
<output omitted>
```

You might be prompted for additional information during the installation. For example, if additional dependent modules are required for a specific module, the installer might ask if the missing modules should be added to the install queue.

NOTE: On some systems, the firewall might reject utilities that are set to use active FTP, and CPAN installation might hang. If this is an issue, set the corresponding environment variable so that passive FTP is enabled.

Installation log files are written to **netconf-perl-release/tmp/output/**. After installation, you can view any missing dependencies by issuing the following command:

```
$ perl required-mod.pl
```

This command lists the modules that still require installation.

Installing the NETCONF Perl Client

After installing the prerequisites package as detailed in [“Extracting and Installing the NETCONF Perl Client Prerequisites Package” on page 700](#), install the NETCONF Perl client software.

To install the client software:

1. Go to the **netconf-perl-release/** directory that was created in [“Extracting the NETCONF Perl Client and Sample Scripts” on page 699](#).
2. Create the makefile.

- To install the Perl client in the standard directory (usually **/usr/local/lib**):

```
# perl Makefile.PL
```

```
Checking if your kit is complete...
Looks good
Writing Makefile for netconf-perl
```

- To install the Perl client in a private directory:

Make sure that the **PERL5LIB**, **MANPATH**, and **PATH** environment variables are set as detailed in [“Extracting and Installing the NETCONF Perl Client Prerequisites Package” on page 700](#), and create the makefile:

```
# perl Makefile.PL LIB=$PERL5LIB INSTALLMAN3DIR=$PERL5LIB/./man/man3
```

3. Install the **Net::NETCONF** module:

```
# make
# make install
```

The NETCONF Perl client application is installed and ready for use. For information about the **Net::NETCONF::Manager**, **Net::NETCONF::Transform**, or **Net::NETCONF::Trace** classes, consult the appropriate man page by invoking the **man** command and specifying the class. For example:

```
$ man Net::NETCONF::Manager
$ man Net::NETCONF::Transform
$ man Net::NETCONF::Trace
```

The sample scripts reside in the **netconf-perl-release/examples/** directory. You can review and run these examples to acquire some familiarity with the client before writing your own applications.

Tutorial: Writing Perl Client Applications

This tutorial explains how to write a Perl client application that requests operational or configuration information from the NETCONF server or loads configuration information onto a device. The following sections use the sample scripts included in the NETCONF XML Protocol Perl distribution as examples:

- [Import Perl Modules and Declare Constants on page 703](#)
- [Connect to the NETCONF Server on page 704](#)
- [Submitting a Request to the NETCONF Server on page 708](#)
- [Parsing and Formatting the Response from the NETCONF Server on page 716](#)
- [Closing the Connection to the NETCONF Server on page 718](#)

Import Perl Modules and Declare Constants

Include the following statement at the start of the application. This statement imports the functions provided by the **Net::Netconf::Manager** object, which the application uses to connect to the NETCONF server on a device.

```
use Net::Netconf::Manager;
```

Include statements to import other Perl modules as appropriate for your application. For example, several of the sample scripts import the following standard Perl modules, which include functions that handle input from the command line:

- **Carp**—Includes functions for user error warnings.
- **Getopt::Std**—Includes functions for reading in keyed options from the command line.
- **Term::ReadKey**—Includes functions for controlling terminal modes, for example suppressing onscreen echo of a typed string such as a password.

If the application uses constants, declare their values at this point. For example, the sample **diagnose_bgp.pl** script includes the following statement to declare a constant for the access method:

```
use constant VALID_ACCESS_METHOD => 'ssh';
```

The **edit_configuration.pl** script includes the following statements to declare constants for reporting return codes and the status of the configuration database:

```
use constant REPORT_SUCCESS => 1;
use constant REPORT_FAILURE => 0;
use constant STATE_CONNECTED => 1;
use constant STATE_LOCKED => 2;
use constant STATE_CONFIG_LOADED => 3;
```

Connect to the NETCONF Server

The following sections explain how to use the **NET::Netconf::Manager** object to connect to the NETCONF server on a device:

- [Satisfy Protocol Prerequisites on page 704](#)
- [Group Requests on page 704](#)
- [Obtain and Record Parameters Required by the NET::Netconf::Manager Object on page 704](#)
- [Obtain Application-Specific Parameters on page 707](#)
- [Establishing the Connection on page 708](#)

Satisfy Protocol Prerequisites

The NETCONF server supports several access protocols. For each connection to the NETCONF server on a device, the application must specify the protocol it is using. Client Perl applications can communicate with the NETCONF server via SSH only.

Before your application can run, you must satisfy the prerequisites for SSH. This involves enabling NETCONF on the device (**set system services netconf ssh**).

Group Requests

Establishing a connection to the NETCONF server on a device is one of the more time-intensive and resource-intensive functions performed by an application. If the application sends multiple requests to a device, it makes sense to send all of them within the context of one connection. If your application sends the same requests to multiple devices, you can structure the script to iterate through either the set of devices or the set of requests. Keep in mind, however, that your application can effectively send only one request to one NETCONF server at a time. This is because the **NET::Netconf::Manager** object does not return control to the application until it receives the closing `</rpc-reply>` tag that represents the end of the NETCONF server's response to the current request.

Obtain and Record Parameters Required by the NET::Netconf::Manager Object

The **NET::Netconf::Manager** object takes the following required parameters, specified as keys in a Perl hash:

- The access protocol to use when communicating with the NETCONF server (key name: **access**). Before the application runs, satisfy the SSH prerequisites.
- The name of the device to which to connect (key name: **hostname**). For best results, specify either a fully-qualified hostname or an IP address.
- The username under which to establish the connection to the NETCONF server and issue requests (key name: **login**). The username must already exist on the specified device and have the permission bits necessary for making the requests invoked by the application.
- The password for the username (key name: **password**).

The sample scripts record the parameters in a Perl hash called **%deviceinfo**, declared as follows:

```
my %deviceinfo = (
    'access' => $access,
    'login' => $login,
    'password' => $password,
    'hostname' => $hostname,
);
```

The sample scripts obtain the parameters from options entered on the command line by a user. Your application can also obtain values for the parameters from a file or database, or you can hardcode one or more of the parameters into the application code if they are constant.

Example: Collect Parameters Interactively

Each sample script obtains the parameters required by the **NET::Netconf::Manager** object from command-line options provided by the user who invokes the script. The script records the options in a Perl hash called **%opt**, using the **getopts** function defined in the **Getopt::Std** Perl module to read the options from the command line. (Scripts used in production environments probably do not obtain parameters interactively, so this section is important mostly for understanding the sample scripts.)

In the following example from the **get_chassis_inventory.pl** script, the first parameter to the **getopts** function defines the acceptable options, which vary depending on the application. A colon after the option letter indicates that it takes an argument.

The second parameter, **\%opt**, specifies that the values are recorded in the **%opt** hash. If the user does not provide at least one option, provides an invalid option, or provides the **-h** option, the script invokes the **output_usage** subroutine, which prints a usage message to the screen:

```
my %opt;
getopts('!p:d:x:f:m:o:h', \%opt) || output_usage();
output_usage() if $opt{'h'};
```

The following code defines the **output_usage** subroutine for the **get_chassis_inventory.pl** script. The contents of the **my \$usage** definition and the **Where** and **Options** sections are specific to the script, and differ for each application.

```
sub output_usage
{
    my $usage = "Usage: $0 [options] <target>
```

Where:

<target> The hostname of the target device.

Options:

```
-l <login> A login name accepted by the target device.
-p <password> The password for the login name.
-m <access> Access method. The only supported method is 'ssh'.
-x <format> The name of the XSL file to display the response.
           Default: xsl/chassis_inventory.xsl
```

```
-f <xmlfile> The name of the XML file to print server response to.  
              Default: xml/chassis_inventory.xml  
-o <filename> output is written to this file instead of standard output.  
-d <level>   Debug level [1-6]\n\n";
```

```
    croak $usage;  
}
```

The `get_chassis_inventory.pl` script includes the following code to obtain values from the command line for the parameters required by the `NET::Netconf::Manager` object. A detailed discussion of the various functional units follows the complete code sample.

```
# Get the hostname  
my $hostname = shift || output_usage();  
  
# Get the access method, can be ssh only  
my $access = $opt{'m'} || 'ssh';  
use constant VALID_ACCESS_METHOD => 'ssh';  
output_usage() unless (VALID_ACCESS_METHOD =~ /$access/);  
  
# Check for login name. If not provided, prompt for it  
my $login = "";  
if ($opt{'l'}) {  
    $login = $opt{'l'};  
} else {  
    print STDERR "login: ";  
    $login = ReadLine 0;  
    chomp $login;  
}  
  
# Check for password. If not provided, prompt for it  
my $password = "";  
if ($opt{'p'}) {  
    $password = $opt{'p'};  
} else {  
    print STDERR "password: ";  
    ReadMode 'noecho';  
    $password = ReadLine 0;  
    chomp $password;  
    ReadMode 'normal';  
    print STDERR "\n";  
}
```

In the first line of the preceding code sample, the script uses the Perl `shift` function to read the hostname from the end of the command line. If the hostname is missing, the script invokes the `output_usage` subroutine to print the usage message, which specifies that a hostname is required:

```
my $hostname = shift || output_usage();
```

The script next determines which access protocol to use, setting the `$access` variable to the value of the `-m` command-line option. If the specified value does not match the only valid value defined by the `VALID_ACCESSSES` constant, the script invokes the `output_usage` subroutine to print the usage message.

```
my $access = $opt{'m'} || 'ssh';
use constant VALID_ACCESS_METHOD => 'ssh';
output_usage() unless (VALID_ACCESS_METHOD =~ /$access/);
```

The script then determines the username, setting the `$login` variable to the value of the `-l` command-line option. If the option is not provided, the script prompts for it and uses the `ReadLine` function (defined in the standard Perl `Term::ReadKey` module) to read it from the command line:

```
my $login = "";
if ($opt{'l'}) {
    $login = $opt{'l'};
} else {
    print STDERR "login: ";
    $login = ReadLine 0;
    chomp $login;
}
```

The script finally determines the password for the username, setting the `$password` variable to the value of the `-p` command-line option. If the option is not provided, the script prompts for it. It uses the `ReadMode` function (defined in the standard Perl `Term::ReadKey` module) twice: first to prevent the password from echoing visibly on the screen and then to return the shell to normal (echo) mode after it reads the password:

```
my $password = "";
if ($opt{'p'}) {
    $password = $opt{'p'};
} else {
    print STDERR "password: ";
    ReadMode 'noecho';
    $password = ReadLine 0;
    chomp $password;
    ReadMode 'normal';
    print STDERR "\n";
}
```

Obtain Application-Specific Parameters

In addition to the parameters required by the `NET::Netconf::Manager` object, applications might need to define other parameters, such as the name of the file to which to write the data returned by the NETCONF server in response to a request, or the name of the Extensible Stylesheet Transformation Language (XSLT) file to use for transforming the data.

As with the parameters required by the `NET::Netconf::Manager` object, your application can hardcode the values in the application code, obtain them from a file, or obtain them interactively. The sample scripts obtain values for these parameters from command-line options in the same manner as they obtain the parameters required by the `NET::Netconf::Manager` object. Several examples follow.

The following line enables a debugging trace if the user includes the **-d** command-line option.

```
my $debug_level = $opt{'d'};
```

The following line sets the **\$outputfile** variable to the value specified by the **-o** command-line option. It names the local file to which the NETCONF server's response is written. If the **-o** option is not provided, the variable is set to the empty string.

```
my $outputfile = $opt{'o'} || "";
```

The following code from the **diagnose_bgp.pl** script defines which XSLT file to use to transform the NETCONF server's response. The first line sets the **\$xslfile** variable to the value specified by the **-x** command-line option. If the option is not provided, the script uses the **text.xsl** file supplied with the script, which transforms the data to ASCII text. The **if** statement verifies that the specified XSLT file exists; the script terminates if it does not.

```
# Get the xsl file
my $xslfile = $opt{'x'} || "xsl/bgp.xsl";

# Check for the existence of the given file
if (! -f $xslfile) {
    croak "XSL file $xslfile does not exist.";
}
```

Establishing the Connection

After obtaining values for the parameters required for the **NET::Netconf::Manager** object, each sample script records them in the **%deviceinfo** hash:

```
my %deviceinfo = (
    'access' => $access,
    'login' => $login,
    'password' => $password,
    'hostname' => $hostname,
);
```

The script then invokes the NETCONF-specific **new** subroutine to create a **NET::Netconf::Manager** object and establish a connection to the specified routing, switching, or security platform. If the connection attempt fails (as tested by the **ref** operator), the script exits.

```
my $jnx = new Net::Netconf::Manager(%deviceinfo);
unless (ref $jnx) {
    croak "ERROR: $deviceinfo{hostname}: failed to connect.\n";
}
```

Submitting a Request to the NETCONF Server

After establishing a connection to a NETCONF server (see [“Submitting a Request to the NETCONF Server” on page 708](#)), your application can submit one or more requests by invoking the Perl methods that are supported in the version of the NETCONF XML protocol and Junos XML API used by the application:

- Each version of software supports a set of methods that correspond to CLI operational mode commands (later releases generally support more methods). For a list of the operational methods supported in the current version, see the files stored in the

`lib\Net\Netconf\Plugins\Plugin\release` directory of the NETCONF Perl distribution (*release* is the Junos OS version code, such as **6.1R1** for the initial version of Junos OS Release 6.1). The files have names in the format *package_methods.pl*, where *package* is a software package.

- The set of methods that correspond to operations on configuration objects is defined in the `lib/Net/Netconf/Plugins.pm` file in the NETCONF distribution.

See the following sections for more information:

- [Providing Method Options or Attributes on page 709](#)
- [Submitting a Request on page 711](#)
- [Example: Get an Inventory of Hardware Components on page 712](#)
- [Example: Edit Configuration Statements on page 713](#)

Providing Method Options or Attributes

Many Perl methods have one or more options or attributes. The following list describes the notation used to define a method's options in the `lib/Net/Netconf/Plugins.pm` and `lib/Net/Netconf/release/package_methods.pl` files, and the notation that an application uses when invoking the method:

- A method without options is defined as **\$NO_ARGS**, as in the following entry for the `get_autoinstallation_status_information` method:

```
## Method : get-autoinstallation-status-information
## Returns: autoinstallation-status-information
## Command: "show system autoinstallation status"
get_autoinstallation_status_information => $NO_ARGS,
```

To invoke a method without options, follow the method name with an empty set of parentheses as in the following example:

```
$jnx->get_autoinstallation_status_information( );
```

- A fixed-form option is defined as type **\$TOGGLE**. In the following example, the `get_software_information` method takes two fixed-form options, **brief** and **detail**:

```
## Method : <get-ancp-neighbor-information>
## Returns: <ancp-neighbor-information>
## Command: "show ancp neighbor"
get_ancp_neighbor_information => {
    brief => $TOGGLE,
    detail => $TOGGLE,
}
```

To include a fixed-form option when invoking a method, set it to the value **1** (one) as in the following example:

```
$jnx->get-ancp-neighbor-information(brief => 1);
```

- An option with a variable value is defined as type **\$STRING**. In the following example, the `get_cos_drop_profile_information` method takes the **profile_name** argument:

```
## Method : <get-passive-monitoring-usage-information>
## Returns: <passive-monitoring-usage-information>
```

```
## Command: "show passive-monitoring usage"
get_passive_monitoring_usage_information => {
  interface_name => $STRING,
}
```

To include a variable value when invoking a method, enclose the value in single quotes as in the following example:

```
$jnx->get_cos_drop_profile_information(profile_name => 'user-drop-profile');
```

- A set of configuration statements or corresponding tag elements is defined as type **\$DOM**. In the following example, the **get_config** method takes a set of configuration statements (along with two attributes):

```
'get_config' => {
  'source' => $DOM_STRING,
  'source_url' => $URL_STRING,
  'filter' => $DOM
},
```

A DOM object is XML code:

```
my $xml_string = "
<filter type=\"subtree\">
<configuration>
  <protocols>
    <bgp></bgp>
  </protocols>
</configuration>
</filter>
";

my %queryargs = (
  'source' => "running",
  'filter' => $xml_string,
);
```

This generates an RPC request:

```
<rpc message-id='1'> <get-config> <source> <running/> </source>
<filter type="subtree">
<configuration>
  <protocols>
    <bgp></bgp>
  </protocols>
</configuration>
</filter>
</get-config></rpc>
```

A method can have a combination of fixed-form options, options with variable values, attributes, and a set of configuration statements. For example, the **get_forwarding_table_information** method has four fixed-form options and five options with variable values:

```
## Method : <get-forwarding-table-information>
## Returns: <forwarding-table-information>
## Command: "show route forwarding-table"
get_forwarding_table_information => {
```

```

detail => $TOGGLE,
extensive => $TOGGLE,
multicast => $TOGGLE,
family => $STRING,
vpn => $STRING,
summary => $TOGGLE,
matching => $STRING,
destination => $STRING,
label => $STRING,
},

```

Submitting a Request

The following code is the recommended way to send a request to the NETCONF server and shows how to handle error conditions. The `$jnx` variable is defined to be a `NET::Netconf::Manager` object.

```

my $res; # Netconf server response

# connect to the Netconf server
my $jnx = new Net::Netconf::Manager(%deviceinfo);
unless (ref $jnx) {
    croak "ERROR: $deviceinfo{hostname}: failed to connect.\n";
}

# Lock the configuration database before making any changes
print "Locking configuration database ... \n";
my %queryargs = ( 'target' => 'candidate' );
$res = $jnx->lock_config(%queryargs);

# See if you got an error
if ($jnx->has_error) {
    print "ERROR: in processing request \n $jnx->{'request'} \n";
    graceful_shutdown($jnx, STATE_CONNECTED, REPORT_FAILURE);
}

# Load the configuration from the given XML file
print "Loading configuration from $xmlfile \n";
if (! -f $xmlfile) {
    print "ERROR: Cannot load configuration in $xmlfile\n";
    graceful_shutdown($jnx, STATE_LOCKED, REPORT_FAILURE);
}

# Read in the XML file
my $config = read_xml_file($xmlfile);
print "\n\n$config \n\n";

%queryargs = (
    'target' => 'candidate',
    'config' => $config
);
$res = $jnx->edit_config(%queryargs);

# See if you got an error
if ($jnx->has_error) {
    print "ERROR: in processing request \n $jnx->{'request'} \n";
}

```

```
# Get the error
my $error = $jnx->get_first_error();
get_error_info(%$error);
# Disconnect
graceful_shutdown($jnx, STATE_LOCKED, REPORT_FAILURE);
}

# Commit the changes
print "Committing the edit-config changes ...\n";
$jnx->commit();
if ($jnx->has_error) {
    print "ERROR: Failed to commit the configuration.\n";
    graceful_shutdown($jnx, STATE_CONFIG_LOADED, REPORT_FAILURE);
}

# Unlock the configuration database and
# disconnect from the Netconf server
print "Disconnecting from the Netconf server ...\n";
graceful_shutdown($jnx, STATE_LOCKED, REPORT_SUCCESS);
```

Example: Get an Inventory of Hardware Components

The **get_chassis_inventory.pl** script retrieves and displays a detailed inventory of the hardware components installed in a routing, switching, or security platform. It is equivalent to issuing the **show chassis hardware detail** command.

After establishing a connection to the NETCONF server, the script defines **get_chassis_inventory** as the request to send and includes the **detail** argument:

```
my $query = "get_chassis_inventory";
my %queryargs = ( 'detail' => 1 );
```

The script sends the query and assigns the results to the **\$res** variable. It performs two tests on the results, and prints an error message if it cannot send the request or if errors occurred when executing it. If no errors occurred, the script uses XSLT to transform the results.

```
# send the command and get the server response
my $res = $jnx->$query(%queryargs);
print "Server request: \n $jnx->{'request'}\n Server response: \n $jnx->{'server_response'}\n";

# print the server response into xmlfile
print_response($xmlfile, $jnx->{'server_response'});

# See if you got an error
if ($jnx->has_error) {
    croak "ERROR: in processing request \n $jnx->{'request'} \n";
} else {
    # Transform the server response using XSL file
    my $res = new Net::Netconf::Transform();
    print "Transforming ...\n";
    my $nm = $res->translateXSLtoRelease('xmlns:lc', $xmlfile,
                                        "$xmlfile.tmp",
                                        $xmlfile);
    if ($nm) {
        format_by_xslt($nm, $xmlfile, );
    }
}
```

```

    } else {
        print STDERR "ERROR: Invalid XSL File $xslfile\n";
    }
}

# Disconnect from the Netconf server
$jnx->disconnect();

```

Example: Edit Configuration Statements

The `edit_configuration.pl` script edits configuration statements and loads the configuration onto a device. It uses the basic structure for sending requests but also defines a `graceful_shutdown` subroutine that handles errors. The following sections describe the different functions that the script performs:

- [Handling Error Conditions on page 713](#)
- [Locking the Configuration on page 714](#)
- [Reading In the Configuration Data on page 714](#)
- [Editing the Configuration Data on page 715](#)
- [Committing the Configuration on page 716](#)

Handling Error Conditions

The `graceful_shutdown` subroutine in the `edit_configuration.pl` script handles errors in a slightly more elaborate manner than the generic structure described in “[Handling Error Conditions](#)” on page 713. It employs the following additional constants:

```

# query execution status constants
use constant REPORT_SUCCESS => 1;
use constant REPORT_FAILURE => 0;
use constant STATE_CONNECTED => 1;
use constant STATE_LOCKED => 2;
use constant STATE_CONFIG_LOADED => 3;

```

The first two `if` statements in the subroutine refer to the `STATE_CONFIG_LOADED` and `STATE_LOCKED` conditions, which apply specifically to loading a configuration in the `edit_configuration.pl` script.

```

sub graceful_shutdown
{
    my ($jnx, $state, $success) = @_;
    if ($state >= STATE_CONFIG_LOADED) {
        # We have already done an <edit-config> operation
        # - Discard the changes
        print "Discarding the changes made ...\n";
        $jnx->discard_changes();
        if ($jnx->has_error) {
            print "Unable to discard <edit-config> changes\n";
        }
    }

    if ($state >= STATE_LOCKED) {
        # Unlock the configuration database
        $jnx->unlock_config();
        if ($jnx->has_error) {

```

```

        print "Unable to unlock the candidate configuration\n";
    }
}

if ($state >= STATE_CONNECTED) {
    # Disconnect from the Netconf server
    $jnx->disconnect();
}

if ($success) {
    print "REQUEST succeeded !!\n";
} else {
    print "REQUEST failed !!\n";
}

exit;
}

```

Locking the Configuration

The main section of the **edit_configuration.pl** script begins by establishing a connection to a NETCONF server. It then invokes the **lock_configuration** method to lock the configuration database. In case of error, the script invokes the **graceful_shutdown** subroutine described in [“Handling Error Conditions” on page 713](#).

```

print "Locking configuration database ...\n";
my %queryargs = ( 'target' => 'candidate' );
$res = $jnx->lock_config(%queryargs);
# See if you got an error
if ($jnx->has_error) {
    print "ERROR: in processing request \n $jnx->{'request'} \n";
    graceful_shutdown($jnx, STATE_CONNECTED, REPORT_FAILURE);
}

```

Reading In the Configuration Data

In the following code sample, the **edit_configuration.pl** script reads in and parses a file that contains Junos XML configuration tag elements or ASCII-formatted statements. A detailed discussion of the functional subsections follows the complete code sample.

```

# Load the configuration from the given XML file
print "Loading configuration from $xmlfile \n";
if (! -f $xmlfile) {
    print "ERROR: Cannot load configuration in $xmlfile\n";
    graceful_shutdown($jnx, STATE_LOCKED, REPORT_FAILURE);
}

# Read in the XML file
my $config = read_xml_file($xmlfile);
print "\n\n$config \n\n";

%queryargs = (
    'target' => 'candidate'
);

# If we are in text mode, use config-text arg with wrapped
# configuration-text, otherwise use config arg with raw XML

```

```

if ($opt{t}) {
    $queryargs{'config-text'} = '<configuration text> . $config . </configuration-text>';
} else {
    $queryargs{'config'} = $config;

```

The first subsection of the preceding code sample verifies the existence of the file containing configuration data. The name of the file was previously obtained from the command line and assigned to the `$xmlfile` variable. If the file does not exist, the script invokes the `graceful_shutdown` subroutine.

```

print "Loading configuration from $xmlfile \n";
if (! -f $xmlfile) {
    print "ERROR: Cannot load configuration in $xmlfile\n";
    graceful_shutdown($jnx, STATE_LOCKED, REPORT_FAILURE);
}

```

The script then invokes the `read_xml_file` subroutine, which opens the file for reading and return its contents in the `$config` variable. The `queryargs` key `target` is set to the value `candidate`. When the script calls the `edit_configuration` method, the candidate configuration is edited.

```

# Read in the XML file
my $config = read_xml_file($xmlfile);
print "\n\n$config \n\n";

%queryargs = (
    'target' => 'candidate'
);

```

If the `-t` command-line option was included when the `edit_configuration.pl` script was invoked, the file referenced by the `$xmlfile` variable should contain ASCII-formatted configuration statements like those returned by the CLI configuration-mode `show` command. If the configuration statements are in ASCII-formatted text, the script encloses the configuration stored in the `$config` variable within the `<configuration-text>` tag element and stores the result in the value associated with the `queryargs` hash key `config-text`.

If the `-t` command-line option was not included when the `edit_configuration.pl` script was invoked, the file referenced by the `$xmlfile` variable contains Junos XML configuration tag elements. In this case, the script stores just the `$config` variable as the value associated with the `queryargs` hash key `config`.

```

if ($opt{t}) {
    $queryargs{'config-text'} = '<configuration text> . $config . </configuration-text>';
} else {
    $queryargs{'config'} = $config;

```

Editing the Configuration Data

The script now invokes the `edit_config` method to edit the candidate configuration on the device. It invokes the `graceful_shutdown` subroutine if the response from the NETCONF server has errors.

```

$res = $jnx->edit_config(%queryargs);

```

```
# See if you got an error
if ($jnx->has_error) {
    print "ERROR: in processing request \n $jnx->{'request'} \n";
    # Get the error
    my $error = $jnx->get_first_error();
    get_error_info(%$error);
    # Disconnect
    graceful_shutdown($jnx, STATE_LOCKED, REPORT_FAILURE);
}
```

Committing the Configuration

If there are no errors, the script invokes the **commit** method:

```
# Commit the changes
print "Committing the <edit-config> changes ... \n";
$jnx->commit();
if ($jnx->has_error) {
    print "ERROR: Failed to commit the configuration.\n";
    graceful_shutdown($jnx, STATE_CONFIG_LOADED, REPORT_FAILURE);
}
```

Parsing and Formatting the Response from the NETCONF Server

As the last step in sending a request, the application verifies that there are no errors with the response from the NETCONF server. It can then write the response to a file, to the screen, or both. If the response is for an operational query, the application usually uses XSLT to transform the output into a more readable format, such as HTML or formatted ASCII. If the response consists of configuration data, the application can store it as XML (the Junos XML tag elements generated by default from the NETCONF server) or transform it into formatted ASCII text.

The following sections discuss parsing and formatting options:

- [Parsing and Formatting an Operational Response on page 716](#)

Parsing and Formatting an Operational Response

The following code sample from the **diagnose_bgp.pl** script uses XSLT to transform an operational response from the NETCONF server into a more readable format. A detailed discussion of the functional subsections follows the complete code sample.

```
# Get the output file
my $outputfile = $opt{'o'} || "";

# Get the xsl file
my $xslfile = $opt{'x'} || "xsl/bgp.xsl";

# Check for the existence of the given file
if (! -f $xslfile) {
    croak "XSL file $xslfile does not exist.";
}

# Get the xmlfile
my $xmlfile = $opt{'f'} || "xsl/bgp.xml";

# send the command and get the server response
```

```

my $res = $jnx->$query();

# print the server response into xmlfile
print_response($xmlfile, $jnx->{'server_response'});

# See if you got an error
if ($jnx->has_error) {
    croak "ERROR: in processing request \n $jnx->{'request'} \n";
} else {
    # Transform the server response using XSL file
    my $res = new Net::Netconf::Transform();
    print "Transforming ...\n";
    my $nm = $res->translateXSLtoRelease('xmlns:lc', $xslfile,
                                        "$xslfile.tmp",
                                        $xmlfile);

    if ($nm) {
        format_by_xslt($nm, $xmlfile, );
    } else {
        print STDERR "ERROR: Invalid XSL File $xslfile\n";
    }
}

```

The first line of the preceding code sample illustrates how the scripts read the `-o` option from the command line to obtain the name of the file into which to write the results of the XSLT transformation:

```
my $outputfile = $opt{'o'} || "";
```

From the `-x` command-line option, the scripts obtain the name of the XSLT file to use, setting a default value if the option is not provided. The scripts exit if the specified file does not exist. The following example is from the **diagnose_bgp.pl** script:

```

my $xslfile = $opt{'x'} || "xsl/bgp.xsl";
if (! -f $xslfile) {
    croak "XSL file $xslfile does not exist.";
}

```

For examples of XSLT files, see the following directories in the NETCONF Perl distribution:

- The **examples/diagnose_bpg/xsl** directory contains an XSLT file for the **diagnose_bpg.pl** script.
- The **examples/get_chassis_inventory/xsl** directory contains XSLT files for the **get_chassis_inventory.pl** script.

The actual parsing operation invokes the **translateXSLtoRelease** function (defined in the **Net::Netconf::Transform** module) to alter one of the namespace definitions in the XSLT file.

```

my $res = new Net::Netconf::Transform();
print "Transforming ...\n";
my $nm = $res->translateXSLtoRelease('xmlns:lc', $xslfile,
                                    "$xslfile.tmp",
                                    $xmlfile);

if ($nm) {
    format_by_xslt($nm, $xmlfile, );
} else {

```

```
        print STDERR "ERROR: Invalid XSL File $xslfile\n";
    }
```

This is necessary because the XSLT 1.0 specification requires that every XSLT file define a specific value for each default namespace used in the data being transformed. The **xmlns** attribute in a NETCONF operational response tag element includes a code representing the Junos OS version, such as **10.3R1** for the initial version of Junos OS Release 10.3. Because the same XSLT file can be applied to operational response tag elements from devices running different versions of the Junos OS, the XSLT file cannot predefine an **xmlns** namespace value that matches all versions. The **translateXSLtoRelease** function alters the namespace definition in the XSLT file identified by the **\$xslfile** variable to match the value in the NETCONF server's response. It assigns the resulting XSLT file to the **\$nm** variable.

After verifying that the **translateXSLtoRelease** function succeeded, the script invokes the **format_by_xslt** function, which builds a command string and assigns it to the **\$command** variable. The first part of the command string invokes the **xsltproc** command and specifies the names of the XSLT and configuration data files (**\$xslfile** and **\$xmlfile**):

```
sub format_by_xslt
{
    my ($xslfile, $xmlfile, $outfile) = @_ ;

    print "Transforming $xmlfile with $xslfile...\n" if $outfile;
    my $command = "xsltproc $xslfile $xmlfile";
    $command .= "> $outfile" if $outfile;
    system($command);
    print "Done\n" if $outfile;
    print "See $outfile\n" if $outfile;
}
```

If the **\$outfile** variable is defined (the file for storing the result of the XSLT transformation exists), the script appends a string to the **\$command** variable to write the results of the **xsltproc** command to the file. (If the file does not exist, the script writes the results to standard out [stdout].) The script then invokes the **system** function to execute the command string and prints status messages to stdout.

If the **translateXSLtoRelease** function fails (the **if (\$nm)** expression evaluates to “false”), the script prints an error:

```
if ($nm) {
    format_by_xslt($nm, $xmlfile, );
} else {
    print STDERR "ERROR: Invalid XSL File $xslfile\n";
}
```

Closing the Connection to the NETCONF Server

To end the NETCONF session and close the connection to the device, each sample script invokes the **disconnect** method. Several of the scripts do this in standalone statements:

```
$jnx->disconnect();
```

The **edit_configuration.pl** script invokes the **graceful_shutdown** method instead.

```
graceful_shutdown($jnx, $xmlfile, STATE_LOCKED, REPORT_SUCCESS);
```

The **graceful_shutdown** method takes the appropriate actions with regard to the configuration database and then invokes the **disconnect** method.

NETCONF XML Management Protocol and Junos XML API Overview

The NETCONF XML management protocol is an XML-based protocol that client applications use to request and change configuration information on routing, switching, and security devices. The NETCONF XML management protocol uses an Extensible Markup Language (XML)-based data encoding for the configuration data and remote procedure calls. The NETCONF protocol defines basic operations that are equivalent to configuration mode commands in the command-line interface (CLI). Applications use the protocol operations to display, edit, and commit configuration statements (among other operations), just as administrators use CLI configuration mode commands to perform those operations.

The Junos XML API is an XML representation of Junos OS configuration statements and operational mode commands. When the client application manages a device running Junos OS, Junos XML configuration tag elements are the content to which the NETCONF XML protocol operations apply. Junos XML operational tag elements are equivalent in function to operational mode commands in the CLI, which administrators use to retrieve status information for a routing platform running Junos OS.

The NETCONF XML management protocol is described in RFC 4741, *NETCONF Configuration Protocol*, which is available at <http://www.ietf.org/rfc/rfc4741.txt>.

Client applications request or change information on a switch, router, or security device by encoding the request with tag elements from the NETCONF XML management protocol and Junos XML API and then sending it to the NETCONF server on the device. On devices running Junos OS, the NETCONF server is integrated into Junos OS and does not appear as a separate entry in process listings. The NETCONF server directs the request to the appropriate software modules within the device, encodes the response in NETCONF and Junos XML API tag elements, and returns the result to the client application. For example, to request information about the status of a device's interfaces, a client application sends

the **<get-interface-information>** tag element from the Junos XML API. The NETCONF server gathers the information from the interface process and returns it in the **<interface-information>** tag element.

You can use the NETCONF XML management protocol and Junos XML API to configure devices running Junos OS or to request information about the device configuration or operation. You can write client applications to interact with the NETCONF server, but you can also use the NETCONF XML management protocol to build custom end-user interfaces for configuration and information retrieval and display, such as a Web browser-based interface.

NETCONF Java Toolkit Overview

The NETCONF Java toolkit provides an object-oriented interface for communicating with a NETCONF server. The toolkit enables programmers familiar with the Java programming language to easily connect to a device, open a NETCONF session, construct configuration hierarchies in XML, and create and execute operational and configuration requests. You can create your own Java applications to manage and configure routing, switching, and security devices.

The NETCONF Java toolkit provides classes with methods that implement the functionality of the NETCONF protocol operations defined in [RFC 4741](#). All basic protocol operations are supported. The NETCONF XML management protocol uses XML-based data encoding for configuration data and remote procedure calls. The toolkit provides classes and methods that aid in creating, modifying, and parsing XML.

The NETCONF Java toolkit has four basic classes, which are described in [Table 32 on page 724](#).

Table 32: NETCONF Java Toolkit Classes

Class	Summary
Device	Defines the device on which the NETCONF server runs, and represents the SSHv2 connection and default NETCONF session with that device.
NetconfSession	Represents a NETCONF session established with the device on which the NETCONF server runs.
XMLBuilder	Creates XML-encoded data.
XML	XML-encoded data that represents an operational or configuration request or configuration data.

A *configuration management server* is generally a PC or workstation that is used to configure a router, switch, or security device remotely. The communication between the configuration management server and the NETCONF server via the NETCONF Java toolkit involves:

- Establishing a NETCONF session over SSHv2 between the configuration management server and the NETCONF server.

- Creating RPCs corresponding to requests and sending these requests to the NETCONF server.
- Receiving and processing the RPC replies from the NETCONF server.

To use the NETCONF Java toolkit, you must install the toolkit and add the .jar path to your CLASSPATH. For more information about installing the NETCONF Java toolkit, see [“Downloading and Installing the NETCONF Java Toolkit” on page 725](#).

Once the toolkit is installed, you connect to a device, create a NETCONF session, and execute operations by adding the associated code to a Java program file, which is then compiled and executed. For more information about creating NETCONF Java toolkit programs, see [“Creating and Executing a NETCONF Java Toolkit Program File” on page 737](#).

NOTE: Juniper Networks devices running Junos OS Release 7.5R1 or later support the NETCONF XML management protocol.

NETCONF Java Toolkit Installation

- [Downloading and Installing the NETCONF Java Toolkit on page 725](#)

Downloading and Installing the NETCONF Java Toolkit

A *configuration management server* is a PC or workstation that is used to configure a router, switch, or security device remotely. To use the NETCONF Java toolkit, download and install the toolkit on the configuration management server. The toolkit contains the Netconf.jar library, which is compatible with Java Version 1.4 and later. The following tasks are discussed:

1. [Downloading the NETCONF Java Toolkit on page 726](#)
2. [Installing the NETCONF Java Toolkit on page 726](#)
3. [Satisfying Requirements for SSHv2 Connections on page 726](#)

Downloading the NETCONF Java Toolkit

To download the NETCONF Java toolkit to the configuration management server:

1. Access the Juniper Networks Customer Support Center Web page at <http://www.juniper.net/support/>.
2. Under Support, click the Download Software link.
3. Under the Network Management section, click the NETCONF XML Management Protocol link.
4. Click the link for the appropriate software release.
5. Select the Software tab.
6. Click the NETCONF API Java Toolkit link, and download the file to the configuration management server.

Installing the NETCONF Java Toolkit

To install the NETCONF Java toolkit on the configuration management server:

1. Unzip the NETCONF API Java Toolkit zip file downloaded in the previous section.
2. Include the **Netconf.jar** file in the CLASSPATH of your local Java development environment.

For more information about setting the CLASSPATH, see <http://download.oracle.com/javase/1.4.2/docs/tooldocs/windows/classpath.html>.

3. Ensure SSHv2/NETCONF connectivity to the device on which the NETCONF server is running.

Satisfying Requirements for SSHv2 Connections

The NETCONF server communicates with client applications within the context of a NETCONF session. The server and client explicitly establish a connection and session before exchanging data, and close the session and connection when they are finished.

The NETCONF Java toolkit accesses the NETCONF server using the SSH protocol and uses the standard SSH authentication mechanism. To establish an SSHv2 connection with a device running Junos OS, you must ensure that the following requirements are met:

- The client application has a user account and can log in to each device where a NETCONF session will be established.
- The login account used by the client application has an SSH public/private key pair or a text-based password.
- The client application can access the public/private keys or text-based password.
- The NETCONF service over SSH is enabled on each device where a NETCONF session will be established.

For information about NETCONF over SSH, see RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*, which is available at <http://www.ietf.org/rfc/rfc4742.txt>.

NETCONF Java Toolkit Class: Device

A **net.juniper.netconf.Device** object represents an SSHv2 connection and a default NETCONF session between the configuration management server and the device on which the NETCONF server resides.

When creating a **Device** object, you must provide the IP address or DNS name and the authentication details to create the SSHv2 connection. Authentication can be user-password based or RSA/DSA key-based. You also have the option of specifying the port number for the SSHv2 connection and the client capabilities to be sent to the NETCONF server.

The constructor syntax is:

```
Device (String hostname, String login, String password, String pemKeyFile)
Device (String hostname, String login, String password, String pemKeyFile, int port)
Device (String hostname, String login, String password, String pemKeyFile,
        ArrayList capabilities)
Device (String hostname, String login, String password, String pemKeyFile, int port,
        ArrayList capabilities)
```

The constructor parameters are:

- **hostname**—(Required) IP address or DNS name of the device on which the NETCONF server is running and to which to connect via SSHv2.
- **login**—(Required) Username for the login account on the device on which the NETCONF server is running.
- **password**—(Required) Password for either user password-based authentication or key-based authentication. If no password is required for key-based authentication, pass this argument as null.
- **pemKeyFile**—(Required) Path of the file containing the DSA/RSA private key in PEM format for key-based authentication. For user password-based authentication, pass this argument as null.
- **port**—(Optional) Port number on which to establish the SSHv2 connection. The default port is 830. If you are connecting to a device that is configured for NETCONF over SSH on a port other than the default port, you must specify that port number in the arguments.
- **capabilities**—(Optional) Client capabilities to be communicated to the NETCONF server, if the capabilities are other than the default capabilities.

The default capabilities sent to the NETCONF server are:

```
urn:ietf:params:xml:ns:netconf:base:1.0
urn:ietf:params:xml:ns:netconf:base:1.0#candidate
urn:ietf:params:xml:ns:netconf:base:1.0#confirmed-commit
urn:ietf:params:xml:ns:netconf:base:1.0#validate
urn:ietf:params:xml:ns:netconf:base:1.0#url?protocol=http,ftp,file
```

The general syntax for creating a **Device** object is:

```
Device device_name = new Device (String hostname, String login,
                                String password, String pemKeyFile,
                                <int port>, <ArrayList capabilities>)
```

By default, a **NetconfSession** object is created when you create a new instance of **Device** and connect to a NETCONF server. Once you have created a **Device** object, you can perform NETCONF operations.

Examples The following example creates a **Device** object with an authenticated SSHv2 connection to IP address 10.10.1.1. The connection uses user password-based authentication with the login name "admin" and the password "PaSsWoRd". When the **connect()** method is called, it connects to the device and automatically establishes a default NETCONF session.

```
Device my_device = new Device("10.10.1.1", "admin", "PaSsWoRd", null);
my_device.connect();
```

To create a **Device** object with a NETCONF-over-SSH connection on port 49000 instead of the default port 830, add the port number to the constructor arguments.

```
Device my_device = new Device("10.10.1.1", "admin", "PaSsWoRd", null, 49000);
```

The default timeout value for connecting to the device is 5000 milliseconds. To set the timeout value to a different interval, call the `setTimeout()` method on the device object.

NETCONF Java Toolkit Class: NetconfSession

A `net.juniper.netconf.NetconfSession` object represents the NETCONF session between the configuration management server and the device on which the NETCONF server resides.

By default, a NETCONF session is created when you create a new instance of `Device` and connect to a NETCONF server, so you do not need to explicitly create a `NetconfSession` object. You can perform the NETCONF operations directly from the `Device` object by calling the associated methods.

However, there might be times when you need multiple NETCONF sessions on the same SSHv2 connection. To create multiple sessions, call the `createNetconfSession()` method on the `Device` object as shown in the following example:

```
Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null);
device.connect();
NetconfSession second_session = device.createNetconfSession();
```

Once you create an additional NETCONF session, you call the NETCONF operation methods for the new `NetconfSession` object in the same way as you call them for the `Device` object.

The `Device` and `NetconfSession` classes contain many identical methods, which perform NETCONF operations such as executing remote procedure calls (RPCs) and performing configuration changes. When you call a method on the `Device` object, it acts on the default NETCONF session. When you call a method on any additional `NetconfSession` object, it acts on that NETCONF session.

Example: Creating Multiple NETCONF Sessions

In the following example, the code snippet creates a new `Device` object. When the `connect()` method is called, the program connects to the remote device and establishes a default NETCONF session. The program creates a second `NetconfSession` object, `second_session`. Calling `device.getSessionID()` returns the session ID of the default NETCONF session, and calling `second_session.getSessionID()` returns the session ID of the second NETCONF session.

```
// Create a device object and a default NETCONF session
Device device = new Device("10.10.1.34", "admin", "PaSsWoRd", null);
device.connect();
```

```
// Create an additional NETCONF session
NetconfSession second_session = device.createNetconfSession();

// There are two independent NETCONF sessions
String default_session_id = device.getSessionID();
String second_session_id = second_session.getSessionID();
```

- [NETCONF Java Toolkit Class: XML on page 733](#)
- [NETCONF Java Toolkit Class: XMLBuilder on page 732](#)
- [NETCONF Java Toolkit Overview on page 724](#)

NETCONF Java Toolkit Class: XMLBuilder

In a NETCONF session, communication between the configuration management server and the NETCONF server is through XML-encoded data. The configuration management server sends remote procedure calls (RPCs) to the NETCONF server, and the NETCONF server processes the RPC and returns an RPC reply. The `net.juniper.netconf.XMLBuilder` and `net.juniper.netconf.XML` objects help create and parse XML-encoded data.

You use the XMLBuilder object to create a new XML object. The constructor syntax is:

```
XMLBuilder ()
```

The XMLBuilder class includes methods to create a configuration hierarchy, an RPC, or an XML object as XML-encoded data. Each method is overloaded to accept multiple hierarchy levels. The methods return an XML object. For example, the methods to construct a configuration, RPC, or XML object with a single-tier hierarchy are:

- `createNewConfig(String elementLevelOne)`
- `createNewRPC(String elementLevelOne)`
- `createNewXML(String elementLevelOne)`

The following sample code creates a new `XMLBuilder` object, `builder`. The `XMLBuilder` object calls the `createNewConfig()` method to construct a three-tier configuration hierarchy consisting of a “security” element, a “policies” element child tag, and a “policy” element that is a child of “policies”.

```
XMLBuilder builder = new XMLBuilder();
XML policy = builder.createNewConfig("security","policies","policy");
```

The resulting XML hierarchy is as follows.

```
<configuration>
  <security>
    <policies>
      <policy>
      </policy>
    </policies>
```

```

    </security>
  </configuration>

```

Notice that the `createNewConfig()` method always encloses the hierarchy within a top-level root element `<configuration>`. Similarly, the `createNewRPC()` method encloses the hierarchy within an `<rpc>` tag element.

Once you generate an XML object, you can call methods from the `XML` class to manipulate that object.

NETCONF Java Toolkit Class: XML

A `net.juniper.netconf.XML` object represents XML-encoded data and provides methods to modify and parse the XML. The XML object internally maintains an `org.w3c.dom.Document` object, corresponding to the XML data it represents.

It is recommended that you work with the XML object to create new configurations, remote procedure calls (RPCs), or any XML-based data. Using an XML object, you can easily add, delete, or modify elements and attributes. To facilitate modification of XML content, the XML object maintains an 'active' element, which represents the hierarchy level exposed for modification.

To create an XML object, you first create an `XMLBuilder` object and construct the initial XML hierarchy. The `XMLBuilder` methods return an XML object on which you can then build. This makes it convenient to create XML-based configurations and RPCs and also parse the XML-based replies received from the NETCONF server.

Example: Creating a Configuration Hierarchy

This example creates the following sample XML configuration hierarchy. The steps used to create the configuration hierarchy are outlined in [Table 33 on page 734](#).

```

<configuration>
  <security>
    <policies>
      <policy>
        <from-zone-name>trust</from-zone-name>
        <to-zone-name>untrust</to-zone-name>
      </policy>
      <policy>
        <name>my-sec-policy</name>
        <match>
          <source-address>any</source-address>
          <destination-address>any</destinationaddress>
          <application>junos-ftp</application>
          <application>junos-ntp</application>
          <application>junos-ssh</application>
        </match>
        <then>
          <permit>

```

```

        </permit>
      </then>
    </policy>
  </policies>
</security>
</configuration>

```

Creating NETCONF Java Toolkit Program Files

- [Creating and Executing a NETCONF Java Toolkit Program File on page 737](#)
- [Example: Using the NETCONF Java Toolkit to Execute an Operational Request RPC on page 739](#)

Creating and Executing a NETCONF Java Toolkit Program File

You can use the NETCONF Java toolkit to connect to a device, open a NETCONF session, and create and execute operational and configuration requests. After installing the NETCONF Java toolkit, which is described in [“Downloading and Installing the NETCONF Java Toolkit” on page 725](#), the general procedure is:

1. Create a Java program that includes code to connect to a device and to execute the desired operations or requests.
2. Compile the Java code and execute the program.

These steps are reviewed in detail in the following sections:

- [Creating a NETCONF Java Toolkit Program File on page 737](#)
- [Compiling and Executing a NETCONF Java Toolkit Program File on page 739](#)

Creating a NETCONF Java Toolkit Program File

NETCONF Java toolkit programs have the same generic framework. To create a basic NETCONF Java toolkit program:

1. Create a **.java** file.

The filename should be identical to the class name, excluding the extension. For example, the **ShowChassis** class is saved in the file **ShowChassis.java**.

2. Create the general boilerplate, which includes the code for import statements, the class declaration, and the Java method, **main()**.

```
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.Device;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import org.xml.sax.SAXException;

public class ShowChassis {
    public static void main(String args[]) throws NetconfException,
```

```
ParserConfigurationException, SAXException, IOException {
```

```
    }  
}
```

3. Within **main()**, create a **Device** object and call the **connect()** method.

This also creates a default NETCONF session with the NETCONF server over SSHv2.

```
Device device = new Device("hostname", "username", "password", null);  
device.connect();
```

4. Execute operational and configuration requests by executing RPCs and performing NETCONF operations on the **Device** object.

For example, to execute an operational request to retrieve chassis inventory information from the device, include the following line of code:

```
XML reply = device.executeRPC("get-chassis-inventory");
```

5. Add code to print, parse, or take action on RPC replies received from the NETCONF server.

The following line of code prints the RPC reply in XML format to standard output:

```
System.out.println(reply.toString());
```

6. Close the device and release resources by calling the **close()** method on the **Device** object.

```
device.close();
```

Sample NETCONF Java Toolkit Program

The following sample code illustrates a simple NETCONF Java toolkit program, **ShowChassis.java**, which connects to a device and executes an operational request for chassis inventory information:

```
/* ShowChassis.java */  
import java.io.IOException;  
import javax.xml.parsers.ParserConfigurationException;  
import net.juniper.netconf.Device;  
import net.juniper.netconf.NetconfException;  
import net.juniper.netconf.XML;  
import org.xml.sax.SAXException;  
  
public class ShowChassis {  
    public static void main(String args[]) throws NetconfException,  
        ParserConfigurationException, SAXException, IOException {  
  
        //Create the device object and establish a NETCONF session  
        Device device = new Device("hostname", "username", "password", null);  
        device.connect();  
  
        //Send RPC and receive RPC reply as XML  
        XML rpc_reply = device.executeRPC("get-chassis-inventory");  
  
        //Print the RPC reply and close the device  
        System.out.println(rpc_reply.toString());  
        device.close();  
    }  
}
```

```
}  
}
```

Compiling and Executing a NETCONF Java Toolkit Program File

To execute a NETCONF Java toolkit program, compile the code and run the program from the configuration management server. You need a Java compiler to compile the source code and to create an executable program.

1. Compile the Java source code to create a Java class file containing Java bytecode.

For example, to compile the **ShowChassis.java** file using the `javac` compiler included in the Java Development Kit (JDK) from Oracle Corporation, you would issue the following command on the command line of the configuration management server:

```
>javac ShowChassis.java
```

This creates the **ShowChassis.class** file.

2. Execute the resulting program.

```
>java ShowChassis
```

Example: Using the NETCONF Java Toolkit to Execute an Operational Request RPC

This NETCONF Java toolkit program executes an RPC to obtain operational information from a device, which is then printed to standard output. This example serves as an instructional example for creating and executing a basic NETCONF Java toolkit program.

- [Requirements on page 739](#)
- [Overview on page 739](#)
- [Configuration on page 740](#)
- [Verification on page 741](#)
- [Troubleshooting on page 742](#)

Requirements

- NETCONF Java toolkit is installed on the configuration management server.
- Client application can log in to the device where the NETCONF server resides.
- NETCONF service over SSH is enabled on the device where the NETCONF server resides.

Overview

You can use the NETCONF Java toolkit to request operational information from a remote device. The following example illustrates how to create a NETCONF Java toolkit program to execute an operational request from the Junos XML API on a device running Junos OS. The example also explains how to compile the code, execute the program, and verify the results.

Configuration

Creating the Java Program

Step-by-Step Procedure

To construct the Java program file that contains the code for the operational request:

1. Give the file a descriptive name.

The filename must be the same as the class name. For this example, the file and class are named **GetChassisInventory**.

2. Include the appropriate import statements, and the code for the class declaration and the Java method, **main()**.

```
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.Device;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import org.xml.sax.SAXException;

public class GetChassisInventory {
    public static void main(String args[]) throws NetconfException,
        ParserConfigurationException, SAXException, IOException {
    }
}
```

3. Within **main()**, create a **Device** object and call the **connect()** method.

This creates a default NETCONF session over SSHv2 with the NETCONF server. You must update the code with the appropriate arguments for connection to and authentication on your specific device.

```
Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null);
device.connect();
```

Having established a **Device** object, you can perform NETCONF operations on the device. For a complete list of available methods corresponding to NETCONF operations, refer to the NETCONF Java toolkit Javadocs.

4. Call the **executeRPC()** method with the operational request RPC command as the argument.

This example uses the Junos XML API **get-chassis-inventory** RPC. The reply, which is returned in XML, is stored in the **rpc_reply** variable.

```
XML rpc_reply = device.executeRPC("get-chassis-inventory");
```

5. Add code to take action on the RPC reply.

The following code converts the NETCONF server's reply to a string and prints it to the screen:

```
System.out.println(rpc_reply.toString());
```

6. Close the device and release resources by calling the **close()** method on the device object.

```
device.close();
```

Results The complete program is:

```

/*GetChassisInventory*/
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.Device;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import org.xml.sax.SAXException;

public class GetChassisInventory {
    public static void main(String args[]) throws NetconfException,
        ParserConfigurationException, SAXException, IOException {

        Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);
        device.connect();
        XML rpc_reply = device.executeRPC("get-chassis-inventory");
        System.out.println(rpc_reply.toString());
        device.close();
    }
}

```

Compiling and Running the Java Program

Step-by-Step Procedure You need a Java compiler to compile the source code and to create an executable program.

To compile the code and run the program on the configuration management server:

1. Compile the **GetChassisInventory.java** file.

```
>javac GetChassisInventory.java
```
2. Execute the resulting **GetChassisInventory** program.

```
>java GetChassisInventory
```

Verification

Verifying Program Execution

Purpose Verify that the GetChassisInventory program runs correctly.

Action If the program executes successfully, it establishes a connection and creates a NETCONF session with the specified device. The program sends the **get-chassis-inventory** RPC to the NETCONF server, and the server responds with the requested operational information enclosed in the **<rpc-reply>** tag element. The program prints the reply to standard out. Following is a sample RPC reply with some output omitted for brevity.

```

<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:junos="http://xml.juniper.net/junos/11.2R1/junos">
  <chassis-inventory xmlns="http://xml.juniper.net/junos/11.2R1/junos-chassis">
  <chassis junos:style="inventory">
  <name>Chassis</name>
  <serial-number>12345</serial-number>
  <description>M7i</description>

```

```
<chassis-module>
...output omitted...

</chassis>
</chassis-inventory>
</rpc-reply>
```

Troubleshooting

- [Troubleshooting NETCONF Exceptions on page 742](#)

Troubleshooting NETCONF Exceptions

Problem A NETCONF exception occurs, and you see the following error message:

```
Exception in thread "main" net.juniper.netconf.NetconfException: There was a
problem while connecting to 10.10.1.1:830
    at net.juniper.netconf.Device.createNetconfSession(Device.java:344)
    at net.juniper.netconf.Device.connect(Device.java:225)
    at GetChassisInventory.main(GetChassisInventory.java:14)
```

NETCONF over SSH might not be enabled on the device where the NETCONF server resides, or it might be enabled on a different port.

Solution Ensure that you have enabled NETCONF over SSH on the device where the NETCONF server resides. Since the example program does not specify a specific port number in the **Device** arguments, the NETCONF session is established on the default NETCONF-over-SSH port, 830. To verify whether NETCONF over SSH is enabled on the default port for a device running Junos OS, enter the following operational mode command on the remote device:

```
user@host> show configuration system services
```

```
ftp;
netconf {
    ssh;
}
```

If the **netconf** configuration hierarchy is absent, issue the following statements in configuration mode to enable NETCONF over SSH on the default port:

```
[edit]
user@host# set system services netconf ssh
user@host# commit
```

If the **netconf** configuration hierarchy specifies a port other than the default port, include the new port number in the **Device** object constructor arguments. For example, the following device is configured for NETCONF over SSH on port 12345:

```
user@host> show configuration system services
netconf {
    ssh {
        port 12345;
    }
}
```

To correct the connection issue, include the new port number in the **Device** arguments.

```
Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null, 12345);
```

Using the NETCONF Java Toolkit to Parse an RPC Reply

After submitting an operational or configuration request to the NETCONF server, the server responds with an RPC reply.

```
XML rpc_reply = device.executeRPC("get-chassis-inventory");
```

There are two approaches to parse an XML reply within the context of the NETCONF Java toolkit:

- Get the **org.w3c.dom.Document** object and use the native parsing methods available in the standard Java class libraries for a **Document** object.
- Use the **findValue(List list)** and **findNodes(List list)** methods available in the **net.juniper.netconf.XML** class on the XML object.

For the first approach, call the **getOwnerDocument()** method on the reply object to return the **Document** object.

```
Document doc = rpc_reply.getOwnerDocument();
```

You can then use methods in the standard Java libraries on the resulting **Document** object. This method is useful for the flexibility and options available in terms of the standard Java library methods.

For the second approach, the **net.juniper.netconf.XML** class contains the **findValue(List list)** and **findNodes(List list)** methods, which you can use to parse the XML object. You must include the "import java.util.*;" statement in your program code to use the functionality of the **List** interface or to create an **Arrays** object as shown in the corresponding examples.

Study the following RPC reply for the **get-interface-information** operational request:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:junos="http://xml.juniper.net/junos/11.310/junos">
  <interface-information>
    <physical-interface>
      <name>ge-0/0/0</name>
      <admin-status>up</admin-status>
      <oper-status>up</oper-status>
      /* hierarchy truncated for brevity */
    </physical-interface>
    <physical-interface>
      <name>ge-0/0/1</name>
      /* hierarchy truncated for brevity */
    </physical-interface>
  </interface-information>
</rpc-reply>
```

**Parsing an RPC Reply
Using findValue()**

You can use the **findValue()** method to determine the value of a given element at any level of the hierarchy. In the example RPC reply for **get-interface-information**, suppose you want to determine the value of the **<admin-status>** element of the physical interface **ge-0/0/0**. Being aware of the format of the RPC reply, you can extract this information using the following code:

```
XML rpc_reply = device.executeRPC("get-interface-information");
List<String> list = Arrays.asList("interface-information", "physical-interface",
    "name~ge-0/0/0", "admin-status");
String admin_status = rpc_reply.findValue(list);
System.out.println(admin_status);
```

Note that the interface name uses a tilde (~) character to identify the particular element. Execution of this code prints "up" to standard output.

**Parsing an RPC Reply
Using findNodes()**

You can use the **findNodes()** method to obtain the list of all nodes under a given hierarchy as **org.w3c.dom.Node** objects. The following code snippet obtains a list of all **<physical-interface>** nodes under the **<interface-information>** tag element in the hierarchy:

```
XML rpc_reply = device.executeRPC("get-interface-information");
List<String> list = Arrays.asList("interface-information", "physical-interface");
List physical_interfaces_list = rpc_reply.findNodes(list);
```

However, you might want to extract a specific node. The following code returns the hierarchy for the **ge-0/0/1** interface only:

```
XML rpc_reply = device.executeRPC("get-interface-information");
List<String> list = Arrays.asList("interface-information", "physical-interface",
    "name~ge-0/0/1");
List physical_interfaces_list = rpc_reply.findNodes(list);
Node ge001_node = (Node)physical_interfaces_list.get(0);
```

**Example: Parsing an
RPC Reply Using
findNodes() (Detailed)**

The following example takes this approach a step further and parses through the child nodes to extract and print the content for just the **<name>** elements. This sample code focuses on the portion of the program that parses the RPC reply and does not represent a complete program.

```
import java.util.Arrays;
import java.util.Iterator;
import java.util.List;
import org.w3c.dom.Node;
import org.w3c.dom.NodeList;

/* code omitted for brevity */

XML rpc_reply = device.executeRPC("get-interface-information");

// Obtain a list of list of 'org.w3c.dom.Node' objects
List<String> list = Arrays.asList("interface-information", "physical-interface");
List physical_interfaces_list = rpc_reply.findNodes(list);

// Print the value for each of the name elements:
Iterator iter = physical_interfaces_list.iterator();
while(iter.hasNext()) {
    Node node = (Node)iter.next();
    NodeList child_nodes_of_phy_interface = node.getChildNodes();
    // child_nodes_of_phy_interface contains nodes like <name> and <admin-status>
```

```

// Get each <name> node from the NodeList
for (int i = 0; i < child_nodes_of_phy_interface.getLength(); i++) {
    Node child_node = child_nodes_of_phy_interface.item(i);
    if (child_node.getNodeType() != Node.ELEMENT_NODE){
        continue;
    }
    if (child_node.getNodeName().equals("name")) {
        // Print the text value of the <name> node
        System.out.println(child_node.getTextContent());
    }
    break;
}
}

```

Troubleshooting Exception Errors in a NETCONF Java Toolkit Program

The following sections outline exception errors that you might encounter when executing a NETCONF Java toolkit program. These sections also present potential causes and solutions for each error.

- [Troubleshooting Connection Errors: Socket Timed Out on page 745](#)
- [Troubleshooting Connection Errors: No Connection on page 746](#)
- [Troubleshooting Authentication Errors on page 746](#)
- [Troubleshooting NETCONF Session Errors on page 747](#)

Troubleshooting Connection Errors: Socket Timed Out

Problem A NETCONF exception occurs, and you see the following error message:

```

Exception in thread "main" net.juniper.netconf.NetconfException: The connect()
operation on the socket timed out.
    at net.juniper.netconf.Device.createNetconfSession(Device.java:344)
    at net.juniper.netconf.Device.connect(Device.java:225)
    at GetChassisInventory.main(GetChassisInventory.java:14)

```

Cause Potential causes for the socket timed out error include:

- The device or interface to which you are connecting is down or unavailable.
- The IP address or DNS name in the arguments for the **Device** object is incorrect.
- The connection timeout value was exceeded before the connection was established.

Solution Ensure that the device is up and running. Also verify that the IP address or DNS name is correct in the arguments of the **Device** constructor in your program code.

The default timeout value for connecting to a device is 5000 milliseconds. To set the timeout value to a larger interval to ensure that the program has sufficient time to establish the connection, call the **setTimeout()** method on the device object. The following code sets the timeout interval to 10 seconds:

```
Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);
device.setTimeout(10000);
device.connect();
```

Troubleshooting Connection Errors: No Connection

Problem An `IllegalStateException` exception occurs, and you see the following error message:

```
Exception in thread "main" java.lang.IllegalStateException: Cannot execute RPC,
you need to establish a connection first.
    at net.juniper.netconf.Device.executeRPC(Device.java:498)
    at GetChassisInventoryRun.main(GetChassisInventoryRun.java:15)
```

Cause An SSHv2 connection or NETCONF session was not established with the remote device.

Solution Call the **connect()** method on the device object to establish an SSHv2 connection and a default NETCONF session with the device on which the NETCONF server runs. Once the connection and session are established, RPC execution should be successful.

Troubleshooting Authentication Errors

Problem A NETCONF exception occurs, and you see the following error message:

```
Exception in thread "main" net.juniper.netconf.NetconfException: Authentication
failed.
    at net.juniper.netconf.Device.createNetconfSession(Device.java:358)
    at net.juniper.netconf.Device.connect(Device.java:225)
    at GetChassisInventory.main(GetChassisInventory.java:14)

<!-- or -->
Could not connect to device:Authentication failed.
```

Cause An error message for failed authentication could have several possible causes, including the following:

- The host or authentication details passed as arguments to the **Device** constructor are incorrectly entered in the program code.
- The arguments for the **Device** object are correct, but there is no corresponding user account created on the device to which you are connecting.

Solution If there is no user account on the device to which you are connecting, create the account with the appropriate authentication. For more information about configuring user accounts on a device running Junos OS, see the *Junos OS System Basics Configuration Guide*.

If the user account exists on the remote device, but the arguments for the **Device** constructor are entered incorrectly in the program code, correct the arguments and recompile the program.

Troubleshooting NETCONF Session Errors

Problem A NETCONF exception occurs, and you see the following error message:

```
Exception in thread "main" net.juniper.netconf.NetconfException: There was a
problem while connecting to 10.10.1.1:830
    at net.juniper.netconf.Device.createNetconfSession(Device.java:344)
    at net.juniper.netconf.Device.connect(Device.java:225)
    at GetChassisInventory.main(GetChassisInventory.java:14)
```

Cause NETCONF over SSH might not be enabled on the device where the NETCONF server resides, or it might be enabled on a different port.

Solution Ensure that you have enabled NETCONF over SSH on the device where the NETCONF server resides. If your NETCONF Java toolkit program does not specify a specific port number in the **Device** arguments, the NETCONF session is established on the default NETCONF-over-SSH port, 830. To verify whether NETCONF over SSH is enabled on the default port for a device running Junos OS, enter the following operational mode command on the remote device:

```
user@host> show configuration system services
```

```
ftp;
netconf {
    ssh;
}
```

If the **netconf** configuration hierarchy is absent, issue the following statements in configuration mode to enable NETCONF over SSH on the default port:

```
[edit]
user@host# set system services netconf ssh
user@host# commit
```

If the **netconf** configuration hierarchy specifies a port other than the default port, you should include the new port number in the **Device** object constructor arguments. For example, the following device is configured for NETCONF over SSH on port 12345:

```
user@host> show configuration system services
netconf {
    ssh {
        port 12345;
    }
}
```

To correct the connection issue, include the new port number in the **Device** arguments.

```
Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null, 12345);
```

- [Using the NETCONF Java Toolkit to Perform Configuration Tasks on page 752](#)

Using the NETCONF Java Toolkit to Perform Operational Tasks

- [Using Device Object Methods to Execute RPCs and Operational Commands on page 748](#)
- [Example: Using the NETCONF Java Toolkit to Execute CLI Commands on page 749](#)

Using Device Object Methods to Execute RPCs and Operational Commands

The NETCONF Java toolkit **Device** object has methods to request information from and perform operational tasks on remote devices. When appropriate, the methods are overloaded to take a number of different formats.

- [Executing RPCs on page 748](#)
- [Executing Operational Mode Commands on page 749](#)

Executing RPCs

To execute a remote procedure call (RPC), call the **executeRPC()** method on the **Device** object. The **executeRPC()** method is overloaded to accept a **String** object, a **net.juniper.netconf.XML** object, or an **org.w3c.dom.Document** object as the argument. The RPC is processed by the NETCONF server, which returns the RPC reply as an XML object.

The method syntax is:

```
public XML executeRPC (String rpcContent)
public XML executeRPC (net.juniper.netconf.XML rpc)
public XML executeRPC (org.w3c.dom.Document rpcDoc)
```

The following code snippet executes the Junos XML API **get-chassis-inventory** RPC using a string argument. The **get-chassis-inventory** RPC is equivalent to the **show chassis hardware** operational mode command in the Junos OS command-line interface (CLI).

```
Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);
device.connect();
try {
    XML rpc_reply = device.executeRPC("get-chassis-inventory");
    System.out.println(rpc_reply.toString());
}
catch (Exception e) {
    System.out.println("exception: " + e.getMessage());
    // additional processing for exception
```

```

    }
    device.close();

```

Executing Operational Mode Commands

To execute an operational mode command to request information from or perform operational tasks on a device running Junos OS, call the `runCliCommand()` method on the `Device` object. The `runCliCommand()` method sends a Junos OS operational mode command to the NETCONF server on the remote device. The argument is a string representing the operational mode command that you would enter in the Junos OS CLI. The RPC is processed by the NETCONF server, which returns the RPC reply. Starting with Junos OS Release 11.4, the return string is the same ASCII-formatted output that you see in the Junos OS CLI. For devices running earlier versions of Junos OS, the return string contains Junos XML tag elements.

The method syntax is:

```
public String runCliCommand (String command)
```

The following code snippet sends the CLI operational mode command **show chassis hardware** to the NETCONF server on a device running Junos OS:

```

Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);
device.connect();
try {
    cli_reply = device.runCliCommand("show chassis hardware");
    System.out.println(cli_reply);
}
catch (Exception e) {
    System.out.println("exception: " + e.getMessage());
    // additional processing for exception
}
device.close();

```

Example: Using the NETCONF Java Toolkit to Execute CLI Commands

This NETCONF Java toolkit program demonstrates the `runCliCommand()` method, which sends the specified Junos OS operational mode command to the NETCONF server to request information from or perform operational tasks on a device running Junos OS.

- [Requirements on page 749](#)
- [Overview on page 750](#)
- [Configuration on page 750](#)
- [Verification on page 751](#)

Requirements

- Routing, switching, or security device running Junos OS.
- NETCONF Java toolkit is installed on the configuration management server.
- Client application can log in to the device where the NETCONF server resides.
- NETCONF service over SSH is enabled on the device where the NETCONF server resides.

Overview

The NETCONF Java toolkit **Device** class contains the **runCliCommand()** method, which takes a Junos OS CLI operational mode command and converts it to an equivalent RPC in XML that can be processed by the NETCONF server. The **runCliCommand()** method takes as an argument the string representing an operational mode command that you enter in the Junos OS CLI.

The following example executes the **show chassis hardware** command on a device running Junos OS. The return value for the method is a string. Starting with Junos OS Release 11.4, the return string is the same ASCII-formatted output that you see in the Junos OS CLI. For devices running earlier versions of Junos OS, the return string contains Junos XML tag elements.

Configuration

Creating the Java program

Step-by-Step Procedure

To construct the Java program file:

1. Give the file a descriptive name.

The filename must be the same as the class name. For this example, the file and class are named **ExecuteCLICommand**.

2. Add the code to the file and update the environment-specific variables such as the remote host IP address, username, password, and **<rpc-reply>** tag elements.

The complete Java code for the **ExecuteCLICommand.java** program is presented here.

```
/*ExecuteCLICommand*/
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.Device;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import org.xml.sax.SAXException;

public class ExecuteCLICommand {
    public static void main(String args[]) throws NetconfException,
        ParserConfigurationException, SAXException, IOException {

        String cli = "show chassis hardware";

        Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);
        device.connect();
        try {
            String cli_reply = device.runCliCommand(cli);
            System.out.println(cli_reply);
        }
        catch (Exception e) {
            System.out.println("exception: " + e.getMessage());
            // additional processing for exception
        }
        device.close();
    }
}
```

```

    }
}

```

Compiling and Running the Java Program

Step-by-Step Procedure You need a Java compiler to compile the source code and to create an executable program.

To compile the code and run the program on the configuration management server:

1. Compile the **ExecuteCLICommand.java** file.

```
>javac ExecuteCLICommand.java
```
2. Execute the resulting **ExecuteCLICommand** program.

```
>java ExecuteCLICommand
```

Verification

Verifying Program Execution

Purpose Verify that the **ExecuteCLICommand** program runs correctly.

Action If the program executes successfully, it establishes a connection and creates a NETCONF session with the specified device. The program converts the Junos OS CLI operational mode command **show chassis hardware** to an RPC and sends the RPC to the NETCONF server. The server responds with the requested operational information enclosed in the **<rpc-reply>** tag element. The program parses the RPC reply and prints the resulting chassis inventory. The following sample output is from a Juniper Networks m7i router.

On a device running Junos OS Release 11.4 or later release, the output is in ASCII-formatted text, which is identical to the output in the CLI.

Hardware inventory:

Item	Version	Part number	Serial number	Description
Chassis			30010	M7I
Midplane	REV 03	710-008761	CB3874	M7i Midplane
Power Supply 0	Rev 04	740-008537	PG10715	AC Power Supply
Routing Engine	REV 07	740-009459	1000445584	RE-5.0
CFEB	REV 07	750-010464	CM4612	Internet Processor II
FPC 0				E-FPC
PIC 0	REV 06	750-002971	CB0032	4x OC-3 SONET, MM
PIC 1	REV 02	750-002982	HS2878	1x Tunnel
PIC 2	REV 08	750-005724	CL9084	2x OC-3 ATM-II IQ, MM
PIC 3	REV 12	750-012838	DJ1107	4x 1GE(LAN), IQ2
Xcvr 0	REV 01	740-013111	7303405	SFP-T

Using Device Object Methods to Load Configuration Changes

The NETCONF Java toolkit **Device** object has methods to help you configure remote devices. When appropriate, the methods are overloaded to take a number of different formats.

To load configuration data on a remote device, the **Device** object has several methods that enable you to define the configuration data as a set of Junos OS configuration mode commands, formatted ASCII text, or Junos XML tag elements. You can supply the

configuration data in the program code, or you can reference data files that include the desired configuration changes.

To configure a private copy of the candidate configuration, call the **openConfiguration("private")** method with the string argument "private" on the device object before loading your configuration changes. This is equivalent to the **configure private** command in the Junos OS CLI. If you omit the call to the **openConfiguration("private")** method, your configuration changes are loaded into the global copy of the candidate configuration.

The method used to load the configuration data depends on the source and the format of the data. In the following methods, the string argument **loadType** has a value of either **merge** or **replace**, which performs the equivalent of the configuration mode commands **load merge** or **load replace** on a device running Junos OS.

- **Junos OS configuration mode commands**—The following methods load configuration data as a set of Junos OS configuration mode commands. These methods are only supported on devices running Junos OS Release 11.4 or a later release. Junos OS executes the configuration instructions line by line. For each element, you can specify the complete statement path in the command, or you can use navigation commands, such as **edit**, to move around the configuration hierarchy as you do in CLI configuration mode.
 - **loadSetConfiguration(String setCommands)**—Specify the configuration data in the program code, either as a method argument or as a variable passed to the method.
 - **loadSetFile(String filePath)**—Load the configuration data from the file specified by *filePath*.
- **Formatted ASCII text**—The following methods load configuration data as formatted ASCII text. Use the standard Junos OS CLI notations—the newline character, tabs, spaces, braces, and square brackets—to indicate the hierarchical relationships between configuration statements.
 - **loadTextConfiguration(String textConfiguration, String loadType)**—Specify the configuration data in the program code, either as a method argument or as a variable passed to the method.
 - **loadTextFile(String filePath, String loadType)**—Load the configuration data from the file specified by *filePath*.
- **Junos XML tag elements**—The following methods load configuration data as Junos XML tag elements. Include the tag elements representing all levels of the configuration hierarchy under the root, the **<configuration>** tag element, down to each new or changed element.
 - **loadXMLConfiguration(String XMLConfiguration, String loadType)**—Specify the configuration data in the program code as a **net.juniper.netconf.XML** object, which is passed to the method.
 - **loadXMLFile(String filePath, String loadType)**—Load the configuration data from the file specified by *filePath*.

The following code snippet merges the **ftp** statement into the candidate configuration at the **[edit system services]** hierarchy level. The Java statement for each type of load configuration method is shown. When loading from a file, the file should contain the appropriate hierarchy in the desired format.

```
/*
r1-config-set.txt:
set system services ftp

r1-config-text.txt:
system {
  services {
    ftp;
  }
}

r1-config-xml.txt:
<system>
  <services>
    <ftp/>
  </services>
</system>
*/

String config_file_set = "configs/r1-config-set.txt"
String config_file_text = "configs/r1-config-text.txt"
String config_file_xml = "configs/r1-config-xml.txt"

XMLBuilder builder = new XMLBuilder();
XML ftp_config = builder.createNewConfig("system", "services", "ftp");

Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null);
device.connect();

//open a private copy of the candidate configuration
device.openConfiguration("private");

// load configuration data as Junos OS configuration mode commands
device.loadSetConfiguration("set system services ftp");
device.loadSetFile(config_file_set);

// load configuration data as formatted ASCII text
device.loadTextConfiguration("system { services { ftp; } }", "merge");
device.loadTextFile(config_file_text, "merge");

// load configuration data as Junos XML tag elements
device.loadXMLConfiguration(ftp_config.toString(), "merge");
device.loadXMLFile(config_file_xml, "merge");

device.commit();
device.close();
```

Example: Using the NETCONF Java Toolkit to Load and Commit a Configuration

The following example NETCONF Java toolkit program constructs a configuration hierarchy, which is then merged with the candidate configuration on the specified device.

The resulting configuration is then committed. The sample configuration hierarchy is for a device running Junos OS.

- [Requirements on page 755](#)
- [Overview on page 755](#)
- [Configuration on page 756](#)
- [Verification on page 757](#)
- [Troubleshooting on page 758](#)

Requirements

- Routing, switching, or security device running Junos OS.
- NETCONF Java toolkit is installed on the configuration management server.
- Client application can log in to the device where the NETCONF server resides.
- NETCONF service over SSH is enabled on the device where the NETCONF server resides.

Overview

The following example performs a **load merge** operation to update the candidate configuration on a device running Junos OS and then commits the new configuration. The XML hierarchy that will be added into the configuration is constructed with the **XMLBuilder** object and stored in the **ftp_config** variable. Alternatively, you can load configuration data as text and, for devices running Junos OS Release 11.4 or a later release, as a set of Junos OS configuration mode commands.

The new configuration hierarchy, which enables FTP service on the device, is:

```
<configuration>
  <system>
    <services>
      <ftp/>
    </services>
  </system>
</configuration>
```

The program code creates a new **Device** object and calls the **connect()** method. This establishes an SSHv2 connection and a default NETCONF session with the device on which the NETCONF server runs.

To prevent conflicts with other users who might simultaneously edit the candidate configuration, the code calls the **lockConfig()** method on the device object to lock the configuration. If the lock fails, the method generates an error message, and the program exits. If the lock is successful, the **loadXMLConfiguration(ftp_config.toString(), "merge")** method loads the new configuration hierarchy into the candidate configuration using the **merge** option. Notice that, although the configuration hierarchy is initially constructed as XML, you must convert it to a string before passing it as an argument to the **loadXMLConfiguration()** method.

Once the new configuration hierarchy is merged with the candidate configuration, the program attempts to commit the configuration. If the commit operation is unsuccessful,

the program prints the associated error message. The program then unlocks the configuration and closes the NETCONF session and device connection.

NOTE: For more information about the **merge** and **replace** options for loading configuration hierarchies and statements into the candidate configuration, see the *CLI User Guide*.

Configuration

Creating the Java Program

Step-by-Step Procedure

To construct the Java program file that contains the code for the configuration changes and requests:

1. Give the file a descriptive name.

The filename must be the same as the class name. For this example, the file and class are named **EditConfig**.

2. Add the code to the file and update the environment-specific variables such as the remote host IP address, username, and password.

The complete Java code for the EditConfig program is presented here.

```
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.CommitException;
import net.juniper.netconf.Device;
import net.juniper.netconf.LoadException;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import net.juniper.netconf.XMLBuilder;
import org.xml.sax.SAXException;

public class EditConfig {
    public static void main(String[] args) throws LoadException, IOException,
        NetconfException, ParserConfigurationException, SAXException {

        /*Build the following XML hierarchy to add to the configuration:
        * <configuration>
        *   <system>
        *     <services>
        *       <ftp/>
        *     </services>
        *   </system>
        * </configuration>
        */

        XMLBuilder builder = new XMLBuilder();
        XML ftp_config = builder.createNewConfig("system", "services", "ftp");

        //Create the device
        Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null);
        device.connect();
```

```

//Lock the configuration
boolean isLocked = device.lockConfig();
if(!isLocked) {
    System.out.println("Could not lock configuration. Exit now.");
    return;
}

//Load and commit the configuration
try {
    device.loadXMLConfiguration(ftp_config.toString(), "merge");
    device.commit();
} catch(LoadException e) {
    System.out.println(e.getMessage());
    return;
} catch(CommitException e) {
    System.out.println(e.getMessage());
    return;
}

//Unlock the configuration and close the device
device.unlockConfig();
device.close();
}
}

```

Compiling and Running the Java Program

Step-by-Step Procedure You need a Java compiler to compile the source code and to create an executable program.

To compile the code and run the program on the configuration management server:

1. Compile the **EditConfig.java** file.
`>javac EditConfig.java`
2. Execute the resulting **EditConfig** program.
`>java EditConfig`

Verification

Verifying Program Execution

Purpose Verify that the **EditConfig** program runs correctly.

Action If the program executes successfully, it establishes a connection and creates a NETCONF session with the specified device. The program merges the new hierarchy with the candidate configuration on the device and commits the configuration.

You can verify that the configuration was correctly merged and committed by viewing the resulting configuration on the remote device. The **ftp** statement should now be in the active configuration. On a device running Junos OS, enter the following operational mode command to view the **[edit system services]** hierarchy:

```
user@host> show configuration system services
```

```
ftp;  
netconf {  
    ssh;  
}
```

Troubleshooting

- [Troubleshooting Error Messages on page 758](#)

Troubleshooting Error Messages

Problem The following error message is printed to the display:

```
Could not lock configuration. Exit now.
```

Solution Another user currently has a lock on the candidate configuration. Wait until the lock is released and execute the program.

Example: Using the NETCONF Java Toolkit to Load Set Configuration Commands

This NETCONF Java toolkit program demonstrates the `loadSetConfiguration()` method, which updates the configuration using a set of Junos OS configuration mode commands.

- [Requirements on page 758](#)
- [Overview on page 758](#)
- [Configuration on page 759](#)
- [Verification on page 761](#)

Requirements

- Routing, switching, or security device running Junos OS Release 11.4 or later.
- NETCONF Java toolkit is installed on the configuration management server.
- Client application can log in to the device where the NETCONF server resides.
- NETCONF service over SSH is enabled on the device where the NETCONF server resides.

Overview

The `Device` class contains the `loadSetConfiguration()` and `loadSetFile()` methods, which load configuration data as a set of Junos OS configuration mode commands on devices running Junos OS Release 11.4 or a later release. For each configuration element, you can specify the complete statement path in the command, or you can use navigation commands, such as `edit`, to move around the configuration hierarchy as you do in CLI configuration mode. The NETCONF Java toolkit converts the command set to the equivalent RPC in XML that can be processed by the NETCONF server on devices running Junos OS. Junos OS executes the configuration instructions line by line.

The method syntax is:

```
public void loadSetConfiguration (String setCommands)  
public void loadSetFile (String filePath)
```

The `loadSetConfiguration()` method takes as an argument the configuration command string that you would enter in Junos OS CLI configuration mode. For example, to add the **ftp** statement at the **[edit system services]** hierarchy level, you use the **set system services ftp** command. The `loadSetFile()` method takes as an argument the path of the file containing the set of configuration commands.

You can also use both methods to load multiple commands. To load multiple commands using the `loadSetConfiguration()` method, you can either list the commands as a single string and separate them with the `\n` newline sequence, or you can execute the method separately for each command. To load multiple commands using the `loadSetFile()` method, place each command on a separate line in the file.

NOTE: When using the `loadSetConfiguration()` method with navigation commands, you should list the commands as a single string and separate them with the `\n` newline sequence. You cannot call the `loadSetConfiguration()` method with a single navigation command such as `up`.

The program in this example loads two configuration commands, which merge two statements into the candidate configuration on a device running Junos OS Release 11.4. The first command, **set system services ftp**, adds the **ftp** statement at the **[edit system services]** hierarchy level. The second command, **set interfaces ge-0/0/0 disable**, adds the **disable** statement at the **[edit interfaces ge-0/0/0]** hierarchy level. The relevant statements in the program code are:

```
String system_config = "set system services ftp";
String interfaces_config = "set interfaces ge-0/0/0 disable";

device.loadSetConfiguration(system_config);
device.loadSetConfiguration(interfaces_config);
```

Configuration

Creating the Java Program

Step-by-Step Procedure

To construct the Java program file:

1. Give the file a descriptive name.

The filename must be the same as the class name. For this example, the file and class are named **LoadSetConfig**.

2. Add the code to the file and update the environment-specific variables such as the remote host IP address, username, password, and **<rpc-reply>** tag elements.

The complete Java code for the **LoadSetConfig.java** program is presented here.

If you load the set of commands from a file, create a file containing the commands, and replace the two `loadSetConfiguration()` method calls with a call to the `loadSetFile()` method.

```
/*LoadSetConfig*/
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
```

```
import net.juniper.netconf.Device;
import net.juniper.netconf.CommitException;
import net.juniper.netconf.LoadException;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import org.xml.sax.SAXException;

public class LoadSetConfig {
    public static void main(String args[]) throws NetconfException,
        ParserConfigurationException, SAXException, IOException {

        String system_config = "set system services ftp";
        String interfaces_config = "set interfaces ge-0/0/0 disable";

        Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);

        try {
            device.connect();
            System.out.println("Connection successful.");

            if (device.lockConfig()) {
                System.out.println("Configuration successfully locked.");
                try {
                    System.out.println("Updating configuration.");
                    device.loadSetConfiguration(system_config);
                    device.loadSetConfiguration(interfaces_config);
                    System.out.println("Committing configuration.");
                    device.commit();
                }
                catch (LoadException e) {
                    System.out.println("LoadException occurred: " + e.getMessage());
                }
                catch (CommitException e) {
                    System.out.println("CommitException occurred: " + e.getMessage());
                }
                device.unlockConfig();
                device.close();
            }
            else {
                System.out.println("Error - cannot lock configuration");
            }
        }
        catch (NetconfException e) {
            System.out.println("Could not connect to device: " + e.getMessage());
        }
    }
}
```

Compiling and Running the Java Program

Step-by-Step Procedure You need a Java compiler to compile the source code and to create an executable program.

To compile the code and run the program on the configuration management server:

1. Compile the **LoadSetConfig.java** file.
`>javac LoadSetConfig.java`
2. Execute the resulting **LoadSetConfig** program.
`>java LoadSetConfig`

Verification

To confirm that the program is working properly:

- [Verifying Program Execution on page 761](#)
- [Verifying the Configuration Changes on page 761](#)
- [Verifying the Commit on page 762](#)

Verifying Program Execution

Purpose Verify that the **LoadSetConfig** program runs correctly.

Action If the program executes successfully, it establishes a connection and creates a NETCONF session with the specified device. The program merges the new statements with the candidate configuration on the device and commits the configuration.

```
>java LoadSetConfig
Connection successful.
Configuration successfully locked.
Updating configuration.
Committing configuration.
```

Verifying the Configuration Changes

Purpose You can verify that the configuration was correctly merged and committed by viewing the resulting configuration on the remote device. The **ftp** and the **disable** statements should now be in the active configuration. On a device running Junos OS, issue the following operational mode commands to view the **[edit system services]** and **[edit interfaces]** hierarchy levels:

Action `admin@host> show configuration system services`
 `ftp;`
 `netconf {`
 `ssh;`
 `}`

 `admin@host> show configuration interfaces`
 `ge-0/0/0 {`
 `disable;`
 `}`

Verifying the Commit

Purpose Additionally, you can review the commit log to verify that the commit was successful. On a device running Junos OS, issue the **show system commit** operational mode command to view the commit log. In this example, the log confirms that the user **admin** committed the candidate configuration in a NETCONF session at the given date and time.

Action Issue the **show system commit** operational mode command and review the commit log.

```
admin@host> show system commit
0   2011-09-02 14:16:44 PDT by admin via netconf
1   2011-07-08 14:33:46 PDT by root via other
```

Example: Using the NETCONF Java Toolkit to Execute an Operational Request RPC

This NETCONF Java toolkit program executes an RPC to obtain operational information from a device, which is then printed to standard output. This example serves as an instructional example for creating and executing a basic NETCONF Java toolkit program.

- [Requirements on page 763](#)
- [Overview on page 763](#)
- [Configuration on page 763](#)

- [Verification on page 765](#)
- [Troubleshooting on page 765](#)

Requirements

- NETCONF Java toolkit is installed on the configuration management server.
- Client application can log in to the device where the NETCONF server resides.
- NETCONF service over SSH is enabled on the device where the NETCONF server resides.

Overview

You can use the NETCONF Java toolkit to request operational information from a remote device. The following example illustrates how to create a NETCONF Java toolkit program to execute an operational request from the Junos XML API on a device running Junos OS. The example also explains how to compile the code, execute the program, and verify the results.

Configuration

Creating the Java Program

Step-by-Step Procedure

To construct the Java program file that contains the code for the operational request:

1. Give the file a descriptive name.

The filename must be the same as the class name. For this example, the file and class are named **GetChassisInventory**.
2. Include the appropriate import statements, and the code for the class declaration and the Java method, **main()**.

```
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.Device;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import org.xml.sax.SAXException;

public class GetChassisInventory {
    public static void main(String args[]) throws NetconfException,
        ParserConfigurationException, SAXException, IOException {
    }
}
```

3. Within **main()**, create a **Device** object and call the **connect()** method.

This creates a default NETCONF session over SSHv2 with the NETCONF server. You must update the code with the appropriate arguments for connection to and authentication on your specific device.

```
Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null);
device.connect();
```

Having established a **Device** object, you can perform NETCONF operations on the device. For a complete list of available methods corresponding to NETCONF operations, refer to the NETCONF Java toolkit Javadocs.

4. Call the **executeRPC()** method with the operational request RPC command as the argument.

This example uses the Junos XML API **get-chassis-inventory** RPC. The reply, which is returned in XML, is stored in the **rpc_reply** variable.

```
XML rpc_reply = device.executeRPC("get-chassis-inventory");
```

5. Add code to take action on the RPC reply.

The following code converts the NETCONF server's reply to a string and prints it to the screen:

```
System.out.println(rpc_reply.toString());
```

6. Close the device and release resources by calling the **close()** method on the device object.

```
device.close();
```

Results The complete program is:

```
/*GetChassisInventory*/
import java.io.IOException;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.Device;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import org.xml.sax.SAXException;

public class GetChassisInventory {
    public static void main(String args[]) throws NetconfException,
        ParserConfigurationException, SAXException, IOException {

        Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);
        device.connect();
        XML rpc_reply = device.executeRPC("get-chassis-inventory");
        System.out.println(rpc_reply.toString());
        device.close();
    }
}
```

Compiling and Running the Java Program

Step-by-Step Procedure You need a Java compiler to compile the source code and to create an executable program.

To compile the code and run the program on the configuration management server:

1. Compile the **GetChassisInventory.java** file.

```
>javac GetChassisInventory.java
```

2. Execute the resulting **GetChassisInventory** program.

```
>java GetChassisInventory
```

Verification

Verifying Program Execution

Purpose Verify that the GetChassisInventory program runs correctly.

Action If the program executes successfully, it establishes a connection and creates a NETCONF session with the specified device. The program sends the **get-chassis-inventory** RPC to the NETCONF server, and the server responds with the requested operational information enclosed in the **<rpc-reply>** tag element. The program prints the reply to standard out. Following is a sample RPC reply with some output omitted for brevity.

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:junos="http://xml.juniper.net/junos/11.2R1/junos">
  <chassis-inventory xmlns="http://xml.juniper.net/junos/11.2R1/junos-chassis">
  <chassis junos:style="inventory">
  <name>Chassis</name>
  <serial-number>12345</serial-number>
  <description>M7i</description>
  <chassis-module>

...output omitted...

</chassis>
</chassis-inventory>
</rpc-reply>
```

Troubleshooting

- [Troubleshooting NETCONF Exceptions on page 765](#)

Troubleshooting NETCONF Exceptions

Problem A NETCONF exception occurs, and you see the following error message:

```
Exception in thread "main" net.juniper.netconf.NetconfException: There was a
problem while connecting to 10.10.1.1:830
    at net.juniper.netconf.Device.createNetconfSession(Device.java:344)
    at net.juniper.netconf.Device.connect(Device.java:225)
    at GetChassisInventory.main(GetChassisInventory.java:14)
```

NETCONF over SSH might not be enabled on the device where the NETCONF server resides, or it might be enabled on a different port.

Solution Ensure that you have enabled NETCONF over SSH on the device where the NETCONF server resides. Since the example program does not specify a specific port number in the **Device** arguments, the NETCONF session is established on the default NETCONF-over-SSH port, 830. To verify whether NETCONF over SSH is enabled on the

default port for a device running Junos OS, enter the following operational mode command on the remote device:

```
user@host> show configuration system services
```

```
ftp;  
netconf {  
    ssh;  
}
```

If the **netconf** configuration hierarchy is absent, issue the following statements in configuration mode to enable NETCONF over SSH on the default port:

```
[edit]  
user@host# set system services netconf ssh  
user@host# commit
```

If the **netconf** configuration hierarchy specifies a port other than the default port, include the new port number in the **Device** object constructor arguments. For example, the following device is configured for NETCONF over SSH on port 12345:

```
user@host> show configuration system services  
netconf {  
    ssh {  
        port 12345;  
    }  
}
```

To correct the connection issue, include the new port number in the **Device** arguments.

```
Device device = new Device("10.10.1.1", "admin", "PaSsWoRd", null, 12345);
```

Example: Using the NETCONF Java Toolkit to Print Component Temperatures

This NETCONF Java toolkit program prints the name and corresponding temperature of components on a device running Junos OS.

- [Requirements on page 767](#)
- [Overview on page 767](#)

- [Configuration on page 767](#)
- [Verification on page 769](#)

Requirements

- Routing, switching, or security device running Junos OS.
- NETCONF Java toolkit is installed on the configuration management server.
- Client application can log in to the device where the NETCONF server resides.
- NETCONF service over SSH is enabled on the device where the NETCONF server resides.

Overview

The following example executes the Junos XML API **get-environment-information** RPC, which is the equivalent of the **show chassis environment** operational mode command on a device running Junos OS. The program parses the RPC reply, and for all components that list a temperature, the program prints the component name and corresponding temperature.

The RPC reply format for the **get-environment-information** RPC request is:

```
<rpc-reply>
  <environment-information>
    <environment-item>
      <name>item-name</name>
      ...
      <temperature>temperature</temperature>
    </environment-item>
    <environment-item>
      <name>item-name2</name>
      ...
      <temperature>temperature</temperature>
    </environment-item>
    ...
  </environment-information>
</rpc-reply>
```

To parse the reply, the program uses the **findNodes()** method to return a list of **org.w3c.dom.Node** objects. For each **<environment-item>** node, the program obtains a list of child nodes. If a temperature element is present in the child node list, the program prints the name and temperature of that environment item.

Configuration

Creating the Java program

Step-by-Step Procedure

To construct the Java program file:

1. Give the file a descriptive name.
The filename must be the same as the class name. For this example, the file and class are named **ShowTemps**.
2. Add the code to the file and update the environment-specific variables such as the remote host IP address, username, password, and **<rpc-reply>** tag elements.

The complete Java code for the **ShowTemps.java** program is presented here.

```
import java.io.IOException;
import java.util.Arrays;
import java.util.Iterator;
import java.util.List;
import javax.xml.parsers.ParserConfigurationException;
import net.juniper.netconf.CommitException;
import net.juniper.netconf.Device;
import net.juniper.netconf.LoadException;
import net.juniper.netconf.NetconfException;
import net.juniper.netconf.XML;
import net.juniper.netconf.XMLBuilder;
import org.xml.sax.SAXException;
import org.w3c.dom.Node;
import org.w3c.dom.NodeList;

public class showTemps {
    public static void main(String[] args) throws LoadException, IOException,
        NetconfException, ParserConfigurationException, SAXException {

        String name="", temp="";

        //Create the device
        Device device = new Device("10.10.1.1","admin","PaSsWoRd",null);
        device.connect();

        //Call executeRPC(String rpc) to send RPC and receive RPC reply
        XML rpc_reply = device.executeRPC("get-environment-information");

        // Parse reply and only print items that have a temperature element
        List<String> list =
            Arrays.asList("environment-information","environment-item");
        List itemlist = rpc_reply.findNodes(list);
        Iterator iter = itemlist.iterator();

        while (iter.hasNext()) {
            Node item_node = (Node) iter.next();
            NodeList child_nodes = item_node.getChildNodes();
            // child_nodes contains nodes like <name> and <temperature>

            for (int i = 0; i < child_nodes.getLength(); i++) {
                Node child = child_nodes.item(i);
                if (child.getNodeType() == Node.ELEMENT_NODE) {

                    if (child.getNodeName().equals("name"))
                        // Capture the text value in <name> node
                        name = child.getTextContent();
                    if (child.getNodeName().equals("temperature")) {
                        // Capture the text value in <temperature> node
                        temp = child.getTextContent();
                        System.out.println(name + ": " + temp);
                    }
                }
            }
        }
    }
}
```

```

        device.close();
    }
}

```

Compiling and Running the Java Program

Step-by-Step Procedure You need a Java compiler to compile the source code and to create an executable program.

To compile the code and run the program on the configuration management server:

1. Compile the **ShowTemps.java** file.
`>javac ShowTemps.java`
2. Execute the resulting **ShowTemps** program.
`>java ShowTemps`

Verification

Verifying the Results

Purpose Verify that the **ShowTemps** program runs correctly.

Action If the program executes successfully, it establishes a connection and creates a NETCONF session with the specified device. The program then executes the Junos XML API **get-environment-information** RPC, parses the RPC reply, and prints all environment items that contain a child node **<temperature>**.

The following sample output is from a Juniper Networks m7i router:

```

Intake: 25 degrees C / 77 degrees F
FPC 0: 26 degrees C / 78 degrees F
Power Supplies: 28 degrees C / 82 degrees F
CFEB Intake: 22 degrees C / 71 degrees F
CFEB Exhaust: 30 degrees C / 86 degrees F
Routing Engine: 28 degrees C / 82 degrees F
Routing Engine CPU: 28 degrees C / 82 degrees F

```

XML and Junos OS

Extensible Markup Language (XML) is a standard for representing and communicating information. It is a metalanguage for defining customized tags that are applied to a data set or document to describe the function of individual elements and codify the hierarchical relationships between them. Junos OS natively supports XML for the operation and configuration of devices running Junos OS.

The Junos OS command-line interface (CLI) and the Junos OS infrastructure communicate using XML. When you issue an operational mode command in the CLI, the CLI converts the command into XML format for processing. After processing, Junos OS returns the output in the form of an XML document, which the CLI converts back into a readable format for display. Remote client applications also use XML-based data encoding for operational and configuration requests on devices running Junos OS.

The Junos XML API is an XML representation of Junos configuration statements and operational mode commands. It defines an XML equivalent for all statements in the Junos configuration hierarchy and many of the commands that you issue in CLI operational mode. Each operational mode command with a Junos XML counterpart maps to a request tag element and, if necessary, a response tag element.

You can view the XML-formatted output of any operational mode command by issuing the command in the CLI and adding the **| display xml** option. The following example shows the text-formatted and XML-formatted output for the **show chassis alarms** operational mode command:

```
user@host> show chassis alarms
No alarms currently active
```

```
user@host> show chassis alarms | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.4B1/junos">
  <alarm-information xmlns="http://xml.juniper.net/junos/10.4B1/junos-alarm">
    <alarm-summary>
      <no-active-alarms/>
    </alarm-summary>
  </alarm-information>
</cli>
  <banner></banner>
</cli>
</rpc-reply>
```

You can view the Junos XML API representation of any operational mode command by issuing the command in the CLI and adding the **| display xml rpc** option. The following example shows the Junos XML API tag element for the **show chassis alarms** command.

```
user@host> show chassis alarms | display xml rpc
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.4B1/junos">
  <rpc>
    <get-alarm-information>
  </get-alarm-information>
  </rpc>
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>
```

As shown in the previous example, the **| display xml rpc** option displays the command's corresponding Junos XML API request tag element that is sent to Junos OS for processing whenever the command is issued. In contrast, the **| display xml** option displays the actual output of the processed command in XML format.

When you issue the **show chassis alarms** operational mode command, the CLI converts the command into its equivalent Junos XML API request tag **<get-alarm-information>** and sends the XML request to the Junos infrastructure for processing. Junos OS processes the request and returns the **<alarm-information>** response tag element to the CLI. The CLI then converts the XML output into the "No alarms currently active" message that is displayed to the user.

Junos automation scripts use XML to communicate with the host device. Junos OS provides XML-formatted input to a script. The script processes the input source tree and then returns XML-formatted output to Junos OS. The script type determines the XML input document that is sent to the script as well as the output document that is returned to Junos OS for processing. Commit script input consists of an XML representation of the post-inheritance candidate configuration file. Event scripts receive an XML document containing the description of the triggering event. All script input documents contain a common node-set with information pertaining to the Junos OS environment.

Junos XML API and Junos XML Management Protocol Overview

The Junos XML Management Protocol is an XML-based protocol that client applications use to request and change configuration information on routing, switching, and security platforms running Junos OS. It uses an XML-based data encoding for the configuration data and remote procedure calls. The protocol defines basic operations that are equivalent to configuration mode commands in the Junos OS command-line interface (CLI). Applications use the protocol operations to display, edit, and commit configuration statements (among other operations), just as administrators use CLI configuration mode commands such as **show**, **set**, and **commit** to perform those operations.

The Junos XML API is an XML representation of Junos configuration statements and operational mode commands. Junos XML configuration tag elements are the content to which the Junos XML protocol operations apply. Junos XML operational tag elements are equivalent in function to operational mode commands in the CLI, which administrators use to retrieve status information for a device.

Client applications request information and change the configuration on a device by encoding the request with tag elements from the Junos XML management protocol and Junos XML API and sending it to the Junos XML protocol server on the device. The Junos XML protocol server is integrated into Junos OS and does not appear as a separate entry in process listings. The Junos XML protocol server directs the request to the appropriate software modules within the device, encodes the response in Junos XML and Junos XML protocol tag elements, and returns the result to the client application. For example, to request information about the status of a device's interfaces, a client application sends the Junos XML API **<get-interface-information>** request tag element. The Junos XML protocol server gathers the information from the interface process and returns it in the Junos XML API **<interface-information>** response tag element.

You can use the Junos XML management protocol and Junos XML API to configure devices running Junos OS or request information about the device configuration or operation. You can write client applications to interact with the Junos XML protocol server, and you can also utilize the Junos XML protocol to build custom end-user interfaces for configuration and information retrieval and display, such as a Web browser-based interface.

XML Overview

Extensible Markup Language (XML) is a language for defining a set of markers, called *tags*, that are applied to a data set or document to describe the function of individual elements and codify the hierarchical relationships between them. Tags look much like Hypertext Markup Language (HTML) tags, but XML is actually a metalanguage used to define tags that best suit the kind of data being marked.

For more details about XML, see *A Technical Introduction to XML* at <http://www.xml.com/pub/a/98/10/guide0.html> and the additional reference material at the <http://www.xml.com> site.

The official XML specification from the World Wide Web Consortium (W3C), *Extensible Markup Language (XML) 1.0*, is available at <http://www.w3.org/TR/REC-xml>.

The following sections discuss general aspects of XML:

- [Tag Elements on page 776](#)
- [Attributes on page 777](#)
- [Namespaces on page 777](#)
- [Document Type Definition on page 778](#)

Tag Elements

XML has three types of tags: opening tags, closing tags, and empty tags. XML tag names are enclosed in angle brackets and are case sensitive. Items in an XML-compliant document or data set are always enclosed in paired opening and closing tags, and the tags must be properly nested. That is, you must close the tags in the same order in which you opened them. XML is stricter in this respect than HTML, which sometimes uses only opening tags. The following examples show paired opening and closing tags enclosing a value. The closing tags are indicated by the forward slash at the start of the tag name.

```
<interface-state>enabled</interface-state>
<input-bytes>25378</input-bytes>
```

The term *tag element* refers to a three-part set: opening tag, contents, and closing tag. The content can be an alphanumeric character string as in the preceding examples, or can itself be a *container* tag element, which contains other tag elements. For simplicity, the term *tag* is often used interchangeably with *tag element* or *element*.

If a tag element is *empty*—has no contents—it can be represented either as paired opening and closing tags with nothing between them, or as a single tag with a forward slash after the tag name. For example, the notation `<snmp-trap-flag/>` is equivalent to `<snmp-trap-flag></snmp-trap-flag>`.

As the preceding examples show, angle brackets enclose the name of the tag element. This is an XML convention, and the brackets are a required part of the complete tag element name. They are not to be confused with the angle brackets used in the documentation to indicate optional parts of Junos OS CLI command strings.

Junos XML and Junos XML protocol tag elements obey the XML convention that the tag element name indicates the kind of information enclosed by the tags. For example, the name of the Junos XML `<interface-state>` tag element indicates that it contains a description of the current status of an interface on the device, whereas the name of the `<input-bytes>` tag element indicates that its contents specify the number of bytes received.

When discussing tag elements in text, this documentation conventionally uses just the opening tag to represent the complete tag element (opening tag, contents, and closing tag). For example, the documentation refers to the `<input-bytes>` tag to indicate the entire `<input-bytes>number-of-bytes</input-bytes>` tag element.

Attributes

XML elements can contain associated properties in the form of *attributes*, which specify additional information about an element. Attributes appear in the opening tag of an element and consist of an attribute name and value pair. The attribute syntax consists of the attribute name followed by an equals sign and then the attribute value enclosed in quotation marks. An XML element can have multiple attributes. Multiple attributes are separated by spaces and can appear in any order.

In the following example, the `configuration` tag element has two attributes, `junos:changed-seconds` and `junos:changed-localtime`.

```
<configuration junos:changed-seconds="1279908006"
junos:changed-localtime="2010-07-23 11:00:06 PDT">
```

The value of the `junos:changed-seconds` attribute is "1279908006", and the value of the `junos:changed-localtime` attribute is "2010-07-23 11:00:06 PDT".

Namespaces

Namespaces allow an XML document to contain the same tag, attribute, or function names for different purposes and avoid name conflicts. For example, many namespaces may define a `print` function, and each may exhibit a different functionality. To use the functionality defined in one specific namespace, you must associate that function with the namespace that defines the desired functionality.

To refer to a tag, attribute, or function from a defined namespace, you must first provide the namespace Uniform Resource Identifier (URI) in your style sheet declaration. You then qualify a tag, attribute, or function from the namespace with the URI. Since a URI is often lengthy, generally a shorter prefix is mapped to the URI.

In the following example the `jcs` prefix is mapped to the namespace identified by the URI `http://xml.juniper.net/junos/commit-scripts/1.0`, which defines extension functions used in commit, op, and event scripts. The `jcs` prefix is then prepended to the `output` function, which is defined in that namespace.

```
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
xmlns:jcs="http://xml.juniper.net/junos/commit-scripts/1.0">
...
<xsl:value-of select="jcs:output('The VPN is up.')" />
</xsl:stylesheet>
```

During processing, the prefix is expanded into the URI reference. Although there may be multiple namespaces that define an **output** element or function, the use of **jcs:output** explicitly defines which **output** function is used. You can choose any prefix to refer to the contents in a namespace, but there must be an existing declaration in the XML document that binds the prefix to the associated URI.

Document Type Definition

An XML-tagged document or data set is *structured*, because a set of rules specifies the ordering and interrelationships of the items in it. The rules define the contexts in which each tagged item can—and in some cases must—occur. A file called a *document type definition*, or *DTD*, lists every tag element that can appear in the document or data set, defines the parent-child relationships between the tags, and specifies other tag characteristics. The same DTD can apply to many XML documents or data sets.

Advantages of Using the Junos XML Management Protocol and Junos XML API

The Junos XML management protocol and Junos XML API fully document all options for every supported Junos operational request, all statements in the Junos configuration hierarchy, and basic operations that are equivalent to configuration mode commands. The tag names clearly indicate the function of an element in an operational or configuration request or a configuration statement.

The combination of meaningful tag names and the structural rules in a DTD makes it easy to understand the content and structure of an XML-tagged data set or document. Junos XML and Junos XML protocol tag elements make it straightforward for client applications that request information from a device to parse the output and find specific information.

Parsing Device Output

The following example illustrates how the Junos XML API makes it easier to parse device output and extract the needed information. The example compares formatted ASCII and XML-tagged versions of output from a device running Junos OS.

The formatted ASCII follows:

```
Physical interface: fxp0, Enabled, Physical link is Up
Interface index: 4, SNMP ifIndex: 3
```

The corresponding XML-tagged version is:

```
<interface>
  <name>fxp0</name>
  <admin-status>enabled</admin-status>
  <operational-status>up</operational-status>
  <index>4</index>
  <snmp-index>3</snmp-index>
</interface>
```

When a client application needs to extract a specific value from formatted ASCII output, it must rely on the value's location, expressed either absolutely or with respect to labels or values in adjacent fields. Suppose that the client application wants to extract the interface index. It can use a regular-expression matching utility to locate specific strings, but one difficulty is that the number of digits in the interface index is not necessarily predictable. The client application cannot simply read a certain number of characters after the **Interface index:** label, but must instead extract everything between the label and the subsequent label **SNMP ifIndex** and also account for the included comma.

A problem arises if the format or ordering of text output changes in a later version of the Junos OS. For example, if a **Logical index** field is added following the interface index number, the new formatted ASCII might appear as follows:

```
Physical interface: fxp0, Enabled, Physical link is Up
Interface index: 4, Logical index: 12, SNMP ifIndex: 3
```

An application that extracts the interface index number delimited by the **Interface index:** and **SNMP ifIndex:** labels now obtains an incorrect result. The application must be updated manually to search for the **Logical index:** label as the new delimiter.

In contrast, the structured nature of XML-tagged output enables a client application to retrieve the interface index by extracting everything within the opening `<index>` tag and closing `</index>` tag. The application does not have to rely on an element's position in the output string, so the Junos XML protocol server can emit the child tag elements in any order within the `<interface>` tag element. Adding a new `<logical-index>` tag element in a future release does not affect an application's ability to locate the `<index>` tag element and extract its contents.

Displaying Device Output

XML-tagged output is also easier to transform into different display formats than formatted ASCII output. For instance, you might want to display different amounts of detail about a given device component at different times. When a device returns formatted ASCII output, you have to write special routines and data structures in your display program to extract and show the appropriate information for a given detail level. In contrast, the inherent structure of XML output is an ideal basis for a display program's own structures. It is also easy to use the same extraction routine for several levels of detail, simply ignoring the tag elements you do not need when creating a less detailed display.

Overview of a Junos XML Protocol Session

Communication between the Junos XML protocol server and a client application is session based. The two parties explicitly establish a connection before exchanging data and close the connection when they are finished. Each request from the client application and each response from the Junos XML protocol server constitutes a *well-formed* XML document, because the tag streams obey the structural rules defined in the Junos XML

protocol and Junos XML DTDs for the kind of information they encode. Client applications must produce a well-formed XML document for each request by emitting tag elements in the required order and only in the legal contexts.

The following list outlines the basic structure of a Junos XML protocol session.

1. The client application establishes a connection to the Junos XML protocol server and opens the Junos XML protocol session.
2. The Junos XML protocol server and client application exchange initialization information, which is used to determine if they are using compatible versions of the Junos OS and the Junos XML management protocol.
3. The client application sends one or more requests to the Junos XML protocol server and parses its responses.
4. The client application closes the Junos XML protocol session and the connection to the Junos XML protocol server.

CHAPTER 18

Using Junos XML Management Protocol and Junos XML Tag Elements

This chapter describes the syntactic and notational conventions used by the Junos XML protocol server and client applications, including the mappings between statements and commands in the Junos OS command-line interface (CLI) and the tag elements in the Junos Extensible Markup Language (XML) application programming interface (API).

For more information about the syntax of CLI commands and configuration statements, see the *CLI User Guide*. For information about specific configuration statements, see the Junos OS configuration guides. For information about specific operational mode commands, see the Junos OS command references.

This chapter discusses the following topics:

- [XML and Junos XML Management Protocol Conventions Overview on page 781](#)
- [Mapping Commands to Junos XML Tag Elements on page 786](#)
- [Mapping Configuration Statements to Junos XML Tag Elements on page 787](#)
- [Using the Same Configuration Tag Elements in Requests and Responses on page 793](#)

XML and Junos XML Management Protocol Conventions Overview

A client application must comply with XML and Junos XML management protocol conventions. Each request from the client application must be a *well-formed* XML document; that is, it must obey the structural rules defined in the Junos XML protocol and Junos XML document type definitions (DTDs) for the kind of information encoded in the request. The client application must emit tag elements in the required order and only in legal contexts. Compliant applications are easier to maintain in the event of changes to the Junos OS or Junos XML management protocol.

Similarly, each response from the Junos XML protocol server constitutes a well-formed XML document (the Junos XML protocol server obeys XML and Junos XML management protocol conventions).

The following sections describe Junos XML management protocol conventions:

- [Request and Response Tag Elements on page 782](#)
- [Child Tag Elements of a Request Tag Element on page 783](#)

- [Child Tag Elements of a Response Tag Element on page 783](#)
- [Spaces, Newline Characters, and Other White Space on page 783](#)
- [XML Comments on page 784](#)
- [XML Processing Instructions on page 784](#)
- [Predefined Entity References on page 784](#)

Request and Response Tag Elements

A *request* tag element is one generated by a client application to request information about a device's current status or configuration, or to change the configuration. A request tag element corresponds to a CLI operational or configuration command. It can occur only within an **<rpc>** tag element. For information about the **<rpc>** tag element, see [“Sending a Request to the Junos XML Protocol Server” on page 816](#).

A *response* tag element represents the Junos XML protocol server's reply to a request tag element and occurs only within an **<rpc-reply>** tag element. For information about the **<rpc-reply>** tag element, see [“Parsing the Junos XML Protocol Server Response” on page 819](#).

The following example represents an exchange in which a client application emits the **<get-interface-information>** request tag element with the **<extensive/>** flag and the Junos XML protocol server returns the **<interface-information>** response tag element.

Client Application

```
<rpc>
  <get-interface-information>
    <extensive/>
  </get-interface-information>
</rpc>
```

Junos XML Protocol Server

```
<rpc-reply xmlns:junos="URL">
  <interface-information xmlns="URL">
    <!-- children of <interface-information> -->
  </interface-information>
</rpc-reply>
```

T1100

NOTE: This example, like all others in this guide, shows each tag element on a separate line, in the tag streams emitted by both the client application and Junos XML protocol server. In practice, a client application does not need to include newline characters between tag elements, because the server automatically discards such white space. For further discussion, see [“Spaces, Newline Characters, and Other White Space” on page 783](#).

For information about the attributes in the opening **rpc-reply** tag, see [“Parsing the Junos XML Protocol Server Response” on page 819](#). For information about the **xmlns** attribute in the opening **<interface-information>** tag, see [“Requesting Operational Information” on page 834](#).

Child Tag Elements of a Request Tag Element

Some request tag elements contain child tag elements. For configuration requests, each child tag element represents a configuration element (hierarchy level or configuration object). For operational requests, each child tag element represents one of the options you provide on the command line when issuing the equivalent CLI command.

Some requests have mandatory child tag elements. To make a request successfully, a client application must emit the mandatory tag elements within the request tag element's opening and closing tags. If any of the children are themselves container tag elements, the opening tag for each must occur before any of the tag elements it contains, and the closing tag must occur before the opening tag for another tag element at its hierarchy level.

In most cases, the client application can emit children that occur at the same level within a container tag element in any order. The important exception is a configuration element that has an *identifier tag element*, which distinguishes the configuration element from other elements of its type. The identifier tag element must be the first child tag element in the container tag element. Most frequently, the identifier tag element specifies the name of the configuration element and is called **<name>**.

Child Tag Elements of a Response Tag Element

The child tag elements of a response tag element represent the individual data items returned by the Junos XML protocol server for a particular request. The children can be either individual tag elements (empty tags or tag element triples) or container tag elements that enclose their own child tag elements. For some container tag elements, the Junos XML protocol server returns the children in alphabetical order. For other elements, the children appear in the order in which they were created in the configuration.

The set of child tag elements that can occur in a response or within a container tag element is subject to change in later releases of the Junos XML API. Client applications must not rely on the presence or absence of a particular tag element in the Junos XML protocol server's output, nor on the ordering of child tag elements within a response tag element. For the most robust operation, include logic in the client application that handles the absence of expected tag elements or the presence of unexpected ones as gracefully as possible.

Spaces, Newline Characters, and Other White Space

As dictated by the XML specification, the Junos XML protocol server ignores white space (spaces, tabs, newline characters, and other characters that represent white space) that occurs between tag elements in the tag stream generated by a client application. Client applications can, but do not need to, include white space between tag elements. However, they must not insert white space within an opening or closing tag. If they include white space in the contents of a tag element that they are submitting as a change to the candidate configuration, the Junos XML protocol server preserves the white space in the configuration database.

In its responses, the Junos XML protocol server includes white space between tag elements to enhance the readability of responses that are saved to a file: it uses newline characters to put each tag element on its own line, and spaces to indent child tag elements to the right compared to their parents. A client application can ignore or discard the white space, particularly if it does not store responses for later review by human users. However, it must not depend on the presence or absence of white space in any particular location when parsing the tag stream.

For more information about white space in XML documents, see the XML specification from the World Wide Web Consortium (W3C), *Extensible Markup Language (XML) 1.0*, at <http://www.w3.org/TR/REC-xml/>.

XML Comments

Client applications and the Junos XML protocol server can insert XML comments at any point between tag elements in the tag stream they generate, but not within tag elements. Client applications must handle comments in output from the Junos XML protocol server gracefully but must not depend on their content. Client applications also cannot use comments to convey information to the Junos XML protocol server, because the server automatically discards any comments it receives.

XML comments are enclosed within the strings `<!--` and `-->`, and cannot contain the string `--` (two hyphens). For more details about comments, see the XML specification at <http://www.w3.org/TR/REC-xml/>.

The following is an example of an XML comment:

```
<!-- This is a comment. Please ignore it. -->
```

XML Processing Instructions

An XML processing instruction (PI) contains information relevant to a particular protocol and has the following form:

```
<?PI-name attributes?>
```

Some PIs emitted during a Junos XML protocol session include information that a client application needs for correct operation. A prominent example is the `<?xml?>` tag element, which the client application and Junos XML protocol server each emit at the beginning of every Junos XML protocol session to specify which version of XML and which character encoding scheme they are using. For more information, see “Emitting the `<?xml?>` PI” on page 809 and “Parsing the Junos XML Protocol Server’s `<?xml?>` PI” on page 811.

The Junos XML protocol server can also emit PIs that the client application does not need to interpret (for example, PIs intended for the CLI). If the client application does not understand a PI, it must treat the PI like a comment instead of exiting or generating an error message.

Predefined Entity References

By XML convention, there are two contexts in which certain characters cannot appear in their regular form:

- In the string that appears between opening and closing tags (the contents of the tag element)
- In the string value assigned to an attribute of an opening tag

When including a disallowed character in either context, client applications must substitute the equivalent *predefined entity reference*, which is a string of characters that represents the disallowed character. Because the Junos XML protocol server uses the same predefined entity references in its response tag elements, the client application must be able to convert them to actual characters when processing response tag elements.

[Table 34 on page 785](#) summarizes the mapping between disallowed characters and predefined entity references for strings that appear between the opening and closing tags of a tag element.

Table 34: Predefined Entity Reference Substitutions for Tag Content Values

Disallowed Character	Predefined Entity Reference
& (ampersand)	&
> (greater-than sign)	>
< (less-than sign)	<

[Table 35 on page 785](#) summarizes the mapping between disallowed characters and predefined entity references for attribute values.

Table 35: Predefined Entity Reference Substitutions for Attribute Values

Disallowed Character	Predefined Entity Reference
& (ampersand)	&
' (apostrophe)	'
>> (greater-than sign)	>
< (less-than sign)	<
" (quotation mark)	"

As an example, suppose that the following string is the value contained by the `<condition>` tag element:

```
if (a<b && b>c) return "Peer's not responding"
```

The **<condition>** tag element looks like this (it appears on two lines for legibility only):

```
<condition>if (a<b &amp;&amp; b>c) return "Peer's not \
    responding"</condition>
```

Similarly, if the value for the **<example>** tag element's **heading** attribute is **Peer's "age" <> 40**, the opening tag looks like this:

```
<example heading="Peer's &quot;age&quot; &lt;&gt; 40">
```

Mapping Commands to Junos XML Tag Elements

The Junos XML API defines tag-element equivalents for many commands in CLI operational mode. For example, the **<get-interface-information>** tag element corresponds to the **show interfaces** command.

Information about the available command equivalents in the current release of the Junos OS can be found in the *Junos XML API Operational Developer Reference*. For the mapping between commands and Junos XML tag elements, see the *Junos XML API Operational Developer Reference* “Mapping Between Operational Tag Elements, Perl Methods, and CLI Commands” chapter. For detailed information about a specific operation, see the *Junos XML API Operational Developer Reference* “Summary of Operational Request Tags” chapter.

The following sections describe the tag elements that map to command options:

- [Mapping for Command Options with Variable Values on page 786](#)
- [Mapping for Fixed-Form Command Options on page 787](#)

Mapping for Command Options with Variable Values

Many CLI commands have options that identify the object that the command affects or reports about, distinguishing the object from other objects of the same type. In some cases, the CLI does not precede the identifier with a fixed-form keyword, but XML convention requires that the Junos XML API define a tag element for every option. To learn the names for each identifier (and any other child tag elements) for an operational request tag element, consult the tag element's entry in the appropriate DTD or in the *Junos XML API Operational Developer Reference*.

The following example shows the Junos XML tag elements for two CLI operational commands that have variable-form options. In the **show interfaces** command, **t3-5/1/0:0** is the name of the interface. In the **show bgp neighbor** command, **10.168.1.222** is the IP address for the BGP peer of interest.

CLI Command	JUNOS XML Tags
show interfaces t3-5/1/0:0	<pre><rpc> <get-interface-information> <interface-name>t3-5/1/0:0</interface-name> </get-interface-information> </rpc></pre>
show bgp neighbor 10.168.1.222	<pre><rpc> <get-bgp-neighbor-information> <neighbor-address>10.168.1.222</neighbor-address> </get-bgp-neighbor-information> </rpc></pre>

T1500

Mapping for Fixed-Form Command Options

Some CLI commands include options that have a fixed form, such as the **brief** and **detail** strings, which specify the amount of detail to include in the output. The Junos XML API usually maps such an option to an empty tag whose name matches the option name.

The following example shows the Junos XML tag elements for the **show isis adjacency** command, which has a fixed-form option called **detail**.

CLI Command	JUNOS XML Tags
show isis adjacency detail	<pre> <rpc> <get-isis-adjacency-information> <detail/> </get-isis-adjacency-information> </rpc> </pre>

T1501

Mapping Configuration Statements to Junos XML Tag Elements

The Junos XML API defines a tag element for every container and leaf statement in the configuration hierarchy. At the top levels of the configuration hierarchy, there is almost always a one-to-one mapping between tag elements and statements, and most tag names match the configuration statement name. At deeper levels of the hierarchy, the mapping is sometimes less direct, because some CLI notational conventions do not map directly to XML-compliant tagging syntax.

NOTE: For some configuration statements, the notation used when you type the statement at the CLI configuration-mode prompt differs from the notation used in a configuration file. The same Junos XML tag element maps to both notational styles.

The following sections describe the mapping between configuration statements and Junos XML tag elements:

- [Mapping for Hierarchy Levels and Container Statements on page 787](#)
- [Mapping for Objects That Have an Identifier on page 788](#)
- [Mapping for Single-Value and Fixed-Form Leaf Statements on page 789](#)
- [Mapping for Leaf Statements with Multiple Values on page 790](#)
- [Mapping for Multiple Options on One or More Lines on page 791](#)
- [Mapping for Comments About Configuration Statements on page 792](#)

Mapping for Hierarchy Levels and Container Statements

The **<configuration>** tag element is the top-level Junos XML container tag element for configuration statements. It corresponds to the **[edit]** hierarchy level in CLI configuration mode. Most statements at the next few levels of the configuration hierarchy are container statements. The Junos XML container tag element that corresponds to a container statement almost always has the same name as the statement.

The following example shows the Junos XML tag elements for two statements at the top level of the configuration hierarchy. Note that a closing brace in a CLI configuration statement corresponds to a closing Junos XML tag.

CLI Configuration Statements	JUNOS XML Tags
system {	<configuration>
login {	<system>
...child statements...	<login>
}	<!-- tags for child statements -->
}	</login>
	</system>
protocols {	<protocols>
ospf {	<ospf>
...child statements...	<!-- tags for child statements -->
}	</ospf>
}	</protocols>
	</configuration>

T1502

Mapping for Objects That Have an Identifier

At some hierarchy levels, the same kind of configuration object can occur multiple times. Each instance of the object has a unique identifier to distinguish it from the other instances. In the CLI notation, the parent statement for such an object consists of a keyword and identifier of the following form:

```
keyword identifier {
... configuration statements for individual characteristics ...
}
```

keyword is a fixed string that indicates the type of object being defined, and **identifier** is the unique name for this instance of the type. In the Junos XML API, the tag element corresponding to the keyword is a container tag element for child tag elements that represent the object's characteristics. The container tag element's name generally matches the **keyword** string.

The Junos XML API differs from the CLI in its treatment of the identifier. Because the Junos XML API does not allow container tag elements to contain both other tag elements and untagged character data such as an identifier name, the identifier must be enclosed in a tag element of its own. Most frequently, identifier tag elements for configuration objects are called **<name>**. Some objects have multiple identifiers, which usually have names other than **<name>**. To verify the name of each identifier tag element for a configuration object, consult the entry for the object in the *Junos XML API Configuration Developer Reference*.

NOTE: The Junos OS reserves the prefix **junos-** for the identifiers of configuration groups defined within the **junos-defaults** configuration group. User-defined identifiers cannot start with the string **junos-**.

Identifier tag elements also constitute an exception to the general XML convention that tag elements at the same level of hierarchy can appear in any order; the identifier tag element always occurs first within the container tag element.

The configuration for most objects that have identifiers includes additional leaf statements, which represent other characteristics of the object. For example, each BGP group configured at the **[edit protocols bgp group]** hierarchy level has an associated name (the identifier) and can have leaf statements for other characteristics such as type, peer autonomous system (AS) number, and neighbor address. For information about the Junos XML mapping for leaf statements, see [“Mapping for Single-Value and Fixed-Form Leaf Statements” on page 555](#), [“Mapping for Leaf Statements with Multiple Values” on page 556](#), and [“Mapping for Multiple Options on One or More Lines” on page 556](#).

The following example shows the Junos XML tag elements for configuration statements that define two BGP groups called **G1** and **G2**. Notice that the Junos XML **<name>** tag element that encloses the identifier of each group (and the identifier of the neighbor within a group) does not have a counterpart in the CLI statements. For complete information about changing routing platform configuration, see [“Changing Configuration Information” on page 623](#).

CLI Configuration Statements	JUNOS XML Tags
protocols {	<configuration>
bgp {	<protocols>
group G1 {	<bgp>
type external;	<group>
peer-as 56;	<name>G1</name>
neighbor 10.0.0.1;	<type>external</type>
}	<peer-as>56</peer-as>
}	<neighbor>
group G2 {	<name>10.0.0.1</name>
type external;	</neighbor>
peer-as 57;	</group>
neighbor 10.0.10.1;	<group>
}	<name>G2</name>
}	<type>external</type>
}	<peer-as>57</peer-as>
	<neighbor>
	<name>10.0.10.1</name>
	</neighbor>
	</group>
	</bgp>
	</protocols>
	</configuration>

T1503

Mapping for Single-Value and Fixed-Form Leaf Statements

A *leaf statement* is a CLI configuration statement that does not contain any other statements. Most leaf statements define a value for one characteristic of a configuration object and have the following form:

keyword *value*;

In general, the name of the Junos XML tag element corresponding to a leaf statement is the same as the **keyword** string. The string between the opening and closing Junos XML tags is the same as the *value* string.

The following example shows the Junos XML tag elements for two leaf statements that have a keyword and a value: the **message** statement at the **[edit system login]** hierarchy level and the **preference** statement at the **[edit protocols ospf]** hierarchy level.

CLI Configuration Statements

```

system {
  login {
    message "Authorized users only";
    ...other statements under login...
  }
}
protocols {
  ospf {
    preference 15;
    ...other statements under ospf...
  }
}

```

JUNOS XML Tags

```

<configuration>
  <system>
    <login>
      <message>Authorized users only</message>
      <!-- tags for other child statements -->
    </login>
  </system>
  <protocols>
    <ospf>
      <preference>15</preference>
      <!-- tags for other child statements -->
    </ospf>
  </protocols>
</configuration>

```

T1504

Some leaf statements consist of a fixed-form keyword only, without an associated variable-form value. The Junos XML API represents such statements with an empty tag. The following example shows the Junos XML tag elements for the **disable** statement at the **[edit forwarding-options sampling]** hierarchy level.

CLI Configuration Statement

```

forwarding-options {
  sampling {
    disable;
    ...other statements under sampling ...
  }
}

```

JUNOS XML Tags

```

<configuration>
  <forwarding-options>
    <sampling>
      <disable/>
      <!-- tags for other child statements -->
    </sampling>
  </forwarding-options>
</configuration>

```

T1505

Mapping for Leaf Statements with Multiple Values

Some Junos leaf statements accept multiple values, which can be either user-defined or drawn from a set of predefined values. CLI notation uses square brackets to enclose all values in a single statement, as in the following:

statement [*value1 value2 value3 ...*];

The Junos XML API instead encloses each value in its own tag element. The following example shows the Junos XML tag elements for a CLI statement with multiple user-defined values. The **import** statement imports two routing policies defined elsewhere in the configuration. For complete information about changing routing platform configuration, see [“Changing Configuration Information” on page 623](#).

CLI Configuration Statements

```

protocols {
  bgp {
    group 23 {
      import [ policy1 policy2 ];
    }
  }
}

```

JUNOS XML Tags

```

<configuration>
  <protocols>
    <bgp>
      <group>
        <name>23</name>
        <import>policy1</import>
        <import>policy2</import>
      </group>
    </bgp>
  </protocols>
</configuration>

```

T1506

The following example shows the Junos XML tag elements for a CLI statement with multiple predefined values. The **permissions** statement grants three predefined permissions to members of the **user-accounts** login class.

CLI Configuration Statements	JUNOS XML Tags
system {	<configuration>
login {	<system>
class user-accounts {	<login>
permissions [configure admin control];	<class>
}	<name>user-accounts</name>
}	<permissions>configure</permissions>
}	<permissions>admin</permissions>
	<permissions>control</permissions>
	</class>
	</login>
	</system>
	</configuration>

T1507

Mapping for Multiple Options on One or More Lines

For some Junos configuration objects, the standard CLI syntax places multiple options on a single line, usually for greater legibility and conciseness. In most such cases, the first option identifies the object and does not have a keyword, but later options are paired keywords and values. The Junos XML API encloses each option in its own tag element. Because the first option has no keyword in the CLI statement, the Junos XML API assigns a name to its tag element.

The following example shows the Junos XML tag elements for a CLI configuration statement with multiple options on a single line. The Junos XML API defines a tag element for both options and assigns a name to the tag element for the first option (**10.0.0.1**), which has no CLI keyword.

CLI Configuration Statements	JUNOS XML Tags
system {	<configuration>
backup-router 10.0.0.1 destination 10.0.0.2;	<system>
	<backup-router>
	<address>10.0.0.1</address>
	<destination>10.0.0.2</destination>
	</backup-router>
}	</system>
	</configuration>

T1508

The syntax for some configuration objects includes more than one multioption line. Again, the Junos XML API defines a separate tag element for each option. The following example shows Junos XML tag elements for a **traceoptions** statement at the **[edit protocols isis]** hierarchy level. The statement has three child statements, each with multiple options.

CLI Configuration Statements

```

protocols {
  isis {
    traceoptions {
      file trace-file size 3m files 10 world-readable;

      flag route detail;

      flag state receive;

    }
  }
}

```

JUNOS XML Tags

```

<configuration>
  <protocols>
    <isis>
      <traceoptions>
        <file>
          <filename>trace-file</filename>
          <size>3m</size>
          <files>10</files>
          <world-readable/>
        </file>
        <flag>
          <name>route</name>
          <detail/>
        </flag>
        <flag>
          <name>state</name>
          <receive/>
        </flag>
      </traceoptions>
    </isis>
  </protocols>
</configuration>

```

T1509

Mapping for Comments About Configuration Statements

A Junos configuration can include comments that describe statements in the configuration. In CLI configuration mode, the **annotate** command specifies the comment to associate with a statement at the current hierarchy level. You can also use a text editor to insert comments directly into a configuration file. For more information, see the *CLI User Guide*.

The Junos XML API encloses comments about configuration statements in the **<junos:comment>** tag element. (These comments are different from the comments that are enclosed in the strings **<!--** and **-->** and are automatically discarded by the protocol server.)

In the Junos XML API, the **<junos:comment>** tag element immediately precedes the tag element for the associated configuration statement. (If the tag element for the associated statement is omitted, the comment is not recorded in the configuration database.) The comment text string can include one of the two delimiters that indicate a comment in the configuration database: either the **#** character before the comment or the paired strings **/*** before the comment and ***/** after it. If the client application does not include the delimiter, the protocol server adds the appropriate one when it adds the comment to the configuration. The protocol server also preserves any white space included in the comment.

The following example shows the Junos XML tag elements that associate comments with two statements in a sample configuration statement. The first comment illustrates how including newline characters in the contents of the **<junos:comment>** tag element (**/* New backbone area */**) results in the comment appearing on its own line in the configuration file. There are no newline characters in the contents of the second **<junos:comment>** tag element, so in the configuration file the comment directly follows the associated statement on the same line.

CLI Configuration Statements	JUNOS XML Tags
<pre> protocols { ospf { /* New backbone area */ area 0.0.0.0 { interface so-0/0/0 { # From jnpr1 to jnpr2 hello-interval 5; } } } } </pre>	<pre> <configuration> <protocols> <ospf> <junos:comment> /* New backbone area */ </junos:comment> <area> <name>0.0.0.0</name> <junos:comment> # From jnpr1 to jnpr2</junos:comment> <interface> <name>so-0/0/0</name> <hello-interval>5</hello-interval> </interface> </area> </ospf> </protocols> </configuration> </pre>

T1510

Using the Same Configuration Tag Elements in Requests and Responses

The Junos XML protocol server encloses its response to each configuration request in **<rpc-reply>** and **<configuration>** tag elements. Enclosing each configuration response within a **<configuration>** tag element contrasts with how the server encloses each different operational response in a tag element named for that type of response—for example, the **<chassis-inventory>** tag element for chassis information or the **<interface-information>** tag element for interface information.

The Junos XML tag elements within the **<configuration>** tag element represent configuration hierarchy levels, configuration objects, and object characteristics, always ordered from higher to deeper levels of the hierarchy. When a client application loads a configuration, it can emit the same tag elements in the same order as the Junos XML protocol server uses when returning configuration information. This consistent representation makes handling configuration information more straightforward. For instance, the client application can request the current configuration, store the Junos XML protocol server's response to a local memory buffer, make changes or apply transformations to the buffered data, and submit the altered configuration as a change to the candidate configuration. Because the altered configuration is based on the Junos XML protocol server's response, it is certain to be syntactically correct. For more information about changing routing platform configuration, see [“Changing Configuration Information” on page 623](#).

Similarly, when a client application requests information about a configuration element (hierarchy level or configuration object), it uses the same tag elements that the Junos XML protocol server will return in response. To represent the element, the client application sends a complete stream of tag elements from the top of the configuration hierarchy (represented by the **<configuration>** tag element) down to the requested element. The innermost tag element, which represents the level or object, is either empty or includes the identifier tag element only. The Junos XML protocol server's response includes the same stream of parent tag elements, but the tag element for the requested configuration element contains all the tag elements that represent the element's characteristics or child levels. For more information, see [“Requesting Configuration Information” on page 838](#).

The tag streams emitted by the Junos XML protocol server and by a client application can differ in the use of white space, as described in [“XML and Junos XML Management Protocol Conventions Overview” on page 781](#).

Controlling the Junos XML Management Protocol Session

This chapter explains how to start and terminate a session with the Junos XML protocol server, and describes the Extensible Markup Language (XML) tag elements from the Junos XML management protocol that client applications and the Junos XML protocol server use to coordinate information exchange during the session. It discusses the following topics:

- [Client Application's Role in a Junos XML Protocol Session on page 795](#)
- [Establishing a Junos XML Management Protocol Session on page 796](#)
- [Exchanging Information with the Junos XML Protocol Server on page 816](#)
- [Locking and Unlocking the Candidate Configuration or Creating a Private Copy on page 823](#)
- [Ending a Junos XML Protocol Session and Closing the Connection on page 827](#)
- [Displaying CLI Output as XML Tag Elements on page 828](#)
- [Displaying the RPC Tags for a Command on page 828](#)
- [Example of a Junos XML Protocol Session on page 829](#)

Client Application's Role in a Junos XML Protocol Session

To create a session and communicate with the Junos XML protocol server, a client application performs the following procedures, which are described in the indicated sections:

1. Establishes a connection to the Junos XML protocol server on the routing platform, as described in ["Connecting to the Junos XML Protocol Server" on page 807](#).
2. Opens a Junos XML protocol session, as described in ["Starting the Junos XML Protocol Session" on page 808](#).
3. (Optional) Locks the candidate configuration or creates a private copy, as described in ["Exchanging Information with the Junos XML Protocol Server" on page 816](#). Locking the configuration prevents other users or applications from changing it at the same time. Creating a private copy of the configuration enables the application to make changes without affecting the candidate or active configuration until the copy is committed.

4. Requests operational or configuration information, or changes configuration information, as described in [“Requesting Information” on page 833](#) and [“Changing Configuration Information” on page 623](#).
5. (Optional) Verifies the syntactic correctness of a configuration before attempting to commit it, as described in [“Verifying a Configuration Before Committing It” on page 919](#).
6. Commits changes made to the configuration, as described in [“Committing a Configuration” on page 919](#).
7. Unlocks the candidate configuration if it is locked, as described in [“Unlocking the Candidate Configuration” on page 825](#).
8. Ends the Junos XML protocol session and closes the connection to the device, as described in [“Ending a Junos XML Protocol Session and Closing the Connection” on page 827](#).

Establishing a Junos XML Management Protocol Session

The Junos XML protocol server communicates with client applications within the context of a Junos XML protocol *session*. The server and client explicitly establish a connection and session before exchanging data and close the session and connection when they are finished.

The streams of Junos XML protocol tag elements and Junos XML tag elements emitted by the Junos XML protocol server and the client application must each constitute well-formed XML by obeying the structural rules defined in the document type definition (DTD) for the kind of information they are exchanging. The client application must emit tag elements in the required order and only in the allowed contexts.

Client applications access the Junos XML protocol server using one of the protocols listed in [“Supported Access Protocols” on page 797](#). To authenticate with the Junos XML protocol server, they use either a Junos XML protocol-specific mechanism or the access protocol's standard authentication mechanism, depending on the protocol. After authentication, the Junos XML protocol server uses the Junos login usernames and classes already configured on the device to determine whether a client application is authorized to make each request.

For information about establishing a connection and a Junos XML protocol session, see the following sections:

- [Supported Access Protocols on page 797](#)
- [Prerequisites for Establishing a Connection on page 797](#)
- [Connecting to the Junos XML Protocol Server on page 807](#)
- [Starting the Junos XML Protocol Session on page 808](#)
- [Authenticating with the Junos XML Protocol Server on page 813](#)

For an example of a complete Junos XML protocol session, see [“Example of a Junos XML Protocol Session” on page 829](#).

Supported Access Protocols

To connect to the Junos XML protocol server, client applications can use the access protocols and associated authentication mechanisms listed in [Table 36 on page 797](#).

Table 36: Supported Access Protocols and Authentication Mechanisms

Access Protocol	Authentication Mechanism
clear-text, a Junos XML protocol-specific access protocol for sending unencrypted text over a Transmission Control Protocol (TCP) connection	Junos XML protocol-specific
SSH	Standard SSH
Outbound SSH	Outbound SSH
Secure Sockets Layer (SSL)	Junos XML protocol-specific
Telnet	Standard Telnet

The SSH and SSL protocols are preferred because they encrypt security information (such as passwords) before transmitting it across the network. Outbound SSH allows you to create an encrypted connection to the device in situations where you cannot connect to the device using standard SSH. The clear-text and Telnet protocols do not encrypt information.

For information about the prerequisites for each access protocol, see [“Prerequisites for Establishing a Connection” on page 797](#). For authentication instructions, see [“Authenticating with the Junos XML Protocol Server” on page 813](#).

Prerequisites for Establishing a Connection

To enable a client application to establish a connection to the Junos XML protocol server, you must satisfy the requirements discussed in the following sections:

- [Prerequisites for All Access Protocols on page 797](#)
- [Prerequisites for Clear-Text Connections on page 799](#)
- [Prerequisites for SSH Connections on page 800](#)
- [Prerequisites for Outbound SSH Connections on page 801](#)
- [Prerequisites for SSL Connections on page 805](#)
- [Prerequisites for Telnet Connections on page 807](#)

Prerequisites for All Access Protocols

A client application must be able to log in to each device on which it establishes a connection with the Junos XML protocol server. The following instructions explain how to create a Junos login account for the application; for detailed information, see the

chapter about configuring user access in the *Junos OS System Basics Configuration Guide*. Alternatively, you can skip this section and enable authentication through RADIUS or TACACS+; for instructions, see the chapter about system authentication in the *Junos OS System Basics Configuration Guide*.

To determine whether a login account exists on a device running Junos OS, enter the CLI configuration mode on the device and issue the following commands:

```
[edit]
user@host# edit system login
[edit system login]
user@host# show user account-name
```

If the appropriate account does not exist, perform the following steps:

1. Include the **user** statement at the **[edit system login]** hierarchy level and specify a username. Also include the **class** statement at the **[edit system login user username]** hierarchy level, and specify a login class that has the permissions required for all actions to be performed by the application. You can also include the optional **full-name** and **uid** statements. Optionally, include the **full-name** and **uid** statements.

```
[edit system login]
user@host# set user account-name class class-name
```

NOTE: For detailed information about creating user accounts, see the chapter about configuring user access in the *Junos OS System Basics Configuration Guide*.

2. Create a text-based password for the account by including either the **plain-text-password** or **encrypted-password** statement at the **[edit system login user account-name authentication]** hierarchy level.

```
[edit system login]
user@host# edit user account-name authentication
```

NOTE: A text-based password is not strictly necessary if the account is used to access the Junos XML protocol server through SSH with public/private key pairs for authentication, but we recommend that you create one anyway. The key pair alone is sufficient if the account is used only for SSH access, but a password is required if the account is also used for any other type of access (for login on the console, for example). The password is also used—the SSH server prompts for it—if key-based authentication is configured but fails. For information about creating a public/private key pair, see “[Prerequisites for SSH Connections](#)” on page 800.

To enter a password as text, issue the following command. You are prompted for the password, which is encrypted before being stored.

```
[edit system login user account-name authentication]
user@host# set plain-text-password
New password: password
```

Retype new password: *password*

To store a password that you have previously created and hashed using Message Digest 5 (MD5) or Secure Hash Algorithm 1 (SHA-1), issue the following command:

```
[edit system login user account-name authentication]
user@host# set encrypted-password "password"
```

3. Issue the **commit** command.

```
[edit system login user account-name authentication]
user@host# top
[edit]
user@host# commit
```

4. Repeat the preceding steps on each device where the client application establishes Junos XML protocol sessions.
5. Enable the client application to access the password and provide it when the Junos XML protocol server prompts for it. There are several possible methods, including the following:
 - Code the application to prompt the user for a password at startup and to store the password temporarily in a secure manner.
 - Store the password in encrypted form in a secure local-disk location or secured database and code the application to access it.

Prerequisites for Clear-Text Connections

A client application that uses the Junos XML protocol-specific clear-text access protocol sends unencrypted text directly over a TCP connection without using any additional protocol (such as SSH, SSL, or Telnet).

NOTE: Devices running the Junos-FIPS software do not accept Junos XML protocol clear-text connections. We recommend that you do not use the clear-text protocol in a Common Criteria environment. For more information, see the *Secure Configuration Guide for Common Criteria and Junos-FIPS*.

To enable client applications to use the clear-text protocol to connect to the Junos XML protocol server, perform the following steps:

1. Verify that the application can access the TCP software. On most operating systems, TCP is accessible in the standard distribution. Do this on each computer where the application runs.
2. Satisfy the prerequisites discussed in [“Prerequisites for All Access Protocols” on page 797](#).
3. Configure the device running Junos OS to accept clear-text connections from client applications on port 3221 by including the **xnm-clear-text** statement at the **[edit system services]** hierarchy level:

```
[edit]
user@host# set system services xnm-clear-text
```

By default, the Junos XML protocol server supports up to 75 simultaneous clear-text sessions and 150 connection attempts per minute. Optionally, you can include either or both the **connection-limit** statement to limit the number of concurrent sessions and the **rate-limit** statement to limit the number of connection attempts. Both statements accept a value from 1 through 250.

```
[edit]
user@host# set system services xnm-clear-text connection-limit limit
user@host# set system services xnm-clear-text rate-limit limit
```

For more information about the **xnm-clear-text** statement, see the *Junos OS System Basics Configuration Guide*.

4. Commit the configuration:

```
[edit]
user@host# commit
```

5. Repeat Step 2 through Step 4 on each device where the client application establishes Junos XML protocol sessions.

Prerequisites for SSH Connections

To enable a client application to use the SSH protocol to connect to the Junos XML protocol server, perform the following steps:

1. Enable the application to access the SSH software.

If the application uses the Junos XML protocol Perl module provided by Juniper Networks, no action is necessary. As part of the installation procedure for the Perl module, you install a prerequisites package that includes the necessary SSH software. For instructions, see [“Downloading the Junos XML Protocol Perl Client and Prerequisites Package” on page 980](#).

If the application does not use the Junos XML protocol Perl module, obtain the SSH software and install it on the computer where the application runs. For information about obtaining and installing SSH software, see <http://www.ssh.com/> and <http://www.openssh.com/>.

2. Satisfy the prerequisites discussed in [“Prerequisites for All Access Protocols” on page 797](#).
3. (Optional) If you want to use key-based SSH authentication for the application, create a public/private key pair and associate it with the Junos OS login account you created in [“Prerequisites for All Access Protocols” on page 797](#). Perform the following steps:
 - a. Working on the computer where the client application runs, issue the **ssh-keygen** command in a standard command shell (not the Junos OS CLI). By providing the appropriate arguments, you encode the public key with either RSA (supported by SSH versions 1 and 2) or the Digital Signature Algorithm (DSA), supported by SSH version 2. For more information, see the man page provided by your SSH vendor for the **ssh-keygen** command. The Junos OS uses SSH version 2 by default but also supports version 1.

```
% ssh-keygen options
```

- b. Enable the application to access the public and private keys. One method is to run the **ssh-agent** program on the computer where the application runs.
- c. On the device running Junos OS that needs to accept SSH connections from Junos XML protocol client applications, associate the public key with the Junos login account by including the **load-key-file** statement at the **[edit system login user account-name authentication]** hierarchy level. First, move to that hierarchy level:

```
[edit]
user@host# edit system login user account-name authentication
```

Issue the following command to copy the contents of the specified file onto the device running Junos OS:

```
[edit system login user account-name authentication]
user@host# set load-key-file URL
```

URL is the path to the file that contains one or more public keys. The **ssh-keygen** command by default stores each public key in a file in the **.ssh** subdirectory of the user home directory; the filename depends on the encoding (DSA or RSA) and SSH version. For information about specifying URLs, see the *CLI User Guide*.

Alternatively, you can include one or both of the **ssh-dsa** and **ssh-rsa** statements at the **[edit system login user account-name authentication]** hierarchy level. We recommend using the **load-key-file** statement, however, because it eliminates the need to type or cut and paste the public key on the command line. For more information about the **ssh-dsa** and **ssh-rsa** statements, see the *Junos OS System Basics Configuration Guide*.

4. Configure the device running Junos OS to accept SSH connections by including the **ssh** statement at the **[edit system services]** hierarchy level. This statement enables SSH access for all users and applications, not just Junos XML protocol client applications.

```
[edit system login user account-name authentication]
user@host# top
[edit]
user@host# set system services ssh
```

5. Commit the configuration:

```
[edit]
user@host# commit
```

6. Repeat Step 1 on each computer where the application runs, and Step 2 through Step 5 on each device to which the application connects.

Prerequisites for Outbound SSH Connections

The outbound SSH feature allows the initiation of an SSH session between devices running Junos OS and Network and System Management servers where client-initiated TCP/IP connections are blocked (for example, when the device is behind a firewall). To configure outbound SSH, you add an **outbound-ssh** configuration statement to the device. Once configured and committed, the device running Junos OS will begin to initiate outbound SSH sessions with the configured management clients. Once the outbound SSH session is initialized and the connection is established, the management server

initiates the SSH sequence as the client and the device running Junos OS, acting as the server, authenticates the client.

Setting up outbound SSH involves:

- Configuring the device running Junos OS for outbound SSH
- Configuring the management server for outbound SSH.

To configure the device for outbound SSH:

1. Satisfy the prerequisites discussed in ["Prerequisites for All Access Protocols" on page 797](#).
2. In the `[edit system services ssh]` hierarchy level, set the SSH protocol to v2:

```
[edit system services ssh]
set protocol-version v2
```
3. Generate/obtain a public/private key pair for the device running Junos OS. This key pair will be used to encrypt the data transferred across the SSH connection. For more information on generating key pairs, see the *Junos OS System Basics Configuration Guide*.
4. If the public key will be installed on the application management system manually, transfer the public key to the NSM server.
5. Add the following **outbound-ssh** statement at the `[edit system services]` hierarchy level:

```
[edit system services]
outbound-ssh client {
  application-id {
    device-id device-id;
    secret secret;
    keep-alive {
      retry number;
      timeout number;
    }
    reconnect-strategy (sticky | in-order) ;
    services netconf;
    address {
      port destination-port;
      retry number;
      timeout number;
    }
  }
}
```

The attributes are as follows:

- **application-id**—(Required) Identifies the **outbound-ssh** configuration stanza on the device. Each **outbound-ssh** stanza represents a single outbound SSH connection. This attribute is not sent to the client.
- **device-id**—(Required) Identifies the device to the client during the initiation sequence.
