**BEST PRACTICE:** Mirror only necessary packets to reduce potential performance impact. We recommend that you:

- Disable your configured mirroring sessions when you are not using them.
- Specify individual interfaces as input to analyzers rather than specifying all interfaces as input.
- Limit the amount of mirrored traffic by using firewall filters.

This example describes how to configure remote mirroring through a transit switch:

- [Requirements on page 4017](#)
- [Overview and Topology on page 4017](#)
- [Mirroring All Employee Traffic for Remote Analysis Through a Transit Switch on page 4018](#)
- [Verification on page 4022](#)

## Requirements

This example uses the following hardware and software components:

- An EX4300 switch connected to another EX4300 switch through a third EX4300 switch
- Junos OS Release 13.2X50-D10 or later for EX Series switches

Before you configure remote mirroring, be sure that:

- You have an understanding of mirroring concepts.
- The interfaces that the analyzer will use as input interfaces have been configured on the switch.

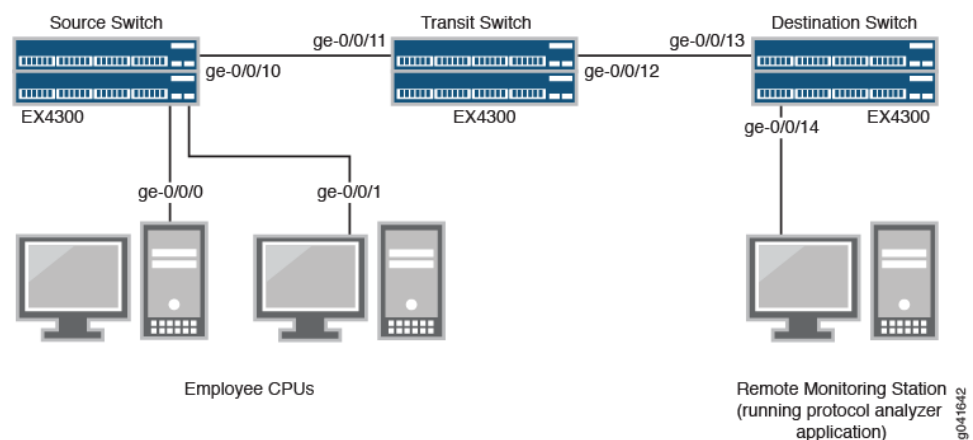

## Overview and Topology

This example describes how to mirror traffic entering ports on the switch to the **remote-analyzer** VLAN through a transit switch so that you can perform analysis from a remote monitoring station. The example shows how to configure a switch to mirror all traffic from employee computers to a remote analyzer.

In this configuration, an analyzer session is required on the destination switch to mirror incoming traffic from the analyzer VLAN to the egress interface to which the remote monitoring station is connected. You must disable MAC learning on the transit switch for the **remote-analyzer** VLAN so that MAC learning is disabled for all member interfaces of the **remote-analyzer** VLAN on the transit switch.

Figure 57 on page 4017 shows the network topology for this example.

**Figure 57: Remote Mirroring Through a Transit Switch Network—Sample Topology**

In this example:

- Interface ge-0/0/0 is a Layer 2 interface, and interface ge-0/0/1 is a Layer 3 interface (both interfaces on the source switch) that serve as connections for employee computers.
- Interface ge-0/0/10 is a Layer 2 interface that connects to the transit switch.
- Interface ge-0/0/11 is a Layer 2 interface on the transit switch.
- Interface ge-0/0/12 is a Layer 2 interface on the transit switch and connects to the destination switch.
- Interface ge-0/0/13 is a Layer 2 interface on the destination switch .
- Interface ge-0/0/14 is a Layer 2 interface on the destination switch and connects to the remote monitoring station.
- VLAN **remote-analyzer** is configured on all switches in the topology to carry the mirrored traffic.

### Mirroring All Employee Traffic for Remote Analysis Through a Transit Switch

To configure mirroring for remote traffic analysis through a transit switch, for all incoming and outgoing employee traffic, perform these tasks:

#### **CLI Quick Configuration**

To quickly configure mirroring for remote traffic analysis through a transit switch, for incoming and outgoing employee traffic, copy the following commands and paste them into the switch terminal window:

- Copy and paste the following commands in the source switch (monitored switch) terminal window:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set forwarding-options analyzer employee-monitor input ingress interface ge-0/0/0.0
set forwarding-options analyzer employee-monitor input ingress interface ge-0/0/1.0
set forwarding-options analyzer employee-monitor input egress interface ge-0/0/0.0
set forwarding-options analyzer employee-monitor input egress interface ge-0/0/1.0
set forwarding-options analyzer employee-monitor output vlan remote-analyzer
```

- Copy and paste the following commands in the transit switch window:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/11 unit 0 family ethernet-switching interface-mode trunk
set vlans remote-analyzer interface ge-0/0/11
set interfaces ge-0/0/12 unit 0 family ethernet-switching interface-mode trunk
set vlans remote-analyzer interface ge-0/0/12
set vlans remote-analyzer no-mac-learning
```

- Copy and paste the following commands in the destination switch window:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/13 unit 0 family ethernet-switching interface-mode trunk
set vlans remote-analyzer interface ge-0/0/13 ingress
set interfaces ge-0/0/14 unit 0 family ethernet-switching interface-mode trunk
```

```
set forwarding-options analyzer employee-monitor input ingress vlan remote-analyzer
set forwarding-options analyzer employee-monitor output interface ge-0/0/14.0
```

### Step-by-Step Procedure

To configure remote mirroring through a transit switch:

1. On the source switch:

- Configure the VLAN ID for the **remote-analyzer** VLAN:

```
[edit vlans]
user@switch# set remote-analyzer vlan-id 999
```

- Configure the interfaces on the network port connected to transit switch for trunk mode and associate it with the **remote-analyzer** VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/10 unit 0 family ethernet-switching interface-mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
```

- Configure the **employee-monitor** analyzer:

```
[edit forwarding-options]
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/0.0
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/1.0
user@switch# set analyzer employee-monitor input egress interface ge-0/0/0.0
user@switch# set analyzer employee-monitor input egress interface ge-0/0/1.0
user@switch# set analyzer employee-monitor output vlan remote-analyzer
```

2. On the transit switch:

- Configure the VLAN ID for the **remote-analyzer** VLAN:

```
[edit vlans]
user@switch# set remote-analyzer vlan-id 999
```

- Configure the **ge-0/0/11** interface for trunk mode, associate it with the **remote-analyzer** VLAN:

```
[edit interfaces]
user@switch# set ge-0/0/11 unit 0 family ethernet-switching interface-mode trunk
```

- Configure the **ge-0/0/12** interface for trunk mode, associate it with the **remote-analyzer** VLAN, and set the interface for egress traffic only:

```
[edit interfaces]
user@switch# set ge-0/0/12 unit 0 family ethernet-switching interface-mode trunk
user@switch# set vlans remote-analyzer interface ge-0/0/12
```

- Configure the **no-mac-learning** option for the **remote-analyzer** VLAN to disable MAC learning on all interfaces that are members of the **remote-analyzer** VLAN:

```
[edit interfaces]
user@switch# set vlans remote-analyzer no-mac-learning
```

3. On the destination switch:

- Configure the VLAN ID for the **remote-analyzer** VLAN:

```
[edit vlans]
user@switch# set remote-analyzer vlan-id 999
```

- Configure the **ge-0/0/13** interface for trunk mode, associate it with the **remote-analyzer** VLAN, and set the interface for ingress traffic only:

```
[edit interfaces]
user@switch# set ge-0/0/13 unit 0 family ethernet-switching interface-mode trunk
```

```
user@switch# set vlans remote-analyzer interface ge-0/0/13 ingress
```

- Configure the interface connected to the remote monitoring station for trunk mode:

```
[edit interfaces]
```

```
user@switch# set ge-0/0/14 unit 0 family ethernet-switching interface-mode trunk
```

- Configure the **employee-monitor** analyzer:

```
[edit forwarding-options]
```

```
user@switch# set analyzer employee-monitor input ingress vlan remote-analyzer
```

```
user@switch# set analyzer employee-monitor output interface ge-0/0/14.0
```

**Results** Check the results of the configuration on the source switch:

```
[edit]
user@switch> show
forwarding-options {
  analyzer employee-monitor {
    input {
      ingress {
        interface ge-0/0/0.0;
        interface ge-0/0/1.0;
      }
      egress {
        interface ge-0/0/0.0;
        interface ge-0/0/1.0;
      }
    }
    output {
      vlan {
        remote-analyzer;
      }
    }
  }
}
vlans {
  remote-analyzer {
    vlan-id 999;
  }
}
interfaces {
  ge-0/0/10 {
    unit 0 {
      family ethernet-switching {
        interface-mode trunk;
        vlan {
          member 999;
        }
      }
    }
  }
}
```

Check the results of the configuration on the transit switch:

```
[edit]
```

```

user@switch> show
vpls {
  remote-analyzer {
    vlan-id 999;
    interface {
      ge-0/0/11.0 {
      }
      ge-0/0/12.0 {
      }
    }
    no-mac-learning;
  }
}
interfaces {
  ge-0/0/11 {
    unit 0 {
      family ethernet-switching {
        interface-mode trunk;
      }
    }
  }
  ge-0/0/12 {
    unit 0 {
      family ethernet-switching {
        interface-mode trunk;
      }
    }
  }
}
}

```

Check the results of the configuration on the destination switch:

```

[edit]
user@switch> show
vpls {
  remote-analyzer {
    vlan-id 999;
    interface {
      ge-0/0/13.0 {
        ingress;
      }
    }
  }
}
interfaces {
  ge-0/0/13 {
    unit 0 {
      family ethernet-switching {
        interface-mode trunk;
      }
    }
  }
  ge-0/0/14 {
    unit 0 {
      family ethernet-switching {
        interface-mode trunk;
      }
    }
  }
}

```

```
    }  
  }  
}  
forwarding-options {  
  analyzer employee-monitor {  
    input {  
      ingress {  
        vlan remote-analyzer;  
      }  
    }  
    output {  
      interface {  
        ge-0/0/14.0;  
      }  
    }  
  }  
}
```

---

### Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That the Analyzer Has Been Correctly Created on page 4022](#)

#### *Verifying That the Analyzer Has Been Correctly Created*

**Purpose** Verify that the analyzer named **employee-monitor** has been created on the switch with the appropriate input interfaces and the appropriate output interface.

**Action** You can verify whether the analyzer is configured as expected by using the **show analyzer** command. To view previously created analyzers that are disabled, go to the J-Web interface.

To verify that the analyzer is configured as expected while monitoring all employee traffic on the source switch, run the **show analyzer** command on the source switch. The following output is displayed for this example configuration:

```
user@switch> show forwarding-options analyzer  
Analyzer name           : employee-monitor  
Mirror rate             : 1  
Maximum packet length   : 0  
State                   : up  
Ingress monitored interfaces : ge-0/0/0.0  
Ingress monitored interfaces : ge-0/0/1.0  
Egress monitored interfaces : ge-0/0/0.0  
Egress monitored interfaces : ge-0/0/1.0  
Output vlan             : default-switch/remote-analyzer
```

**Meaning** This output shows that the **employee-monitor** analyzer has a ratio of 1 (mirroring every packet, the default), is mirroring the traffic entering ge-0/0/0 and ge-0/0/1, and sending the mirrored traffic to the analyzer **remote-analyzer**.

## Example: Configuring Ethernet OAM Connectivity Fault Management on EX Series Switches

Ethernet interfaces on EX Series switches and Junos OS for EX Series switches support the IEEE 802.1ag standard for Operation, Administration, and Management (OAM). The IEEE 802.1ag specification provides for Ethernet connectivity fault management (CFM).

This example describes how to enable and configure OAM CFM on a Gigabit Ethernet interface:

- [Requirements on page 4023](#)
- [Overview and Topology on page 4023](#)
- [Configuring Ethernet OAM Connectivity Fault Management on Switch 1 on page 4023](#)
- [Configuring Ethernet OAM Connectivity Fault Management on Switch 2 on page 4024](#)
- [Verification on page 4026](#)

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.2 or later for EX Series switches
- Two EX Series switches connected by a point-to-point Gigabit Ethernet link

### Overview and Topology

CFM can be used to monitor the physical link between two switches. In the following example, two switches are connected by a point-to-point Gigabit Ethernet link. The link between these two switches is monitored using CFM.

### Configuring Ethernet OAM Connectivity Fault Management on Switch 1

- CLI Quick Configuration**
- To quickly configure Ethernet OAM CFM, copy the following commands and paste them into the switch terminal window:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain]
set name-format character-string
set maintenance-domain private level 0
set maintenance-association private-ma
set continuity-check hold-interval 1s
```

**Step-by-Step  
Procedure**

To enable and configure OAM CFM on switch 1:

1. Specify the maintenance domain name format:  

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain]  
user@switch1# set name-format character-string
```
2. Specify the maintenance domain name and the maintenance domain level:  

```
[edit protocols oam ethernet connectivity-fault-management]  
user@switch1# set maintenance-domain private level 0
```
3. Create a maintenance association:  

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
private]  
user@switch1# set maintenance-association private-ma
```
4. Enable the continuity check protocol and specify the continuity check hold interval:  

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
private maintenance-association private-ma]  
user@switch1# set continuity-check hold-interval 1s
```
5. Configure the maintenance association end point (MEP):  

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
private maintenance-association private-ma]  
user@switch1# set mep 100 interface ge-1/0/1 auto-discovery direction down
```

**Results**

Check the results of the configuration.

```
[edit]  
user@switch1 > show  
  
protocols {  
  oam {  
    ethernet {  
      connectivity-fault-management {  
        maintenance-domain private {  
          level 0;  
          maintenance-association private-ma {  
            continuity-check {  
              interval 1s;  
            }  
            mep 100 {  
              interface ge-1/0/1;  
              auto-discovery;  
              direction down;  
            }  
          }  
        }  
      }  
    }  
  }  
}
```

---

**Configuring Ethernet OAM Connectivity Fault Management on Switch 2**

---

**CLI Quick  
Configuration**

To quickly configure Ethernet OAM CFM, copy the following commands and paste them into the switch terminal window:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain]  
set name-format character-string
```

```

set maintenance-domain private level 0
set maintenance-association private-ma
set continuity-check hold-interval 1s

```

### Step-by-Step Procedure

The configuration on switch 2 mirrors that on switch 2.

1. Specify the maintenance domain name format:  

```

[edit protocols oam ethernet connectivity-fault-management]
user@switch2# set name-format character-string

```
2. Specify the maintenance domain name and the maintenance domain level:  

```

[edit protocols oam ethernet connectivity-fault-management]
user@switch2# set maintenance-domain private level 0

```
3. Create a maintenance association:  

```

[edit protocols oam ethernet connectivity-fault-management maintenance-domain
private]
user@switch2# set maintenance-association private-ma

```
4. Enable the continuity check protocol and specify the continuity check hold interval:  

```

[edit protocols oam ethernet connectivity-fault-management maintenance-domain
private maintenance-association private-ma]
user@switch2# set continuity-check hold-interval 1s

```
5. Configure the maintenance association end point (MEP)  

```

[edit protocols oam ethernet connectivity-fault-management maintenance-domain
private maintenance-association private-ma]
user@switch2# set mep 200 interface ge-0/2/5 auto-discovery direction down

```

### Results

Check the results of the configuration.

```

[edit]
user@switch2 > show

protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        maintenance-domain private {
          level 0;
          maintenance-association private-ma {
            continuity-check {
              interval 1s;
            }
            mep 200 {
              interface ge-0/2/5;
              auto-discovery;
              direction down;
            }
          }
        }
      }
    }
  }
}

```

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That OAM CFM Has Been Configured Properly on page 4026](#)

### *Verifying That OAM CFM Has Been Configured Properly*

**Purpose** Verify that OAM CFM has been configured properly.

**Action** Use the `show oam ethernet connectivity-fault-management interfaces detail` command:

```
user@switch1# show oam ethernet connectivity-fault-management interfaces detail
```

## Sample Output

```
Interface name: ge-1/0/1.0, Interface status: Active, Link status: Up
Maintenance domain name: private, Format: string, Level: 0
Maintenance association name: private-ma, Format: string
Continuity-check status: enabled, Interval: 1ms, Loss-threshold: 3 frames
MEP identifier: 100, Direction: down, MAC address: 00:90:69:0b:4b:94
MEP status: running
Defects:
  Remote MEP not receiving CCM                : no
  Erroneous CCM received                      : yes
  Cross-connect CCM received                  : no
  RDI sent by some MEP                       : yes
Statistics:
  CCMs sent                                  : 76
  CCMs received out of sequence              : 0
  LBMs sent                                  : 0
  Valid in-order LBRs received               : 0
  Valid out-of-order LBRs received           : 0
  LBRs received with corrupted data          : 0
  LBRs sent                                  : 0
  LTMs sent                                  : 0
  LTMs received                             : 0
  LTRs sent                                  : 0
  LTRs received                             : 0
  Sequence number of next LTM request        : 0
Remote MEP count: 2
  Identifier  MAC address      State  Interface
  2001       00:90:69:0b:7f:71  ok    ge-0/2/5.0
```

**Meaning** When the output displays that continuity-check status is **enabled** and displays details of the remote MEP, it means that connectivity fault management (CFM) has been configured properly.

**Related Documentation**

- [Understanding Ethernet OAM Connectivity Fault Management for an EX Series Switch on page 3973](#)
- [Junos OS Network Interfaces Configuration Guide](#)

## Example: Configuring Ethernet OAM Link Fault Management on EX Series Switches

Junos OS for EX Series switches allows the Ethernet interfaces on these switches to support the IEEE 802.3ah standard for the Operation, Administration, and Maintenance (OAM) of Ethernet in access networks. The standard defines OAM link fault management (LFM). You can configure IEEE 802.3ah OAM LFM on point-to-point Ethernet links that are connected either directly or through Ethernet repeaters.

This example describes how to enable and configure OAM LFM on a Gigabit Ethernet interface:

- [Requirements on page 4027](#)
- [Overview and Topology on page 4027](#)
- [Configuring Ethernet OAM Link Fault Management on Switch 1 on page 4027](#)
- [Configuring Ethernet OAM Link Fault Management on Switch 2 on page 4028](#)
- [Verification on page 4029](#)

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.4 or later for EX Series switches
- Two EX3200 or EX4200 switches connected directly

### Overview and Topology

Junos OS for EX Series switches allows the Ethernet interfaces on these switches to support the IEEE 802.3ah standard for the Operation, Administration, and Maintenance (OAM) of Ethernet in access networks. The standard defines OAM link fault management (LFM). You can configure IEEE 802.3ah OAM LFM on point-to-point Ethernet links that are connected either directly or through Ethernet repeaters.

This example uses two EX4200 switches connected directly. Before you begin configuring Ethernet OAM LFM on two switches, connect the two switches directly through a trunk interface.

### Configuring Ethernet OAM Link Fault Management on Switch 1

**CLI Quick Configuration** To quickly configure Ethernet OAM LFM, copy the following commands and paste them into the switch terminal window:

```
[edit protocols oam ethernet link-fault-management]
set interface ge-0/0/0
set interface ge-0/0/0 link-discovery active
set interface ge-0/0/0 pdu-interval 800
set interface ge-0/0/0 remote-loopback
```

**Step-by-Step Procedure** To configure Ethernet OAM LFM on switch 1:

1. Enable IEEE 802.3ah OAM support on an interface:
 

```
[edit protocols oam ethernet link-fault-management]
user@switch1# set interface (OAM LFM) ge-0/0/0
```

2. Specify that the interface initiates the discovery process by configuring the link discovery mode to **active**:  

```
[edit protocols oam ethernet link-fault-management]  
user@switch1# set interface ge-0/0/0 link-discovery active
```
3. Set the periodic OAM PDU-sending interval (in milliseconds) to 800 on switch 1:  

```
[edit protocols oam ethernet link-fault-management]  
user@switch1# set interface pdu-interval 800
```
4. Set a remote interface into loopback mode so that all frames except OAM PDUs are looped back without any changes made to the frames. Ensure that the remote DTE supports remote loopback mode. To set the remote DTE in loopback mode  

```
[edit protocols oam ethernet link-fault-management]  
user@switch1# set interface ge-0/0/0.0 remote-loopback
```

### Results

Check the results of the configuration:

```
[edit]  
user@switch1# show  
  
protocols {  
  oam {  
    ethernet {  
      link-fault-management {  
        interface ge-0/0/0 {  
          pdu-interval 800;  
          link-discovery active;  
          remote-loopback;  
        }  
      }  
    }  
  }  
}
```

---

### Configuring Ethernet OAM Link Fault Management on Switch 2

**CLI Quick Configuration** To quickly configure Ethernet OAM LFM on switch 2, copy the following commands and paste them into the switch terminal window:

```
[edit protocols oam ethernet link-fault-management ]  
set interface ge-0/0/1  
set interface ge-0/0/1 negotiation-options allow-remote-loopback
```

**Step-by-Step Procedure** To configure Ethernet OAM LFM on switch 2:

1. Enable OAM on the peer interface on switch 2:  

```
[edit protocols oam ethernet link-fault-management]  
user@switch2# set interface ge-0/0/1
```
2. Enable remote loopback support for the local interface:  

```
[edit protocols oam ethernet link-fault-management]  
user@switch2# set interface ge-0/0/1 negotiation-options allow-remote-loopback
```

**Results** Check the results of the configuration:

```
[edit]
```

```

user@switch2# show

protocols {
  oam {
    ethernet {
      link-fault-management {
        interface ge-0/0/1 {
          negotiation-options {
            allow-remote-loopback;
          }
        }
      }
    }
  }
}

```

### Verification

#### *Verifying That OAM LFM Has Been Configured Properly*

**Purpose** Verify that OAM LFM has been configured properly.

**Action** Use the `show oam ethernet link-fault-management` command:

```
user@switch1#show oam ethernet link-fault-management
```

### Sample Output

```

Interface: ge-0/0/0.0
Status: Running, Discovery state: Send Any
Peer address: 00:19:e2:50:3b:e1
Flags:Remote-Stable Remote-State-Valid Local-Stable 0x50
Remote entity information:
Remote MUX action: forwarding, Remote parser action: forwarding
Discovery mode: active, Unidirectional mode: unsupported
Remote loopback mode: supported, Link events: supported
Variable requests: unsupported

```

**Meaning** When the output displays the MAC address and the discover state is **Send Any**, it means that OAM LFM has been configured properly.

### Example: Configuring Enhanced Network Analytics Features

This example shows how to configure the enhanced network analytics feature, including queue and traffic monitoring.

- [Requirements on page 4030](#)
- [Overview on page 4030](#)
- [Configuration on page 4031](#)
- [Verification on page 4035](#)

## Requirements

---

This example uses the following hardware and software components:

- A QFX5100 standalone switch
- A external streaming server to collect data
- Junos OS Release 13.2X51-D15 software
- TCP server software (for remote streaming servers)

Before you configure network analytics, be sure you have:

- Junos OS Release 13.2X51-D15 or later software installed and running on the QFX5100 switch.
- (Optional for streaming servers for the JSON, CSV, and TSV formats) TCP or UDP server software set up for processing records separated by a newline character (\n) on the remote streaming server.
- (Optional for streaming servers for the GPB format) TCP or UDP build streaming server using the **analytics.proto** file.
- All other network devices running.

## Overview

---

The network analytics feature provides visibility into the performance and behavior of the data center infrastructure. This feature collects data from the switch, analyzes the data using sophisticated algorithms, and captures the results in reports. Network administrators can use the reports to help troubleshoot problems, make decisions, and adjust resources as needed.

You enable network analytics by first defining a resource profile template, and then applying the profile to the system (for a global configuration) or to individual interfaces.

**NOTE:** You can configure queue and traffic monitoring on physical network interfaces only; logical interfaces and Virtual Chassis physical (VCP) interfaces are not supported.

Disabling of the queue or traffic monitoring supersedes the configuration (enabling) of this feature. You disable monitoring by applying a resource profile that includes the **no-queue-monitoring** or **no-traffic-monitoring** configuration statement at the [edit services analytics resource-profiles] hierarchy level.

---

## Topology

In this example, the QFX5100 switch is connected to an external server used for streaming statistics data.

## Configuration

To configure the network analytics features, perform these tasks:

- [Configuring the Polling Interval for Queue and Traffic Monitoring on page 4031](#)
- [Configuring a Local Statistics File on page 4032](#)
- [Configuring and Applying a Resource Profile for the System on page 4032](#)
- [Configuring and Applying a Resource Profile for an Interface on page 4032](#)
- [Configuring an Export Profile and Collector for Streaming Data on page 4033](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
[edit]
set services analytics resource system polling-interval queue-monitoring 1000
set services analytics resource system polling-interval traffic-monitoring 5
set services analytics collector local file an.stats
set services analytics collector local file an files 3
set services analytics collector local file an size 10m
set services analytics resource-profiles sys-rp queue-monitoring
set services analytics resource-profiles sys-rp traffic-monitoring
set services analytics resource-profiles sys-rp depth-threshold high 999999 low 99
set services analytics resource system resource-profile sys-rp
set services analytics resource-profiles if-rp queue-monitoring
set services analytics resource-profiles if-rp traffic-monitoring
set services analytics resource-profiles if-rp latency-threshold high 2300 low 20
set services analytics resource interfaces xe-0/0/16 resource-profile if-rp
set services analytics resource interfaces xe-0/0/18 resource-profile if-rp
set services analytics resource interfaces xe-0/0/19 resource-profile if-rp
set services analytics export-profiles ep stream-format gpb
set services analytics export-profiles ep interface information
set services analytics export-profiles ep interface statistics queue
set services analytics export-profiles ep interface statistics traffic
set services analytics export-profiles ep interface status link
set services analytics export-profiles ep system information
set services analytics export-profiles ep system status queue
set services analytics export-profiles ep system status traffic
set services analytics collector address 10.94.198.11 port 50001 transport tcp export-profile
ep
set services analytics collector address 10.94.184.25 port 50013 transport udp
export-profile ep
```

### *Configuring the Polling Interval for Queue and Traffic Monitoring*

#### Step-by-Step Procedure

To configure the polling interval queue and traffic monitoring globally:

1. Configure the queue monitoring polling interval (in milliseconds) for the system:  

```
[edit]
set services analytics resource system polling-interval queue-monitoring 1000
```
2. Configure the traffic monitoring polling interval (in seconds) for the system:

```
[edit]
set services analytics resource system polling-interval traffic-monitoring 5
```

### *Configuring a Local Statistics File*

#### **Step-by-Step Procedure**

To configure a file for local statistics collection:

1. Configure the filename:  

```
[edit]
set services analytics collector local file an.stats
```
2. Configure the number of files:  

```
[edit]
set services analytics collector local file an files 3
```
3. Configure the file size:  

```
[edit]
set services analytics collector local file an size 10m
```

### *Configuring and Applying a Resource Profile for the System*

#### **Step-by-Step Procedure**

To define a resource profile template for queue and traffic monitoring resources:

1. Configure a resource profile and enable queue monitoring:  

```
[edit]
set services analytics resource-profiles sys-rp queue-monitoring
```
2. Enable traffic monitoring in the profile:  

```
[edit]
set services analytics resource-profiles sys-rp traffic-monitoring
```
3. Configure the depth-threshold (high and low values) for queue monitoring in the profile:  

```
[edit]
set services analytics resource-profiles sys-rp depth-threshold high 999999 low 99
```
4. Apply the resource profile template to the system resource type for a global configuration:  

```
[edit]
set services analytics resource system resource-profile sys-rp
```

### *Configuring and Applying a Resource Profile for an Interface*

#### **Step-by-Step Procedure**

You can configure queue and traffic monitoring for one or more specific interfaces. The interface-specific configuration supersedes the global (system) configuration. To define a resource profile template for queue and traffic monitoring resources for an interface:

1. Configure a resource profile and enable queue monitoring:  

```
[edit]
set services analytics resource-profiles if-rp queue-monitoring
```

2. Enable traffic monitoring in the profile:
 

```
[edit]
set services analytics resource-profiles if-rp traffic-monitoring
```
3. Configure the latency-threshold (high and low values) for queue monitoring in the profile:
 

```
[edit]
set services analytics resource-profiles if-rp latency-threshold high 2300 low 20
```
4. Apply the resource profile template to the interfaces resource type for specific interfaces:
 

```
[edit]
set services analytics resource interfaces xe-0/0/16 resource-profile if-rp
set services analytics resource interfaces xe-0/0/18 resource-profile if-rp
set services analytics resource interfaces xe-0/0/19 resource-profile if-rp
```

### *Configuring an Export Profile and Collector for Streaming Data*

#### **Step-by-Step Procedure**

To configure a collector (streaming server) for receiving monitoring data:

1. Create an export profile and specify the stream format:
 

```
[edit]
set services analytics export-profiles ep stream-format gpb
```
2. Configure the export profile to include interface information:
 

```
[edit]
set services analytics export-profiles ep interface information
```
3. Configure the export profile to include interface queue statistics:
 

```
[edit]
set services analytics export-profiles ep interface statistics queue
```
4. Configure the export profile to include interface traffic statistics:
 

```
[edit]
set services analytics export-profiles ep interface statistics traffic
```
5. Configure the export profile to include interface status link information:
 

```
[edit]
set services analytics export-profiles ep interface status link
```
6. Configure the export profile to include system information:
 

```
[edit]
set services analytics export-profiles ep system information
```
7. Configure the export profile to include system queue status:
 

```
[edit]
set services analytics export-profiles ep system status queue
```
8. Configure the export profile to include system traffic status:
 

```
[edit]
set services analytics export-profiles ep system status traffic
```

9. Configure the transport protocol for the collector addresses and apply an export profile:

```
[edit]
set services analytics collector address 10.94.198.11 port 50001 transport tcp
export-profile ep
set services analytics collector address 10.94.184.25 port 50013 transport udp
export-profile ep
```

**NOTE:** If you configure the `tcp` or `udp` option for the JSON, CSV, and TSV formats, you must also set up the TCP or UDP client software on the remote collector to process records that are separated by the newline character (`\n`) on the remote server.

If you configure the `tcp` or `udp` option for the GPB format, you must also set up the TCP or UDP build streaming server using the `analytics.proto` file.

**Results** Display the results of the configuration:

```
[edit services analytics]
user@switch# run show configuration
services {
  analytics {
    export-profiles {
      ep {
        stream-format gpb;
        interface {

            }
        }
    }
}
}
}

```

### Verification

Confirm that the configuration is correct and works as expected by performing these tasks:

- [Verifying the Network Analytics Configuration on page 4036](#)
- [Verifying the Network Analytics Status on page 4036](#)

- [Verifying the Collector Configuration on page 4037](#)
- [Verifying Queue Statistics on page 4037](#)
- [Verifying Traffic Statistics on page 4038](#)

### ***Verifying the Network Analytics Configuration***

**Purpose** Verify the configuration for network analytics.

**Action** From operational mode, enter the **show analytics configuration** command to display the traffic and queue monitoring configuration.

```
user@host> show analytics configuration
Traffic monitoring status is enabled
Traffic monitoring polling interval : 5 seconds
Queue monitoring status is enabled
Queue monitoring polling interval : 1000 milliseconds
Queue depth high threshold : 99999 bytes
Queue depth low threshold : 99 bytes
```

| Interface | Traffic<br>Statistics | Queue<br>Statistics | Queue depth<br>threshold |     | Latency<br>threshold |     |
|-----------|-----------------------|---------------------|--------------------------|-----|----------------------|-----|
|           |                       |                     | High                     | Low | High                 | Low |
|           |                       |                     | (bytes)                  |     | (nanoseconds)        |     |
| xe-0/0/16 | enabled               | enabled             | n/a                      | n/a | 2300                 | 20  |
| xe-0/0/18 | enabled               | enabled             | n/a                      | n/a | 2300                 | 20  |
| xe-0/0/19 | enabled               | enabled             | n/a                      | n/a | 2300                 | 20  |

**Meaning** The output displays the traffic and queue monitoring configuration information on the switch.

### ***Verifying the Network Analytics Status***

**Purpose** Verify the network analytics operational status of the switch.

**Action** From operational mode, enter the **show analytics status global** command to display global traffic and queue monitoring status.

```
user@host> show analytics status global
Traffic monitoring status is enabled
Traffic monitoring polling interval : 5 seconds
Queue monitoring status is enabled
Queue monitoring polling interval : 1000 milliseconds
Queue depth high threshold : 99999 bytes
Queue depth low threshold : 99 bytes
```

From operational mode, enter the **show analytics status** command to display both the interface and global queue monitoring status.

```
user@host> show analytics status
Traffic monitoring status is enabled
Traffic monitoring polling interval : 5 seconds
Queue monitoring status is enabled
Queue monitoring polling interval : 1000 milliseconds
Queue depth high threshold : 99999 bytes
Queue depth low threshold : 99 bytes
```

| Interface | Traffic<br>Statistics | Queue<br>Statistics | Queue depth<br>threshold |     | Latency<br>threshold |     |
|-----------|-----------------------|---------------------|--------------------------|-----|----------------------|-----|
|           |                       |                     | High                     | Low | High                 | Low |
|           |                       |                     | (bytes)                  |     | (nanoseconds)        |     |
| xe-0/0/16 | enabled               | enabled             | n/a                      | n/a | 2300                 | 20  |
| xe-0/0/18 | enabled               | enabled             | n/a                      | n/a | 2300                 | 20  |
| xe-0/0/19 | enabled               | enabled             | n/a                      | n/a | 2300                 | 20  |

**Meaning** The output displays the global and interface status of traffic and queue monitoring on the switch.

### *Verifying the Collector Configuration*

**Action** Verify the configuration for the collector for streamed data is working.

From operational mode, enter the **show analytics collector** command to display the streaming servers configuration.

```
user@host> show analytics collector
Address      Port  Transport Stream format State      Sent
10.94.184.25 50013 udp      gpb        n/a        484
10.94.198.11 50001 tcp      gpb        In progress 0
```

**Meaning** The output displays the collector configuration.

**NOTE:** The connection state of a port configured with the **udp** transport protocol is always displayed as **n/a**.

### *Verifying Queue Statistics*

**Purpose** Verify that queue statistics collection is working.

**Action** From operational mode, enter the **show analytics queue-statistics** command to display the queue statistics.

```
user@host> show analytics queue-statistics
CLI issued at 2014-03-04 15:37:03.116018

## Configuring SNMP (J-Web Procedure)

**NOTE:** This topic applies only to the J-Web Application package.

You can use the J-Web interface to define system identification information, create SNMP communities, create SNMP trap groups, and configure health monitor options for EX Series switches.

To configure SNMP features:

1. Select **Configure > Services > SNMP**.
2. Enter information into the configuration page for SNMP as described in [Table 427 on page 4041](#).
3. To apply the configuration click **Apply**.

**NOTE:** After you make changes to the configuration on this page, you must commit the changes for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes](#) for details about all commit options.

Table 427: SNMP Configuration Page

| Field                                   | Function                                                                                                                                                                                                                                                                                                                                                                | Your Action                                                                                   |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Identification                          |                                                                                                                                                                                                                                                                                                                                                                         |                                                                                               |
| Contact Information                     | Free-form text string that specifies an administrative contact for the system.                                                                                                                                                                                                                                                                                          | Type contact information for the administrator of the system (such as name and phone number). |
| System Description                      | Free-form text string that specifies a description for the system.                                                                                                                                                                                                                                                                                                      | Type information that describes the system                                                    |
| Local Engine ID                         | Provides an administratively unique identifier of an SNMPv3 engine for system identification.<br><br>The local engine ID contains a prefix and a suffix. The prefix is formatted according to specifications defined in RFC 3411. The suffix is defined by the local engine ID. Generally, the local engine ID suffix is the MAC address of Ethernet management port 0. | Type the MAC address of Ethernet management port 0.                                           |
| System Location                         | Free-form text string that specifies the location of the system.                                                                                                                                                                                                                                                                                                        | Type location information for the system (lab name or rack name, for example).                |
| System Override Name                    | Free-form text string that overrides the system hostname.                                                                                                                                                                                                                                                                                                               | Type the hostname of the system.                                                              |
| <b>Communities</b>                      |                                                                                                                                                                                                                                                                                                                                                                         |                                                                                               |
| To add a community, click <b>Add</b>    |                                                                                                                                                                                                                                                                                                                                                                         |                                                                                               |
| Community Name                          | Specifies the name of the SNMP community.                                                                                                                                                                                                                                                                                                                               | Type the name of the community being added.                                                   |
| Authorization                           | Specifies the type of authorization (either read-only or read-write) for the SNMP community being configured.                                                                                                                                                                                                                                                           | Select the authorization (either read-only or read-write) from the list.                      |

## Configuring Mirroring on EX4300 Switches to Analyze Traffic (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring Port Mirroring to Analyze Traffic (CLI Procedure)*. For ELS details, see *Getting Started with Enhanced Layer 2 Software*.

EX4300 switches enable you to configure mirroring to send copies of packets to either a local interface for local monitoring or to a VLAN for remote monitoring. You can use mirroring to copy these packets:

- Packets entering or exiting a port
- Packets entering a VLAN

**BEST PRACTICE:** Mirror only necessary packets to reduce potential performance impact. We recommend that you:

- Disable your configured mirroring configurations when you are not using them.
- Specify individual interfaces as input to analyzers rather than specifying all interfaces as input.
- Limit the amount of mirrored traffic by using firewall filters.

**NOTE:** If you want to create additional analyzers without deleting the existing analyzers, then disable the existing analyzers by using the `disable analyzer analyzer-name` statement from the command-line interface or the J-Web configuration page for mirroring.

**NOTE:** Interfaces used as output for an analyzer must be configured under the `ethernet-switching` family.

---

### Configuring an Analyzer for Local Traffic Analysis

---

To mirror interface traffic or VLAN traffic on the switch to an interface on the switch (by using analyzers):

1. Choose a name for the analyzer and specify the input:

```
[edit forwarding-options]
user@switch# set analyzer analyzer-name input ingress interface interface-name
```

For example, create an analyzer called **employee-monitor** for which the input traffic is packets entering interfaces ge-0/0/0.0 and ge-0/0/1.0:

```
[edit forwarding-options]
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/0.0
[edit forwarding-options]
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/1.0
```

2. Configure the destination interface for the mirrored packets:

```
[edit forwarding-options]
user@switch# set analyzer analyzer-name output interface interface-name
```

For example, configure ge-0/0/10.0 as the destination interface for the **employee-monitor** analyzer:

```
[edit forwarding-options]
user@switch# set analyzer employee-monitor output interface ge-0/0/10.0
```

---

### Configuring an Analyzer for Remote Traffic Analysis

---

To mirror traffic that is traversing interfaces or a VLAN on the switch to a VLAN for analysis from a remote location (by using analyzers):

1. Configure a VLAN to carry the mirrored traffic:

```
[edit]
user@switch# set vlans analyzer-name vlan-id vlan-ID
```

For example, define an analyzer VLAN called **remote-analyzer** and assign it a VLAN ID of **999**:

```
[edit]
user@switch# set vlans remote-analyzer vlan-id 999
```

2. Set the uplink module interface that is connected to the distribution switch to trunk mode and associate it with the analyzer VLAN:

```
[edit]
user@switch# set interfaces interface-name unit 0 family ethernet-switching interface-mode
trunk vlan members vlan-ID
```

For example, set the interface ge-0/1/1 to trunk mode and associate it with the analyzer VLAN ID 999:

```
[edit]
user@switch# set interfaces ge-0/1/1 unit 0 family ethernet-switching interface-mode trunk
vlan members 999
```

3. Configure the analyzer:

- a. Define an analyzer and specify the traffic to be mirrored:

```
[edit forwarding-options]
user@switch# set analyzer analyzer-name input ingress interface interface-name
```

For example, define the **employee-monitor** analyzer for which traffic to be mirrored is packets entering interfaces ge-0/0/0.0 and ge-0/0/1.0:

```
[edit forwarding-options]
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/0.0
[edit forwarding-options]
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/1.0
```

- b. Specify the analyzer VLAN as the output for the analyzer:

```
[edit forwarding-options]
user@switch# set analyzer analyzer-name output vlan vlan-ID
```

For example, specify the **remote-analyzer** VLAN as the output analyzer for the **employee-monitor** analyzer:

```
[edit forwarding-options]
user@switch# set analyzer employee-monitor output vlan 999
```

## Configuring Port Mirroring

To filter packets to be mirrored to a port-mirroring instance, create the instance and then use it as the action in the firewall filter. You can use firewall filters in both local and remote mirroring configurations.

If the same port-mirroring instance is used in multiple filters or terms, the packets are copied to the analyzer output port or analyzer VLAN only once.

To filter mirrored traffic, create a port-mirroring instance under the **[edit forwarding-options]** hierarchy level, and then create a firewall filter. The filter can use any of the available match conditions and must have **port-mirror-instance *instance-name*** as an action. This action in the firewall filter configuration provides the input to the port-mirroring instance.

To configure a port-mirroring instance with firewall filters:

1. Configure the port-mirroring instance name (here, **employee-monitor**) and the output:

- a. For local analysis, set the output to the local interface to which you will connect the computer running the protocol analyzer application:

```
[edit forwarding-options]
```

```
user@switch# set port-mirroring instance employee-monitor output interface ge-0/0/10.0
```

- b. For remote analysis, set the output to the **remote-analyzer** VLAN:

```
[edit forwarding-options]
user@switch# set port-mirroring instance employee-monitor output vlan 999
```

2. Create a firewall filter by using any of the available match conditions and assign **employee-monitor** to the **port-mirror-instance** action:

This step shows a firewall filter **example-filter**, with two terms (**no-analyzer** and **to-analyzer**):

- a. Create the first term to define the traffic that should not pass through to the port-mirroring instance **employee-monitor**:

```
[edit firewall family ethernet-switching]
user@switch# set filter (Firewall Filters) example-filter term no-analyzer from
source-address ip-address
[edit firewall family ethernet-switching]
user@switch# set filter example-filter term no-analyzer from destination-address
ip-address
[edit firewall family ethernet-switching]
user@switch# set filter example-filter term no-analyzer then accept
```

- b. Create the second term to define the traffic that should pass through to the port-mirroring instance **employee-monitor**:

```
[edit firewall family ethernet-switching]
user@switch# set filter example-filter term to-analyzer from destination-port 80
[edit firewall family ethernet-switching]
user@switch# set filter example-filter term to-analyzer then port-mirror-instance
employee-monitor
[edit firewall family ethernet-switching]
user@switch# set filter example-filter term to-analyzer then accept
```

3. Apply the firewall filter to the interfaces or VLAN that provide input to the port-mirroring instance:

```
[edit]
user@switch# set interfaces ge-0/0/0 unit 0 family ethernet-switching filter input
example-filter
[edit]
user@switch# set vlan (802.1Q Tagging) remote-analyzer filter input example-filter
```

## Configuring Port Mirroring to Analyze Traffic (J-Web Procedure)

**NOTE:** This topic applies only to the J-Web Application package.

EX Series switches allow you to configure port mirroring to send copies of packets to either a local interface for local monitoring or to a VLAN for remote monitoring. You can use port mirroring to copy these packets:

- Packets entering or exiting a port
- Packets entering a VLAN on EX2200, EX3200, EX3300, EX4200, EX4300, EX4500, EX6200 switches
- Packets exiting a VLAN on EX8200 switches

To configure port mirroring on an EX Series switch using the J-Web interface:

1. Select **Configure > Security > Port Mirroring**.

The top of the screen displays analyzer details such as the name, status, analyzer port, ratio, and loss priority.

The bottom of the screen lists ingress and egress ports of the selected analyzer.

**NOTE:** After you make changes to the configuration on this page, you must commit the changes for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes](#) for details about all commit options.

2. Click one of the following options:

- **Add**—Add an analyzer. Enter information as specified in [Table 428 on page 4048](#).
- **Edit**—Modify details of the selected analyzer. Enter information as specified in [Table 428 on page 4048](#).
- **Delete**—Delete the selected analyzer.
- **Enable/Disable**—Enable or disable the selected analyzer (toggle).

**NOTE:** On EX2200, EX3200, EX4200, and EX4500 switches, only one analyzer can be enabled at a time. On EX8200 switches, a maximum of seven analyzers can be enabled. On EX4300 switches a maximum of four Analyzers/Port Mirror instances can be enabled.

**NOTE:** When an analyzer is deleted or disabled, any filter association is removed.

Table 428: Port Mirroring Configuration Settings

| Field                                                                                 | Function                                                                                                                                                                                                                                                                                                                                                        | Your Action                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Analyzer Name                                                                         | Specifies the name of the analyzer.                                                                                                                                                                                                                                                                                                                             | Type a name for the analyzer.                                                                                                                                                                                                                                                |
| Ratio<br><br><b>NOTE:</b> This option is not supported on EX4300 switches.            | Specifies the ratio of packets to be mirrored. For example: <ul style="list-style-type: none"> <li>A ratio of 1 sends copies of all packets.</li> <li>A ratio of 2047 sends copies of 1 out of every 2047 packets.</li> </ul>                                                                                                                                   | Enter a number from 0 through 2047.                                                                                                                                                                                                                                          |
| Loss Priority<br><br><b>NOTE:</b> This option is not supported on EX4300 switches.    | Specifies the loss priority of the mirrored packets.<br><br>By default, the switch applies a lower priority to mirrored data than to regular port-to-port data—mirrored traffic is dropped in preference to regular traffic when capacity is exceeded.<br><br>For port-mirroring configurations with output to an analyzer VLAN, set the loss priority to high. | Keep the default of low, unless the output is to a VLAN.                                                                                                                                                                                                                     |
| Analyzer Port                                                                         | Specifies a local interface or VLAN to which mirrored packets are sent.<br><br><b>NOTE:</b> A VLAN must have only one associated interface to be specified as an analyzer interface.                                                                                                                                                                            | Click <b>Select</b> . In the Select Analyzer Port/VLAN window, select either port or VLAN as the <b>Analyzer Type</b> . Next, select the required port or VLAN. For an EX8200 Virtual Chassis configuration, select the member, FPC, and the port (interface) from the list. |
| Analyzer Type<br><br><b>NOTE:</b> This option is supported only on EX4300 switches.   | Specifies the analyzer type.                                                                                                                                                                                                                                                                                                                                    | Select the <b>Analyzer Type</b> from the list.                                                                                                                                                                                                                               |
| No Filter check<br><br><b>NOTE:</b> This option is supported only on EX4300 switches. | Enable this option to skip checking for filters on port-mirroring instance.                                                                                                                                                                                                                                                                                     | To enable this option, select the check box.                                                                                                                                                                                                                                 |
| Ingress                                                                               | Specifies interfaces or VLANs for which entering traffic is mirrored.                                                                                                                                                                                                                                                                                           | Click <b>Add</b> . For an EX8200 Virtual Chassis configuration, select the member, FPC, and the interface from the list.<br><br>Click <b>Remove</b> to delete an ingress interface or VLAN.                                                                                  |
| Egress                                                                                | Specifies interfaces for which exiting traffic is mirrored.                                                                                                                                                                                                                                                                                                     | Click <b>Add</b> and select <b>Port</b> or <b>VLAN</b> . For an EX8200 Virtual Chassis configuration, select the member, FPC, and the interface from the list.<br><br>Click <b>Remove</b> to remove egress interfaces.                                                       |

## Configuring sFlow Technology for Network Monitoring (CLI Procedure)

sFlow technology is a network monitoring technology for high-speed switched or routed networks. It is a technology that is based on statistical sampling. You can configure sFlow technology to continuously monitor traffic at wire speed on all interfaces simultaneously. Junos OS fully supports the sFlow standard described in RFC 3176, *InMon Corporation's sFlow: A Method for Monitoring Traffic in Switched and Routed Networks*.

To configure sFlow features:

1. Configure the IP address and the UDP port of the collector:

```
[edit protocols]
user@switch# set sflow collector ip-address udp-port port-number
```

The default UDP port is 6343,

2. Enable sFlow technology on a specific interface:

```
[edit protocols sflow]
user@switch# set interfaces interface-name
```

**NOTE:** You cannot enable sFlow technology on a Layer 3 VLAN-tagged interface.

You cannot enable sFlow technology on a link aggregation group (LAG), but you can enable it on the member interfaces of a LAG.

3. Specify in seconds how often the sFlow agent polls interfaces:

```
[edit protocols sflow]
user@switch# set polling-interval seconds
```

**NOTE:** Specify 0 if you do not want to poll the interface.

4. Specify the rate at which packets must be sampled. You can specify either an egress or an ingress sampling rate, or both.

**NOTE:** We recommend that you configure the same sampling rates on all the ports on a line card. If you configure different sampling rates on different ports, the lowest value is used for all ports. You could still configure different rates on different line cards.

To specify an egress sampling rate:

```
[edit protocols sflow]
user@switch# set sample-rate egress number
```

To specify an ingress sampling rate:

```
[edit protocols sflow]
user@switch# set sample-rate ingress number
```

5. To configure the polling interval and the egress and ingress sampling rates at the interface level:

```
[edit protocols sflow interfaces interface-name]
user@switch# set polling-interval seconds
[edit protocols sflow interfaces]
user@switch# set sample-rate egress number
[edit protocols sflow interfaces]
user@switch# set sample-rate ingress number
```

**NOTE:** The interface-level configuration overrides the global configuration.

6. To specify an IP address to be used as the agent ID for the sFlow agent:

```
[edit protocols sflow]
user@switch# set agent-id ip-address
```

7. To specify the source IP address to be used for sFlow datagrams:

```
[edit protocols sflow]
user@switch# set source-ip ip-address
```

## Configuring Real-Time Performance Monitoring (J-Web Procedure)

**NOTE:** This topic applies only to the J-Web Application package.

Real-time performance monitoring (RPM) in EX Series switches enables you to configure and send probes to a specified target and monitor the analyzed results to determine packet loss, round-trip time, and jitter. Jitter is the difference in relative transit time between two consecutive probes. You can set up probe owners and configure one or more performance probe tests under each probe owner.

The ways in which you can use RPM include:

- Monitor time delays between devices.
- Monitor time delays at the protocol level.

- Set thresholds to trigger SNMP traps when threshold values are exceeded. You can configure thresholds for round-trip time, ingress or egress delay, standard deviation, jitter, successive lost probes, and total lost probes per test.
- Determine automatically whether a path exists between a host switch and its configured Border Gateway Protocol (BGP) neighbors. You can view the results of the discovery using an SNMP client.
- Use the history of the most recent 50 probes to analyze trends in your network and predict future needs.

Probes collect packets per destination and per application, including PING Internet Control Message Protocol (ICMP) packets, User Datagram Protocol and Transmission Control Protocol (UDP/TCP) packets with user-configured ports, user-configured Differentiated Services code point (DSCP) type-of-service (ToS) packets, and Hypertext Transfer Protocol (HTTP) packets.

EX Series switches support the following tests and probe types:

- Ping tests:
  - ICMP echo
  - ICMP timestamp
- HTTP tests:
  - HTTP get (not available for BGP RPM services)
- UDP and TCP tests with user-configured ports:
  - UDP echo
  - TCP connection
  - UDP timestamp

To account for latency in the communication of probe messages, you can enable timestamping of the probe packets. You must configure both the requester and the responder to timestamp the RPM packets. The RPM features provides an additional configuration option to set one-way hardware timestamps. Use one-way timestamps when you want information about one-way, rather than round-trip, times for packets to traverse the network between the requester and the responder.

#### NOTE:

- EX Series switches support hardware timestamps for UDP and ICMP probes. EX Series switches do not support hardware timestamps for HTTP or TCP probes.
- If the responder does not support hardware timestamps, RPM can only report the round-trip measurements, it cannot calculate round-trip jitter.
- In EX Series switches timestamps apply only to IPv4 traffic.

To configure RPM using the J-Web interface:

1. Select **Troubleshoot > RPM > Configure RPM**.
2. In the **Configure RPM** page, enter information as specified in [Table 429 on page 4052](#).
  - a. Click **Add** to set up the **Owner Name** and **Performance Probe Tests**.
  - b. Select a probe owner from **Probe Owners** list and click **Delete** to remove the selected probe owner
  - c. Double-click one of the probe owners in **Probe Owners** list to display the list of performance probe tests.
  - d. Double-click one of the performance probe tests to edit the test parameters.
3. Enter the **Maximum Number of Concurrent Probes** and specify the **Probe Servers**.
4. Click **Apply** to apply the RPM probe settings.

**Table 429: RPM Probe Owner, Concurrent Probes, and Probe Servers Configuration Fields**

| Field                               | Function                                                                                                                                                             | Your Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Probe Owners                        | Identifies a owner for whom one or more RPM tests are configured. In most implementations, the owner name identifies a network on which a set of tests is being run. | <ol style="list-style-type: none"> <li>1. Click <b>Add</b> and type an owner name.</li> <li>2. In <b>Performance Probe Tests</b>, click <b>Add</b> to define the RPM test parameters. See <a href="#">Table 430 on page 4053</a> for information on configuring RPM test parameters.</li> <li>3. Click <b>OK</b> to save the settings or <b>Cancel</b> to exit from the window without saving the changes.</li> </ol>                                                          |
| Maximum Number of Concurrent Probes | Specifies the maximum number of concurrent probes allowed.                                                                                                           | Type a number from 1 through 500.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Probe Servers                       | Specifies the servers that act as receivers and transmitters for the probes.                                                                                         | Set up the following servers: <ul style="list-style-type: none"> <li>• TCP Probe Server—Specifies the port on which the device is to receive and transmit TCP probes. Type the number 7 (a standard TCP port number) or a port number from 49160 through 65535.</li> <li>• UDP Probe Server—Specifies the port on which the device is to receive and transmit UDP probes. Type the number 7 (a standard TCP port number) or a port number from 49160 through 65535.</li> </ul> |

Table 430: Performance Probe Tests Configuration Fields

| Field                      | Function                                                                                                                                         | Your Action                                                                                                                                                                                                                                                                                             |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Identification</b>      |                                                                                                                                                  |                                                                                                                                                                                                                                                                                                         |
| Test Name                  | Identifies the RPM test.                                                                                                                         | Type a test name.                                                                                                                                                                                                                                                                                       |
| Target (Address or URL)    | Specifies the IP address or the URL of the probe target.                                                                                         | Type the IP address in dotted decimal notation or the URL of the probe target. If the target is a URL, type a fully formed URL that includes <b>http://</b> .                                                                                                                                           |
| Source Address             | Specifies the IP address to be used as the probe source address.                                                                                 | Type the source address to be used for the probe. If you do not supply this value, the packet uses the outgoing interface's address as the probe source address.                                                                                                                                        |
| Routing Instance           | Specifies the routing instance over which the probe is sent.                                                                                     | Type the routing instance name. The routing instance applies only to <b>icmp-ping</b> and <b>icmp-ping-timestamp</b> probe types. The default routing instance is <b>inet.0</b> .                                                                                                                       |
| History Size               | Specifies the number of probe results to be saved in the probe history.                                                                          | Type a number from 0 through 255. The default history size is 50.                                                                                                                                                                                                                                       |
| <b>Request Information</b> |                                                                                                                                                  |                                                                                                                                                                                                                                                                                                         |
| Probe Type                 | Specifies the type of probe to send as part of the test.                                                                                         | Select a probe type from the list: <ul style="list-style-type: none"> <li>• <b>http-get</b></li> <li>• <b>http-get-metadata</b></li> <li>• <b>icmp-ping</b></li> <li>• <b>icmp-ping-timestamp</b></li> <li>• <b>tcp-ping</b></li> <li>• <b>udp-ping</b></li> <li>• <b>udp-ping-timestamp</b></li> </ul> |
| Interval                   | Sets the wait time (in seconds) between probe transmissions.                                                                                     | Type a number from 1 through 255 .                                                                                                                                                                                                                                                                      |
| Test Interval              | Sets the wait time (in seconds) between tests.                                                                                                   | Type a number from 0 through 86400 .                                                                                                                                                                                                                                                                    |
| Probe Count                | Sets the total number of probes to be sent for each test.                                                                                        | Type a number from 1 through 15.                                                                                                                                                                                                                                                                        |
| Moving Average Size        | Specifies the number of samples to be used in the statistical calculation operations to be performed across a number of the most recent samples. | Type a number from 0 through 255.                                                                                                                                                                                                                                                                       |

Table 430: Performance Probe Tests Configuration Fields (*continued*)

| Field                           | Function                                                                                                                                                                                                                                                                                                           | Your Action                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Destination Port                | Specifies the TCP or UDP port to which probes are sent.<br><br>To use TCP or UDP probes, you must configure the remote server as a probe receiver. Both the probe server and the remote server must be Juniper Networks network devices configured to receive and transmit RPM probes on the same TCP or UDP port. | Type the number 7 (a standard TCP or UDP port number) or a port number from 49160 through 65535. |
| DSCP Bits                       | Specifies the Differentiated Services code point (DSCP) bits. This value must be a valid 6-bit pattern.                                                                                                                                                                                                            | Type a valid 6-bit pattern.                                                                      |
| Data Size                       | Specifies the size (in bytes) of the data portion of the ICMP probes.                                                                                                                                                                                                                                              | Type a number from 0 through 65507.                                                              |
| Data Fill                       | Specifies the hexadecimal value of the data portion of the ICMP probes.                                                                                                                                                                                                                                            | Type a hexadecimal value from 1h through 800h .                                                  |
| <b>Hardware Timestamp</b>       |                                                                                                                                                                                                                                                                                                                    |                                                                                                  |
| One Way Hardware Timestamp      | Enables one-way hardware timestamp.                                                                                                                                                                                                                                                                                | To enable timestamping, select the check box.                                                    |
| Destination Interface           | Enables hardware timestamp on the specified interface.                                                                                                                                                                                                                                                             | Select an interface from the list.                                                               |
| <b>Maximum Probe Thresholds</b> |                                                                                                                                                                                                                                                                                                                    |                                                                                                  |
| Successive Lost Probes          | Sets the number of probes that can be lost successively, if exceeded, triggers a probe failure and generates a system log message.                                                                                                                                                                                 | Type a number from 0 through 15.                                                                 |
| Lost Probes                     | Sets the number of probes that can be lost , if exceeded, triggers a probe failure and generates a system log message.                                                                                                                                                                                             | Type a number from 0 through 15.                                                                 |
| Round Trip Time                 | Sets the round-trip time (in microseconds), from the switch to the remote server, if exceeded, triggers a probe failure and generates a system log message.                                                                                                                                                        | Type a number from 0 through 60000000.                                                           |
| Jitter                          | Sets the jitter (in microseconds), if exceeded, triggers a probe failure and generates a system log message.                                                                                                                                                                                                       | Type a number from 0 through 60000000.                                                           |

Table 430: Performance Probe Tests Configuration Fields (*continued*)

| Field                              | Function                                                                                                                                                     | Your Action                                                                                                                                                           |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Standard Deviation                 | Sets the maximum allowable standard deviation (in microseconds), if exceeded, triggers a probe failure and generates a system log message.                   | Type a number from 0 through 60000000.                                                                                                                                |
| Egress Time                        | Sets the one-way time (in microseconds), from the switch to the remote server, if exceeded, triggers a probe failure and generates a system log message.     | Type a number from 0 through 60000000.                                                                                                                                |
| Ingress Time                       | Sets the one-way time (in microseconds), from the remote server to the switch, if exceeded, triggers a probe failure and generates a system log message.     | Type a number from 0 through 60000000 (microseconds).                                                                                                                 |
| Jitter Egress Time                 | Sets the outbound-time jitter (in microseconds), if exceeded triggers a probe failure and generates a system log message.                                    | Type a number from 0 through 60000000.                                                                                                                                |
| Jitter Ingress Time                | Sets the inbound-time jitter (in microseconds), if exceeded, triggers a probe failure and generates a system log message.                                    | Type a number from 0 and 60000000.                                                                                                                                    |
| Egress Standard Deviation          | Sets the maximum allowable standard deviation of outbound times (in microseconds), if exceeded, triggers a probe failure and generates a system log message. | Type a number from 0 through 60000000.                                                                                                                                |
| Ingress Standard Deviation         | Sets the maximum allowable standard deviation of inbound times (in microseconds), if exceeded, triggers a probe failure and generates a system log message.  | Type a number from 0 through 60000000.                                                                                                                                |
| <b>Traps</b>                       |                                                                                                                                                              |                                                                                                                                                                       |
| Egress Jitter Exceeded             | Generates SNMP traps when the threshold for jitter in outbound time is exceeded.                                                                             | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Egress Standard Deviation Exceeded | Generates SNMP traps when the threshold for standard deviation in outbound times is exceeded.                                                                | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |

## Configuring the Interface for RPM Timestamping for Client/Server on an EX Series Switch (CLI Procedure)

Use real-time performance monitoring (RPM) to configure active probes to track and monitor traffic across the network and to investigate network problems. To configure basic RPM probes on the EX Series switch, you must configure the probe owner, the test, and the specific parameters of the RPM probe.

You can also set a timestamp to improve the measurement of latency or jitter. The probe is timestamped by the device originating the probe (the RPM client). If you do not enable hardware timestamps, the timer values are set. You should configure both the RPM client (the requester) and the RPM server (the responder) to timestamp the RPM packets. However, if the RPM server does not support hardware timestamps, RPM can only report the round-trip measurements.

Timestamps apply only to IPv4 traffic.

You can enable hardware timestamps for the following RPM probe types:

- **icmp-ping**
- **icmp-ping-timestamp**
- **udp-ping**
- **udp-ping-timestamp**

To configure RPM probes and enable hardware timestamping:

1. Specify the probe owner:
 

```
[edit services rpm]
user@switch# set probe owner
```
2. Specify a test name. A test represents the range of probes over which the standard deviation, average, and jitter are calculated.
 

```
[edit services rpm probe owner]
user@switch# set test test-name
```
3. Specify the packet and protocol contents of the probe:
 

```
[edit services rpm probe owner test test-name]
user@switch# set probe-type type
```
4. Specify the destination IPv4 address to be used for the probes:
 

```
[edit services rpm probe owner test test-name]
user@switch# set target address
```
5. Specify the number of probes within a test:
 

```
[edit services rpm probe owner test test-name]
user@switch# set probe-count count
```
6. Specify the time, in seconds, to wait between sending packets:
 

```
[edit services rpm probe owner test test-name]
```

```
user@switch# set probe-interval interval
```

7. Specify the time, in seconds, to wait between tests:

```
[edit services rpm probe owner test test-name]  
user@switch# set test-interval interval
```

8. Specify the source IP address to be used for probes. If the source IP address is not one of the switch's assigned addresses, the packet uses the outgoing interface's address as its source.

```
[edit services rpm probe owner test test-name]  
user@switch# set source-address address
```

9. Specify the value of the Differentiated Services (DiffServ) field within the IP header. The DiffServ code point (DSCP) bits value must be set to a valid 6-bit pattern.

```
[edit services rpm probe owner test test-name]  
user@switch# set dscp-code-point dscp-bits
```

10. If you are using ICMP probes, specify the size of the data portion of ICMP probes:

```
[edit services rpm probe owner test test-name]  
user@switch# set data-size size
```

11. Enable hardware timestamping of RPM probe messages:

```
[edit services rpm probe owner test test-name]  
user@switch# set hardware-timestamp
```

## Configuring Ethernet OAM Connectivity Fault Management (CLI Procedure)

Ethernet interfaces on Juniper Networks EX Series Ethernet Switches and Juniper Networks Junos OS for EX Series switches support the IEEE 802.1ag standard for Operation, Administration, and Management (OAM). The IEEE 802.1ag specification provides for Ethernet connectivity fault management (CFM).

This topic describes these tasks:

1. [Creating the Maintenance Domain on page 4058](#)
2. [Configuring the Maintenance Domain MIP Half Function on page 4059](#)
3. [Creating a Maintenance Association on page 4059](#)
4. [Configuring the Continuity Check Protocol on page 4060](#)
5. [Configuring a Maintenance Association End Point on page 4060](#)
6. [Configuring a Connectivity Fault Management Action Profile on page 4061](#)
7. [Configuring the Linktrace Protocol on page 4061](#)

### Creating the Maintenance Domain

---

A maintenance domain comprises network entities such as operators, providers, and customers. To enable connectivity fault management (CFM) on an Ethernet interface, you must create a maintenance domains, maintenance associations, and MEPs.

To create a maintenance domain:

1. Specify a name for the maintenance domain:

```
[edit protocols oam ethernet connectivity-fault-management]
user@switch# set maintenance-domain domain-name
```

2. Specify a format for the maintenance domain name. If you specify **none**, no name is configured:

- A plain ASCII character string
- A domain name service (DNS) format
- A media access control (MAC) address plus a two-octet identifier in the range 0 through 65,535
- **none**

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
domain-name]
user@switch# set name-format format
```

For example, to specify the name format as MAC address plus a two-octet identifier:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
domain-name]
user@switch# set name-format mac+2oct
```

3. Configure the maintenance domain level, which is used to indicate the nesting relationship between this domain and other domains. Use a value from 0 through 7:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
domain-name]
user@switch# set level level
```

### Configuring the Maintenance Domain MIP Half Function

MIP Half Function (MHF) divides the maintenance association intermediate point (MIP) functionality into two unidirectional segments, improves visibility with minimal configuration, and improves network coverage by increasing the number of points that can be monitored. MHF extends monitoring capability by responding to loop-back and link-trace messages to help isolate faults. Whenever a MIP is configured, the MIP half function value for all maintenance domains and maintenance associations must be the same.

To configure the MIP half function:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
domain-name]
user@switch# set mip-half-function (none | default | explicit)
```

### Creating a Maintenance Association

In a CFM maintenance domain, each service instance is called a maintenance association.

To create a maintenance association:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
domain-name]
user@switch# set maintenance-association ma-name
```

## Configuring the Continuity Check Protocol

---

The continuity check protocol is used for fault detection by a maintenance association end point (MEP) within a maintenance association. The MEP periodically sends continuity check multicast messages. The receiving MEPs use the continuity check messages (CCMs) to build a MEP database of all MEPs in the maintenance association.

To configure the continuity check protocol:

1. Enable the continuity check protocol:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
domain-name maintenance-association ma-name]  
user@switch# set continuity-check
```

2. Specify the continuity check hold interval. The hold interval is the number of minutes to wait before flushing the MEP database if no updates occur. The default value is 10 minutes.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
domain-name maintenance-association ma-name continuity-check]  
user@switch# set hold-interval number
```

3. Specify the CCM interval. The interval is the time between the transmission of CCMs. You can specify 10 minutes (10m), 1 minute (1m), 10 seconds (10s), 1 second (1s), 100 milliseconds (100ms), or 10 milliseconds (10ms).

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
domain-name maintenance-association ma-name continuity-check]  
user@switch# set interval number
```

4. Specify the number of CCMs (that is, protocol data units) that can be lost before the MEP is marked as down. The default number of protocol data units (PDUs) is 3.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
domain-name maintenance-association ma-name continuity-check]  
user@switch# set loss-threshold number
```

## Configuring a Maintenance Association End Point

---

To configure a maintenance association end point:

1. Specify an ID for the MEP. The value can be from 1 through 8191.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
domain-name maintenance-association ma-name]  
user@switch# set mep mep-id]
```

2. Enable maintenance endpoint automatic discovery if you want to have the MEP accept continuity check messages (CCMs) from all remote MEPs of the same maintenance association:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
domain-name maintenance-association ma-name mep mep-id]  
user@switch# set auto-discovery
```

3. You can specify that CFM packets (CCMs) be transmitted only in one direction for the MEP, that is, the direction be set as **down** so that CCMs are transmitted only out of (not into) the interface configured on this MEP.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain  
domain-name maintenance-association ma-name mep mep-id]  
user@switch# set direction down
```

- Specify the logical interface to which the MEP is attached. It can be either an access interface or a trunk interface. If you specify a trunk interface, the VLAN associated with that interface must have a VLAN ID.

**NOTE:** You cannot associate an access interface that belongs to multiple VLANs with the MEP.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
domain-name maintenance-association ma-name mep mep-id]
user@switch# set interface interface-name
```

- You can configure a remote MEP from which CCMs are expected. If autodiscovery is not enabled, the remote MEP must be configured under the **mep** statement. If the remote MEP is not configured under the **mep** statement, the CCMs from the remote MEP are treated as errors.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
domain-name maintenance-association ma-name mep mep-id]
user@switch# set remote-mep mep-id
```

### Configuring a Connectivity Fault Management Action Profile

You can configure an action profile and specify the action to be taken when any of the configured events occur. Alternatively, you can configure an action profile and specify default actions when connectivity to a remote MEP fails.

To configure an action profile:

- Specify a name for an action profile:

```
[edit protocols oam ethernet connectivity-fault-management]
user@switch# set action-profile profile-name
```

- Configure the action of the action profile:

```
[edit protocols oam ethernet connectivity-fault-management action-profile
profile-name]
user@switch# set action interface-down
```

- Configure one or more events under the action profile, the occurrence of which will trigger the corresponding action to be taken:

```
[edit protocols oam ethernet connectivity-fault-management action-profile
profile-name]
user@switch# set event event
```

See [Junos OS Network Interfaces Configuration Guide](#)

### Configuring the Linktrace Protocol

The linktrace protocol is used for path discovery between a pair of maintenance points. Linktrace messages are triggered by an administrator using the **traceroute** command to verify the path between a pair of MEPs under the same maintenance association. Linktrace messages can also be used to verify the path between a MEP and a MIP under the same maintenance domain.

To configure the linktrace protocol:

1. Configure the linktrace path age timer. If no response to a linktrace request is received, the request and response entries are deleted after the age timer expires:

```
[edit protocols oam ethernet connectivity-fault-management]
user@switch# set linktrace age time
```

2. Configure the number of linktrace reply entries to be stored per linktrace request:

```
[edit protocols oam ethernet connectivity-fault-management]
user@switch# set linktrace path-database-size path-database-size
```

#### Related Documentation

## Configuring Ethernet OAM Link Fault Management (CLI Procedure)

Ethernet OAM link fault management (LFM) can be used for physical link-level fault detection and management. The IEEE 802.3ah LFM works across point-to-point Ethernet links either directly or through repeaters.

To configure Ethernet OAM LFM using the CLI:

1. Enable IEEE 802.3ah OAM support on an interface:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name
```

**NOTE:** You can configure Ethernet OAM LFM on aggregated interfaces.

**NOTE:** The remaining steps are optional. You can choose which of these features to configure for Ethernet OAM LFM on your switch.

2. Specify whether the interface or the peer initiates the discovery process by configuring the link discovery mode to **active** or **passive** (**active** = interface initiates; **passive** = peer initiates):

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name link-discovery active
```

3. Configure a periodic OAM PDU-sending interval (in milliseconds) for fault detection:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface pdu-interval interval
```

4. Specify the number of OAM PDUs that an interface can miss before the link between peers is considered down:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name pdu-threshold threshold-value
```

5. Configure event threshold values on an interface for the local errors that trigger the sending of link event TLVs:

- Set the threshold value (in seconds) for sending frame-error events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds frame-error count
```

- Set the threshold value (in seconds) for sending frame-period events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds frame-period count
```

- Set the threshold value (in seconds) for sending frame-period-summary events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds frame-period-summary count
```

- Set the threshold value (in seconds) for sending symbol-period events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds symbol-period count
```

**NOTE:** You can disable the sending of link event TLVs.

To disable the sending of link event TLVs:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name negotiation-options no-allow-link-events
```

6. Create an action profile to define event fault flags and thresholds to be taken when the link fault event occurs. Then apply the action profile to one or more interfaces. (You can also apply multiple action profiles to a single interface.)

- a. Name the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set action-profile profile-name
```

- b. Specify actions to be taken by the system when the link fault event occurs:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set action-profile profile-name action syslog
user@switch# set action-profile profile-name action link-down
```

- c. Specify events for the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set action-profile profile-name event link-adjacency-loss
```

**NOTE:** For each action profile, you must specify at least one link event and one action. The actions are taken only when all of the events in the action profile are true. If more than one action is specified, all actions are executed. You can set a low threshold for a specific action such as logging the error and set a high threshold for another action such as system logging.

7. Set a remote interface into loopback mode so that all frames except OAM PDUs are looped back without any changes made to the frames. Set the remote DTE in loopback

mode (the remote DTE must support remote-loopback mode) and then enable remote loopback support for the local interface.

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name remote-loopback
user@switch# set interface interface-name negotiation-options allow-remote-loopback
```

## Configuring Interfaces for Uplink Failure Detection (CLI Procedure)

You can configure uplink failure detection on EX Series switches to help ensure balanced traffic flow. Using this feature, switches can monitor and detect link failure on uplink interfaces and can propagate the failure to downlink interfaces so that servers connected to those downlink interfaces can switch over to secondary interfaces.

Follow these configuration guidelines:

- You can configure a maximum of 48 groups for each switch.
- You can configure a maximum of 48 uplink interfaces and 48 downlink interfaces in each group.
- You can configure physical links and logical links in separate groups.
- Ensure that all the interfaces in the group are up. If the interfaces are down, uplink failure detection does not work.

**NOTE:** Routed VLAN interfaces (RVIs) cannot be configured as uplink interfaces to be monitored.

To configure uplink failure detection on a switch:

1. Specify a name for the group:

```
[edit protocols]
user@switch# set uplink-failure-detection group group-name
```

2. Add an uplink interface to the group:

```
[edit protocols]
user@switch# set uplink-failure-detection group group-name link-to-monitor interface-name
```

3. Repeat Step 2 for adding each uplink interface to the group.

**NOTE:** An interface can be configured as link-to-monitor in multiple groups.

4. Add a downlink interface to the group:

```
[edit protocols]
user@switch# set uplink-failure-detection group group-name link-to-disable interface-name
```

5. Repeat Step 4 for adding each downlink interface to the group.

**NOTE:** After you have configured a group, use the [show uplink-failure-detection group \*group-name\*](#) command to verify that all interfaces in the group are up.

## Configuring MEP Interfaces on Switches to Support Ethernet Frame Delay Measurements (CLI Procedure)

Ethernet frame delay measurement is a useful tool for providing performance statistics or supporting or challenging service-level agreements (SLAs). By default, Ethernet frame delay measurement uses software for timestamping and delay calculations. You can configure an EX Series switch to perform and display Ethernet frame delay measurements on Ethernet interfaces. The switches support software-assisted timestamping.

Before you can begin configuring MEP interfaces to support Ethernet frame delay measurements on switches, ensure that you have:

- Configured Operation, Administration, and Maintenance (OAM) connectivity fault management (CFM) correctly
- Enabled distributed periodic packet management (PPM) (distributed PPM is enabled by default)

To configure MEP interfaces on switches to support Ethernet frame delay measurements:

1. Enable the Ethernet frame delay measurement by issuing the [monitor ethernet delay-measurement](#) operational mode command. In this command, you must specify one measurement type (either one-way or two-way measurement), and you must specify either the unicast MAC address of the peer MEP or its numeric identifier.

Optionally, you can also specify the following parameters:

- Number of frames to send to the peer MEP (**count *count***)
- Number of seconds to wait between sending frames (**wait *time***)
- Priority value of the delay measurement request frame (**priority *value***)
- Size of the data in the data TLV of the request packet (**size *value***)
- Suppression of the insertion of the session ID TLV in the request packet (**no-session-id-tlv**)

```
user@switch> monitor ethernet delay-measurement maintenance-domain md-name
maintenance-association ma-name one-way mep remote-mep-id count count wait
time priority value size value no-session-id-tlv
```

**Related Documentation**

- [Understanding Ethernet Frame Delay Measurements on Switches on page 3974](#)

## Configuring One-Way Ethernet Frame Delay Measurements on Switches (CLI Procedure)

Ethernet frame delay measurement is a useful tool for providing performance statistics or supporting or challenging service-level agreements (SLAs). You can configure the frame delay measurements in either a one-way mode or a two-way (round-trip) mode to gather frame delay statistics. For one-way Ethernet frame delay measurement, clocks at the local and remote MEPs need to be synchronized. However, clock synchronization is not required for two-way Ethernet frame delay measurement.

Before you begin configuring one-way Ethernet frame delay measurements on two EX Series switches, ensure that you have:

- Configured Operation, Administration, and Maintenance (OAM) connectivity fault management (CFM) correctly on both the switches
- Synchronized the system clocks of both the switches

To configure one-way Ethernet frame delay measurements:

1. Configure the maintenance domain, maintenance association, and MEP ID on both the switches.
2. From either switch, start a one-way Ethernet frame delay measurement:

```
user@switch> monitor ethernet delay-measurement maintenance-domain md-name
maintenance-association ma-name one-way mep remote-mep-id count count wait
time
```

You can view the result on the other switch:

```
user@switch> show oam ethernet connectivity-fault-management delay-statistics
maintenance-domain md-name maintenance-association ma-name local-mep mep-id
remote-mep mep-id
```

## Configuring an Iterator Profile on a Switch (CLI Procedure)

Ethernet frame delay measurement provides fine control to operators for triggering delay measurement on a given service and can be used to monitor service-level agreements (SLAs). You can create an iterator profile with its parameters to periodically transmit SLA measurement packets in the form of ITU-Y.1731-compliant frames for two-way delay measurement.

To create an iterator profile:

1. Specify a name for an SLA iterator profile—for example, i1:

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring]
user@switch# edit sla-iterator-profiles i1
```

2. (Optional) Configure the cycle time, which is the time (in milliseconds) between back-to-back transmissions of SLA frames.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
sla-iterator-profiles i1]
user@switch# set cycle-time cycle-time-value
```

3. (Optional) Configure the iteration period, which indicates the maximum number of cycles per iteration (the number of connections registered to an iterator cannot exceed this value).

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
sla-iterator-profiles i1]
user@switch# set iteration-period iteration-period-value
```

4. Configure the measurement type as two-way delay measurement.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
sla-iterator-profiles i1]
user@switch# set measurement-type two-way-delay
```

5. (Optional) Configure the calculation weight for delay.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
sla-iterator-profiles i1]
user@switch# set calculation-weight delay delay-value
```

6. (Optional) Configure the calculation weight for delay variation.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
sla-iterator-profiles i1]
user@switch# set calculation-weight delay-variation delay-variation-value
```

7. Configure a remote MEP with the iterator profile.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
md-name maintenance-association ma-name mep mep-id remote-mep
remote-mep-id]
user@switch# set sla-iterator-profiles i1
```

## Triggering an Ethernet Frame Delay Measurement Session on a Switch

To trigger Ethernet frame delay measurement, use the **monitor ethernet delay-measurement** operational command and specify the following values:

- Either one-way (**one-way**) or two-way (**two-way**) measurement
- Either the MAC address (**remote-mac-address**) or the MEP ID (**mep**) of the remote host
- The maintenance domain (**maintenance-domain**)
- The maintenance association (**maintenance-association**)
- (Optional) Any or all of these options: **count**, **size**, **wait**, **no-session-id-tlv**, **priority**

For example:

```
user@switch> monitor ethernet delay-measurement one-way 00:05:85:73:39:4a
maintenance-domain md6 maintenance-association ma6 count 10 size 50 wait 5 no-session-id-tlv
priority 1
```

## Configuring Two-Way Ethernet Frame Delay Measurements on Switches (CLI Procedure)

Ethernet frame delay measurement is a useful tool for providing performance statistics or supporting or challenging service-level agreements (SLAs). You can configure the frame delay measurements in either a one-way mode or a two-way (round-trip) mode to gather frame delay statistics. For one-way Ethernet frame delay measurement, clocks at the local and remote MEPs need to be synchronized. However, clock synchronization is not required for two-way Ethernet frame delay measurement.

Before you begin configuring two-way Ethernet frame delay measurements on two EX Series switches, ensure that you have:

- Configured Operation, Administration, and Maintenance (OAM) connectivity fault management (CFM) correctly on both the switches

To configure two-way Ethernet frame delay measurements:

1. Configure the maintenance domain, maintenance association, and MEP ID on both the switches.
2. From either switch, start a two-way Ethernet frame delay measurement:

```
user@switch> monitor ethernet delay-measurement maintenance-domain md-name
maintenance-association ma-name two-way mep remote-mep-id count count wait
time
```

You can view the result on the other switch:

```
user@switch> show oam ethernet connectivity-fault-management delay-statistics
maintenance-domain md-name maintenance-association ma-name local-mep mep-id
remote-mep mep-id
```

## Configuring Queue Monitoring

Network analytics queue monitoring provides visibility into the performance and behavior of the data center infrastructure. This feature collects data from the switch, analyzes the data using sophisticated algorithms, and captures the results in reports. You can use the reports to help troubleshoot problems, make decisions, and adjust resources as needed.

You enable queue monitoring by first defining a resource profile template, and then applying the profile to the system (for a global configuration) or to individual interfaces.

**NOTE:** You can configure queue monitoring on physical network interfaces only; logical interfaces and Virtual Chassis physical (VCP) interfaces are not supported.

**NOTE:** This procedure requires Junos OS Release 13.2X51-D15 or later to be installed on your device.

To configure queue monitoring on a QFX Series standalone switch:

1. Configure the queue monitoring polling interval (in milliseconds) globally (for the system):

[edit]

**set services analytics resource system polling-interval queue-monitoring *interval***

2. Configure a resource profile for the system, and enable queue monitoring:

[edit]

**set services analytics resource-profiles *profile-name* queue-monitoring**

3. Configure high and low values of the depth-threshold (in bytes) for queue monitoring in the system profile:

[edit]

**set services analytics resource-profiles *profile-name* depth-threshold high *number* low *number***

For both high and low values, the range is from 1 to 1,250,000,000 bytes, and the default value is 0 bytes.

**NOTE:** You can configure either the depth-threshold or latency threshold for the system, but not both.

4. Apply the resource profile template to the system for a global configuration:

[edit]

**set services analytics resource system resource-profile *profile-name***

5. Configure an interface-specific resource profile and enable queue monitoring for the interface:

```
[edit]
set services analytics resource-profiles profile-name queue-monitoring
```

6. Configure the latency-threshold (high and low values) for queue monitoring in the interface-specific profile:

```
[edit]
set services analytics resource-profiles profile-name latency-threshold high number
low number
```

For both high and low values, the range is from 1 to 100,000,000 nanoseconds, and the default value is 1,000,000 nanoseconds.

**NOTE:** You can configure either the depth-threshold or latency threshold for interfaces, but not both.

7. Apply the resource profile template for interfaces to one or more interfaces:

```
[edit]
set services analytics resource interfaces interface-name resource-profile profile-name
```

**NOTE:** If a conflict arises between the system and interface configurations, the interface-specific configuration supersedes the global (system) configuration.

## Configuring Traffic Monitoring

Network analytics queue monitoring provides visibility into the performance and behavior of the data center infrastructure. This feature collects data from the switch, analyzes the data using sophisticated algorithms, and captures the results in reports. You can use the reports to help troubleshoot problems, make decisions, and adjust resources as needed.

You enable traffic monitoring by first defining a resource profile template, and then applying the profile to the system (for a global configuration) or to individual interfaces.

**NOTE:** You can configure traffic monitoring on physical network interfaces only; logical interfaces and Virtual Chassis physical (VCP) interfaces are not supported.

**NOTE:** This procedure requires Junos OS Release 13.2X51-D15 or later to be installed on your device.

To configure traffic monitoring on a QFX Series standalone switch:

1. Configure the traffic monitoring polling interval (in seconds) for the system:

[edit]

**set services analytics resource system polling-interval traffic-monitoring *interval***

2. Configure a resource profile for the system, and enable traffic monitoring in the profile:

[edit]

**set services analytics resource-profiles *profile-name* traffic-monitoring**

3. Apply the resource profile to the system for a global configuration:

[edit]

**set services analytics resource system resource-profile *profile-name***

4. Configure a resource profile for interfaces, and enable traffic monitoring in the profile:

[edit]

**set services analytics resource-profiles *profile-name* traffic-monitoring**

**NOTE:** If a conflict arises between the system and interface configurations, the interface-specific configuration supersedes the global (system) configuration.

5. Apply the resource profile template to one or more interfaces:

[edit]

**set services analytics resource interfaces *interface-name* resource-profile *profile-name***

## Configuring a Local File for Network Analytics Data

The network analytics feature provides visibility into the performance and behavior of the data center infrastructure. This feature collects data from the switch, analyzes the data using sophisticated algorithms, and captures the results in reports. Network administrators can use the reports to help troubleshoot problems, make decisions, and adjust resources as needed.

To save the queue and traffic statistics data in a local file, you must configure a filename to store it.

**NOTE:** This procedure requires Junos OS Release 13.2X51-D15 or later to be installed on your device.

To configure a local file for storing queue and traffic monitoring statistics:

1. Configure a filename:

[edit]

**set services analytics collector local file *filename***

There is no default filename. If you do not configure a filename, network analytics statistics are not saved locally.

2. Configure the number of files (from 2 to 1000 files):

[edit]

**set services analytics collector local file *filename* files *number***

3. Configure the file size (from 10 to 4095 MB) in the format of xm:

[edit]

**set services analytics collector local file an size *size***

## Configuring a Remote Collector for Streaming Analytics Data

The network analytics feature provides visibility into the performance and behavior of the data center infrastructure. This feature collects data from the switch, analyzes the data using sophisticated algorithms, and captures the results in reports. Network administrators can use the reports to help troubleshoot problems, make decisions, and adjust resources as needed.

You can configure an export profile to define the stream format and type of data, and one or more remote servers (collectors) to receive streaming network analytics data.

**NOTE:** This procedure requires Junos OS Release 13.2X51-D15 or later to be installed on your device.

To configure a collector for receiving streamed analytics data:

1. Create an export profile and specify the stream format:

```
[edit]
set services analytics export-profiles profile-name stream-format format
```

2. Configure the export profile to include interface information:

```
[edit]
set services analytics export-profiles profile-name interface information
```

3. Configure the export profile to include interface queue statistics:

```
[edit]
set services analytics export-profiles profile-name interface statistics queue
```

4. Configure the export profile to include interface traffic statistics:

```
[edit]
set services analytics export-profiles profile-name interface statistics traffic
```

5. Configure the export profile to include interface status link information:

```
[edit]
set services analytics export-profiles profile-name interface status link
```

6. Configure the export profile to include system information:

```
[edit]
set services analytics export-profiles profile-name system information
```

7. Configure the export profile to include system queue status:

```
[edit]
set services analytics export-profiles profile-name system status queue
```

8. Configure the export profile to include system traffic status:

```
[edit]
set services analytics export-profiles profile-name system status traffic
```

9. Configure the transport protocol for the collector addresses and apply the export profile:

[edit]

set services analytics collector address *ip-address* port *port* transport *protocol*  
export-profile *profile-name*

set services analytics collector address *ip-address* port *port* transport *protocol*  
export-profile *profile-name*

**NOTE:** If you configure the `tcp` or `udp` option for the JSON, CSV, and TSV formats, you must also set up the TCP or UDP client software on the remote collector to process records that are separated by the newline character (`\n`) on the remote server.

If you configure the `tcp` or `udp` option for the GPB format, you must also set up the TCP or UDP build streaming server using the `analytics.proto` file.

## [edit snmp] Configuration Statement Hierarchy on EX Series Switches

This topic lists supported and unsupported configuration statements in the **[edit snmp]** hierarchy level on EX Series switches.

- *Supported* statements are those that you can use to configure some aspect of a software feature on the switch.
- *Unsupported* statements are those that appear in the command-line interface (CLI) on the switch, but that have no effect on switch operation if you configure them.
- Not all features are supported on all switch platforms. For detailed information about feature support on specific EX Series switch platforms, see *EX Series Switch Software Features Overview*

This topic lists:

- [Supported Statements in the \[edit snmp\] Hierarchy Level on page 4078](#)
- [Unsupported Statements in the \[edit snmp\] Hierarchy Level on page 4083](#)

### Supported Statements in the [edit snmp] Hierarchy Level

---

The following hierarchy shows the **[edit snmp]** configuration statements supported on EX Series switches:

```
snmp {
  client-list list-name {
    address {
      restrict;
    }
  }
  community community-name {
    authorization (read-only | read-write);
    client-list-name list-name;
    clients {
      address <restrict>;
    }
    routing-instance instance-name;
    routing-instance instance-name {
      client-list-name list-name;
      clients {
        address <restrict>;
      }
    }
  }
  view view-name;
}
contact contact-information;
description description;
engine-id {
  (local engine-id | use-default-ip-address | use-mac-address);
}
filter-duplicates;
filter-interfaces {
  interfaces
  all-internal-interfaces;
```

```

interface 1;
interface 2;
}
health-monitor {
  falling-threshold percentage;
  idp {
    falling-threshold;
    interval seconds;
    rising-threshold;
  }
  interval seconds;
  rising-threshold percentage;
}
interface [ interface-names ];
location location;
name system-name;
nonvolatile {
  commit-delay seconds;
}
rmon {
  alarm index {
    description description;
    falling-event-index index;
    falling-threshold integer;
    falling-threshold-interval seconds;
    interval seconds;
    request-type (get-next-request | get-request | walk-request);
    rising-event-index index;
    rising-threshold integer;
    sample-type (absolute-value | delta-value);
    startup-alarm (falling-alarm | rising-alarm | rising-or-falling alarm);
    syslog-subtag text-string;
    variable oid-variable;
  }
  event index {
    community community-name;
    description description;
    type (log | log-and-trap | none | snmptrap);
  }
  history index {
    bucket-size number;
    interface interface-name;

```

---

### Unsupported Statements in the [edit snmp] Hierarchy Level

---

All statements in the **[edit snmp]** hierarchy level that are displayed in the command-line interface (CLI) on the switch are supported on the switch and operate as documented with the following exceptions:

**Table 431: Unsupported [edit snmp] Configuration Statements on EX Series Switches**

| Statement | Hierarchy |
|-----------|-----------|
|-----------|-----------|

**NOTE:** Variables, such as *community-name*, are not shown in the statements or hierarchies.

---

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                              |
| <b>Description</b>              | Set the agent address of all SNMPv1 traps generated by this router or switch. Currently, the only option is <b>outgoing-interface</b> , which sets the agent address of each SNMPv1 trap to the address of the outgoing interface of that trap.                                                                                        |
| <b>Options</b>                  | <b>outgoing-interface</b> —Value of the agent address of all SNMPv1 traps generated by this router or switch. The <b>outgoing-interface</b> option sets the agent address of each SNMPv1 trap to the address of the outgoing interface of that trap.<br><b>Default:</b> disabled (the agent address is not specified in SNMPv1 traps). |
| <b>Required Privilege Level</b> | <b>snmp</b> —To view this statement in the configuration.<br><b>snmp-control</b> —To add this statement to the configuration.                                                                                                                                                                                                          |

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Statement introduced in Junos OS Release 11. for the QFX Series.                                                                                                                                                      |
| <b>Description</b>         | Define an SNMP community to authorize SNMPv1 or SNMPv2c clients in an SNMPv3 system. When you configure a community in SNMPv3, you can also specify a security name. The access privileges associated with the security name determine which MIB objects are available and which operations (read, write, or notify) are allowed on those objects. |
| <b>Options</b>             | <b><i>community-name</i></b> —Community string for an SNMPv1 or SNMPv2c community. If unconfigured, it is the same as the community index. If the name includes spaces, enclose the name in quotation marks (" ").                                                                                                                                 |

**NOTE:** Community names must be unique. You cannot configure the same community name at the `[edit snmp community]` and `[edit snmp v3 snmp-community community-index]` hierarchy levels.

The community name at the `[edit snmp v3 snmp-community community-index]` hierarchy level is encrypted and not displayed in the command-line interface (CLI).

| <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | The local engine ID is defined as the administratively unique identifier of an SNMPv3 engine, and is used for identification, not for addressing. There are two parts of an engine ID: prefix and suffix. The prefix is formatted according to the specifications defined in RFC 3411, <i>An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks</i> . You can configure the suffix here. |
| <div> <b>NOTE:</b> SNMPv3 authentication and encryption keys are generated based on the associated passwords and the engine ID. If you configure or change the engine ID, you must commit the new engine ID before you configure SNMPv3 users. Otherwise the keys generated from the configured passwords are based on the previous engine ID.</div> <p>For the engine ID, we recommend using the MAC address of the management port.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.0.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | The lower threshold is expressed as a percentage of the maximum possible value for the sampled variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the <b>rising-threshold</b> . |
| <b>Options</b>                  | <b><i>percentage</i></b> —The lower threshold for the alarm entry.<br><b>Range:</b> 1 through 100<br><b>Default:</b> 70 percent of the maximum possible value                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## group (Configuring Access Privileges)

---

**Syntax**    `group group-name {  
                  (default-context-prefix | context-prefix context-prefix){  
                    security-model (any | usm | v1 | v2c) {  
                      security-level (authentication | none | privacy) {  
                        notify-view view-name;  
                        read-view view-name;  
                        write-view view-name;  
                      }  
                    }  
                  }  
                  }  
                  }`

**Hierarchy Level**    [edit snmp v3 vacm access]

**Release Information**    Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description**    Assign the security name to a group, and specify the SNMPv3 context applicable to the group. The **default-context-prefix** statement, when included, adds all the contexts configured on the device to the group, whereas the **context-prefix context-prefix** statement enables you to specify a context and to add that particular context to the group.

(Not applicable to the QFX Series.) When the context prefix is specified as default (for example, **context-prefix default**), the context associated with the master routing instance is added to the group. To specify a routing instance that is part of a logical system, specify it as **logical system/routing instance**. For example, to specify routing instance ri1 in logical system ls1, include **context-prefix ls1/ri1**.

The remaining statements under this hierarchy are explained separately.

**Options**    *group-name*—SNMPv3 group name created for the SNMPv3 group.

**Required Privilege Level**    snmp—To view this statement in the configuration.  
snmp-control—To add this statement to the configuration.

**Related Documentation**    • *Configuring the Group*

| <b>Description</b>              | <p>Configure RMON history group entries. This RMON feature can be used with the Simple Network Management Protocol (SNMP) agent in the switch to monitor all the traffic flowing among switches on all connected LAN segments. It collects statistics in accordance with user-configurable parameters.</p> <p>The history group controls the periodic statistical sampling of data from various types of networks. This group contains configuration entries that specify an interface, polling period, and other parameters. The <b>interface (SNMP RMON History)</b> <i>interface-name</i> statement is mandatory. Other statements in the history group are optional.</p> |
| <b>Default</b>                  | Not configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | The upper threshold is expressed as a percentage of the maximum possible value for the sampled variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the <b>falling-threshold</b> . |
| <b>Options</b>                  | <b><i>percentage</i></b> —The lower threshold for the alarm entry.<br><b>Range:</b> 1 through 100<br><b>Default:</b> 80 percent of the maximum possible value                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>              | Upper threshold for the sampled variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold, and the associated startup alarm value is equal to the falling alarm or rising or falling alarm value. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the falling threshold. |
| <b>Options</b>                  | <i>integer</i> —The lower threshold for the alarm entry.<br><b>Range:</b> -2,147,483,648 through 2,147,483,647                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b>              | <p>RMON is an existing feature of Junos OS.</p> <p>The RMON specification provides network administrators with comprehensive network fault diagnosis, planning, and performance tuning information. It delivers this information in nine groups of monitoring elements, each providing specific sets of data to meet common network monitoring requirements. Each group is optional, so that vendors do not need to support all the groups within the MIB.</p> <p>Junos OS supports RMON Statistics, History, Alarm, and Event groups. The EX Series documentation describes only the <b>rmon history</b> statement, which was added with this release.</p> <p>The statements are explained separately.</p> |
| <b>Default</b>                  | Disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | Set the source address of every SNMP trap packet sent by this router to a single address regardless of the outgoing interface. If the source address is not specified, the default is to use the address of the outgoing interface as the source address.                                                                                                                                                                                          |
| <b>Options</b>                  | <b>address</b> —Source address of SNMP traps. You can configure the source address of trap packets two ways: <b>lo0</b> or a valid IPv4 address configured on one of the router interfaces. The value <b>lo0</b> indicates that the source address of all SNMP trap packets is set to the lowest loopback address configured at interface <b>lo0</b> .<br><b>Default:</b> Disabled. (The source address is the address of the outgoing interface.) |
| <b>Required Privilege Level</b> | snmp—To view this statement in the configuration.<br>snmp-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                      |

## target-parameters

**Syntax** At the `[edit snmp v3]` hierarchy level:

```
target-parameters target-parameters-name {
  profile-name;
  parameters {
    message-processing-model (v1 | v2c | V3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}
```

At the `[edit snmp v3 target-address target-address-name]` hierarchy level:

```
target-parameters target-parameters-name;
```

**Hierarchy Level** `[edit snmp v3]`  
`[edit snmp v3 target-address target-address-name]`

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure the message processing and security parameters for sending notifications to a particular management target. The target parameters are configured at the `[edit snmp v3]` hierarchy level. The remaining statements at this level are explained separately.

Then apply the target parameters configured at the `[edit snmp v3 target-parameters target-parameters-name]` hierarchy level to the target address configuration at the `[edit snmp v3]` hierarchy level.

**Required Privilege Level** snmp—To view this statement in the configuration.  
snmp-control—To add this statement to the configuration.

| <b>Hierarchy Level</b>     | [edit snmp]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Release Information</b> | <p>Statement introduced before Junos OS Release 7.4.</p> <p><b>file <i>filename</i></b> option added in Junos OS Release 8.1.</p> <p><b>world-readable   no-world-readable</b> option added in Junos OS Release 8.1.</p> <p><b>match <i>regular-expression</i></b> option added in Junos OS Release 8.1.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p><b>memory-trace</b> and <b>no-default-memory-trace</b> options introduced in Junos OS Release 13.3.</p>                                                                                                                                                                                                                                                                                            |
| <b>Description</b>         | <p>The output of the tracing operations is placed into log files in the <b>/var/log</b> directory. Each log file is named after the SNMP agent that generates it. Currently, the following logs are created in the <b>/var/log</b> directory when the <b>traceoptions</b> statement is used:</p> <ul style="list-style-type: none"> <li>• chassisd</li> <li>• craftd</li> <li>• ilmid</li> <li>• mib2d</li> <li>• rmopd</li> <li>• serviced</li> <li>• snmpd</li> </ul>                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—By default, the name of the log file that records trace output is the name of the process being traced (for example, <b>mib2d</b> or <b>snmpd</b>). Use this option to specify another name.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files per SNMP subagent. When a trace file (for example, <b>snmpd</b>) reaches its maximum size, it is archived by being renamed to <b>snmpd.0</b>. The previous <b>snmpd.1</b> is renamed to <b>snmpd.2</b>, and so on. The oldest archived file is deleted.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 10 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements:</p> |

- **all**—Log all SNMP events.
- **general**—Log general events.
- **interface-stats**—Log physical and logical interface statistics.
- **nonvolatile-sets**—Log nonvolatile SNMP set request handling.
- **pdu**—Log SNMP request and response packets.
- **protocol-timeouts**—Log SNMP response timeouts.
- **routing-socket**—Log routing socket calls.
- **subagent**—Log subagent restarts.
- **timer**—Log internally generated events.
- **varbind-error**—Log variable binding errors.

**memory-trace**—Enable tracing in memory. If **file** and **memory-trace** are configured, tracing will occur in file and memory.

**NOTE:** By default, memory tracing is enabled with default trace flags even after **snmp traceoptions** config statement is disabled.

---

**match *regular-expression***—(Optional) Refine the output to include lines that contain the regular expression.

**no-default-memory-trace**—(Optional) Disable default memory-tracing.

**size *size***—(Optional) Maximum size, in kilobytes (KB), of each trace file before it is closed and archived.

**Range:** 10 KB through 1 GB

**Default:** 1000 KB

**world-readable | no-world-readable**—(Optional) By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.

**Required Privilege Level**    **snmp**—To view this statement in the configuration.  
                                      **snmp-control**—To add this statement to the configuration.

- [vlan \(Mirroring\) on page 4165](#)

### [\[edit forwarding-options\] Configuration Statement Hierarchy on EX Series Switches](#)

This topic lists supported and unsupported configuration subhierarchies in the **[edit forwarding-options]** hierarchy level on EX Series switches.

- *Supported* subhierarchies are those that you can use to configure some aspect of a software feature on the switch.
- *Unsupported* subhierarchies are those that appear in the command-line interface (CLI) on the switch, but that have no effect on switch operation if you configure them.
- Not all features are supported on all switch platforms. For detailed information about feature support on specific EX Series switch platforms, see [Feature Explorer](#).
- [Supported Subhierarchies in the \[edit forwarding-options\] Hierarchy Level on page 4156](#)
- [Unsupported Subhierarchies in the \[edit forwarding-options\] Hierarchy Level on page 4156](#)

### Supported Subhierarchies in the [edit forwarding-options] Hierarchy Level

The following list shows the [edit forwarding-options] subhierarchies supported on EX Series switches:

Each of the following topics lists the statements at a subhierarchy of the [edit forwarding-options] hierarchy.

- [\[edit forwarding-options analyzer\] Configuration Statement Hierarchy on page 4158](#)
- [\[edit forwarding-options dhcp-relay\] Configuration Statement Hierarchy for EX Series Switches on page 1550](#)
- [\[edit forwarding-options enhanced-hash-key\] Configuration Statement Hierarchy on EX Series Switches](#)
- [\[edit forwarding-options port-mirroring\] Configuration Statement Hierarchy on page 4157](#)
- [\[edit forwarding-options storm-control-profiles\] Configuration Statement Hierarchy for EX Series Switches on page 2211](#)

### Unsupported Subhierarchies in the [edit forwarding-options] Hierarchy Level

All subhierarchies in the [edit forwarding-options] hierarchy level that are displayed in the command-line interface (CLI) on the switch are supported on the switch and operate as documented with the following exceptions:

**Table 432: Unsupported [edit forwarding-options] Subhierarchies on EX Series Switches**

| Subhierarchy | Hierarchy Level           |
|--------------|---------------------------|
| accounting   | [edit forwarding-options] |
| helpers      | [edit forwarding-options] |
| sampling     | [edit forwarding-options] |

## address (Analytics Collector)

---

**Syntax**     `address ip-address {  
                  port number {  
                    transport protocol {  
                      export-profile profile-name;  
                    }  
                  }  
          }`

**Hierarchy Level**     [edit services analytics collector]

**Release Information**     Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description**     Configure the address of a remote server to receive streamed analytics (queue and traffic statistics) data.

**NOTE:** The `address` statement is not available in Junos OS Releases prior to 13.2X51-D15.

**Options**     `ip-address`—IP address of the remote server receiving the streamed data.

`port number`—Port number of the remote server receiving the streaming data.

`export-profile profile-name`—Name of the export profile containing the parameters for the analytics data being streamed.

`transport protocol`—A transport protocol used to stream data to the port.

**Values:**

- `tcp`—Transmission Control Protocol (TCP)
- `udp`—User Datagram Protocol (UDP)

**Required Privilege Level**     interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## analytics

**Syntax** *Junos OS Release 13.2X51-D15 and later:*

```

analytics {
  collector {
    local {
      file filename {
        size size;
        files number;
      }
    }
    address ip-address {
      port number {
        transport protocol {
          export-profile profile-name;
        }
      }
    }
  }
  export-profiles {
    profile-name {
      interface {
        information;
        statistics {
          queue;
          traffic;
        }
        status {
          link;
          queue;
          traffic;
        }
      }
    }
    stream-format format;
    system {
      information;
      status {
        queue;
        traffic;
      }
    }
  }
  resource {
    interfaces {
      interface-name {
        resource-profile name;
      }
    }
    system {
      polling-interval {
        queue-monitoring interval;
        traffic-monitoring interval;
      }
    }
  }
}

```

```
        resource-profile name;  
    }  
}  
resource-profiles {  
    profile-name {  
        depth-threshold {  
            high number;  
            low number;  
        }  
        latency-threshold {  
            high number;  
            low number;  
        }  
        no-queue-monitoring;  
        no-traffic-monitoring;  
        queue-monitoring;  
        traffic-monitoring;  
    }  
}  
traceoptions {  
    file filename {  
        files number;  
        size size;  
    }  
}
```

*Junos OS Release 13.2X50-D15 and 13.2X51-D10 only:*

```

analytics {
  interfaces {
    all {
      depth-threshold high number low number;
      latency-threshold high number low number;
      queue-statistics;
      no-queue-statistics;
      traffic-statistics;
      no-traffic-statistics;
    }
    interface-name {
      depth-threshold high number low number;
      latency-threshold high number low number;
      queue-statistics;
      no-queue-statistics;
      traffic-statistics;
      no-traffic-statistics;
    }
  }
  queue-statistics {
    file filename {
      files number-of-files;
      size size;
    }
    interval interval;
  }
  streaming-servers {
    address ip-address {
      port number {
        stream-format format;
        stream-type type
      }
    }
  }
  traceoptions {
    file filename {
      files number;
      size size;
    }
  }
  traffic-statistics {
    file filename {
      files number-of-files;
      size size;
    }
    interval interval;
  }
}

```

**Hierarchy Level** [edit services]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Configure the network analytics feature that includes monitoring for traffic and queue statistics. The network analytics processes running on the Packet Forwarding Engine and Routing Engine collect and analyze the data, and generate reports that may be saved in log files or sent as streaming data to remote servers.

The remaining statements are explained separately.

**Required Privilege** interface—To view this statement in the configuration.  
**Level** interface-control—To add this statement to the configuration.

## collector (Analytics)

```
Syntax collector {
    local {
        file filename {
            size size;
            files number;
        }
    }
    address ip-address {
        port number {
            transport protocol {
                export-profile profile-name;
            }
        }
    }
}
```

**Hierarchy Level** [edit services analytics]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Configure a local file for storing network analytics statistics and/or a remote server for receiving streamed statistics data.

**NOTE:** The `collector` statement is not available in Junos OS Releases prior to 13.2X51-D15.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

                    queue;
                    traffic;
                }
            }
            status {
                link;
                queue;
                traffic;
            }
        }
    }
    stream-format format;
    system {
        information;
        status {
            queue;
            traffic;
        }
    }
}
```

**Hierarchy Level** [edit services analytics]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Configure an profile to specify the network analytics data being streamed to remote servers. Each profile is a template that defines the type of data being streamed.

**NOTE:** The `export-profile` statement is not available in Junos OS Releases prior to 13.2X51-D15.

**Options** *profile-name*—Name of the export profile containing the configuration of the data being streamed.

*stream-format format*—Format of the streaming data being sent to a server. Only one format can be sent to each port on a server.

**Values:**

- **csv**—Comma-separated Values (CSV). Data sent in this format is newline separated, and each record contains one stream type (queue or traffic data) per interface. Each record contains either a “q” for a queue statistics, or a “t” for a traffic statistics.

- **gpb**—Google Protocol Buffer (GPB). Data sent in this format has a hierarchical format, and is categorized by resource type (system or interfaces), which is specified in the message header. You can generate data formatted in other formats (CSV, TSV, and JSON) from GPB-encoded data.

Each message includes a 8-byte header containing the following information:

- Bytes 0 to 3—Length of the message.
- Byte 4—Message version.
- Bytes 5 to 7—Reserved for future use.

**NOTE:** A schema file called `analytics.proto` containing the definitions of the GPB messages is available for downloading from the following location:

[http://www.juniper.net/techpubs/en\\_US/junos132/topics/reference/proto-files/analytics-prototxt](http://www.juniper.net/techpubs/en_US/junos132/topics/reference/proto-files/analytics-prototxt)

---

- **json**—JavaScript Object Notation (JSON). Data sent in this format is newline separated, and each record contains one stream type (queue or traffic data) per interface. Each record contains either “queue-statistics” or “traffic-statistics” in the “record type” field.
- **tsv**—Tab-separated Values (TSV). Data sent in this format is newline separated, and each record contains one stream type (queue or traffic data) per interface. Each record contains a “q” for a queue statistics, or a “t” for a traffic statistics.

The remaining statements are explained separately.

## interface (Export Profiles)

---

**Syntax**

```
interface {  
    information;  
    statistics {  
        queue;  
        traffic;  
    }  
    status {  
        link;  
        queue;  
        traffic;  
    }  
}
```

**Hierarchy Level** [edit services analytics export-profiles]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Configure an export profile for streaming network analytics data for a specific interface to remote servers. Each profile is a template that defines the type of data being streamed for that interface.

**NOTE:** The `interface` statement is not available in Junos OS Releases prior to 13.2X51-D15.

---

**Options** **information**—Information about the specified interface, including SNMP index, interface index, slot, port number, media type, capability, and port type.

**statistics**—Type of monitoring statistics to be streamed.

**Values:**

- `queue`
- `traffic`

**status**—Status information about the interface to be streamed.

**Values:**

- `link`
- `queue`
- `traffic`

**Required Privilege Level** `interface`—To view this statement in the configuration.  
`interface-control`—To add this statement to the configuration.

## interfaces (Analytics Resource)

**Syntax**

```
interfaces {
  interface-name {
    resource-profile profile-name;
  }
}
```

**Hierarchy Level** [edit services analytics resource]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Apply the network analytics resource profile to an interface for which you wish to enable queue or traffic statistics monitoring. The resource profile is a template that specifies the parameters for queue and traffic monitoring, as well as for the depth and latency thresholds.

**NOTE:** The `interfaces` statement in the [edit services analytics resource] hierarchy is not available in Junos OS Releases prior to 13.2X51-D15.

**Options** *interface-name*—Name of the interface for which a resource profile has been configured.

*resource-profile profile-name*—Name of a resource profile containing the analytics parameters that have been specified for interfaces. Information contained in a resource profile includes the configuration of queue and traffic monitoring (whether enabled or disabled), and values for the depth and latency thresholds (if applicable).

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Syntax</b>              | latency-threshold {<br>high <i>number</i> ;<br>low <i>number</i> ;<br>}                                                                                                                                                                                                                                                                                                |
| <b>Hierarchy Level</b>     | [edit services analytics interfaces]<br>[edit services analytics resource-profiles]                                                                                                                                                                                                                                                                                    |
| <b>Release Information</b> | Statement introduced in Junos OS Release 13.2 for the QFX Series.<br>Statement in the <b>[edit services analytics resource-profiles]</b> hierarchy level introduced in Junos OS Release 13.2X51-D15.<br>Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.                                                                                   |
| <b>Description</b>         | If network analytics queue statistics monitoring is enabled, specify the high and low values (in microseconds) of the latency threshold of the queue. If you configure a latency threshold, you cannot configure the depth threshold. You can configure the latency threshold for one interface or all interfaces. Specify the high and low latency threshold numbers: |

**NOTE:** The configuration for a specific interface supersedes the global configuration for all interfaces.

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## local (Analytics Collector)

**Syntax**

```
local {
  file filename {
    size size;
    files number;
  }
}
```

**Hierarchy Level** [edit services analytics collector]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Configure a local file for logging network analytics (queue and traffic) statistics.

**NOTE:** The `local` statement is not available in Junos OS Releases prior to 13.2X51-D15.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## resource (Analytics)

---

**Syntax**

```
resource {  
  interfaces {  
    interface-name {  
      resource-profile profile-name;  
    }  
  }  
  system {  
    polling-interval {  
      queue-monitoring interval;  
      traffic-monitoring interval;  
    }  
    resource-profile profile-name;  
  }  
}
```

**Hierarchy Level** [edit services analytics]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Configure network analytics resources such as resource profiles (for interfaces and system), and polling intervals (for queue and traffic monitoring).

**NOTE:** The **resource** statement is not available in Junos OS Releases prior to 13.2X51-D15.

---

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## resource-profiles (Analytics)

**Syntax**

```
resource-profiles {
  profile-name {
    depth-threshold {
      high number;
      low number;
    }
    latency-threshold {
      high number;
      low number;
    }
    no-queue-monitoring;
    no-traffic-monitoring;
    queue-monitoring;
    traffic-monitoring;
  }
}
```

**Hierarchy Level** [edit services analytics]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Configure resource profiles that are used as templates for specifying network analytics parameters. You use resource profiles to enable and disable queue and traffic monitoring, and specify depth and latency thresholds as applicable. Once you have defined a resource profile, you can apply it specifically to individual interfaces, or globally to a system.

**NOTE:** The `resource-profiles` statement is not available in Junos OS Releases prior to 13.2X51-D15.

The remaining statements are explained separately.

**Options** *profile-name*—Specify a name for the resource profile.

*no-queue-monitoring*—Disable queue monitoring.

*no-traffic-monitoring*—Disable traffic monitoring.

*queue-monitoring*—Enable queue monitoring.

*traffic-monitoring*—Enable traffic monitoring.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## [\[edit protocols sflow\] Configuration Statement Hierarchy on EX Series Switches](#)

This topic lists supported and unsupported configuration statements in the [\[edit protocols sflow\]](#) hierarchy level on EX Series switches.

- *Supported* statements are those that you can use to configure some aspect of a software feature on the switch.
- *Unsupported* statements are those that appear in the command-line interface (CLI) on the switch, but that have no effect on switch operation if you configure them.
- Not all features are supported on all switch platforms. For detailed information about feature support on specific EX Series switch platforms, see *EX Series Switch Software Features Overview*.

This topic lists:

- [Supported Statements in the \[edit protocols sflow\] Hierarchy Level on page 4187](#)
- [Unsupported Statements in the \[edit sflow\] Hierarchy Level on page 4187](#)

### Supported Statements in the [edit protocols sflow] Hierarchy Level

The following hierarchy shows the [edit protocols sflow] configuration statements supported on EX Series switches:

```
sflow {
  agent-id;
  collector {
    ip-address;
    udp-port port-number;
  }
  interfaces interface-name {
    polling-interval seconds;
    sample-rate {
      egress number;
      ingress number;
    }
  }
  polling-interval seconds;
  sample-rate {
    egress number;
    ingress number;
  }
  source-ip;
}
traceoptions {
  file filename <files number> <no-stamp> <replace> <size size> <world-readable |
  no-world-readable>;
  flag (all | client-server | configuration | interface | rtsock);
}
```

### Unsupported Statements in the [edit sflow] Hierarchy Level

All statements in the [edit protocols sflow] hierarchy level that are displayed in the command-line interface (CLI) on the EX Series switch are supported on the switch and operate as documented.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.3 for EX Series switches.                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | Configure the interval (in seconds) that the switch waits between port statistics update messages. <i>Polling</i> refers to the switch gathering various statistics for the network interfaces configured for sFlow monitoring and exporting the statistics to the configured sFlow collector.                                                                                                      |
| <b>Default</b>                  | If no polling interval is configured for a particular interface, the switch waits the number of seconds that is configured as the polling interval in the global sFlow configuration. If no polling interval is specified in the global configuration, the switch waits 20 seconds between messages.                                                                                                |
| <b>Options</b>                  | <i>seconds</i> —Number of seconds between port statistics update messages. A value of <b>0</b> (zero) specifies that polling is disabled.<br><b>Range:</b> 0 through 3600 seconds<br><b>Default:</b> 20 seconds                                                                                                                                                                                     |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                 |

| Hierarchy Level     | [edit protocols <a href="#">sflow</a> ],<br>[edit protocols <a href="#">sflow interfaces</a> <i>interface-name</i> ]                                                                                                                                                                            |
| Release Information | Statement introduced in Junos OS Release 9.3 for EX Series switches.<br>The option <i>number</i> (which immediately followed <b>sample-rate</b> ) is deprecated and options <b>egress <i>number</i></b> and <b>ingress <i>number</i></b> added in Junos OS Release 10.4 for EX Series switches. |
| Description         | Specify the number of egress or ingress packets out of which one packet is sampled. If no interface sampling rates are configured, the global sampling rates take effect. If neither is configured, by default both ingress and egress packet sampling is disabled                              |
| Default             | By default, both egress and ingress sampling rates are disabled.                                                                                                                                                                                                                                |

**NOTE:** The **sample-rate *number*** (the global sampling rate) statement has been deprecated and might be removed from future product releases. We strongly recommend that you phase out its use.

                          remote-mep mep-id {  
                              action-profile profile-name;  
                          }  
                        }  
                  }  
                }`

**Hierarchy Level**    [edit protocols [oam](#) [ethernet](#) [connectivity-fault-management](#) ]

**Release Information**    Statement introduced in Junos OS Release 10.2 for EX Series switches.

**Description**    Configure the name of the maintenance domain in IEEE-compliant format.

**Options**    *domain-name*—The name for the maintenance domain.

The remaining statements are explained separately.

**Required Privilege Level**    routing—To view this statement in the configuration.  
                                  routing-control—To add this statement to the configuration.

## performance-monitoring (OAM LFM)

```
Syntax performance-monitoring {
    sla-iterator-profiles {
        profile-name {
            calculation-weight {
                delay delay-value;
                delay-variation delay-variation-value;
            }
            cycle-time cycle-time-value;
            iteration-period iteration-period-value;
            measurement-type two-way-delay;
            passive;
        }
    }
}
```

**Hierarchy Level** [edit protocols [oam ethernet connectivity-fault-management](#)]

**Release Information** Statement introduced in Junos OS Release 11.4 for EX Series switches.

**Description** Specify performance monitoring support for Ethernet frame delay measurement.

The remaining statements are explained separately.

**Required Privilege Level** Configure—To enter configuration mode.  
Control—To modify any configuration.

**Hierarchy Level** [edit protocols]

**Release Information** Statement introduced in Junos OS Release 9.4 for EX Series switches.  
**connectivity-fault-management** introduced in Junos OS Release 10.2 for EX Series switches.

**Description** Provide IEEE 802.3ah Operation, Administration, and Maintenance (OAM) link fault management (LFM) support for Ethernet interfaces on EX Series switches or configure connectivity fault management (CFM) for IEEE 802.lag Operation, Administration, and Management (OAM) support on the switches.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
 interface-control—To add this statement to the configuration.

## data-size

|                            |                                                                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>data-size size;</code>                                                                                                                                                                                        |
| <b>Hierarchy Level</b>     | [edit services rpm bgp],<br>[edit services rpm <b>probe</b> owner <b>test</b> test-name]                                                                                                                            |
| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.3 for EX Series switches.<br>Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers. |
| <b>Description</b>         | Specify the size of the data portion of ICMP probes. The <b>data-size</b> statement is not valid with the <b>http-get</b> or <b>http-metadata-get</b> probe type.                                                   |
| <b>Options</b>             | <b>data</b> —The size can be from 0 through 65400<br><b>Default:</b> 0                                                                                                                                              |

**NOTE:** If you configure the hardware timestamp feature (see *Configuring RPM Timestamping*):

- The **data-size** default value is 32 bytes and 32 is the minimum value for explicit configuration. The UDP timestamp probe type is an exception; it requires a minimum data size of 52 bytes.
- The **data-size** must be at least 100 bytes smaller than the default MTU of the interface of the RPM client interface.

## hardware-timestamp

---

**Syntax** hardware-timestamp;

**Hierarchy Level** [edit services rpm **probe** owner **test** test-name]

**Release Information** Statement introduced in Junos OS Release 8.1.  
Statement applied to MX Series routers in Junos OS Release 10.0.  
Statement introduced in Junos OS Release 10.3 for EX Series switches.

**Description** On MX Series routers, on M-320 routers using the Enhanced Queuing MPC, and on EX Series switches only, enable timestamping of RPM probe messages in the Packet Forwarding Engine host processor. This feature is supported only with **icmp-ping**, **icmp-ping-timestamp**, **udp-ping**, and **udp-ping-timestamp** probe types.

When you configure either **probe-type udp-ping** or **probe-type udp-ping-timestamp** along with the **hardware-timestamp** command, the value for the **destination-port** can be only 7. A constraint check prevents you for configuring any other value for the destination port in this case.

This constraint does not apply when you are configuring **one-way-hardware-timestamp**.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## probe-server

---

**Syntax**    `probe-server {  
              tcp {  
                  destination-interface interface-name;  
                  port number;  
              }  
              udp {  
                  destination-interface interface-name;  
                  port number;  
              }  
          }`

**Hierarchy Level**    [edit services rpm]

**Release Information**    Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.3 for EX Series switches.  
Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

**Description**    Specify the server to act as a receiver for the probes.  
  
The remaining statements are explained separately.

**NOTE:** The `destination-interface` statement is not supported on PTX Series routers.

---

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                  interface-control—To add this statement to the configuration.

| <b>Description</b>              | Specify thresholds used for the probes. A system log message is generated when the configured threshold is exceeded. Likewise, an SNMP trap (if configured) is generated when a threshold is exceeded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Options</b>                  | <p><b>thresholds</b>—Specify one or more threshold measurements. The following options are supported:</p> <ul style="list-style-type: none"> <li>• <b>egress-time</b>—Measures maximum source-to-destination time per probe.</li> <li>• <b>ingress-time</b>—Measures maximum destination-to-source time per probe.</li> <li>• <b>jitter-egress</b>—Measures maximum source-to-destination jitter per test.</li> <li>• <b>jitter-ingress</b>—Measures maximum destination-to- source jitter per test.</li> <li>• <b>jitter-rtt</b>—Measures maximum jitter per test, from 0 through 60,000,000 microseconds.</li> <li>• <b>rtt</b>—Measures maximum round-trip time per probe, in microseconds.</li> <li>• <b>std-dev-egress</b>—Measures maximum source-to-destination standard deviation per test.</li> <li>• <b>std-dev-ingress</b>—Measures maximum destination-to-source standard deviation per test.</li> <li>• <b>std-dev-rtt</b>—Measures maximum standard deviation per test, in microseconds.</li> <li>• <b>successive-loss</b>—Measures successive probe loss count, indicating probe failure.</li> <li>• <b>total-loss</b>—Measures total probe loss count indicating test failure, from 0 through 15.</li> </ul> |
| <b>Required Privilege Level</b> | <p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b>         | Set the trap bit to generate traps for probes. Traps are sent if the configured threshold is met or exceeded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>             | <p><b>traps</b>—Specify one or more traps. The following options are supported:</p> <ul style="list-style-type: none"><li>• <b>egress-jitter-exceeded</b>—Generates traps when the jitter in egress time threshold is met or exceeded.</li><li>• <b>egress-std-dev-exceeded</b>—Generates traps when the egress time standard deviation threshold is met or exceeded.</li><li>• <b>egress-time-exceeded</b>—Generates traps when the maximum egress time threshold is met or exceeded.</li><li>• <b>ingress-jitter-exceeded</b>—Generates traps when the jitter in ingress time threshold is met or exceeded.</li><li>• <b>ingress-std-dev-exceeded</b>—Generates traps when the ingress time standard deviation threshold is met or exceeded.</li><li>• <b>ingress-time-exceeded</b>—Generates traps when the maximum ingress time threshold is met or exceeded.</li><li>• <b>jitter-exceeded</b>—Generates traps when the jitter in round-trip time threshold is met or exceeded.</li><li>• <b>probe-failure</b>—Generates traps for successive probe loss thresholds crossed.</li><li>• <b>rtt-exceeded</b>—Generates traps when the maximum round-trip time threshold is met or exceeded.</li><li>• <b>std-dev-exceeded</b>—Generates traps when the round-trip time standard deviation threshold is met or exceeded.</li><li>• <b>test-completion</b>—Generates traps when a test is completed.</li><li>• <b>test-failure</b>—Generates traps when the total probe loss threshold is met or exceeded.</li></ul> |

**NOTE:** For RPM traps to be generated, you must configure the remote-operations SNMP trap category by including the **categories** statement at the [edit snmp trap-group trap-group-name hierarchy level.

## udp

**Syntax**

```
udp {
    destination-interface interface-name;
    port port;
}
```

**Hierarchy Level** [edit services rpm [probe-server](#)]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.3 for EX Series switches.  
Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

**Description** Specify the port information for the UDP server.  
  
The remaining statements are explained separately.

**NOTE:** The `destination-interface` statement is not supported on PTX Series routers.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Release Information</b> | Statement introduced in Junos OS Release 12.1 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>         | Define tracing operations for uplink failure detection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default</b>             | The <b>traceoptions</b> feature is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>             | <p><b>file <i>filename</i></b> —Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks.</p> <p><b>files <i>number</i></b> —(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached (<b>xk</b> to specify KB, <b>xm</b> to specify MB, or <b>xg</b> to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 3 files</p> <p><b>flag <i>flag</i></b> —Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"><li>• <b>all</b>—Trace everything.</li><li>• <b>dcd</b>—Trace ufdi interaction with dcd.</li><li>• <b>groups</b>—Trace uplink-failure-detection group handling.</li><li>• <b>interface</b>—Trace interface notification handlers of ufdi.</li><li>• <b>parse</b>—Trace configuration parsing.</li></ul> <p><b>no-stamp</b>—(Optional) Do not place a timestamp on any trace file.</p> <p><b>no-world-readable</b>—(Optional) Restricted file access to the user who created the file.</p> <p><b>size <i>size</i></b> —(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the <b>files</b> option.</p> <p><b>Syntax:</b> <b>xk</b> to specify KB, <b>xm</b> to specify MB, or <b>xg</b> to specify gigabytes</p> |

**Range:** 10 KB through 1 GB

**Default:** 128 KB

**world-readable**—(Optional) Enable unrestricted file access.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

## uplink-failure-detection

**Syntax**

```
uplink-failure-detection {
  action {
    log;
  }
  group group-name {
    link-to-monitor interface-name;
    link-to-disable interface-name;
  }
  traceoptions {
    file filename <files number> <no-stamp> <replace> <size size> <world-readable |
    no-world-readable>;
    flag flag);
  }
}
```

**Hierarchy Level** [edit protocols]

**Release Information** Statement introduced in Junos OS Release 11.1 for EX Series switches.

**Description** Configure uplink and downlink interfaces in a group to monitor uplink failures and to propagate uplink failures to the downlink interfaces.

The remaining statements are explained separately.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

### Monitoring Hosts Using the J-Web Ping Host Tool

#### Purpose

**NOTE:** This topic applies only to the J-Web Application package.

Use the J-Web ping host tool to verify that the host can be reached over the network. The output is useful for diagnosing host and network connectivity problems. The switch sends a series of ICMP echo (ping) requests to a specified host and receives ICMP echo responses.

**Action** To use the J-Web ping host tool:

1. Select **Troubleshoot>Ping Host**.
2. Next to Advanced options, click the expand icon.
3. Enter information into the Ping Host page, as described in [Table 433 on page 4264](#).

The Remote Host field is the only required field.

4. Click **Start**.

The results of the ping operation are displayed in the main pane. If no options are specified, each ping response is in the following format:

*bytes bytes from ip-address: icmp\_seq=number ttl=number time=time*

5. To stop the ping operation before it is complete, click **OK**.

**Meaning** [Table 433 on page 4264](#) lists the fields.

**Table 433: J-Web Ping Host Field Summary**

| Field                   | Function                                                                                                                                                                    | Your Action                                                                                                                                                                                                              |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote Host             | Identifies the host to ping.                                                                                                                                                | Type the hostname or IP address of the host to ping.                                                                                                                                                                     |
| <b>Advanced Options</b> |                                                                                                                                                                             |                                                                                                                                                                                                                          |
| Don't Resolve Addresses | Determines whether to display hostnames of the hops along the path.                                                                                                         | <ul style="list-style-type: none"> <li>• To suppress the display of the hop hostnames, select the check box.</li> <li>• To display the hop hostnames, clear the check box.</li> </ul>                                    |
| Interface               | Specifies the interface on which the ping requests are sent.                                                                                                                | Select the interface on which ping requests are sent from the list. If you select <b>any</b> , the ping requests are sent on all interfaces.                                                                             |
| Count                   | Specifies the number of ping requests to send.                                                                                                                              | Select the number of ping requests to send from the list.                                                                                                                                                                |
| Don't Fragment          | Specifies the Don't Fragment (DF) bit in the IP header of the ping request packet.                                                                                          | <ul style="list-style-type: none"> <li>• To set the DF bit, select the check box.</li> <li>• To clear the DF bit, clear the check box.</li> </ul>                                                                        |
| Record Route            | Sets the record route option in the IP header of the ping request packet. The path of the ping request packet is recorded within the packet and displayed in the main pane. | <ul style="list-style-type: none"> <li>• To record and display the path of the packet, select the check box.</li> <li>• To suppress the recording and display of the path of the packet, clear the check box.</li> </ul> |
| Type-of-Service         | Specifies the type-of-service (TOS) value in the IP header of the ping request packet.                                                                                      | Select the decimal value of the TOS field from the list.                                                                                                                                                                 |
| Routing Instance        | Name of the routing instance for the ping attempt.                                                                                                                          | Select the routing instance name from the list.                                                                                                                                                                          |
| Interval                | Specifies the interval, in seconds, between transmissions of individual ping requests.                                                                                      | Select the interval from the list.                                                                                                                                                                                       |
| Packet Size             | Specifies the size of the ping request packet.                                                                                                                              | Type the size, in bytes, of the packet. The size can be from 0 through 65468. The switch adds 8 bytes of ICMP header to the size.                                                                                        |

Table 433: J-Web Ping Host Field Summary (*continued*)

| Field          | Function                                                                                                                                                                                                                                                                            | Your Action                                                                                                                                                                                                                                                |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source Address | Specifies the source address of the ping request packet.                                                                                                                                                                                                                            | Type the source IP address.                                                                                                                                                                                                                                |
| Time-to-Live   | Specifies the time-to-live (TTL) hop count for the ping request packet.                                                                                                                                                                                                             | Select the TTL value from the list.                                                                                                                                                                                                                        |
| Bypass Routing | <p>Determines whether ping requests are routed by means of the routing table.</p> <p>If the routing table is not used, ping requests are sent only to hosts on the interface specified in the Interface box. If the host is not on that interface, ping responses are not sent.</p> | <ul style="list-style-type: none"> <li>To bypass the routing table and send the ping requests to hosts on the specified interface only, select the check box.</li> <li>To route the ping requests using the routing table, clear the check box.</li> </ul> |

## Monitoring Network Traffic Using Traceroute

### Purpose

**NOTE:** This topic applies only to the J-Web Application package.

Use the Traceroute page in the J-Web interface to trace a route between the switch and a remote host. You can use a traceroute task to display a list of waypoints between the switch and a specified destination host. The output is useful for diagnosing a point of failure in the path from the switch platform to the destination host and addressing network traffic latency and throughput problems.

### Action

To use the traceroute tool:

1. Select **Troubleshoot > Traceroute**.
2. Next to **Advanced options**, click the expand icon.
3. Enter information into the Traceroute page.  
The **Remote Host** field is the only required field.
4. Click **Start**.
5. To stop the traceroute operation before it is complete, click **OK** while the results of the traceroute operation are being displayed.

### Meaning

The switch generates the list of waypoints by sending a series of ICMP traceroute packets in which the time-to-live (TTL) value in the messages sent to each successive waypoint is incremented by 1. (The TTL value of the first traceroute packet is set to 1.) In this manner, each waypoint along the path to the destination host replies with a Time Exceeded packet from which the source IP address can be obtained.

The results of the traceroute operation are displayed in the main pane. If no options are specified, each line of the traceroute display is in the following format:

**hop-number host (ip-address) [as-number] time1 time2 time3**

The switch sends a total of three traceroute packets to each waypoint along the path and displays the round-trip time for each traceroute operation. If the switch times out before receiving a **Time Exceeded** message, an asterisk (\*) is displayed for that round-trip time.

**Table 434: Traceroute field summary**

| Field                   | Function                                                                                                                                                                                                                                                                              | Your Action                                                                                                                                      |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote Host             | Identifies the destination host of the traceroute.                                                                                                                                                                                                                                    | Type the hostname or IP address of the destination host.                                                                                         |
| Advanced Options        |                                                                                                                                                                                                                                                                                       |                                                                                                                                                  |
| Don't Resolve Addresses | Determines whether hostnames of the hops along the path are displayed, in addition to IP addresses.                                                                                                                                                                                   | To suppress the display of the hop hostnames, select the check box.                                                                              |
| Gateway                 | Specifies the IP address of the gateway to route through.                                                                                                                                                                                                                             | Type the gateway IP address.                                                                                                                     |
| Source Address          | Specifies the source address of the outgoing traceroute packets.                                                                                                                                                                                                                      | Type the source IP address.                                                                                                                      |
| Bypass Routing          | Determines whether traceroute packets are routed by means of the routing table. If the routing table is not used, traceroute packets are sent only to hosts on the interface specified in the Interface box. If the host is not on that interface, traceroute responses are not sent. | To bypass the routing table and send the traceroute packets to hosts on the specified interface only, select the check box.                      |
| Interface               | Specifies the interface on which the traceroute packets are sent.                                                                                                                                                                                                                     | From the list, select the interface on which traceroute packets are sent. If you select any, the traceroute requests are sent on all interfaces. |
| Time-to-live            | Specifies the maximum time-to-live (TTL) hop count for the traceroute request packet.                                                                                                                                                                                                 | From the list, select the TTL.                                                                                                                   |
| Type-of-Service         | Specifies the type-of-service (TOS) value to include in the IP header of the traceroute request packet.                                                                                                                                                                               | From the list, select the decimal value of the TOS field.                                                                                        |
| Resolve AS Numbers      | Determines whether the autonomous system (AS) number of each intermediate hop between the router and the destination host is displayed.                                                                                                                                               | To display the AS numbers, select the check box.                                                                                                 |

## Verifying Input and Output for Port Mirroring Analyzers on EX Series Switches

**Purpose** Verify that an analyzer has been created on the switch and has the appropriate output interfaces, and appropriate output interface.

**Action** You can verify the port mirror analyzer is configured as expected using the **show analyzer** command.

```
[edit]
user@switch> show analyzer
Analyzer name           : employee-monitor
Output VLAN             : remote-analyzer
Mirror ratio            : 1
Loss priority           : High
Ingress monitored interfaces : ge-0/0/0.0
Ingress monitored interfaces : ge-0/0/1.0
```

You can view all of the port mirror analyzers configured on the switch, including any that are disabled, using the **show ethernet-switching-options** command in configuration mode.

```
user@switch# show ethernet-switching-options
inactive: analyzer employee-web-monitor {
    loss-priority high;
    output {

analyzer employee-monitor {
    loss-priority high;
    input {
        ingress {
            interface ge-0/0/0.0;
            interface ge-0/0/1.0;
        }
    }
    output {
        vlan {
            remote-analyzer;
        }
    }
}
```

**Meaning** This output shows that the employee-monitor analyzer has a ratio of 1 (mirroring every packet, the default), a loss priority of high (set this option to high whenever the analyzer output is to a VLAN), is mirroring the traffic entering **ge-0/0/0** and **ge-0/0/1**, and sending the mirrored traffic to the analyzer called remote-analyzer.

## Viewing Real-Time Performance Monitoring Information

**NOTE:** This topic applies only to the J-Web Application package.

Real-time performance monitoring (RPM) on EX Series switches enables you to configure and send probes to a specified target and monitor the analyzed results to determine packet loss, round-trip time, and jitter. The J-Web interface provides a graphical view of RPM information for EX Series switches.

To view the RPM information using the J-Web interface:

1. Select **Troubleshoot > RPM > View RPM**.
2. Select the **Round Trip Time** check box to display the graph with round-trip time included. Clear the check-box to view the graph without the round-trip time.
3. From the **Refresh Time** list, select a refresh time interval for the graph.

## Verifying That Uplink Failure Detection Is Working Correctly

**Purpose** Verify that the switch disables the downlink interface when it detects an uplink failure.

- Action** 1. View the current uplink-failure-detection status:

```
user@switch> show uplink-failure-detection
Group                : group1
Uplink               : ge-0/0/0*
Downlink             : ge-0/0/1*
Failure Action       : Inactive
```

**NOTE:** The asterisk (\*) indicates that the link is up.

2. Disable the uplink interface:

```
[edit]
user@switch# set interface ge-0/0/0 disable
```

3. Save the configuration on the switch.

4. View the current uplink-failure-detection status:

```
user@switch> show uplink-failure-detection
Group                : group1
Uplink               : ge-0/0/0
Downlink             : ge-0/0/1
Failure Action       : Active
```

**Meaning** The output in Step 1 shows that the uplink interface is up, and hence that the downlink interface is also up, and that the status of **Failure Action** is **Inactive**.

The output in Step 4 shows that both the uplink and downlink interfaces are down and that the status of **Failure Action** is changed to **Active**. This output shows that uplink failure detection is working.

## Operational Commands: General

- [monitor traffic](#)
- [ping](#)
- [show pfe statistics bridge](#)
- [traceroute](#)

## monitor traffic

---

**Syntax**    monitor traffic  
              <brief | detail | extensive>  
              <absolute-sequence>  
              <count *count*>  
              <interface *interface-name*>  
              <layer2-headers>  
              <matching *matching*>  
              <no-domain-names>  
              <no-promiscuous>  
              <no-resolve>  
              <no-timestamp>  
              <print-ascii>  
              <print-hex>  
              <resolve-timeout>  
              <size *size*>

**Release Information**    Command introduced before Junos OS Release 7.4.  
                              Command introduced in Junos OS Release 9.0 for EX Series switches.  
                              Command introduced in Junos OS Release 11.1 for the QFX Series.

**Description**    Display packet headers or packets received and sent from the Routing Engine.

**NOTE:**

- Using the **monitor-traffic** command can degrade router or switch performance.
  - Delays from DNS resolution can be eliminated by using the **no-resolve** option.
- 
- 

**NOTE:** This command is not supported on the QFabric system.

---

**Options**    **none**—(Optional) Display packet headers transmitted through **fxp0**. On a TX Matrix Plus router, display packet headers transmitted through **em0**.

**brief | detail | extensive**—(Optional) Display the specified level of output.

**absolute-sequence**—(Optional) Display absolute TCP sequence numbers.

**count *count***—(Optional) Specify the number of packet headers to display (0 through 1,000,000). The monitor traffic command quits automatically after displaying the number of packets specified.

**interface *interface-name***—(Optional) Specify the interface on which the **monitor traffic** command displays packet data. If no interface is specified, the **monitor traffic** command displays packet data arriving on the lowest-numbered interface.

**layer2-headers**—(Optional) Display the link-level header on each line.

**matching *matching***—(Optional) Display packet headers that match a regular expression. Use matching expressions to define the level of detail with which the **monitor traffic** command filters and displays packet data.

**no-domain-names**—(Optional) Suppress the display of the domain portion of hostnames. With the **no-domain-names** option enabled, the **monitor traffic** command displays only **team** for the hostname **team.company.net**.

**no-promiscuous**—(Optional) Do not put the interface into promiscuous mode.

**no-resolve**—(Optional) Suppress reverse lookup of the IP addresses.

**no-timestamp**—(Optional) Suppress timestamps on displayed packets.

**print-ascii**—(Optional) Display each packet in ASCII format.

**print-hex**—(Optional) Display each packet, except the link-level header, in hexadecimal format.

**resolve-timeout *timeout***—(Optional) Amount of time the router or switch waits for each reverse lookup before timing out. You can set the timeout for 1 through 4,294,967,295 seconds. The default is 4 seconds. To display each packet, use the **print-ascii**, **print-hex**, or **extensive** option.

**size *size***—(Optional) Read but do not display up to the specified number of bytes for each packet. When set to **brief** output, the default packet size is 96 bytes and is adequate for capturing IP, ICMP, UDP, and TCP packet data. When set to **detail** and **extensive** output, the default packet size is 1514. The **monitor traffic** command truncates displayed packets if the matched data exceeds the configured size.

**Additional Information** In the **monitor traffic** command, you can specify an expression to match by using the **matching** option and including the expression in quotation marks:

```
monitor traffic matching "expression"
```

Replace ***expression*** with one or more of the match conditions listed in [Table 435 on page 4272](#).

Table 435: Match Conditions for the monitor traffic Command

| Match Type    | Condition                                             | Description                                                                                                                                                                                                                                                                            |
|---------------|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Entity        | <b>host</b> [ <i>address</i>   <i>hostname</i> ]      | Matches packets that contain the specified address or hostname.<br><br>The protocol match conditions <b>arp</b> , <b>ip</b> , or <b>rarp</b> , or any of the directional match conditions can be prepended to the <b>host</b> match condition.                                         |
|               | <b>net</b> <i>address</i>                             | Matches packets with source or destination addresses containing the specified network address.                                                                                                                                                                                         |
|               | <b>net</b> <i>address mask mask</i>                   | Matches packets containing the specified network address and subnet mask.                                                                                                                                                                                                              |
|               | <b>port</b> ( <i>port-number</i>   <i>port-name</i> ) | Matches packets containing the specified source or destination TCP or UDP port number or port name.<br><br>In place of the numeric port address, you can specify a text synonym, such as <b>bgp</b> (179), <b>dhcp</b> (67), or <b>domain</b> (53) (the port numbers are also listed). |
| Directional   | <b>dst</b>                                            | Matches packets going to the specified destination. This match condition can be prepended to any of the entity type match conditions.                                                                                                                                                  |
|               | <b>src</b>                                            | Matches packets from a specified source. This match condition can be prepended to any of the entity type match conditions.                                                                                                                                                             |
|               | <b>src and dst</b>                                    | Matches packets that contain the specified source and destination addresses. This match condition can be prepended to any of the entity type match conditions.                                                                                                                         |
|               | <b>src or dst</b>                                     | Matches packets containing either of the specified addresses. This match condition can be prepended to any of the entity type match conditions.                                                                                                                                        |
| Packet Length | <b>less</b> <i>value</i>                              | Matches packets shorter than or equal to the specified value, in bytes.                                                                                                                                                                                                                |
|               | <b>greater</b> <i>value</i>                           | Matches packets longer than or equal to the specified value, in bytes.                                                                                                                                                                                                                 |

Table 435: Match Conditions for the monitor traffic Command (*continued*)

| Match Type | Condition                                                | Description                                                                                                                                                                                                                                                                                                                     |
|------------|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol   | <b>amt</b>                                               | Matches all AMT packets. Use the extensive level of output to decode the inner IGMP packets in addition to the AMT outer packet.                                                                                                                                                                                                |
|            | <b>arp</b>                                               | Matches all ARP packets.                                                                                                                                                                                                                                                                                                        |
|            | <b>ether</b>                                             | Matches all Ethernet packets.                                                                                                                                                                                                                                                                                                   |
|            | <b>ether (broadcast   multicast)</b>                     | Matches broadcast or multicast Ethernet frames. This match condition can be prepended with <b>src</b> and <b>dst</b> .                                                                                                                                                                                                          |
|            | <b>ether protocol (address   (arp   ip   rarp))</b>      | Matches packets with the specified Ethernet address or Ethernet packets of the specified protocol type. The <b>ether protocol</b> arguments <b>arp</b> , <b>ip</b> , and <b>rarp</b> are also independent match conditions, so they must be preceded by a backslash (\) when used in the <b>ether protocol</b> match condition. |
|            | <b>icmp</b>                                              | Matches all ICMP packets.                                                                                                                                                                                                                                                                                                       |
|            | <b>ip</b>                                                | Matches all IP packets.                                                                                                                                                                                                                                                                                                         |
|            | <b>ip (broadcast   multicast)</b>                        | Matches broadcast or multicast IP packets.                                                                                                                                                                                                                                                                                      |
|            | <b>ip protocol (address   (icmp   igmp   tcp   udp))</b> | Matches packets with the specified address or protocol type. The <b>ip protocol</b> arguments <b>icmp</b> , <b>tcp</b> , and <b>udp</b> are also independent match conditions, so they must be preceded by a backslash (\) when used in the <b>ip protocol</b> match condition.                                                 |
|            | <b>isis</b>                                              | Matches all IS-IS routing messages.                                                                                                                                                                                                                                                                                             |
|            | <b>rarp</b>                                              | Matches all RARP packets.                                                                                                                                                                                                                                                                                                       |
|            | <b>tcp</b>                                               | Matches all TCP datagrams.                                                                                                                                                                                                                                                                                                      |
|            | <b>udp</b>                                               | Matches all UDP datagrams.                                                                                                                                                                                                                                                                                                      |

To combine expressions, use the logical operators listed in [Table 436 on page 4273](#).

Table 436: Logical Operators for the monitor traffic Command

| Logical Operator (Highest to Lowest Precedence) | Description                                                                          |
|-------------------------------------------------|--------------------------------------------------------------------------------------|
| <b>!</b>                                        | Logical NOT. If the first condition does not match, the next condition is evaluated. |

Table 436: Logical Operators for the monitor traffic Command (*continued*)

| Logical Operator (Highest to Lowest Precedence) | Description                                                                                                                                         |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| &&                                              | Logical AND. If the first condition matches, the next condition is evaluated. If the first condition does not match, the next condition is skipped. |
|                                                 | Logical OR. If the first condition matches, the next condition is skipped. If the first condition does not match, the next condition is evaluated.  |
| ()                                              | Group operators to override default precedence order. Parentheses are special characters, each of which must be preceded by a backslash (\).        |

You can use relational operators to compare arithmetic expressions composed of integer constants, binary operators, a length operator, and special packet data accessors. The arithmetic expression matching condition uses the following syntax:

```
monitor traffic matching "ether[0] & 1 != 0"arithmetic_expression relational_operator arithmetic_expression
```

The packet data accessor uses the following syntax:

```
protocol [byte-offset <size>]
```

The optional *size* field represents the number of bytes examined in the packet header. The available values are 1, 2, or 4 bytes. The following sample command captures all multicast traffic:

```
user@host> monitor traffic matching "ether[0] & 1 != 0"
```

To specify match conditions that have a numeric value, use the arithmetic and relational operators listed in [Table 437 on page 4275](#).

**NOTE:** Because the Packet Forwarding Engine removes Layer 2 header information before sending packets to the Routing Engine:

- The **monitor traffic** command cannot apply match conditions to inbound traffic.
- The **monitor traffic interface** command also cannot apply match conditions for Layer 3 and Layer 4 packet data, resulting in the match pipe option (`| match`) for this command for Layer 3 and Layer 4 packets not working either. Therefore, ensure that you specify match conditions as described in this command summary. For more information about match conditions, see [Table 435 on page 4272](#).
- The 802.1Q VLAN tag information included in the Layer 2 header is removed from all inbound traffic packets. Because the **monitor traffic interface ae[x]** command for aggregated Ethernet interfaces (such as ae0) only shows inbound traffic data, the command does not show VLAN tag information in the output.

**Table 437: Arithmetic and Relational Operators for the monitor traffic Command**

| Arithmetic or Relational Operator                         | Description                                                                         |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Arithmetic Operator</b>                                |                                                                                     |
| +                                                         | Addition operator.                                                                  |
| -                                                         | Subtraction operator.                                                               |
| /                                                         | Division operator.                                                                  |
| &                                                         | Bitwise AND.                                                                        |
| *                                                         | Bitwise exclusive OR.                                                               |
|                                                           | Bitwise inclusive OR.                                                               |
| <b>Relational Operator (Highest to Lowest Precedence)</b> |                                                                                     |
| <=                                                        | If the first expression is less than or equal to the second, the packet matches.    |
| >=                                                        | If the first expression is greater than or equal to the second, the packet matches. |
| <                                                         | If the first expression is less than the second, the packet matches.                |
| >                                                         | If the first expression is greater than the second, the packet matches.             |
| =                                                         | If the compared expressions are equal, the packet matches.                          |
| !=                                                        | If the compared expressions are unequal, the packet matches.                        |

| <b>Description</b>         | <p>Check host reachability and network connectivity. The <b>ping</b> command sends Internet Control Message Protocol (ICMP) ECHO_REQUEST messages to elicit ICMP ECHO_RESPONSE messages from the specified host. Press Ctrl+c to interrupt a ping command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Options</b>             | <p><b>host</b>—IP address or hostname of the remote system to ping.</p> <p><b>bypass-routing</b>—(Optional) Bypass the normal routing tables and send ping requests directly to a system on an attached network. If the system is not on a directly attached network, an error is returned. Use this option to ping a local system through an interface that has no route through it.</p> <p><b>count requests</b>—(Optional) Number of ping requests to send. The range of values is 1 through 2,000,000,000. The default value is an unlimited number of requests.</p> <p><b>detail</b>—(Optional) Include in the output the interface on which the ping reply was received.</p> <p><b>do-not-fragment</b>—(Optional) Set the do-not-fragment (DF) flag in the IP header of the ping packets. For IPv6 packets, this option disables fragmentation.</p> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p> <b>NOTE:</b> In Junos OS Release 11.1 and later, when issuing the <b>ping</b> command for an IPv6 route with the <b>do-not-fragment</b> option, the maximum ping packet size is calculated by subtracting 48 bytes (40 bytes for the IPV6 header and 8 bytes for the ICMP header) from the MTU. Therefore, if the ping packet size (including the 48-byte header) is greater than the MTU, the ping operation might fail.</p> </div> <p><b>inet</b>—(Optional) Ping Packet Forwarding Engine IPv4 routes.</p> <p><b>inet6</b>—(Optional) Ping Packet Forwarding Engine IPv6 routes.</p> <p><b>interface source-interface</b>—(Optional) Interface to use to send the ping requests.</p> <p><b>interval seconds</b>—(Optional) How often to send ping requests. The range of values, in seconds, is 1 through infinity. The default value is 1.</p> <p><b>logical-system logical-system-name</b>—(Optional) Name of logical system from which to send the ping requests.</p> <p>Alternatively, enter the <b>set cli logical-system logical-system-name</b> command and then run the <b>ping</b> command. To return to the main router or switch, enter the <b>clear cli logical-system</b> command.</p> |

**loose-source value**—(Optional) Intermediate loose source route entry (IPv4). Open a set of values.

**mac-address mac-address**—(Optional) Ping the physical or hardware address of the remote system you are trying to reach.

**no-resolve**—(Optional) Do not attempt to determine the hostname that corresponds to the IP address.

**pattern string**—(Optional) Specify a hexadecimal fill pattern to include in the ping packet.

**rapid**—(Optional) Send ping requests rapidly. The results are reported in a single message, not in individual messages for each ping request. By default, five ping requests are sent before the results are reported. To change the number of requests, include the **count** option.

**record-route**—(Optional) Record and report the packet's path (IPv4).

**routing-instance routing-instance-name**—(Optional) Name of the routing instance for the ping attempt.

**size bytes**—(Optional) Size of ping request packets. The range of values, in bytes, is 0 through 65,468. The default value is 56, which is effectively 64 bytes because 8 bytes of ICMP header data are added to the packet.

**source source-address**—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

**strict**—(Optional) Use the strict source route option (IPv4).

**strict-source value**—(Optional) Intermediate strict source route entry (IPv4). Open a set of values.

**tos type-of-service**—(Optional) Set the type-of-service (ToS) field in the IP header of the ping packets. The range of values is 0 through 255.

If the device configuration includes the **dscp-code-point value** statement at the **[edit class-of-service host-outbound-traffic]** hierarchy level, the configured DSCP value overrides the value specified in this command option. In this case, the ToS field of ICMP echo request packets sent on behalf of this command carries the DSCP value specified in the **dscp-code-point** configuration statement instead of the value you specify in this command option.

**ttl value**—(Optional) Time-to-live (TTL) value to include in the ping request (IPv6). The range of values is 0 through 255.

**verbose**—(Optional) Display detailed output.

**vpls instance-name**—(Optional) Ping the instance to which this VPLS belongs.

**wait seconds**—(Optional) Maximum wait time, in seconds, after the final packet is sent. If this option is not specified, the default delay is 10 seconds. If this option is used without the count option, a default count of 5 packets is used.

                           `<tos value>`  
                           `<ttl value>`  
                           `<wait seconds>`

**Release Information**    Command introduced before Junos OS Release 7.4.  
                           Command introduced in Junos OS Release 9.0 for EX Series switches.  
                           **mpls** option introduced in Junos OS Release 9.2.  
                           Command introduced in Junos OS Release 11.1 for the QFX Series.  
                           **propagate-ttl** option introduced in Junos OS Release 12.1.

**Description**    Display the route that packets take to a specified network host. Use **traceroute** as a debugging tool to locate points of failure in a network.

**Options**    **host**—IP address or name of remote host.

**as-number-lookup**—(Optional) Display the autonomous system (AS) number of each intermediate hop on the path from the host to the destination.

**bypass-routing**—(Optional) Bypass the normal routing tables and send requests directly to a system on an attached network. If the system is not on a directly attached

network, an error is returned. Use this option to display a route to a local system through an interface that has no route through it.

**clns**—(Optional) Trace the route belonging to the Connectionless Network Service (CLNS).

**gateway address**—(Optional) Address of a router or switch through which the route transits.

**inet | inet6**—(Optional) Trace the route belonging to IPv4 or IPv6, respectively.

**interface interface-name**—(Optional) Name of the interface over which to send packets.

**logical-system logical-system-name**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**monitor host**—(Optional) Display real-time monitoring information for the specified host.

**mpls (ldp FEC address | rsvp label-switched-path name)**—(Optional) See *traceroute mpls ldp* and *traceroute mpls rsvp*.

**no-resolve**—(Optional) Do not attempt to determine the hostname that corresponds to the IP address.

**propagate-ttl**—(Optional) On the PE routing device, use this option to view locally generated Routing Engine transit traffic. This is applicable for MPLS L3VPN traffic only.

Use for troubleshooting, when you want to view hop-by-hop information from the local provider router to the remote provider router, when TTL decrementing is disabled on the core network using the **no-propagate-ttl** configuration statement.

**NOTE:** Using **propagate-ttl** with **traceroute** on the CE router does not show hop-by-hop information.

---

**routing-instance routing-instance-name**—(Optional) Name of the routing instance for the traceroute attempt.

**source source-address**—(Optional) Source address of the outgoing traceroute packets.

**tos value**—(Optional) Value to include in the IP type-of-service (ToS) field. The range of values is 0 through 255.

**ttl value**—(Optional) Maximum time-to-live value to include in the traceroute request. The range of values is 0 through 128.

**wait seconds**—(Optional) Maximum time to wait for a response to the traceroute request.

**Required Privilege Level**    network

- [traceroute \(Through an MPLS LSP\) on page 4292](#)

**Output Fields** [Table 439 on page 4291](#) describes the output fields for the **traceroute** command. Output fields are listed in the approximate order in which they appear.

**Table 439: traceroute Output Fields**

| Field Name             | Field Description                                             |
|------------------------|---------------------------------------------------------------|
| <b>traceroute to</b>   | IP address of the receiver.                                   |
| <b>hops max</b>        | Maximum number of hops allowed.                               |
| <b>byte packets</b>    | Size of packets being sent.                                   |
| <b>number-of-hops</b>  | Number of hops from the source to the named router or switch. |
| <b>router-name</b>     | Name of the router or switch for this hop.                    |
| <b>address</b>         | Address of the router or switch for this hop.                 |
| <b>Round trip time</b> | Average round-trip time, in milliseconds (ms).                |

## Sample Output

### traceroute

```
user@host> traceroute santacruz
traceroute to green.company.net (10.156.169.254), 30 hops max, 40 byte packets
 1 blue23 (10.168.1.254)  2.370 ms  2.853 ms  0.367 ms
 2 red14 (10.168.255.250) 0.778 ms  2.937 ms  0.446 ms
 3 yellow (10.156.169.254) 7.737 ms  89.905 ms  0.834 ms
```

### traceroute as-number-lookup host

```
user@host> traceroute as-number-lookup 10.100.1.1
traceroute to 10.100.1.1 (10.100.1.1), 30 hops max, 40 byte packets
 1 10.39.1.1 (10.39.1.1) 0.779 ms  0.728 ms  0.562 ms
 2 10.39.1.6 (10.39.1.6) [AS 32] 0.657 ms  0.611 ms  0.617 ms
 3 10.100.1.1 (10.100.1.1) [AS 10, 40, 50] 0.880 ms  0.808 ms  0.774 ms
```

### traceroute no-resolve

```
user@host> traceroute santacruz no-resolve
```

```
traceroute to green.company.net (10.156.169.254), 30 hops max, 40 byte packets
 1  10.168.1.254  0.458 ms  0.370 ms  0.365 ms
 2  10.168.255.250  0.474 ms  0.450 ms  0.444 ms
 3  10.156.169.254  0.931 ms  0.876 ms  0.862 ms
```

### traceroute propagate-ttl

```
user@host> traceroute propagate-ttl 100.200.2.2 routing-instance VPN-A
traceroute to 100.200.2.2 (100.200.2.2) from 1.1.0.2, 30 hops max, 40 byte packets

 1  1.2.0.2 (1.2.0.2)  2.456 ms  1.753 ms  1.672 ms
    MPLS Label=299776 CoS=0 TTL=1 S=0
    MPLS Label=299792 CoS=0 TTL=1 S=1
 2  1.3.0.2 (1.3.0.2)  1.213 ms  1.225 ms  1.166 ms
    MPLS Label=299792 CoS=0 TTL=1 S=1
 3  100.200.2.2 (100.200.2.2)  1.422 ms  1.521 ms  1.443 ms
```

### traceroute (Between CE Routers, Layer 3 VPN)

```
user@host> traceroute vpn09
traceroute to vpn09.skybank.net (10.255.14.179), 30 hops max, 40
byte packets
 1  10.39.10.21 (10.39.10.21)  0.598 ms  0.500 ms  0.461 ms
 2  10.39.1.13 (10.39.1.13)  0.796 ms  0.775 ms  0.806 ms
    MPLS Label=100006 CoS=0 TTL=1 S=1
 3  vpn09.skybank.net (10.255.14.179)  0.783 ms  0.716 ms  0.686
```

### traceroute (Through an MPLS LSP)

```
user@host> traceroute mpls1
traceroute to 10.168.1.224 (10.168.1.224), 30 hops max, 40 byte packets
 1  mpls1-sr0.company.net (10.168.200.101)  0.555 ms  0.393 ms  0.367 ms
    MPLS Label=1024 CoS=0 TTL=1
 2  mpls5-lo0.company.net (10.168.1.224)  0.420 ms  0.394 ms  0.401 ms
```

| <b>Output Fields</b>            | Table 441 on page 4294 lists the output fields for the <b>show services rpm history-results</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                            |

**Table 441: show services rpm history-results Output Fields**

| Field Name             | Field Description                                                                                                                                                                                                                                                                                                          | Level of Output |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Owner</b>           | Probe owner.                                                                                                                                                                                                                                                                                                               | All levels      |
| <b>Test</b>            | Name of a test for a probe instance.                                                                                                                                                                                                                                                                                       | All levels      |
| <b>Probe received</b>  | Timestamp when the probe result was determined.                                                                                                                                                                                                                                                                            | All levels      |
| <b>Round trip time</b> | Average ping round-trip time (RTT), in microseconds.                                                                                                                                                                                                                                                                       | All levels      |
| <b>Probe results</b>   | <p>Result of a particular probe performed by a remote host. The following information is contained in the results:</p> <ul style="list-style-type: none"> <li><b>Response received</b>—Timestamp when the probe result was determined.</li> <li><b>Rtt</b>—Average ping round-trip time (RTT), in microseconds.</li> </ul> | <b>detail</b>   |

Table 441: show services rpm history-results Output Fields (*continued*)

| Field Name                       | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Results over current test</b> | Displays the results for the current test by probe at the time each probe was completed, as well as the status of the current test at the time the probe was completed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <b>detail</b>   |
| <b>Probes sent</b>               | Number of probes sent with the current test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>detail</b>   |
| <b>Probes received</b>           | Number of probe responses received within the current test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>detail</b>   |
| <b>Loss percentage</b>           | Percentage of lost probes for the current test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>detail</b>   |
| <b>Measurement</b>               | <p>Increment of measurement. Possible values are round-trip time delay and, for the probe type icmp-pin-timestamp, the egress and ingress delay:</p> <ul style="list-style-type: none"> <li>• <b>Minimum</b>—Minimum RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li>• <b>Maximum</b>—Maximum RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li>• <b>Average</b>—Average RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li>• <b>Jitter</b>—Difference, in microseconds, between the maximum and minimum RTT measured over the course of the current test.</li> <li>• <b>Stddev</b>—Standard deviation of the round-trip time, in microseconds, measured over the course of the current test.</li> </ul> | <b>detail</b>   |

## show services rpm probe-results

|                                 |                                                                                                                                                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | show services rpm probe-results<br><owner <i>owner</i> ><br><test <i>name</i> >                                                                                                                                                                        |
| <b>Release Information</b>      | Command introduced before Junos OS Release 7.4.<br>Command introduced in Junos OS Release 9.0 for EX Series switches.<br>Command introduced in Junos OS Release 13.2 for PTX Series Packet Transport Series Routers.                                   |
| <b>Description</b>              | Display the results of the most recent real-time performance monitoring (RPM) probes.                                                                                                                                                                  |
| <b>Options</b>                  | <b>none</b> —Display all results of the most recent RPM probes.<br><br><b>owner <i>owner</i></b> —(Optional) Display information for the specified probe owner.<br><br><b>test <i>name</i></b> —(Optional) Display information for the specified test. |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                   |
| <b>List of Sample Output</b>    | <a href="#">show services rpm probe-results on page 4300</a><br><a href="#">show services rpm probe-results (BGP Neighbor Discovery) on page 4302</a>                                                                                                  |
| <b>Output Fields</b>            | <a href="#">Table 442 on page 4297</a> lists the output fields for the <b>show services rpm probe-results</b> command. Output fields are listed in the approximate order in which they appear.                                                         |

**Table 442: show services rpm probe-results Output Fields**

| Field Name            | Field Description                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Owner</b>          | Owner name. When you configure the probe owner statement at the <b>[edit services rpm]</b> hierarchy level, this field displays the configured owner name. When you configure BGP neighbor discovery through RPM, the output for this field is <b>Rpm-Bgp-Owner</b> .                                                                                                     |
| <b>Test</b>           | Name of a test representing a collection of probes. When you configure the test test-name statement at the <b>[edit services rpm probe owner]</b> hierarchy level, the field displays the configured test name. When you configure BGP neighbor discovery through RPM, the output for this field is <b>Rpm-BGP-Test-<i>n</i></b> , where <i>n</i> is a cumulative number. |
| <b>Target address</b> | Destination address used for the probes.                                                                                                                                                                                                                                                                                                                                  |
| <b>Source address</b> | Source address used for the probes.                                                                                                                                                                                                                                                                                                                                       |
| <b>Probe type</b>     | Protocol configured on the receiving probe server: <b>http-get</b> , <b>http-metadata-get</b> , <b>icmp-ping</b> , <b>icmp-ping-timestamp</b> , <b>tcp-ping</b> , <b>udp-ping</b> , or <b>udp-ping-timestamp</b> .                                                                                                                                                        |
| <b>Test size</b>      | Number of probes within a test.                                                                                                                                                                                                                                                                                                                                           |

Table 442: show services rpm probe-results Output Fields (*continued*)

| Field Name                       | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Routing Instance Name</b>     | <p>(BGP neighbor discovery) Name of the configured (if any) routing instance, logical system name, or both, in which the probe is configured:</p> <ul style="list-style-type: none"> <li>When a routing instance is defined within a logical system, the logical system name is followed by the routing instance name. A slash ( / ) is used to separate the two entities. For example, if the routing instance called <b>R1</b> is configured within the logical system called <b>LS</b>, the name in the output field is <b>LS/R1</b>.</li> <li>When a routing instance is configured but the default logical system is used, the name in the output field is the name of the routing instance.</li> <li>When a logical system is configured but the default routing instance is used, the name in the output field is the name of the logical system followed by <b>default</b>. A slash ( / ) is used to separate the two entities. For example, <b>LS/default</b>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Probe results</b>             | <p>Raw measurement of a particular probe sample done by a remote host. This data is provided separately from the calculated results. The following information is contained in the raw measurement:</p> <ul style="list-style-type: none"> <li><b>Response received</b>—Timestamp when the probe result was determined.</li> <li><b>Client and server hardware timestamps</b>—If timestamps are configured, an entry appears at this point.</li> <li><b>Rtt</b>—Average ping round-trip time (RTT), in microseconds.</li> <li><b>Egress jitter</b>—Egress jitter, in microseconds.</li> <li><b>Ingress jitter</b>—Ingress jitter, in microseconds.</li> <li><b>Round trip jitter</b>—Round-trip jitter, in microseconds.</li> <li><b>Egress interarrival jitter</b>—Egress interarrival jitter, in microseconds.</li> <li><b>Ingress interarrival jitter</b>—Ingress interarrival jitter, in microseconds.</li> <li><b>Round trip interarrival jitter</b>—Round-trip interarrival jitter, in microseconds.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Results over current test</b> | <p>Probes are grouped into tests, and the statistics are calculated for each test. If a test contains 10 probes, the average, minimum, and maximum results are calculated from the results of those 10 probes. If the command is issued while the test is in progress, the statistics use information from the completed probes.</p> <ul style="list-style-type: none"> <li><b>Probes sent</b>—Number of probes sent within the current test.</li> <li><b>Probes received</b>—Number of probe responses received within the current test.</li> <li><b>Loss percentage</b>—Percentage of lost probes for the current test.</li> <li><b>Measurement</b>—Measurement type. Possible values are round-trip time, positive round-trip jitter, negative round-trip jitter, egress time, positive egress jitter, negative egress jitter, ingress time, positive ingress jitter, negative ingress jitter, and, for the probe type <b>icmp-ping-timestamp</b>, the egress delay and ingress delay.</li> </ul> <p>For each measurement type, the following individual calculated results are provided:</p> <ul style="list-style-type: none"> <li><b>Samples</b>—Number of probes.</li> <li><b>Minimum</b>—Minimum RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li><b>Maximum</b>—Maximum RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li><b>Average</b>—Average RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li><b>Peak to peak</b>—Peak-to-peak difference, in microseconds.</li> <li><b>Stddev</b>—Standard deviation, in microseconds.</li> <li><b>Sum</b>—Statistical sum.</li> </ul> |

## Sample Output

### show services rpm probe-results

```

user@host> show services rpm probe-results
Owner: ADSN-J4300.ADSN-J2300.D2, Test: 75300002
Target address: 172.16.54.172, Source address: 10.206.0.1,
Probe type: udp-ping-timestamp, Test size: 10 probes
Probe results:
  Response received, Tue Feb  6 14:53:15 2007,
  Client and server hardware timestamps
  Rtt: 575 usec, Egress jitter: 5 usec, Ingress jitter: 8 usec,
  Round trip jitter: 12 usec, Egress interarrival jitter: 8 usec,
  Ingress interarrival jitter: 7 usec, Round trip interarrival jitter: 7 usec,

  Round trip interarrival jitter: 669 usec
Results over current test:
  Probes sent: 10, Probes received: 10, Loss percentage: 0
  Measurement: Round trip time
    Samples: 10, Minimum: 805 usec, Maximum: 2859 usec, Average: 1644 usec,
    Peak to peak: 2054 usec, Stddev: 738 usec, Sum: xxxx usec
  Measurement: Positive round trip jitter
    Samples: 5, Minimum: 5 usec, Maximum: 2054 usec, Average: 876 usec,
    Peak to peak: 2049 usec, Stddev: 679 usec, Sum: xxxx usec
  Measurement: Negative round trip jitter
    Samples: 5, Minimum: 5 usec, Maximum: 1812 usec, Average: 926 usec,
    Peak to peak: 1807 usec, Stddev: 665 usec, Sum: xxxx usec
  Measurement: Egress time
    Samples: 10, Minimum: 805 usec, Maximum: 2859 usec, Average: 1644 usec,
    Peak to peak: 2054 usec, Stddev: 738 usec, Sum: xxxx usec
  Measurement: Positive Egress jitter
    Samples: 5, Minimum: 5 usec, Maximum: 2054 usec, Average: 876 usec,
    Peak to peak: 2049 usec, Stddev: 679 usec, Sum: xxxx usec
  Measurement: Negative Egress jitter
    Samples: 5, Minimum: 5 usec, Maximum: 1812 usec, Average: 926 usec,
    Peak to peak: 1807 usec, Stddev: 665 usec, Sum: xxxx usec
  Measurement: Ingress time
    Samples: 10, Minimum: 805 usec, Maximum: 2859 usec, Average: 1644 usec,
    Peak to peak: 2054 usec, Stddev: 738 usec, Sum: xxxx usec
  Measurement: Positive Ingress jitter
    Samples: 5, Minimum: 5 usec, Maximum: 2054 usec, Average: 876 usec,
    Peak to peak: 2049 usec, Stddev: 679 usec, Sum: xxxx usec
  Measurement: Negative Ingress jitter
    Samples: 5, Minimum: 5 usec, Maximum: 1812 usec, Average: 926 usec,
    Peak to peak: 1807 usec, Stddev: 665 usec, Sum: xxxx usec
Results over last test:
  Probes sent: 10, Probes received: 10, Loss percentage: 0

```

## Sample Output

### clear snmp statistics

In the following example, SNMP statistics are displayed before and after the **clear snmp statistics** command is issued:

```
user@host> show snmp statistics
SNMP statistics:
  Input:
    Packets: 8, Bad versions: 0, Bad community names: 0,
    Bad community uses: 0, ASN parse errors: 0,
    Too bigs: 0, No such names: 0, Bad values: 0,
    Read onlys: 0, General errors: 0,
    Total request varbinds: 8, Total set varbinds: 0,
    Get requests: 0, Get nexts: 8, Set requests: 0,
    Get responses: 0, Traps: 0,
    Silent drops: 0, Proxy drops 0
  Output:
    Packets: 2298, Too bigs: 0, No such names: 0,
    Bad values: 0, General errors: 0,
    Get requests: 0, Get nexts: 0, Set requests: 0,
    Get responses: 8, Traps: 2290
```

```
user@host> clear snmp statistics
```

```
user@host> show snmp statistics
SNMP statistics:
  Input:
    Packets: 0, Bad versions: 0, Bad community names: 0,
    Bad community uses: 0, ASN parse errors: 0,
    Too bigs: 0, No such names: 0, Bad values: 0,
    Read onlys: 0, General errors: 0,
```

```
Total request varbinds: 0, Total set varbinds: 0,  
Get requests: 0, Get nexts: 0, Set requests: 0,  
Get responses: 0, Traps: 0,  
Silent drops: 0, Proxy drops 0  
Output:  
Packets: 0, Too bigs: 0, No such names: 0,  
Bad values: 0, General errors: 0,  
Get requests: 0, Get nexts: 0, Set requests: 0,  
Get responses: 0, Traps: 0
```

## request snmp spoof-trap

| <b>Output Fields</b>            | <a href="#">Table 444 on page 4319</a> describes the output fields for the <b>show snmp inform-statistics</b> command. Output fields are listed in the approximate order in which they appear. |

**Table 444: show snmp inform-statistics Output Fields**

| Field Name            | Field Description                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Target Name</b>    | Name of the device configured to receive and respond to SNMP informs.                                                                              |
| <b>Address</b>        | IP address of the target device.                                                                                                                   |
| <b>Sent</b>           | Number of informs sent to the target device and acknowledged by the target device.                                                                 |
| <b>Pending</b>        | Number of informs held in memory pending a response from the target device.                                                                        |
| <b>Discarded</b>      | Number of informs discarded after the specified number of retransmissions to the target device were attempted.                                     |
| <b>Timeouts</b>       | Number of informs that did not receive an acknowledgement from the target device within the timeout specified.                                     |
| <b>Probe Failures</b> | Connection failures that occurred (for example, when the target server returned invalid content or you incorrectly configured the target address). |

## Sample Output

### show snmp inform-statistics

```

user@host> show snmp inform-statistics
Inform Request Statistics:
  Target Name: TA1_v3_md5_none Address: 172.17.20.184
    Sent: 176, Pending: 0
    Discarded: 0, Timeouts: 0, Probe Failures: 0
  Target Name: TA2_v3_sha_none Address: 192.168.110.59

```

Sent: 0, Pending: 4  
Discarded: 84, Timeouts: 0, Probe Failures: 258  
Target Name: TA5\_v2\_none Address: 172.17.20.184  
Sent: 0, Pending: 0

| <b>Description</b>              | Display local Simple Network Management Protocol (SNMP) Management Information Base (MIB) object values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Options</b>                  | <p><b>get</b>—Retrieve and display one or more SNMP object values.</p> <p><b>get-next</b>—Retrieve and display the next SNMP object values.</p> <p><b>walk</b>—Retrieve and display the SNMP object values that are associated with the requested object identifier (OID). When you use this option, the Junos OS displays the objects below the subtree that you specify.</p> <p><b>ascii</b>—Display the SNMP object's string indices as an ASCII-key representation.</p> <p><b>decimal</b>—Display the SNMP object values in the decimal (default) format. The <b>decimal</b> option is the default option for this command. Therefore, issuing the <b>show snmp mib (get   get-next   walk) decimal object-id</b> and the <b>show snmp mib (get   get-next   walk) object-id</b> commands display the same output.</p> <p><b>object-id</b>—The object can be represented by a sequence of dotted integers (such as 1.3.6.1.2.1.2) or by its subtree name (such as <b>interfaces</b>). When entering multiple objects, enclose the objects in quotation marks.</p> |
| <b>Required Privilege Level</b> | snmp—To view this statement in the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Table 445: show snmp mib Output Fields

| Field Name          | Field Description                                                               |
|---------------------|---------------------------------------------------------------------------------|
| <i>name</i>         | Object name and numeric instance value.                                         |
| <i>object value</i> | Object value. The Junos OS translates OIDs into the corresponding object names. |

## Sample Output

### show snmp mib get

```
user@host> show snmp mib get sysObjectID.0
sysObjectID.0 = jnxProductNameM20
```

### show snmp mib get (Multiple Objects)

```
user@host> show snmp mib get ?sysObjectID.0 sysUpTime.0?
sysObjectID.0 = jnxProductNameM20
sysUpTime.0 = 1640992
```

### show snmp mib get (Layer 2 Policer)

```
user@host> show snmp mib get ifInOctets.25970
ifInOctets.25970 = 7545720
```

### show snmp mib get-next

```
user@host> show snmp mib get-next jnxMibs
jnxBoxClass.0 = jnxProductLineM20.0
```

### show snmp mib get-next (Specify an OID)

```
user@host> show snmp mib get-next 1.3.6.1
sysDescr.0 = Juniper Networks, Inc. m20 internet router, kernel
Junos OS Release: 2004-1 Build date: build date UTC Copyright (c) 1996-2004 Juniper
Networks, Inc.
```

### show snmp mib walk

```
user@host> show snmp mib walk system
sysDescr.0 = Juniper Networks, Inc. m20 internet router, kernel
Junos OS Release #0: 2004-1 Build date: build date UTC Copyright (c) 1996-2004

| <b>Output Fields</b>            | Table 447 on page 4328 lists the output fields for the <b>show smp rmon history</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                      |

Table 447: show smp rmon history Output Fields

| Field Name               | Field Description                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------|
| History Index            | Identifies this RMON history entry within the RMON history group.                            |
| Owner                    | The entity that configured this entry. Range is 0 to 32 alphanumeric characters.             |
| Status                   | The status of the RMON history entry.                                                        |
| Interface or Data Source | The ifindex object that identifies the interface that is being monitored.                    |
| Interval                 | The interval (in seconds) configured for this RMON history entry.                            |
| Buckets Requested        | The requested number of buckets ( <b>intervals</b> ) configured for this RMON history entry. |
| Buckets Granted          | The number of buckets granted for this RMON history entry.                                   |

Table 447: show snmp rmon history Output Fields (*continued*)

| Field Name          | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sample Index</b> | <p>The sample statistics taken at the specified interval.</p> <ul style="list-style-type: none"> <li>• <b>Drop Events</b>—Number of packets dropped by the input queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism.</li> <li>• <b>Octets</b>—Total number of octets and packets. For Gigabit Ethernet IQ PICs, the received octets count varies by interface type.</li> <li>• <b>Packets</b>—Total number of packets.</li> <li>• <b>Broadcast Packets</b>—Number of broadcast packets.</li> <li>• <b>Multicast Packets</b>—Number of multicast packets.</li> <li>• <b>CRC errors</b>—Total number of packets received that had a length (excluding framing bits, but including FCS octets) of between 64 and 1518 octets, inclusive, and had either a bad FCS with an integral number of octets (FCS error) or a bad FCS with a nonintegral number of octets (alignment error).</li> <li>• <b>Undersize Pkts</b>—Number of packets received during this sampling interval that were less than 64 octets long (excluding framing bits but including FCS octets) and were otherwise well formed.</li> <li>• <b>Oversize Pkts</b>—Number of packets received during the sampling interval that were longer than 1518 octets (excluding framing bits, but including FCS octets) but were otherwise well formed.</li> <li>• <b>Fragments</b>—Total number of packets that were less than 64 octets in length (excluding framing bits, but including FCS octets), and had either an FCS error or an alignment error. Fragment frames normally increment because both runts (which are normal occurrences caused by collisions) and noise hits are counted.</li> <li>• <b>Jabbers</b>—Number of frames that were longer than 1518 octets (excluding framing bits, but including FCS octets), and had either an FCS error or an alignment error. This definition of jabber is different from the definition in IEEE-802.3 section 8.2.1.5 (10BASE5) and section 10.3.1.4 (10BASE2). These documents define jabber as the condition in which any packet exceeds 20 ms. The allowed range to detect jabber is from 20 ms to 150 ms.</li> <li>• <b>Collisions</b>—Number of Ethernet collisions. The Gigabit Ethernet PIC supports only full-duplex operation, so for Gigabit Ethernet PICs, this number should always remain 0. If it is nonzero, there is a software bug.</li> <li>• <b>Utilization(%)</b>—The best estimate of the mean physical layer network utilization on this interface during this sampling interval, in hundredths of a percent.</li> </ul> |

## Sample Output

| <b>Engine ID</b>      | <p>Information about engine ID:</p> <ul style="list-style-type: none"> <li>• <b>Local engine ID</b>—Identifier that uniquely and unambiguously identifies the local SNMPv3 engine.</li> <li>• <b>Engine boots</b>—Number of times the local SNMPv3 engine has rebooted or reinitialized since the engine ID was last changed.</li> <li>• <b>Engine time</b>—Number of seconds since the local SNMPv3 engine was last rebooted or reinitialized.</li> <li>• <b>Max msg size</b>—Maximum message size the sender can accommodate.</li> <li>• <b>Engine ID</b>—SNMPv3 engine ID associated with each user.</li> <li>• <b>User</b>—SNMPv3 user.</li> <li>• <b>Auth/Priv</b>—Authentication and encryption algorithm available for use by each user.</li> <li>• <b>Storage</b>—Indicates whether a user is saved to the configuration file (nonvolatile) or not (volatile). Applies only to users with active status.</li> <li>• <b>Status</b>—Status of the conceptual row. Only rows with an active status are used by the SNMPv3 engine.</li> </ul> |
| <b>Group name</b>     | Name of the group to which this entry belongs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Security model</b> | Identifies the security model context for the security name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Security name</b>  | Used with the security model; identifies a specific security name instance. Each security model/security name combination can be assigned to a specific group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Storage type</b>   | Indicates whether a user is saved to the configuration file (nonvolatile) or not (volatile). Applies only to users with active status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Status</b>         | Status of the conceptual row. Only rows with active status are used by the SNMPv3 engine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Sample Output

### show snmp v3

```
user@host> show snmp v3
Local engine ID: 80 00 0a 4c e04 31 32 33 34

| <b>Output Fields</b>            | <a href="#">Table 451 on page 4341</a> lists the output fields for the <b>show forwarding-options analyzer</b> command. Output fields are listed in the approximate order in which they appear.                  |

**Table 451: show forwarding-options analyzer Output Fields**

| Field Name                   | Field Description                                                                                                            |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Analyzer name                | Displays the name of the analyzer.                                                                                           |
| Mirror rate                  | Displays the ratio of packets to be mirrored.                                                                                |
| Maximum packet length        | Displays the maximum packet length used for port mirroring.                                                                  |
| State                        | Specifies the Instance state, either <b>up</b> or <b>down</b> .                                                              |
| Ingress monitored interfaces | Displays interfaces for which traffic entering the interfaces is mirrored.                                                   |
| Output VLAN                  | Specifies a VLAN to which mirrored packets are sent. An analyzer can have output to either an interface or a VLAN, not both. |

## Sample Output

### show forwarding-options analyzer

```

user@switch> show forwarding-options analyzer
Analyzer name           : employee-monitor
Mirror rate             : 1
Maximum packet length   : 0
State                   : up
Ingress monitored interfaces : ge-0/0/0.0
Ingress monitored interfaces : ge-0/0/1.0

```

Output VLAN : default-switch/remote-analyzer

---

## Commands for Network Analytics

- [monitor start \(Analytics\)](#)
- [show analytics collector](#)
- [show analytics configuration](#)
- [show analytics queue-statistics](#)
- [show analytics status](#)
- [show analytics traffic-statistics](#)

## monitor start (Analytics)

**Syntax** `monitor start filename`

**Release Information** Command introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Start the display of the queue statistics or traffic statistics file if you had enabled queue or traffic monitoring on your device. The output is displayed in the JavaScript Object Notation (JSON) format.

**NOTE:** This topic describes the local file output in Junos OS Release 13.2X50-D15 and 13.2X51-D10 only. For information about 13.2X51-D15 and later, see [“Understanding Enhanced Analytics Local File Output” on page 3991](#)

**Options** *filename*—Name of the queue statistics or traffic statistics file.

**Required Privilege Level** trace

**Related Documentation**

- [Network Analytics Overview on page 3978](#)
- [analytics on page 4167](#)

**List of Sample Output**

[monitor start Using the Queue Statistics File \(Junos OS Release 13.2X51-D10\) on page 4344](#)  
[monitor start Using the Queue Statistics File \(Junos OS Release 13.2X50-D15\) on page 4345](#)

[monitor start Using the Traffic Statistics File \(Junos OS Release 13.2X50-D15\) on page 4345](#)

**Output Fields** [Table 452 on page 4343](#) describes the output fields for the **monitor start** command. Output fields are listed in the approximate order in which they appear.

**Table 452: monitor start Command Output Fields**

| Field                                                | Description                                                        |
|------------------------------------------------------|--------------------------------------------------------------------|
| hostname (used in Junos OS Release 13.2X50-D15 only) | Name of the network analytics host device.                         |
| record type                                          | Type of statistics. May be queue statistics or traffic statistics. |
| time                                                 | Time at which the statistics were captured.                        |
| router-id                                            | ID of the network analytics host device.                           |

Table 452: monitor start Command Output Fields (*continued*)

| Field                                         | Description                                                                                        |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------|
| latency                                       | For queue statistics only. Traffic queue latency in milliseconds.                                  |
| port                                          | Name of the physical port configured for network analytics.                                        |
| queue depth                                   | For queue statistics only. Depth of the traffic queue in bytes.                                    |
| rxpkt                                         | For traffic statistics monitoring only. Total packets received.                                    |
| rxpps                                         | For traffic statistics monitoring only. Total packets received per second.                         |
| rxbyte                                        | For traffic statistics monitoring only. Total bytes received.                                      |
| rxbps                                         | For traffic statistics monitoring only. Total bytes received per second.                           |
| rxdrop                                        | For traffic statistics monitoring only. Total incoming packets dropped.                            |
| rxerr                                         | For traffic statistics monitoring only. Total packets with errors.                                 |
| rxutil (in Junos OS Release 13.2X50-D15 only) | For traffic statistics monitoring only. Total percent of traffic utilization for incoming traffic. |
| txpkt                                         | For traffic statistics monitoring only. Total packets transmitted.                                 |
| txpps                                         | For traffic statistics monitoring only. Total packets transmitted per second.                      |
| txbyte                                        | For traffic statistics monitoring only. Total bytes transmitted.                                   |
| txbps                                         | For traffic statistics monitoring only. Total bytes transmitted per second.                        |
| txdrop                                        | For traffic statistics monitoring only. Total transmitted bytes dropped.                           |
| txerr                                         | For traffic statistics monitoring only. Total transmitted packets with errors (dropped).           |
| txutil (in Junos OS Release 13.2X50-D15 only) | For traffic statistics monitoring only. Total percent of traffic utilization for outgoing traffic. |

## Sample Output

### monitor start Using the Queue Statistics File (Junos OS Release 13.2X51-D10)

```

user@host> monitor start analytics.qs
{"record-type":"queue-stats","time":"2013 Nov 3 4:40:42.840",
"router-id":"qfx5100-switch","port":"xe-0/0/18","latency":0,"queue-depth":208}

## show analytics collector

**Syntax** show analytics collector

**Release Information** Command introduced in Junos OS Release 13.2 for the QFX Series.  
Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.

**Description** Show the list of network analytics remote collectors and related information. Remote collectors can be configured to receive streaming output for queue statistics and traffic statistics from the network analytics process (Analyticsd) running on the Routing Engine.

**NOTE:** The show analytics collector command is not available in Junos OS Releases prior to 13.2X51-D15.

**Required Privilege Level** interface-control

**Related Documentation**

| Field                               | Descriptions                                                                                                                                                                                                                                        |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Global Configurations</b>        |                                                                                                                                                                                                                                                     |
| Traffic monitoring status           | Settings are enabled or disabled. If traffic statistics monitoring is not enabled, this field is not shown.                                                                                                                                         |
| Traffic monitoring polling interval | Interval for traffic statistics polling in seconds.<br><br><b>NOTE:</b> Due to limitations and variations in hardware capability in different devices, there might be a difference in value between the actual interval and configured interval.    |
| Queue monitoring status             | Settings are enabled or disabled. If queue statistics monitoring is not enabled, this field is not shown.                                                                                                                                           |
| Queue monitoring polling interval   | Interval for queue statistics polling in milliseconds.<br><br><b>NOTE:</b> Due to limitations and variations in hardware capability in different devices, there might be a difference in value between the actual interval and configured interval. |
| Queue depth high threshold          | Upper limit of the depth threshold configuration in number of bytes.<br><br>If the queue depth threshold is not configured, this field is not shown.                                                                                                |
| Queue depth low threshold           | Lower limit of the depth threshold configuration in number of bytes.<br><br>If the queue depth threshold is not configured, this field is not shown.                                                                                                |

**Table 454: show analytics configuration Command Output Fields (Junos OS Release 13.2X51-D15 and Later) (continued)**

| Field                           | Descriptions                                                                                                                                          |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Queue latency high threshold    | Upper limit of the latency threshold configuration in nanoseconds.<br><br>If the queue latency threshold is not configured, this field is not shown.  |
| Queue latency low threshold     | Lower limit of the latency threshold configuration in microseconds.<br><br>If the queue latency threshold is not configured, this field is not shown. |
| <b>Interface Configurations</b> |                                                                                                                                                       |
| Interface                       | Name of interface that is configured for network analytics. The interface configuration overrides the global network analytics configuration.         |
| Traffic Statistics              | Settings are Enabled or Disabled for the interface.                                                                                                   |
| Queue Statistics                | Settings are Enabled or Disabled for the interface.                                                                                                   |
| Queue depth threshold High      | Upper limit of the depth threshold configuration in number of bytes.<br><br>If the queue depth threshold is not configured, <b>n/a</b> is displayed.  |
| Queue depth threshold Low       | Lower limit of the depth threshold configuration in number of bytes.<br><br>If the queue depth threshold is not configured, <b>n/a</b> is displayed.  |
| Latency threshold High          | Upper limit of the latency threshold configuration in nanoseconds.<br><br>If the latency threshold is not configured, <b>n/a</b> is displayed.        |
| Latency threshold Low           | Lower limit of the latency threshold configuration in nanoseconds.<br><br>If the latency threshold is not configured, <b>n/a</b> is displayed.        |

[Table 455 on page 4349](#) describes the output fields for the **show analytics configuration** command in Junos OS Release 13.2X51-D10 and 13.2X50-D15.

**Table 455: show analytics configuration Command Output Fields (Junos OS Release 13.2X51-D10 and earlier)**

| Field                        | Descriptions                                                                                                               |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Global Configurations</b> |                                                                                                                            |
| Traffic statistics           | Settings are Auto, Enabled, or Disabled.<br><br>If <b>Auto</b> is displayed, traffic statistics monitoring is not enabled. |

**Table 455: show analytics configuration Command Output Fields (Junos OS Release 13.2X51-D10 and earlier) (continued)**

| Field                              | Descriptions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Poll interval (traffic statistics) | <p>Interval for traffic statistics polling in seconds.</p> <p>If the output displays a setting of 0 seconds, the polling interval was not configured, and the default interval applies.</p> <p><b>NOTE:</b> The default interval is 1 second in Junos OS Release 13.2X50-D15 and later, except for EX4300 switches, on which the default interval is 5 seconds, and 2 seconds in Junos OS Release 13.2X51-D10.</p> <p><b>NOTE:</b> Due to limitations and variations in hardware capability in different devices, there might be a difference in value between the actual interval and configured interval.</p> |
| Queue statistics                   | <p>Settings are Auto, Enabled, or Disabled.</p> <p>If <b>Auto</b> is displayed, queue statistics monitoring is not enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Poll interval (queue statistics)   | <p>Interval for queue statistics polling in milliseconds.</p> <p><b>NOTE:</b> The default interval is 8 milliseconds in Junos OS Release 13.2X50-D15 and later, and 10 milliseconds in Junos OS Release 13.2X51-D10 or later.</p> <p><b>NOTE:</b> Due to limitations and variations in hardware capability in different devices, there might be a difference in value between the actual interval and configured interval.</p>                                                                                                                                                                                  |
| Depth threshold high               | <p>Upper limit of the depth threshold configuration in number of bytes.</p> <p>If <b>0</b> is displayed, depth threshold is not enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Depth threshold low                | <p>Lower limit of the depth threshold configuration in number of bytes.</p> <p>If <b>0</b> is displayed, depth threshold is not enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Latency threshold high             | <p>Upper limit of the latency threshold configuration in microseconds.</p> <p>If <b>0</b> is displayed, latency threshold is not enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Latency threshold low              | <p>Lower limit of the latency threshold configuration in microseconds.</p> <p>If <b>0</b> is displayed, latency threshold is not enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Interface Configurations</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Interface                          | Name of interface that is configured for network analytics. The interface configuration overrides the global network analytics configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Traffic Statistics                 | Settings are Enabled or Disabled for the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Queue Statistics                   | Settings are Enabled or Disabled for the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Depth-threshold High               | <p>Upper limit of the depth threshold configuration in number of bytes.</p> <p>If <b>0</b> is displayed, depth threshold is not enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 455: show analytics configuration Command Output Fields (Junos OS Release 13.2X51-D10 and earlier) (continued)**

| Field                  | Descriptions                                                                                                                    |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Depth-threshold Low    | Lower limit of the depth threshold configuration in number of bytes.<br><br>If 0 is displayed, depth threshold is not enabled.  |
| Latency-threshold High | Upper limit of the latency threshold configuration in microseconds.<br><br>If 0 is displayed, latency threshold is not enabled. |
| Latency-threshold Low  | Lower limit of the latency threshold configuration in microseconds.<br><br>If 0 is displayed, latency threshold is not enabled. |

## Sample Output

### show analytics configuration (Junos OS Release 13.2X51-D15 and Later)

```

user@host> show analytics configuration
Traffic monitoring status is enabled
Traffic monitoring polling interval : 5 seconds
Queue monitoring status is enabled
Queue monitoring polling interval : 1000 milliseconds
Queue depth high threshold : 99999 bytes
Queue depth low threshold : 99 bytes

```

| Interface | Traffic<br>Statistics | Queue<br>Statistics | Queue depth<br>threshold |     | Latency<br>threshold  |     |
|-----------|-----------------------|---------------------|--------------------------|-----|-----------------------|-----|
|           |                       |                     | High<br>(bytes)          | Low | High<br>(nanoseconds) | Low |
| xe-0/0/16 | enabled               | enabled             | n/a                      | n/a | 2300                  | 20  |
| xe-0/0/18 | enabled               | enabled             | n/a                      | n/a | 2300                  | 20  |
| xe-0/0/19 | enabled               | enabled             | n/a                      | n/a | 2300                  | 20  |

### show analytics configuration (Junos OS Release 13.2X51-D10 and Earlier)

```

user@host> show analytics configuration
Global configurations:
  Traffic statistics: Enabled, Poll interval: 2 seconds
  Queue statistics: Auto, Poll interval: 10 milliseconds
  Depth threshold high: 0 bytes, low: 0 bytes
  Latency threshold high: 0 microseconds, low: 0 microseconds

```

| Interface | Traffic<br>Statistics | Queue<br>Statistics | Depth-threshold |     | Latency-threshold      |     |
|-----------|-----------------------|---------------------|-----------------|-----|------------------------|-----|
|           |                       |                     | High<br>(bytes) | Low | High<br>(microseconds) | Low |
| xe-0/0/0  | Auto                  | Auto                | 204800          | 10  | 0                      | 0   |

## show analytics queue-statistics

|                                 |                                                                                                                                                                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | <code>show analytics queue-statistics</code><br><code>&lt;interface <i>interface-name</i>&gt;</code>                                                                                                                                                                                                |
| <b>Release Information</b>      | Command introduced in Junos OS Release 13.2 for the QFX Series.<br>Statement introduced in Junos OS Release 13.2X51-D25 for EX Series switches.                                                                                                                                                     |
| <b>Description</b>              | Show the queue statistics (queue length and latency) that are collected for all interfaces that are enabled for network analytics on a device. Optionally, if you wish to see the queue statistics for one interface only, you may specify the interface.                                           |
| <b>Options</b>                  | <code>interface <i>interface-name</i></code> —(Optional) Display the queue statistics for the specified interface only.                                                                                                                                                                             |
| <b>Required Privilege Level</b> | interface-control                                                                                                                                                                                                                                                                                   |

## Sample Output

### show analytics status (Junos OS Release 13.2X51-D15 or Later)

```

user@host> show analytics status
Traffic monitoring status is auto
Traffic monitoring polling interval : 5 seconds
Queue monitoring status is enabled
Queue monitoring status polling interval : 1000 milliseconds
Queue depth high threshold : 1000000000 bytes
Queue depth low threshold : 99 bytes

```

| Interface | Traffic<br>Statistics | Queue<br>Statistics | Queue depth<br>threshold |     | Latency<br>threshold |     |
|-----------|-----------------------|---------------------|--------------------------|-----|----------------------|-----|

### show analytics status global (Junos OS Release 13.2X51-D15 or Later)

```

user@host> show analytics status global

Traffic monitoring status is auto
Traffic monitoring polling interval : 5 seconds
Queue monitoring status is enabled
Queue monitoring status polling interval : 1000 milliseconds
Queue depth high threshold : 1000000000 bytes
Queue depth low threshold : 99 bytes

```

### show analytics status (Junos OS Release 13.2X50-D15 and 13.2X51-D10)

```

user@host> show analytics status

```

## Global configurations:

Traffic statistics: Auto, Poll interval: 2 seconds

Queue statistics: Auto, Poll interval: 10 milliseconds

Depth threshold high: 0 bytes, low: 0 bytes

Latency threshold high: 1000 microseconds, low: 50 microseconds

| Interface | Traffic<br>Statistics | Queue<br>Statistics | Depth-threshold |     | Latency-threshold |     |

**Table 459: show sflow Output Fields**

| Field Name          | Field Description                                                                                                   | Level of Output |
|---------------------|---------------------------------------------------------------------------------------------------------------------|-----------------|
| sFlow               | Status of the feature: <b>enabled</b> or <b>disabled</b> .                                                          | All levels      |
| Sample rate egress  | Rate at which egress packets are sampled.                                                                           | All levels      |
| Sample rate ingress | Rate at which ingress packets are sampled.                                                                          | All levels      |
| Sample limit        | Number of packets sampled per second. The sampling limit cannot be configured and is set to 300 packets per second. | All levels      |
| Polling interval    | Interval at which the sFlow agent polls the interface.                                                              | All levels      |
| Agent ID            | The IP address assigned to the sFlow agent.                                                                         | All levels      |

Table 459: show sflow Output Fields (*continued*)

| Field Name        | Field Description                      | Level of Output |
|-------------------|----------------------------------------|-----------------|
| Source IP address | The IP address for the sFlow datagram. | All levels      |

## Sample Output

show sflow

```
sFlow          : Enabled
Sample rate egress : 1:1000
Sample rate ingress : 1: 2048: Disabled
Sample limit      : 300 packets/second
Polling interval : 20 seconds
Agent ID         : 10.93.54.7
Source IP address : 10.93.54.7
```

## show sflow interface

| <b>Output Fields</b>            | <a href="#">Table 461 on page 4365</a> lists the output fields for the <b>show sflow collector</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                 |

**Table 461: show sflow collector Output Fields**

| Field Name    | Field Description                    | Level of Output |
|---------------|--------------------------------------|-----------------|
| IP address    | IP address of the collector.         | All levels      |
| UDP port      | UDP port number.                     | All levels      |
| No of samples | Number of samples sent to collector. | All levels      |

## Sample Output

### show sflow collector

```

IP-address    UDP-Port    No of samples
10.204.32.46  5600        1000
100.204.32.76 3400        1000

```

## clear sflow collectors statistics

### Sample Output

clear oam ethernet connectivity-fault-management statistics

```
user@host> clear oam ethernet connectivity-fault-management statistics
Cleared statistics of all CFM sessions
```

## monitor ethernet delay-measurement

**Syntax** monitor ethernet delay-measurement maintenance-domain *md-name*  
 maintenance-association *ma-name* (one-way | two-way) (*remote-mac-address* | mep  
*remote-mep-id*) <count *count*> <no-session-id-tlv> <priority *802.1p value*> <size *size*>  
 <wait *time*>

**Release Information** Command introduced in Junos OS Release 11.4 for EX Series switches.

**Description** Start an ITU-T Y.1731 Ethernet frame delay measurement session between the specified local connectivity fault management (CFM) maintenance association end point (MEP) and the specified remote MEP, and display a summary of the frames exchanged in the measurement session. Frame delay measurement statistics are stored at one of the MEPs for later retrieval.

**NOTE:** If you attempt to monitor delays to a nonexistent MAC address, you must type Ctrl +C to explicitly quit the **monitor ethernet delay-measurement** command and return to the CLI command prompt.

To start an Ethernet frame delay measurement session, the switch initiates an exchange of frames carrying one-way or two-way frame delay measurement protocol data units (PDUs) between the local and remote MEPs. The frame counts—the types of and number of Ethernet frame delay measurement PDU frames exchanged to measure frame delay times—are displayed as the run-time output of the **monitor ethernet delay-measurement** command and are also stored at both the initiator and receiver MEPs for later retrieval. Ethernet frame delay measurement statistics, described below, are measured and stored at only one of the MEPs:

**Frame delay**—The difference, in microseconds, between the time a frame is sent and when it is received.

**Frame delay variation**—The difference, in microseconds, between consecutive frame delay values. Frame delay variation is sometimes called “frame jitter.”

For one-way Ethernet frame delay measurement, only the receiver MEP (on the remote system) collects statistics. For two-way Ethernet frame delay measurement, only the initiator MEP (on the local system) collects statistics.

**Options** **count** *count*—(Optional) Number of frames to send to the specified peer MEP. The range of values is 1 through 65,535 frames. The default value is 10 frames.

**maintenance-association** *ma-name*—Name of an existing CFM maintenance association.

**maintenance-domain** *md-name*—Name of an existing CFM maintenance domain.

**mep** *remote-mep-id*—Numeric identifier of the peer MEP with which to perform Ethernet frame delay measurement. The discovered MAC address of the peer MEP is used. The range of values is 1 through 8191.

**no-session-id-tlv**—(Optional) Prevent insertion of the session ID TLV in the request frame.

**one-way**—Measurement type is one-way Ethernet frame delay measurement, which is based on the difference between the time at which the initiator MEP sends a one-way delay measurement request (IDM) frame and the time at which the receiver MEP receives the frame.

**priority 802.1p value**—(Optional) Priority of the delay measurement request frame supported by both one-way delay measurement and two-way delay measurement. The range of values is from 0 through 7. The default value is zero.

**remote-mac-address**—Unicast MAC address of the peer MEP with which to perform Ethernet frame delay measurement. Specify the MAC address as six hexadecimal bytes in *nn:nn:nn:nn:nn:nn* format. Multicast MAC addresses are not supported.

**size size** —(Optional) Size of the data TLV to be included in the request frame. The range of values is from 1 through 1400 bytes.

**two-way**—Measurement type is two-way Ethernet frame delay measurement, which is based on the difference between the time at which the initiator MEP sends a two-way delay measurement message (DMM) frame and the time at which the initiator MEP receives an associated two-way delay measurement reply (DMR) frame from the responder MEP, subtracting the time elapsed at the responder MEP.

**wait time**—(Optional) Number of seconds to wait between sending frames. The range of values is from 1 through 255 seconds. The default value is 1 second.

**Required Privilege Level** trace and maintenance

**Output Fields** The **monitor ethernet delay-measurement** command displays different output at the CLI, depending on whether you start a one-way or two-way frame delay measurement:

- [Table 462 on page 4373](#) lists the run-time output fields for the **monitor ethernet delay-measurement one-way** command.
- [Table 463 on page 4373](#) lists the run-time output fields for the **monitor ethernet delay-measurement two-way** command.

Output fields are listed in the approximate order in which they appear.

**Table 462: monitor ethernet delay-measurement one-way Output Fields**

| Output Field Name                | Output Field Description                                                                       |
|----------------------------------|------------------------------------------------------------------------------------------------|
| <b>One-way ETH-DM request to</b> | Unicast MAC address of the remote peer MEP.                                                    |
| <b>Interface</b>                 | Name of the Ethernet physical, logical, or trunk interface to which the local MEP is attached. |
| <b>IDM Frames sent</b>           | PDU frames sent to the remote MEP in this ETH-DM session.                                      |
| <b>Packets transmitted</b>       | Total number of IDM PDU frames sent to the remote MEP during this measurement session.         |
| <b>Average delay</b>             | Average two-way frame delay measured in this session.                                          |
| <b>Average delay variation</b>   | Average frame jitter measured in this session.                                                 |
| <b>Best case delay</b>           | Lowest two-way frame delay measured in this session.                                           |
| <b>Worst case delay</b>          | Highest two-way frame delay measured in this session.                                          |

**NOTE:** For one-way delay measurement, these CLI output fields display **NA** ("not applicable") at the initiator MEP because one-way frame delay measurements occur at the receiver MEP.

**Table 463: monitor ethernet delay-measurement two-way Output Fields**

| Output Field Name                                          | Output Field Description                                                                                          |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Two-way Ethernet frame delay measurement request to</b> | Unicast MAC address of the remote peer MEP.                                                                       |
| <b>Interface</b>                                           | Name of the Ethernet physical, logical, or trunk interface to which the local MEP is attached.                    |
| <b>DMR received from</b>                                   | Unicast MAC address of the remote MEP that transmitted this DMR frame in response to a DMM frame.                 |
| <b>Delay</b>                                               | Two-way delay, in microseconds, for the initiator-transmitted DMM frame.                                          |
| <b>Delay variation</b>                                     | Difference, in microseconds, between the current and previous delay values. This is also known as <i>jitter</i> . |
| <b>Packets transmitted</b>                                 | Total number of DMM PDU frames sent to the remote MEP in this measurement session.                                |
| <b>Valid packets received</b>                              | Total number of DMR PDU frames received from the remote MEP in this measurement session.                          |
| <b>Average delay</b>                                       | Average two-way frame delay measured in this session.                                                             |
| <b>Average delay variation</b>                             | Average frame jitter measured in this session.                                                                    |

Table 463: monitor ethernet delay-measurement two-way Output Fields (*continued*)

| Output Field Name       | Output Field Description                              |
|-------------------------|-------------------------------------------------------|
| <b>Best case delay</b>  | Lowest two-way frame delay measured in this session.  |
| <b>Worst case delay</b> | Highest two-way frame delay measured in this session. |

## Sample Output

| <b>Loss-threshold</b>                   | Lost continuity-check message threshold.                                                                                                                                                                       | <b>detail extensive</b> |
| <b>MEP identifier</b>                   | Maintenance association end point (MEP) identifier.                                                                                                                                                            | All levels              |
| <b>Neighbours</b>                       | Number of MEP neighbors.                                                                                                                                                                                       | All levels              |
| <b>Direction</b>                        | MEP direction configured.                                                                                                                                                                                      | <b>detail extensive</b> |
| <b>MAC address</b>                      | MAC address configured for the MEP.                                                                                                                                                                            | <b>detail extensive</b> |
| <b>MEP status</b>                       | Indicates the status of the Connectivity Fault Management (CFM) protocol running on the MEP: <b>Running</b> , <b>inactive</b> , <b>disabled</b> , or <b>unsupported</b> .                                      | <b>detail extensive</b> |
| <b>Remote MEP not receiving CCM</b>     | Whether the remote MEP is not receiving connectivity check messages (CCMs).                                                                                                                                    | <b>detail extensive</b> |
| <b>Erroneous CCM received</b>           | Whether erroneous CCMs have been received.                                                                                                                                                                     | <b>detail extensive</b> |
| <b>Cross-connect CCM received</b>       | Whether cross-connect CCMs have been received.                                                                                                                                                                 | <b>detail extensive</b> |
| <b>RDI sent by some MEP</b>             | Whether the remote defect indication (RDI) bit is set in messages that have been received. The absence of the RDI bit in a CCM indicates that the transmitting MEP is receiving CCMs from all configured MEPs. | <b>detail extensive</b> |
| <b>CCMs sent</b>                        | Number of CCMs transmitted.                                                                                                                                                                                    | <b>detail extensive</b> |
| <b>CCMs received out of sequence</b>    | Number of CCMs received out of sequence.                                                                                                                                                                       | <b>detail extensive</b> |

**Table 466: show oam ethernet connectivity-fault-management interfaces Output Fields (continued)**

| Field Name                                 | Field Description                                                                                                                                                                                                               | Level of Output         |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>LBM sent</b>                            | Number of loopback request messages (LBMs) sent.                                                                                                                                                                                | <b>detail extensive</b> |
| <b>Valid in-order LBRs received</b>        | Number of loopback response messages (LBRs) received that were valid messages and in sequence.                                                                                                                                  | <b>detail extensive</b> |
| <b>Valid out-of-order LBRs received</b>    | Number of LBRs received that were valid messages and not in sequence.                                                                                                                                                           | <b>detail extensive</b> |
| <b>LBRs received with corrupted data</b>   | Number of LBRs received that were corrupted.                                                                                                                                                                                    | <b>detail extensive</b> |
| <b>LBRs sent</b>                           | Number of LBRs transmitted.                                                                                                                                                                                                     | <b>detail extensive</b> |
| <b>LTMs sent</b>                           | Linktrace messages (LTMs) transmitted.                                                                                                                                                                                          | <b>detail extensive</b> |
| <b>LTMs received</b>                       | Linktrace messages received.                                                                                                                                                                                                    | <b>detail extensive</b> |
| <b>LTRs sent</b>                           | Linktrace responses (LTRs) transmitted.                                                                                                                                                                                         | <b>detail extensive</b> |
| <b>LTRs received</b>                       | Linktrace responses received.                                                                                                                                                                                                   | <b>detail extensive</b> |
| <b>Sequence number of next LTM request</b> | Sequence number of next LTM request to be transmitted.                                                                                                                                                                          | <b>detail extensive</b> |
| <b>1DMs sent</b>                           | If the interface is attached to an initiator MEP for a one-way ETH-DM session:<br>Number of one-way delay measurement (1DM) PDU frames sent to the peer MEP in this session.<br><br>For all other cases, this field displays 0. | <b>detail extensive</b> |
| <b>Valid 1DMs received</b>                 | If the interface is attached to a receiver MEP for a one-way ETH-DM session:<br>Number of valid 1DM frames received.<br><br>For all other cases, this field displays 0.                                                         | <b>detail extensive</b> |
| <b>Invalid 1DMs received</b>               | If the interface is attached to a receiver MEP for a one-way ETH-DM session:<br>Number of invalid 1DM frames received.<br><br>For all other cases, this field displays 0.                                                       | <b>detail extensive</b> |
| <b>DMMs sent</b>                           | If the interface is attached to an initiator MEP for a two-way ETH-DM session:<br>Number of Delay Measurement Message (DMM) PDU frames sent to the peer MEP in this session.<br><br>For all other cases, this field displays 0. | <b>detail extensive</b> |
| <b>DMRs sent</b>                           | If the interface is attached to a responder MEP for a two-way ETH-DM session:<br>Number of Delay Measurement Reply (DMR) frames sent.<br><br>For all other cases, this field displays 0.                                        | <b>detail extensive</b> |

**Table 466: show oam ethernet connectivity-fault-management interfaces Output Fields (continued)**

| Field Name                      | Field Description                                                                                                                                                     | Level of Output         |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                      |

**Table 467: show oam ethernet connectivity-fault-management linktrace path-database Output Fields**

| Field Name                     | Field Description                                                           |
|--------------------------------|-----------------------------------------------------------------------------|
| <b>Linktrace to</b>            | MAC address of the 802.1ag node to which the linktrace message is targeted. |
| <b>Interface</b>               | Interface used by the local MEP to send the linktrace message (LTM).        |
| <b>Maintenance Domain</b>      | Maintenance domain identifier specified in the traceroute command.          |
| <b>Maintenance Association</b> | Maintenance association identifier specified in the traceroute command.     |
| <b>Level</b>                   | Maintenance domain level configured for the maintenance domain.             |

**Table 467: show oam ethernet connectivity-fault-management linktrace path-database Output Fields (continued)**

| Field Name                    | Field Description                                                                                                                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Local Mep</b>              | MEP identifier of the local MEP originating the linktrace.                                                                                                                                                                                                                    |
| <b>Hop</b>                    | Sequential hop count of the linktrace path.                                                                                                                                                                                                                                   |
| <b>TTL</b>                    | Number of hops remaining in the linktrace message (LTM). The time to live (TTL) is decremented at each hop.                                                                                                                                                                   |
| <b>Source MAC address</b>     | MAC address of the 802.1ag maintenance intermediate point (MIP) that is forwarding the LTM.                                                                                                                                                                                   |
| <b>Next hop MAC address</b>   | MAC address of the 802.1ag node that is the next hop in the LTM path.                                                                                                                                                                                                         |
| <b>Transaction Identifier</b> | 4-byte identifier maintained by the MEP. Each LTM uses a transaction identifier. The transaction identifier is maintained globally across all maintenance domains. Use the transaction identifier to match an incoming linktrace responses (LTR), with a previously sent LTM. |

## Sample Output

### show oam ethernet connectivity-fault-management path-database

```

user@host> show oam ethernet connectivity-fault-management path-database
maintenance-domain MD1 maintenance-association MA1 00:01:02:03:04:05
Linktrace to 00:01:02:03:04:05, Interface : ge-5/0/0.0
Maintenance Domain: MD1, Level: 7
Maintenance Association: MA1, Local Mep: 1

Hop      TTL      Source MAC address      Next hop MAC address
Transaction Identifier:100001
1         63      00:00:aa:aa:aa:aa      00:00:bb:bb:bb:bb

| <b>Continuity-check status</b>          | Continuity-check status.                                                                                                                                                                                       |
| <b>Interval</b>                         | Continuity-check message interval.                                                                                                                                                                             |
| <b>MEP identifier</b>                   | Maintenance association end point (MEP) identifier.                                                                                                                                                            |
| <b>Direction</b>                        | MEP direction configured.                                                                                                                                                                                      |
| <b>MAC address</b>                      | MAC address configured for the MEP.                                                                                                                                                                            |
| <b>Auto-discovery</b>                   | Whether automatic discovery is enabled or disabled.                                                                                                                                                            |
| <b>Priority</b>                         | Priority used for CCMs and linktrace messages transmitted by the MEP.                                                                                                                                          |
| <b>Interface name</b>                   | Interface identifier.                                                                                                                                                                                          |
| <b>Interface status</b>                 | Local interface status.                                                                                                                                                                                        |
| <b>Link status</b>                      | Local link status.                                                                                                                                                                                             |
| <b>Remote MEP not receiving CCM</b>     | Whether the remote MEP is not receiving CCMs.                                                                                                                                                                  |
| <b>Erroneous CCM received</b>           | Whether erroneous CCMs have been received.                                                                                                                                                                     |
| <b>Cross-connect CCM received</b>       | Whether cross-connect CCMs have been received.                                                                                                                                                                 |
| <b>RDI sent by some MEP</b>             | Whether the remote defect indication (RDI) bit is set in messages that have been received. The absence of the RDI bit in a CCM indicates that the transmitting MEP is receiving CCMs from all configured MEPs. |
| <b>CCMs sent</b>                        | Number of CCMs transmitted.                                                                                                                                                                                    |
| <b>CCMs received out of sequence</b>    | Number of CCMs received out of sequence.                                                                                                                                                                       |

**Table 468: show oam ethernet connectivity-fault-management mep-database Output Fields (*continued*)**

| Field Name                                 | Field Description                                                                                                                                                                                             |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LBMs sent</b>                           | Number of loopback messages (LBMs) sent.                                                                                                                                                                      |
| <b>Valid in-order LBRs received</b>        | Number of loopback response messages (LBRs) received that were valid messages and in sequence.                                                                                                                |
| <b>Valid out-of-order LBRs received</b>    | Number of LBRs received that were valid messages and not in sequence.                                                                                                                                         |
| <b>LBRs received with corrupted data</b>   | Number of LBRs received that were corrupted.                                                                                                                                                                  |
| <b>LBRs sent</b>                           | Number of LBRs transmitted.                                                                                                                                                                                   |
| <b>LTMs sent</b>                           | Linktrace messages (LTMs) transmitted.                                                                                                                                                                        |
| <b>LTMs received</b>                       | Linktrace messages received.                                                                                                                                                                                  |
| <b>LTRs sent</b>                           | Linktrace responses (LTRs) transmitted.                                                                                                                                                                       |
| <b>LTRs received</b>                       | Linktrace responses received.                                                                                                                                                                                 |
| <b>Sequence number of next LTM request</b> | Sequence number of the next linktrace message request to be transmitted.                                                                                                                                      |
| <b>1DMs sent</b>                           | <p>If the MEP is an initiator for a one-way ETH-DM session: Number of one-way delay measurement (1DM) PDU frames sent to the peer MEP in this session.</p> <p>For all other cases, this field displays 0.</p> |
| <b>Valid 1DMs received</b>                 | <p>If the MEP is a receiver for a one-way ETH-DM session: Number of valid 1DM frames received.</p> <p>For all other cases, this field displays 0.</p>                                                         |
| <b>Invalid 1DMs received</b>               | <p>If the MEP is a receiver for a one-way ETH-DM session: Number of invalid 1DM frames received.</p> <p>For all other cases, this field displays 0.</p>                                                       |
| <b>DMMs sent</b>                           | <p>If the MEP is an initiator for a two-way ETH-DM session: Number of Delay Measurement Message (DMM) PDU frames sent to the peer MEP in this session.</p> <p>For all other cases, this field displays 0.</p> |
| <b>DMRs sent</b>                           | <p>If the MEP is a responder for a ETH-DM session: Number of Delay Measurement Reply (DMR) frames sent.</p> <p>For all other cases, this field displays 0.</p>                                                |

Table 468: show oam ethernet connectivity-fault-management mep-database Output Fields (*continued*)

| Field Name               | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b>              | Display the Ethernet Operation, Administration, and Maintenance (OAM) service-level agreement (SLA) iterator statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <p><b>maintenance-domain</b> <i>md-name</i>—Name of an existing connectivity fault management (CFM) maintenance domain.</p> <p><b>maintenance-association</b> <i>ma-name</i>—Name of an existing CFM maintenance association.</p> <p><b>sla-iterator</b> <i>sla-iterator</i>— Name of the iterator profile.</p> <p><b>local-mep</b> <i>local-mep-id</i>—(Optional) Numeric identifier of the local MEP. The range of values is 1 through 8191.</p> <p><b>remote-mep</b> <i>remote-mep-id</i>—(Optional) Numeric identifier of the remote MEP. The range of values is 1 through 8192.</p> |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Output fields are listed in the approximate order in which they appear.</p>                                                                                                                                                                                                                                                                                                                                            |

**Table 470: show oam ethernet connectivity-fault-management sla-iterator-statistics Output Fields**

| Output Field Name  | Output Field Description        |
|--------------------|---------------------------------|
| Maintenance domain | Name of the maintenance domain. |

Table 470: show oam ethernet connectivity-fault-management sla-iterator-statistics Output Fields (*continued*)

| Output Field Name                     | Output Field Description                                                                                     |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Level                                 | Level of the maintenance domain level configured.                                                            |
| Maintenance association               | Name of the maintenance association.                                                                         |
| Local MEP id                          | Numeric identifier of the local MEP.                                                                         |
| Remote MEP id                         | Numeric identifier of the remote MEP.                                                                        |
| Remote MAC address                    | Unicast MAC address of the remote MEP.                                                                       |
| Iterator name                         | Name of iterator.                                                                                            |
| Iterator Id                           | Numeric identifier of the iterator.                                                                          |
| Iterator cycle time                   | Number of cycles (in milliseconds) taken between back-to-back transmission of SLA frames for this connection |
| Iteration period                      | Maximum number of cycles per iteration                                                                       |
| Iterator status                       | Current status of iterator whether running or stopped.                                                       |
| Infinite iterations                   | Status of iteration as infinite or finite.                                                                   |
| Counter reset time                    | Date and time when the counter was reset.                                                                    |
| Reset reason                          | Reason to reset counter.                                                                                     |
| Delay weight                          | Calculation weight of delay.                                                                                 |
| Delay variation weight                | Calculation weight of delay variation.                                                                       |
| DMM sent                              | Delay measurement message (DMM) PDU frames sent to the peer MEP in this session.                             |
| DMM skipped for threshold hit         | Number of DMM frames sent to the peer MEP in this session skipped during threshold hit.                      |
| DMM skipped for threshold hit window  | Number of DMM frames sent to the peer MEP in this session skipped during the last threshold hit window.      |
| DMR received                          | Number of delay measurement reply (DMR) frames received.                                                     |
| DMR out of sequence                   | Total number of DMR out of sequence packets received.                                                        |
| DMR received with invalid time stamps | Total number of DMR frames received with invalid timestamps.                                                 |

**Table 470: show oam ethernet connectivity-fault-management sla-iterator-statistics Output Fields (*continued*)**

| Output Field Name                                 | Output Field Description                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Average two-way delay                             | Average two-way frame delay for the statistics displayed.                                                                                                                                                                                                                                                                         |
| Average two-way delay variation                   | Average two-way “frame jitter” for the statistics displayed.                                                                                                                                                                                                                                                                      |
| Average one-way forward delay variation           | Average one-way forward delay variation for the statistics displayed in microseconds.                                                                                                                                                                                                                                             |
| Average one-way backward delay variation          | Average one-way backward delay variation for the statistics displayed in microseconds.                                                                                                                                                                                                                                            |
| Weighted average two-way delay                    | Weighted average two-way delay for the statistics displayed in microseconds.                                                                                                                                                                                                                                                      |
| Weighted average two-way delay variation          | Weighted average two-way delay variation for the statistics displayed in microseconds.                                                                                                                                                                                                                                            |
| Weighted average one-way backward delay variation | Weighted average one-way backward delay variation for the statistics displayed in microseconds.                                                                                                                                                                                                                                   |
| Weighted average one-way forward delay variation  | Weighted average one-way forward delay variation for the statistics displayed in microseconds.                                                                                                                                                                                                                                    |
| SLM packets sent                                  | Total number of synthetic loss message (SLM) PDU frames sent from the source MEP to the remote MEP during this ETH-SLM session.                                                                                                                                                                                                   |
| SLM packets received                              | Total number of synthetic loss message (SLM) PDU frames that the remote MEP received from the source MEP during this ETH-SLM session.                                                                                                                                                                                             |
| SLR packets sent                                  | Total number of synthetic loss reply (SLR) PDU frames that the remote MEP sent to the source MEP during this measurement session.                                                                                                                                                                                                 |
| SLR packets received                              | Total number of synthetic loss reply (SLR) PDU frames that the source MEP received from the remote MEP during this measurement session.                                                                                                                                                                                           |
| Local TXFC1 value                                 | Number of synthetic frames transmitted to the peer MEP for a test ID. A test ID is used to distinguish each synthetic loss measurement because multiple measurements can be simultaneously activated also on a given CoS and MEP pair. It must be unique at least within the context of any SLM for the MEG and initiating MEP.   |
| Local RXFC1 value                                 | Number of synthetic frames received from the peer MEP for a test ID. The MEP generates a unique Test ID for the session, adds the source MEP ID, and initializes the local counters for the session before SLM initiation. For each SLM PDU transmitted for the session (test ID), the local counter TXFC1 is sent in the packet. |
| Last Received SLR frame TXFCf(tc)                 | Value of the local counter TxFC1 at the time of SLM frame transmission.                                                                                                                                                                                                                                                           |

Table 470: show oam ethernet connectivity-fault-management sla-iterator-statistics Output Fields (*continued*)

| Output Field Name               | Output Field Description                                                |
|---------------------------------|-------------------------------------------------------------------------|
| Last Received SLR frame TXFCb(t | Value of the local counter RxFCI at the time of SLR frame transmission. |
| Frame loss (near-end)           | Count of frame loss associated with ingress data frames.                |
| Frame loss (far-end)            | Count of frame loss associated with egress data frames.                 |

## Sample Output

### show oam ethernet connectivity-fault-management sla-iterator-statistics

```

user@switch> show oam ethernet connectivity-fault-management sla-iterator-statistics
sla-iterator il maintenance-domain default-1 maintenance-association ma1 local-mep 1
remote-mep 2
Iterator statistics:

|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Flags</b>                     | Information about the interface. <ul style="list-style-type: none"> <li><b>Remote-Stable</b>—Indicates remote OAM client acknowledgment of, and satisfaction with local OAM state information. <b>False</b> indicates that remote DTE has either not seen or is unsatisfied with local state information. <b>True</b> indicates that remote DTE has seen and is satisfied with local state information.</li> <li><b>Local-Stable</b>—Indicates local OAM client acknowledgment of, and satisfaction with remote OAM state information. <b>False</b> indicates that local DTE either has not seen or is unsatisfied with remote state information. <b>True</b> indicates that local DTE has seen and is satisfied with remote state information.</li> <li><b>Remote-State-Valid</b>—Indicates the OAM client has received remote state information found within Local Information TLVs of received Information OAM PDUs. <b>False</b> indicates that OAM client has not seen remote state information. <b>True</b> indicates that the OAM client has seen remote state information.</li> </ul>                                                                      | All levels      |
| <b>Remote loopback status</b>    | Indicates the remote loopback status. An OAM entity can put its remote peer into loopback mode using the Loopback control OAM PDU. In loopback mode, every frame received is transmitted back on the same port (except for OAM PDUs, which are needed to maintain the OAM session).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | All levels      |
| <b>Remote entity information</b> | Remote entity information. <ul style="list-style-type: none"> <li><b>Remote MUX action</b>—Indicates the state of the multiplexer functions of the OAM sublayer. Device is forwarding non-OAM PDUs to the lower sublayer or discarding non-OAM PDUs.</li> <li><b>Remote parser action</b>—Indicates the state of the parser function of the OAM sublayer. Device is forwarding non-OAM PDUs to higher sublayer, looping back non-OAM PDUs to the lower sublayer, or discarding non-OAM PDUs.</li> <li><b>Discovery mode</b>—Indicates whether discovery mode is active or inactive.</li> <li><b>Unidirectional mode</b>—Indicates the ability to operate a link in a unidirectional mode for diagnostic purposes.</li> <li><b>Remote loopback mode</b>—Indicates whether remote loopback is supported or not supported.</li> <li><b>Link events</b>—Indicates whether interpreting link events is supported or not supported on the remote peer.</li> <li><b>Variable requests</b>—Indicates whether variable requests are supported or not supported. The Variable Request OAM PDU, is used to request one or more MIB variables from the remote peer.</li> </ul> | All levels      |

## Troubleshooting Procedures

---

- [Troubleshooting Port Mirroring Configuration Error Messages on page 4413](#)

## Troubleshooting Port Mirroring Configuration Error Messages

Troubleshooting issues with port mirroring on EX Series switches:

1. [An Analyzer Configuration Returns a “Multiple interfaces cannot be configured as a member of Analyzer output VLAN” Error Message on page 4413](#)

### [An Analyzer Configuration Returns a “Multiple interfaces cannot be configured as a member of Analyzer output VLAN” Error Message](#)

---

**Problem** **Description:** In an analyzer configuration, if the VLAN to which mirrored traffic is sent contains more than one member interface, the following error message is displayed in the CLI when you commit the analyzer configuration and the commit fails:

```
Multiple interfaces cannot be configured as a member of Analyzer output VLAN <vlan
name>
```

**Solution** You must direct the mirrored traffic to a VLAN that has a single member interface. You can do this by completing either of these tasks:

- Reconfigure the existing VLAN to contain a single member interface. You can choose this method if you want to use the existing VLAN.
- Create a new VLAN with a single member interface and associate the VLAN with the analyzer.

To reconfigure the existing VLAN to contain only one member interface:

1. Remove member interfaces from the VLAN repeatedly by using either the **delete vlan** command or the **delete interface** command until the VLAN contains a single member interface:

- [edit]  
user@switch# **delete** vlan *vlan-id* interface *interface-name*
  - [edit]  
user@switch# **delete** interface *interface-name* unit 0 family *family-name* vlan member *vlan-id*
2. (Optional) Confirm that the VLAN contains only one interface:
- [edit]  
user@switch# **show** vlans *vlan-name*
- The output for this command must display only one interface.

To create a new VLAN with a single member interface:

1. Configure a VLAN to carry the mirrored traffic:
- [edit]  
user@switch# **set** vlans *vlan-name*
2. Associate an interface with the VLAN:
- [edit]  
user@switch# **set** interfaces *interface-name* unit *logical-unit-number* family *family-name* vlan members *vlan-name*
3. Associate the VLAN with the analyzer:
- [edit ethernet-switching-options]  
user@switch# **set** analyzer *analyzer-name* output vlan *vlan-name*

| <b>Release Information</b>      | Command introduced in Junos OS Release 12.1 for EX Series switches.                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | Display information about the number of packets discarded in the ingress pipeline of the Packet Forwarding Engine, packets discarded because of egress filtering or congestion filtering, number of control packets, and general counters for dropped packets. You can use this information to inform troubleshooting investigations.                                                                          |
| <b>Options</b>                  | <b>none</b> —Display bridge counter statistics for all Flexible PIC Concentrator (FPC) slots.<br><b>fpc slot</b> —(Optional) Display bridge counter statistics for a specific FPC slot.                                                                                                                                                                                                                        |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                                                           |

## Understanding PoE on EX Series Switches

Power over Ethernet (PoE) enables electric power, along with data, to be passed over a copper Ethernet LAN cable. Powered devices—such as VoIP telephones, wireless access points, video cameras, and point-of-sale devices—that support PoE can receive power safely from the same access ports that are used to connect personal computers to the network. This reduces the amount of wiring in a network, and also eliminates the need to position a powered device near an AC power outlet, making network design more flexible and efficient.

**NOTE:** We recommend that you do not connect an enabled PoE port on one switch to an enabled PoE port on a second switch. If there is a large voltage difference between the power supplies of the two switches, the resulting negative current will trigger a fail-safe mechanism on the second switch that prevents the power sourcing equipment (PSE) from delivering power to the other PoE ports on that switch.

This topic describes PoE on Juniper Networks EX Series Ethernet Switches.

- [PoE, PoE+, and Enhanced PoE on page 4423](#)
- [PoE Power Allocation on page 4425](#)

## PoE, PoE+, and Enhanced PoE

---

PoE was first defined in the IEEE 802.3af standard. In this standard, the amount of power that can be supplied to a powered device is limited to 15.4 W. A later standard, IEEE 802.3at, defined PoE+, which increases the amount of power to 30 W. The PoE+ standard provides support for legacy PoE devices—an IEEE 802.3af powered device can operate normally when connected to IEEE 802.3at (PoE+) power sourcing equipment.

Beginning in Juniper Networks Junos operating system (Junos OS) Release 11.1, Juniper Networks provides enhanced PoE on EX3200 and EX4200 switches. Enhanced PoE is a Juniper Networks extension to the IEEE 802.3af standard that provides power of up to 18.6 W per PoE port.

[Table 474 on page 4424](#) lists EX Series switches and line cards and the version of PoE they support.

**Table 474: PoE Version Support**

| Switch or Line Card                                                                                                                         | PoE Version                                                                                                                                                                                                                                                                                                                                                                                                                      |

| EX8200-2XS-40P (40-port PoE+ with 4-port SFP and 2-port SFP+) line card<br><br>EX8200-48PL (2-port SFP+ and 48-port PoE+ 20 Gbps) line card | PoE+ (IEEE 802.3at)—Ports 0 through 11, and PoE (IEEE 802.3af)—remaining PoE ports.                                                                                                                                                                                                                                                                                                                                              |

**NOTE:** This topic and its related topics use the term PoE as a generic term to refer to PoE, PoE+, and enhanced PoE.

## PoE Power Allocation

A switch or line card that supports PoE has a PoE controller that keeps track of the PoE power consumption on the switch or line card, and allocates power to the PoE ports. The following factors determine how the PoE controller allocates power to the PoE ports:

- [PoE Power Budget on page 4425](#)
- [PoE Interface Power Allocation on page 4429](#)
- [PoE Interface Power Priority on page 4431](#)

### **PoE Power Budget**

The PoE power budget is the total amount of power available for the PoE controller to allocate to the PoE ports. In allocating power, the PoE controller cannot exceed its PoE power budget and does not allocate power to a PoE port if the allocation exceeds the PoE power budget.

How the PoE power budget is determined depends on the switch model:

- [PoE Power Budget on EX2200, EX3200, EX3300, EX4200, EX4300, and EX4600 Switches on page 4425](#)
- [PoE Power Budget on EX6200 and EX8200 Switches on page 4428](#)

### **PoE Power Budget on EX2200, EX3200, EX3300, EX4200, EX4300, and EX4600 Switches**

The PoE power budget on EX2200, EX3200, EX3300, EX4200, and EX4300 switches depends on the switch model and the capacities of the power supplies installed. To find the PoE power budget for each switch model, see [Table 475 on page 4426](#) for EX2200 switch models, [Table 476 on page 4426](#) for EX3200 switch models, [Table 477 on page 4427](#) for EX3300 switch models, [Table 478 on page 4427](#) for EX4200 switch models, and [Table 479 on page 4428](#) for EX4300 switch models.

**NOTE:** EX4600 switches support PoE only in a mixed Virtual Chassis with EX4300 switches. The PoE controller on the EX4600 switch that is in the master role in the Virtual Chassis allocates power to the PoE-enabled ports on the EX4300 member switches by using the power budgets for those EX4300 switches.

Use the [show poe controller](#) command to display a switch's PoE power budget.

If your switch supports power supplies of different capacities, keep the following points in mind:

- If you change your existing power supply to a lower-capacity power supply, the PoE power budget might no longer be sufficient to power all the PoE ports on the switch.

- If your switch supports redundant power supplies and you have installed power supplies of different capacities, the PoE power budget is based on the wattage of the lowest-capacity power supply.
- You cannot increase the number of PoE-capable ports on a switch by installing a power supply that has a higher capacity.

[Table 475 on page 4426](#) lists the EX2200 switch models, number of PoE-enabled ports, power supply ratings, and PoE power budgets.

**Table 475: PoE Power Budget for EX2200 Switches**

| Switch Model Number | Number of PoE-Enabled Ports | Power Supply Rating | PoE Power Budget |
|---------------------|-----------------------------|---------------------|------------------|
| EX2200-C-12T        | –                           | 30 W                | –                |
| EX2200-C-12P        | 12                          | 180 W               | 100 W            |
| EX2200-24T          | –                           | 75 W                | –                |

***PoE Power Budget on EX6200 and EX8200 Switches***

For EX6200 and EX8200 switches, each line card that supports PoE has its own PoE controller and PoE power budget. The PoE power budget is allocated to the line card by the switch's power management, while PoE power is allocated to the ports on the line card by the PoE controller. Because EX6200 and EX8200 switches can differ in the number and capacity of power supplies installed and in the number and types of line cards installed, the amount of power available for PoE power can vary for switches of the same model.

Power management allocates PoE power to line cards that support PoE only after it has allocated base power to and powered on all line cards. It then allocates the remaining power to the PoE power budgets of PoE line cards in order of line card power priority. (In a default configuration, power priority is determined by the line card slot number, with slot 0 having the highest priority.) If the remaining power is insufficient to provide PoE power to all PoE line cards, a low-priority line card might receive no PoE power or partial PoE power.

By default, power management allocates enough PoE power to a line card to power all PoE ports at their maximum supported power. If the powered devices connected to that line card require less power than that, you can configure a smaller PoE power budget for the line card. For example, power management normally allocates 915 W of PoE power to a 48-port PoE+ 20 Gbps (EX8200-48PL) line card. If the powered devices connected to that line card consume no more than a total of 250 W, you can set the PoE power budget for the line card to 250 W. Doing so frees 665 W, which then can be used to fulfill the PoE power needs of lower-priority line cards.

You can also configure the power priority of the PoE ports on a line card. If power management is unable to allocate enough power to a line card to meet its PoE power budget, the line card PoE controller turns off power to PoE ports in reverse priority order as required to meet the reduced power allocation.

Power management adjusts PoE power allocations as power availability and demand in a switch changes. As a general rule, power management allocates power to power on line cards before it allocates PoE power. For example, if you add a line card and there is insufficient power available to power it on, power management reduces the PoE power it provides to line cards, starting with the lowest priority line card, until it frees enough power to power on the new line card. When power management reduces the PoE power budget for a line card because of insufficient power, it logs a message in the system log.

Note that the actual power consumed by the powered devices does not affect power management's power allocation for a line card. If you have set the PoE budget for a line card to 500 W, power management allocates 500 W even if the powered devices are consuming less power than that. Similarly, the PoE power budget is not increased if you add additional powered devices: if the powered devices require more than the 500 W PoE budget that you have configured, lower-priority devices do not receive power.

You can display the switch's power budget maintained by power management, including its PoE power allocations, by using the [show chassis power-budget-statistics](#) command. You can also display the PoE power budget for each line card in a switch by using the [show poe controller](#) command.

For more information about how power management allocates power, including PoE power, see ["Understanding Power Management on EX Series Switches" on page 2495](#).

### **PoE Interface Power Allocation**

You can configure how the switch determines the maximum power for a PoE interface and how power is allocated to the PoE interfaces. If the power consumption of a powered device exceeds the maximum power allocated to the interface, the switch turns off power to the interface.

These PoE power allocation methods are available:

- [LLDP Power Negotiation on page 4429](#)
- [Class PoE Management Mode on page 4430](#)
- [Static PoE Management Mode on page 4430](#)

### **LLDP Power Negotiation**

Link Layer Discovery Protocol (LLDP) power negotiation enables the PoE controller to dynamically allocate power to LLDP-enabled powered devices based on their power needs. The PoE controller allocates to an interface only the power currently required by the connected powered device, and it can allocate the power in small increments.

When the PoE **management** is set to **class** and LLDP is enabled (both are default settings), LLDP power negotiation is enabled by default. If you disable LLDP power negotiation or the powered device does not support it, the switch uses the class of the powered device to determine the maximum power for interfaces.

**NOTE:** LLDP power negotiation is not supported on EX3200 and EX4200 (except EX4200 PX models) switches.

### Class PoE Management Mode

In the **class** PoE management mode, the maximum power for an interface is determined by the class of the connected powered device. The PoE standards IEEE 802.3af and IEEE 802.3at define classes of powered devices based on the levels of power that they require. [Table 480 on page 4430](#) lists the classes of powered devices and associated power levels.

**Table 480: Class of Powered Device and Power Levels**

| Standard                                   | Class | Maximum Power Delivered by PoE Port | Power Range of Powered Device |
|--------------------------------------------|-------|-------------------------------------|-------------------------------|
| IEEE 802.3af (PoE) and IEEE 802.3at (PoE+) | 0     | 15.4 W                              | 0.44 through 12.95 W          |
|                                            | 1     | 4.0 W                               | 0.44 through 3.84 W           |
|                                            | 2     | 7.0 W                               | 3.84 through 6.49 W           |
|                                            | 3     | 15.4 W                              | 6.49 through 12.95 W          |
| IEEE 802.3at (PoE+)                        | 4     | 30.0 W                              | 12.95 through 25.5 W          |

Because of line loss, the power range of the powered device is less than the maximum power delivered at the PoE port for each class. Line loss is influenced by cable length, quality, and other factors and is typically less than 16 percent of the maximum power.

The powered device communicates to the PoE controller which class it belongs to when it is connected. The PoE controller then allocates to the interface the maximum power required by the class (see [Table 480 on page 4430](#)). It does not allocate power to an interface until a powered device is connected. **Class 0** is the default class for powered devices that do not provide class information. Class 4 powered devices are supported only by PoE ports that support IEEE 802.3at (PoE+).

By default, when the **management** option is set to **class** and LLDP are enabled, LLDP power negotiation is also enabled on supported switches. See [“LLDP Power Negotiation” on page 4429](#) for more information.

### Static PoE Management Mode

In the **static** PoE management mode, you specify the maximum power for each PoE interface. The PoE controller then allocates this amount of power to the interface from its total budget. For example, if you specify a maximum value of 8.0 W for ge-0/0/3, the PoE controller allocates 8.0 W out of its total power budget for this interface. This amount is allocated to the interface irrespective of whether a powered device is connected to the interface or the connected powered device uses less power than 8.0 W.

Because of line loss, the power received by the powered device can be less than the power available at the PoE port. [Table 481 on page 4431](#) shows the maximum power available at a PoE port and the resulting power guaranteed to the powered device.

Table 481: Maximum Power per Port in Static Mode

| Switch or Line Card                                                                                                                   | Maximum Power Delivered by PoE Port                                                                                                                                    | Guaranteed Power to Powered Devices |
|---------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| EX2200 switches, EX3300 switches, EX4200 PX model switches, EX4300 switches, and EX4600 switches operating in a mixed Virtual Chassis | 30 W                                                                                                                                                                   | 25.5 W                              |

**PoE Interface Power Priority**

You can configure a PoE interface to have a power priority. The power priority determines which interfaces receive power if PoE power demands are greater than the PoE power budget. If the total power allocated for all interfaces exceeds the switch budget, PoE power to lower-priority interfaces is turned off and the power allocated to those interfaces drops to 0. Thus you must set interfaces that connect to critical powered devices, such as security cameras and emergency phones, to high priority.

Among PoE interfaces that have the same assigned priority, power priority is determined by the port number, with lower-numbered ports having higher priority.

For EX6200 and EX8200 switches, interface power priority determines the relative priority of the interfaces on a line card, not on the switch as a whole. The relative priority of interfaces residing on different line cards is determined by line card priority. For example, if line card 1 has a higher power priority than line card 2 and a power shortage occurs, power is removed from the PoE interfaces in this order:

- Low-priority interfaces on line card 2
- High-priority interfaces on line card 2
- Low-priority interfaces on line card 1
- High-priority interfaces on line card 1

You can manually configure PoE interface power priority, or you can enable LLDP power priority, which assigns each interface the power priority provided by the connected LLDP-enabled powered device. [Table 482 on page 4432](#) describes how the switch converts LLDP power priorities to switch power priorities.

Table 482: LLDP Power Priority Conversion

| LLDP Power Priority | Switch Power Priority |
|---------------------|-----------------------|
| Critical, High      | High                  |
| Low                 | Low                   |

NOTE: LLDP power priority requires LLDP power negotiation to be enabled, which is enabled by default when the PoE management option is set to class.

NOTE: LLDP power priority is not supported on EX3200 and EX4200 (except EX4200 PX model) switches.

### Configuration Examples

---

- [Example: Configuring PoE Interfaces on an EX Series Switch on page 4433](#)
- [Example: Configuring PoE Interfaces with Different Priorities on an EX Series Switch on page 4435](#)

#### Example: Configuring PoE Interfaces on an EX Series Switch

Power over Ethernet (PoE) ports supply electric power over the same ports that are used to connect network devices and enable you to plug in devices that require both network connectivity and electric power, such as VoIP phones, wireless access points, and some IP cameras. This reduces the amount of wiring in a network, and also eliminates the need to position a powered device near an AC power outlet, making network design more flexible and efficient.

You do not need to configure PoE unless you want to modify the default values or disable PoE on a specific interface.

This example describes a default configuration of PoE interfaces on an EX Series switch:

- [Requirements on page 4433](#)
- [Overview and Topology on page 4434](#)
- [Configuration on page 4434](#)
- [Verification on page 4435](#)

#### Requirements

---

This example uses the following hardware and software components:

- One EX Series switch that supports PoE

**NOTE:** EX4600 switches support PoE only when operating in a mixed Virtual Chassis with EX4300 switches.

- Avaya IP telephones
- Wireless access point
- Junos OS Release 9.0 or later for EX Series switches

Before you configure PoE, be sure you have:

- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (CLI Procedure)* or *Connecting and Configuring an EX Series Switch (J-Web Procedure)* for details.

### Overview and Topology

The topology used in this example consists of a switch that has 24 ports. Eight of the ports support PoE (IEEE 802.3af), which means they provide both network connectivity and electric power for powered devices such as VoIP telephones, wireless access points, and IP security cameras that require 12.95 W or less. The remaining 16 ports provide only network connectivity. You use the standard ports to connect devices that have their own power sources, such as desktop and laptop computers, printers, and servers.

[Table 483 on page 4434](#) details the topology used in this configuration example.

**Table 483: Components of the PoE Configuration Topology**

| Property                                                                                                                           | Settings                                                                                                                                             |
|------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Switch hardware                                                                                                                    | EX Series switch with 24 Gigabit Ethernet ports: 8 PoE interfaces (ge-0/0/0 through ge-0/0/7) and 16 non-PoE interfaces (ge-0/0/8 through ge-0/0/23) |
| VLAN name                                                                                                                          | default                                                                                                                                              |
| Connection to a wireless access point (requires PoE)                                                                               | ge-0/0/0                                                                                                                                             |
| Connections to Avaya IP telephones with integrated hubs that allow phone and desktop PC to connect to a single port (requires PoE) | ge-0/0/1 through ge-0/0/7                                                                                                                            |
| Direct connections to desktop PCs, file servers, integrated printer/fax/copier machines (no PoE required)                          | ge-0/0/8 through ge-0/0/20                                                                                                                           |
| Unused ports (for future expansion)                                                                                                | ge-0/0/21 through ge-0/0/23                                                                                                                          |

### Configuration

To enable the default PoE configuration on the switch:

#### CLI Quick Configuration

To quickly enable the default configuration on the switch:

Simply connect the powered devices to the PoE ports.

#### Step-by-Step Procedure

To use the PoE interfaces with default values:

1. Make sure the switch is powered on.
2. Connect the wireless access point to interface ge-0/0/0.
3. Connect the Avaya phones to interfaces ge-0/0/1 through ge-0/0/7.

#### Verification

To verify that PoE interfaces have been created and are operational, perform this task:

- [Verifying That the PoE Interfaces Have Been Created on page 4435](#)

#### *Verifying That the PoE Interfaces Have Been Created*

**Purpose** Verify that the PoE interfaces have been created on the switch.

**Action** List all the PoE interfaces configured on the switch:

```
user@switch> show poe interface
```

| Interface | Admin status | Oper status | Max power | Priority | Power consumption | Class |
|-----------|--------------|-------------|-----------|----------|-------------------|-------|
| ge-0/0/0  | Enabled      | ON          | 15.4W     | Low      | 7.9W              | 0     |
| ge-0/0/1  | Enabled      | ON          | 15.4W     | Low      | 3.2W              | 2     |
| ge-0/0/2  | Enabled      | ON          | 15.4W     | Low      | 3.2W              | 2     |
| ge-0/0/3  | Enabled      | ON          | 15.4W     | Low      | 3.2W              | 2     |
| ge-0/0/4  | Enabled      | ON          | 15.4W     | Low      | 3.2W              | 2     |
| ge-0/0/5  | Enabled      | ON          | 15.4W     | Low      | 3.2W              | 2     |
| ge-0/0/6  | Enabled      | ON          | 15.4W     | Low      | 3.2W              | 2     |
| ge-0/0/7  | Enabled      | ON          | 15.4W     | Low      | 3.2W              | 2     |

**Meaning** The `show poe interface` command lists PoE interfaces configured on the switch, with their status, priority, power consumption, and class. This output shows that eight interfaces have been created with default values and are consuming power at the expected rates.

#### Related Documentation

- [Example: Configuring PoE Interfaces with Different Priorities on an EX Series Switch on page 4435](#)
- [Configuring PoE on EX Series Switches \(CLI Procedure\) on page 4440](#)

### Example: Configuring PoE Interfaces with Different Priorities on an EX Series Switch

Power over Ethernet (PoE) ports supply electric power over the same ports that are used to connect network devices. These ports enable you to plug in devices that need both network connectivity and electric power, such as VoIP phones, wireless access points, and some IP cameras.

By default, PoE ports on EX Series switches are set to low power priority. You can configure a PoE port to have a high power priority setting. If a situation arises where there is not

sufficient power for all the PoE ports, the available power is directed to the higher priority ports, while power to the lower priority ports is shut down as needed. Thus you must set ports that connect to security cameras, emergency phones, and other high priority powered devices to high-priority.

This example describes how to configure a few high-priority PoE interfaces.

- [Requirements on page 4436](#)
- [Overview and Topology on page 4436](#)
- [Configuration on page 4437](#)
- [Verification on page 4439](#)

### Requirements

This example uses the following hardware and software components:

- One EX Series switch that supports PoE

**NOTE:** EX4600 switches support PoE only when operating in a mixed Virtual Chassis with EX4300 switches.

- Powered devices—wireless access point, VoIP telephones, and IP security cameras—that require PoE
- Junos OS Release 9.0 or later for EX Series switches

Before you configure PoE, be sure you have:

- Performed the initial switch configuration. See *Connecting and Configuring an EX Series Switch (CLI Procedure)* or *Connecting and Configuring an EX Series Switch (J-Web Procedure)* for details.

### Overview and Topology

The topology used in this example consists of a switch that has 24 ports. Eight of the ports support PoE (IEEE 802.3af), which means they provide both network connectivity and electric power for powered devices such as VoIP telephones, wireless access points, and IP security cameras that require 12.95 W or less. The remaining 16 ports provide only network connectivity. You use the standard ports to connect devices that have their own power sources, such as desktop and laptop computers, printers, and servers.

[Table 484 on page 4436](#) details the topology used in this configuration example.

**Table 484: Components of the PoE Configuration Topology**

| Property        | Settings                                                                                                                                   |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Switch hardware | Switch with 24 Gigabit Ethernet ports: 8 PoE interfaces (ge-0/0/0 through ge-0/0/7) and 16 non-PoE interfaces (ge-0/0/8 through ge-0/0/23) |
| VLAN name       | default                                                                                                                                    |

Table 484: Components of the PoE Configuration Topology (*continued*)

| Property                                                                                                  | Settings                    |
|-----------------------------------------------------------------------------------------------------------|-----------------------------|
| Connection to a wireless access point (requires PoE)                                                      | ge-0/0/0                    |
| Security IP Cameras (require PoE)                                                                         | ge-0/0/1 and ge-0/0/2 high  |
| Emergency VoIP phone (requires PoE)                                                                       | ge-0/0/3 high               |
| VoIP phone in Executive Office (requires PoE)                                                             | ge-0/0/4 high               |
| Other VoIP phones (require PoE)                                                                           | ge-0/0/5 through ge-0/0/7   |
| Direct connections to desktop PCs, file servers, integrated printer/fax/copier machines (no PoE required) | ge-0/0/8 through ge-0/0/20  |
| Unused ports (for future expansion)                                                                       | ge-0/0/21 through ge-0/0/23 |

### Configuration

To configure PoE interfaces:

#### CLI Quick Configuration

By default, PoE interfaces are created for all PoE ports and PoE is enabled. The default priority for PoE interfaces is **low**.

To quickly set some interfaces to high priority and to include descriptions of the interfaces, copy the following commands and paste them into the switch terminal window:

```
[edit]
set poe interface ge-0/0/1 priority high telemetries
set poe interface ge-0/0/2 priority high telemetries
set poe interface ge-0/0/3 priority high telemetries
set poe interface ge-0/0/4 priority high telemetries
set interfaces ge-0/0/0 description "wireless access point"
set interfaces ge-0/0/1 description "security camera front door"
set interfaces ge-0/0/2 description "security camera back door"
set interfaces ge-0/0/3 description "emergency phone"
set interfaces ge-0/0/4 description "Executive Office VoIP phone"
set interfaces ge-0/0/5 description "staff VoIP phone"
set interfaces ge-0/0/6 description "staff VoIP phone"
set interfaces ge-0/0/7 description "staff VoIP phone"
```

#### Step-by-Step Procedure

To configure PoE interfaces with different priorities:

1. Set the interfaces connected to high-priority powered devices to high priority. Include the **telemetries** statement for the high-priority interfaces, thus enabling the logging of power consumption on those interfaces:

```
[edit poe]
user@switch# set interface ge-0/0/1 priority high telemetries
user@switch# set interface ge-0/0/2 priority high telemetries
user@switch# set interface ge-0/0/3 priority high telemetries
user@switch# set interface ge-0/0/4 priority high telemetries
```

2. Provide descriptions for the PoE interfaces:

```
[edit interfaces]
```

```
user@switch# set ge-0/0/0 description "wireless access point"
user@switch# set ge-0/0/1 description "security camera front door"
user@switch# set ge-0/0/2 description "security camera back door"
user@switch# set ge-0/0/3 description "emergency phone"
user@switch# set ge-0/0/4 description "Executive Office VoIP phone"
user@switch# set ge-0/0/5 description "staff VoIP phone"
user@switch# set ge-0/0/6 description "staff VoIP phone"
user@switch# set ge-0/0/7 description "staff VoIP phone"
```

3. Connect the wireless access point to interface ge-0/0/0. This interface uses the default PoE settings.
4. Connect the two security cameras to interfaces ge-0/0/1 and ge-0/0/2. These interfaces are set to high priority with telemetries enabled.
5. Connect the emergency VoIP phone to interface ge-0/0/3. This interface is set to high priority with telemetries enabled.
6. Connect the Executive Office VoIP phone to interface ge-0/0/4. This interface is set to high priority with telemetries enabled.
7. Connect the staff VoIP phones to ge-0/0/5, ge-0/0/6, and ge-0/0/7. These interfaces use the default PoE settings.

### Results

Check the results of the configuration:

```
[edit]
user@switch# show
interfaces {
  ge-0/0/0 {
    description "wireless access point";
    unit 0 {
      family ethernet-switching;
    }
  }
  ge-0/0/1 {
    description "security camera front door";
    unit 0 {
      family ethernet-switching;
    }
  }
  ge-0/0/2 {
    description "security camera back door";
    unit 0 {
      family ethernet-switching;
    }
  }
  ge-0/0/3 {
    description "emergency phone";
    unit 0 {
      family ethernet-switching;
    }
  }
  ge-0/0/4 {
```

```

        description "Executive Office VoIP phone";
        unit 0 {
            family ethernet-switching;
        }
    }
    ge-0/0/5 {
        description "staff VoIP phone";
        unit 0 {
            family ethernet-switching;
        }
    }
    ge-0/0/6 {
        description "staff VoIP phone";
        unit 0 {
            family ethernet-switching;
        }
    }
    ge-0/0/7 {
        description "staff VoIP phone";
        unit 0 {
            family ethernet-switching;
        }
    }
}
poe {
    interface all;
    interface ge-0/0/1 {
        priority high;
        telemetries;
    }
    interface ge-0/0/2 {
        priority high;
        telemetries;
    }
    interface ge-0/0/3 {
        priority high;
        telemetries;
    }
    interface ge-0/0/4 {
        priority high;
        telemetries;
    }
}

```

### Verification

To verify that PoE interfaces have been created and are operational, perform the following tasks:

- [Verifying That the PoE Interfaces Have Been Created with the Correct Priorities on page 4439](#)

#### *Verifying That the PoE Interfaces Have Been Created with the Correct Priorities*

**Purpose** Verify that the PoE interfaces on the switch are now set to the correct priority settings.

**Action** List all the PoE interfaces configured on the switch:

```
user@switch> show poe interface
```

| Interface | Admin<br>status | Oper<br>status | Max<br>power | Priority | Power<br>consumption | Class |
|-----------|-----------------|----------------|--------------|----------|----------------------|-------|
| ge-0/0/0  | Enabled         | ON             | 15.4W        | Low      | 7.9W                 | 0     |
| ge-0/0/1  | Enabled         | ON             | 15.4W        | High     | 4.8W                 | 0     |
| ge-0/0/2  | Enabled         | ON             | 15.4W        | High     | 4.8W                 | 0     |
| ge-0/0/3  | Enabled         | ON             | 15.4W        | High     | 3.3W                 | 2     |
| ge-0/0/4  | Enabled         | ON             | 15.4W        | High     | 4.7W                 | 2     |
| ge-0/0/5  | Enabled         | ON             | 15.4W        | Low      | 3.2W                 | 2     |
| ge-0/0/6  | Enabled         | ON             | 15.4W        | Low      | 3.3W                 | 2     |
| ge-0/0/7  | Enabled         | ON             | 15.4W        | Low      | 3.3W                 | 2     |

**Meaning** The **show poe interface** command lists PoE interfaces configured on the switch, with their status, priority, power consumption, and class. This output shows that eight PoE interfaces are enabled. Interfaces ge-0/0/1 through ge-0/0/4 are configured as priority **high**. The remaining PoE interfaces are configured with the default priority value of **low**.

### Configuring PoE on EX Series Switches (CLI Procedure)

Power over Ethernet (PoE) ports on EX Series switches supply electric power over the same ports that are used to connect network devices. These ports enable you to plug in devices that require both network connectivity and electric power, such as VoIP phones, wireless access points, and some IP cameras. This reduces the amount of wiring in a network, and also eliminates the need to position a powered device near an AC power outlet, making network design more flexible and efficient.

This topic describes:

- [PoE Configurable Options on page 4441](#)
- [Configuring the PoE Controller on EX2200, EX3200, EX3300, EX4200, and EX4300 Switches on page 4443](#)
- [Configuring the PoE Controllers on EX6200 and EX8200 Switches on page 4445](#)
- [Configuring PoE Interfaces on page 4446](#)

## PoE Configurable Options

For EX Series switches that support PoE ports, the factory default configuration enables PoE on the PoE-capable ports, with default settings in effect. You might not have to do any additional configuration if the default settings work for you. [Table 485 on page 4441](#) shows the configurable PoE options and their default settings for the PoE controller and for the PoE interfaces.

**NOTE:** On EX8200 switches, the factory default configuration enables PoE on all interfaces starting at Junos OS Release 11.2. Switches that have been upgraded to Release 11.2 from an earlier release might not have PoE enabled by default. To enable PoE on all PoE-capable ports on a switch, use the `set poe interface all` configuration command.

**NOTE:** EX4600 switches support PoE only in a mixed Virtual Chassis with EX4300 switches. EX4600 switches do not have PoE ports; therefore, the factory default configuration does not enable PoE.

**Table 485: Configurable PoE Options and Default Settings**

| Option                     | Default                               | Description                                                                                                                                                                                                                                                                                                 |

| Interface Options                    |                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>af-mode</b>                       | Not included in default configuration                                                                                                                                                                                    | (EX6200 switches only) When included in the configuration, restricts a PoE interface to supporting IEEE 802.3af only. The maximum power that can be delivered by the PoE interface is 15.4 W.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>disable (Power over Ethernet)</b> | Not included in default configuration                                                                                                                                                                                    | When included in the configuration, disables PoE on the interface. The interface maintains network connectivity but no longer supplies power to a connected powered device. Power is not allocated to the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 485: Configurable PoE Options and Default Settings (*continued*)

| Option                                | Default                                                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>maximum-power (Interface)</b>      | <p><b>30.0 W</b> for interfaces that support PoE+ (IEEE 802.3at)</p> <p><b>15.4 W</b> for interfaces that support PoE (IEEE 802.3af)</p> | <p>Sets the maximum power that can be delivered by a PoE interface when the power management mode is <b>static</b>:</p> <ul style="list-style-type: none"> <li>Up to 30 W for EX2200, EX3300, EX4200, EX4300, EX6200, and EX8200 switches</li> <li>Up to 18.6 W for EX3200 switches</li> </ul> <p>This setting is ignored if the power management mode is <b>class</b>.</p> <p><b>NOTE:</b> The <b>maximum-power</b> setting permitted by the CLI might be greater than the maximum power a given PoE port can deliver. For example, the CLI permits you to set any port on an EX8200 line card to 30 W; however, only ports 0 through 11 support 30 W. Similarly, the CLI permits you to set any port on an EX4200 switch to 30 W, but some EX4200 models support only 18.6 W per port. If you configure a <b>maximum-power</b> value that is greater than the maximum power supported by a port, the power allocated to the port will be the maximum supported.</p> |
| <b>priority (Power over Ethernet)</b> | <b>low</b>                                                                                                                               | <p>Sets an interface's power priority to either <b>low</b> or <b>high</b>. If power is insufficient for all PoE interfaces, the PoE power to low-priority interfaces is shut down before power to high-priority interfaces is shut down. Among interfaces that have the same assigned priority, the power priority is determined by port number, with lower-numbered ports having higher priority.</p> <p>If LLDP power priority is enabled, the switch assigns each interface the power priority provided by the connected LLDP-enabled powered device rather than the interface's configured priority.</p> <p>On EX6200 and EX8200 switches, <b>priority</b> determines the interface's power priority relative to the other interfaces on the line card, not the interfaces on the switch as a whole. If power management cannot provide the line card with its full PoE power budget, PoE power to interfaces with low priority is shut down first.</p>           |
| <b>telemetries</b>                    | Not included in default configuration                                                                                                    | <p>When included in the configuration, enables the logging of power consumption records on an interface. Logging occurs every 5 minutes for 1 hour unless you specify a different value for <b>interval (Power over Ethernet)</b> or <b>duration</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### Configuring the PoE Controller on EX2200, EX3200, EX3300, EX4200, and EX4300 Switches

To configure the PoE controller on EX2200, EX3200, EX3300, EX4200, EX4300, and EX4600 switches:

- To change the management mode or to configure a guard band setting for a standalone switch or for all members of an EX3300 Virtual Chassis, an EX4200 Virtual Chassis, an EX4300 Virtual Chassis, a mixed EX4200 and EX4500 Virtual Chassis that supports PoE, or a mixed EX4300 and EX4600 Virtual Chassis that supports PoE:

```
[edit]
user@switch# set poe management mode guard-band watts
```

For example, to set the management mode to static and to configure a guard band of 15 W:

```
[edit]
user@switch# set poe management static guard-band 15
```

**NOTE:** If the PoE power budget for the switch is insufficient to provide maximum power to all the PoE ports, we recommend that you do not change the management mode from class to static. If you change the power management mode to static and do not change the other default settings, the PoE controller allocates maximum power to the PoE ports in the order of port number, which means PoE will be disabled on higher-numbered ports when the PoE power budget runs out.

In class mode, on the other hand, the PoE controller does not allocate power to a port until a powered device is connected. The class of the connected device determines the amount of power allocated. Thus in class mode, any PoE port can be used to power a device and all the PoE ports on the switch can be used as long as the combined power demand does not exceed the PoE power budget.

**NOTE:** On EX3200 and EX4200 switches that support enhanced PoE, you must change the management mode from class to static to take advantage of the higher per-port power limits of enhanced PoE.

- To enable PoE SNMP traps on a standalone switch or on a specific member of a Virtual Chassis:

```
[edit]
user@switch# set poe notification-control fpc number
```

For example, to enable PoE SNMP traps on a standalone switch or on member 0 of a Virtual Chassis:

```
[edit]
user@switch# set poe notification-control fpc 0
```

### Configuring the PoE Controllers on EX6200 and EX8200 Switches

On EX6200 and EX8200 switches, each line card that supports PoE has its own PoE controller. This means that the PoE controller options are configured separately for each line card.

In addition, each line card has its own separate, configurable PoE power budget. The default power budget for a line card is the amount of power needed to supply all PoE ports on the line card with their maximum supported power. Because there might not be enough power available in a switch to supply each PoE line card with the default PoE power budget, you can configure smaller power budgets for one or more line cards, freeing power for other line cards.

To configure the line card PoE controllers in an EX6200 or EX8200 switch:

- To configure a guard band setting, to change the management mode, or to configure the PoE power budget for a specific line card:

```
[edit]
user@switch# set poe fpc number guard-band watts management mode
maximum-power watts
```

For example, to configure a PoE budget of 350 W and a guard band of 15 W on line card 1:

```
[edit]
user@switch# set poe fpc 1 guard-band 15 maximum-power 350
```

**NOTE:** If you configure a PoE power budget for a line card that is smaller than the default power budget, we recommend that you do not change the management mode from class to static. If you change the power management mode to static and do not change the interface default settings, the PoE controller allocates maximum power to the PoE ports in the order of port number. As a result, PoE will be disabled on higher-numbered ports when the PoE power budget runs out.

In class mode, on the other hand, the PoE controller does not allocate power to a port until a powered device is connected. The class of the connected device determines the amount of power allocated. Thus in class mode, any PoE port can be used to power a device and all the PoE ports on the switch can be used as long as the combined power demand does not exceed the PoE power budget.

- To configure the same guard band value, management mode, or PoE power budget for all line cards in a switch:

```
[edit]
user@switch# set poe fpc all guard-band watts management mode maximum-power
watts
```

For example, to configure a PoE budget of 1000 W and static management mode for all line cards in a switch:

```
[edit]
user@switch# set poe fpc all management static maximum-power 1000
```

If you configure different settings for a specific line card, those settings override the settings configured with the **fpc all** statement.

- To enable PoE SNMP traps on a line card:

```
[edit]
user@switch# set poe notification-control fpc number
```

For example, to enable PoE SNMP traps on line card 7:

```
[edit]
user@switch# set poe notification-control fpc 7
```

## Configuring PoE Interfaces

---

To configure the PoE interfaces on a switch that supports PoE:

- To configure all PoE interfaces with the same setting or settings:

```
[edit]
user@switch# set poe interface all options
```

For example, to enable telemetry collection on all interfaces, using the default collection duration and interval:

```
[edit]
user@switch# set poe interface all telemetries
```

**NOTE:** For PoE to be enabled on all PoE-capable interfaces, the configuration must include the **interface all** statement in the **[edit poe]** hierarchy level. With the exception of EX8200 switches that were shipped from the factory with a Junos OS release earlier than Release 11.2, the factory default configurations of switches that support PoE include this statement.

- To configure individual PoE interfaces with different settings:

```
[edit]
user@switch# set poe interface interface-name options
```

For example:

```
[edit]
user@switch# set poe interface ge-0/0/0 priority high telemetries duration 24
```

```
[edit]
user@switch# set poe interface ge-0/0/1
```

```
[edit]
user@switch# set poe interface ge-0/0/5 maximum-power 18.6
```

```
[edit]
user@switch# set poe interface ge-5/0/7 disable
```

When you configure an individual interface, its configuration overrides any settings you configure with the **set poe interface all** command. For example, ge-0/0/1 in the preceding example retains the default settings, regardless of any settings configured with the **set poe interface all** command.

## Configuring PoE (J-Web Procedure)

**NOTE:** This topic applies only to the J-Web Application package.

Power over Ethernet (PoE) ports supply electric power over the same ports that are used to connect network devices to EX Series switches. These ports allow you to plug in devices that require both network connectivity and electric power, such as VoIP phones, wireless access points, and some IP cameras. Using the Power over Ethernet (PoE) Configuration page in the J-Web interface, you can modify the settings of all interfaces that are PoE-enabled.

This topic includes:

- [Configuring PoE on EX2200, EX2200-C, EX3200, EX3300, EX4200, and EX4300 Switches on page 4447](#)
- [Configuring PoE on EX6200 Switches on page 4448](#)

### Configuring PoE on EX2200, EX2200-C, EX3200, EX3300, EX4200, and EX4300 Switches

To configure PoE:

1. Select **Configure > Power over Ethernet**.

The page displays a list of all PoE-capable interfaces except uplink ports. Specific operational details about an interface are displayed in the Details section of the page. The details include the PoE operational status and port class.

**NOTE:** If you are configuring a Virtual Chassis, the PoE configuring option is displayed if any member of the Virtual Chassis supports PoE, even if the Virtual Chassis master does not support PoE.

**NOTE:** After you make changes to the configuration on this page, you must commit the changes for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes](#) for details about all commit options.

2. Click one of the following options:

- **Edit**—Changes PoE settings for the selected port as described in [Table 486 on page 4448](#).
- **System Settings**—Modifies general PoE settings as described in [Table 487 on page 4448](#).

**Table 486: PoE Edit Settings**

| Field         | Description                                                                                      | Your Action                                                                                                             |
|---------------|--------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Enable PoE    | Specifies that PoE is enabled on the interface.                                                  | Select this option to enable PoE or PoE+ on the interface.                                                              |
| Priority      | Lists the power priority (low or high) configured on the interface enabled for PoE.              | Set the priority as <b>High</b> or <b>Low</b> .                                                                         |
| Maximum Power | Specifies the maximum PoE wattage available to provision the active PoE interface on the switch. | Select a value in watts. If no value is specified, the default is 15.4 for PoE interfaces and 30.0 for PoE+ interfaces. |

**Table 487: System Settings**

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                | Your Action                                                                                                       |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| PoE Management     | Specifies the power management mode. The options are: <b>static</b> and <b>class</b> .<br><br><b>NOTE:</b> When the power management mode is set to <b>class</b> , the maximum power value is overridden by the maximum power value of the class of the powered device that is connected to the switch on the PoE port. When the power management mode is set to <b>static</b> , you can specify the maximum power for each PoE interface. | By default, the power management mode is <b>class</b> . Select <b>static</b> to change the power management mode. |
| Guard Band (watts) | Specifies the amount of power reserved for power spikes from the PoE power budget of the switch.                                                                                                                                                                                                                                                                                                                                           | Enter a value to set the guard band value in watts. The default value is 0.                                       |

### Configuring PoE on EX6200 Switches

To configure PoE:

1. Select **Configure > Power over Ethernet**.

The page displays a list of all PoE-capable interfaces for each FPC. Specific operational details about an interface are displayed in the Details section of the page. The details include the PoE operational status and port class.

**NOTE:** After you make changes to the configuration on this page, you must commit the changes for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes](#) for details about all commit options.

2. Click one of the following options:

- **Edit**—Changes PoE settings for the selected port as described in [Table 488 on page 4449](#).

- **FPC Settings**—Changes PoE settings of PoE-capable FPCs.

To configure FPC settings, click one of the following options:

- **Add**—Adds a PoE setting for an FPC as described in [Table 489 on page 4449](#).
- **Edit**—Modifies a PoE setting for an FPC as described in [Table 489 on page 4449](#).
- **Delete**—Deletes an existing PoE settings for an FPC.

**Table 488: Edit PoE Settings**

| Field         | Description                                                                              | Your Action                                                                                                             |
|---------------|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Enable PoE    | Specifies that PoE is enabled on the interface.                                          | Select this option to enable PoE or PoE+ on the interface.                                                              |
| Type          | Specifies whether the interface is PoE or PoE+.                                          | Select an option from the list.                                                                                         |
| Priority      | Lists the power priority (low or high) configured on the interface enabled for PoE.      | Set the priority as <b>High</b> or <b>Low</b> .                                                                         |
| Maximum Power | Specifies the maximum PoE wattage available to provision active PoE ports on the switch. | Select a value in watts. If no value is specified, the default is 15.4 for PoE interfaces and 30.0 for PoE+ interfaces. |

**Table 489: FPC PoE Settings**

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                  | Your Action                                                                                                       |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| FPC            | Specifies the FPC number.                                                                                                                                                                                                                                                                                                                                                                                                    | Select a value from the list.                                                                                     |
| PoE Management | <p>Specifies the power management mode. The options are <b>static</b> and <b>class</b>.</p> <p><b>NOTE:</b> When the power management mode is set to <b>class</b>, the maximum power value is overridden by the maximum power value for the interface that is connected to the switch on the PoE port. When the power management mode is set to <b>static</b>, you can specify the maximum power for each PoE interface.</p> | By default, the power management mode is <b>class</b> . Select <b>static</b> to change the power management mode. |

Table 489: FPC PoE Settings (*continued*)

| Field              | Description                                                                                                                                                                                                         | Your Action                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Guard Band (watts) | Specifies the amount of power reserved for power spikes from the PoE power budget of the switch.                                                                                                                    | Enter a value to set the guard band value in watts. The default value is 0. |
| Maximum Power      | Specifies the maximum PoE wattage available to provision active PoE ports on the FPC. For example, if you specify 1000 W, the PoE controller is limited to a power budget of 1000 W to distribute to the PoE ports. | Select a value in watts.                                                    |

### [edit poe] Configuration Statement Hierarchy on EX Series Switches

This topic lists supported configuration statements in the **[edit poe]** hierarchy level on EX Series switches.

- *Supported* statements are those that you can use to configure some aspect of a software feature on the switch.
- Not all features are supported on all switch platforms. For detailed information about feature support on specific EX Series switch platforms, see [Feature Explorer](#).

This topic lists:

- [Supported Statements in the \[edit poe\] Hierarchy Level on page 4451](#)

### Supported Statements in the [edit poe] Hierarchy Level

The following hierarchy shows the **[edit poe]** configuration statements supported on EX Series switches except for EX6200 and EX8200 switches:

```
poe {
  guard-band watts;
  interface (all | interface-name) {
    disable;
    maximum-power watts;
    priority (high | low);
    telemetries {
      disable;
      duration hours;
      interval minutes;
    }
  }
  lldp-priority;
  management (class | static);
  notification-control {
    fpc slot-number {
      disable;
    }
  }
}
```

The following hierarchy shows the **[edit poe]** configuration statements supported on EX Series switches for EX6200 and EX8200 switches:

```
poe {
  fpc (all | slot-number) {
    guard-band watts;
    lldp-priority;
    management (class | static);
    maximum-power watts;
  }
  interface (all | interface-name) {
    af-mode;
    disable;
    maximum-power watts;
    priority (high | low);
    telemetries {
      disable;
      duration hours;
      interval minutes;
    }
  }
}
```

```
    }  
    notification-control {  
      fpc slot-number {  
        disable;  
      }  
    }  
  }  
}
```

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Statement introduced in Junos OS Release 12.2 for ACX2000 Universal Access Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | <p>Disable a PoE interface, disable the collection of power consumption data for a PoE interface, or disable the generation of the PoE SNMP traps. The action of the <b>disable</b> statement depends on which statement it is used with:</p> <ul style="list-style-type: none"> <li>When used with <b>interface</b>—Disable the PoE capability of this interface. The interface operates as a standard network access interface, and power is no longer allocated to it from the PoE power budget. Although the PoE capability is disabled, the PoE configuration for the interface is retained. To re-enable the PoE capability of this interface, delete the <b>disable</b> statement from the <b>interface</b> entry in the configuration.</li> <li>When used with <b>telemetries</b>—Disable the collection of PoE power consumption records for this interface. Any previously collected records are deleted. However, the <b>telemetries</b> configuration is retained, including the values for <a href="#">interval</a> and <a href="#">duration</a>. To re-enable record collection, delete the <b>disable</b> statement from the <b>telemetries</b> entry in the configuration.</li> <li>When used with <b>notification-control</b>—Disable the generation of PoE SNMP traps. To re-enable PoE traps, delete the <b>disable</b> statement from the <b>notification-control</b> entry in the configuration.</li> </ul> |
| <b>Required Privilege Level</b> | system—To view this statement in the configuration.<br>system-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Statement introduced in Junos OS Release 12.2 for ACX2000 Universal Access Routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | Designate how the PoE controller allocates power to the PoE interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default</b>                  | class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>                  | <ul style="list-style-type: none"> <li>• <b>class</b>—The amount of power allocated to the interface is determined by the class of the connected powered device. If no powered device is connected, standard 15.4 W power is allocated to the interface. See <a href="#">“Understanding PoE on EX Series Switches” on page 4423</a> for more information about classes of powered devices.</li> <li>• <b>static</b>—The amount of power allocated to the interface is determined by the value of the <a href="#">maximum-power</a> statement, not the class of the connected powered device. This amount is allocated even when a powered device is not connected to the interface, ensuring that power is available when needed.</li> <li>• <b>high-power</b>—(ACX2000 routers only) ACX2000 PoE interfaces support power delivery of up to 65 W per port using all four pairs of Ethernet RJ45 cables. Traditional PoE ports use only two pairs of Ethernet cable for power delivery. According to the IEEE 802.3af standard, each port can deliver a maximum power of up to 32 W. With <b>high-power</b> mode of power delivery over all four pairs, the power sourcing equipment (PSE) has an option to deliver up to 65 W per port, provided the powered devices request this high power over all four pairs of the Ethernet cable. By default, <b>high-power</b> mode is not enabled and has to be explicitly enabled. When the PoE controller is configured for <b>high-power</b> mode, the PoE controller does not deliver power to normal powered devices that request power over two pairs.</li> </ul> |

|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>maximum-power watts;</code>                                                                                                          |
| <b>Hierarchy Level</b>     | [edit <code>poe interface</code> (all   <i>interface-name</i> )]                                                                           |
| <b>Release Information</b> | Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Statement introduced in Junos OS Release 12.2 for ACX2000 routers. |
| <b>Description</b>         | Set the maximum amount of power that the switch can supply to the PoE port.                                                                |

**NOTE:** Although you can set this value when PoE power management is in class mode, it does not establish the maximum power for the port. Instead, the IEEE 802.3af (PoE) or IEEE 802.3at (PoE+) class of the connected device determines the maximum power for the port.

**Options** `watts`—The maximum power in watts that can be supplied to the ports..

For EX2200, EX3300, EX4200, EX4300, EX4600, EX6200, and EX8200 switches:

**Range:** 0.0 through 30.0

**Default:** 15.4 W for ports that support IEEE 802.3af and 30 W for ports that support IEEE 802.3at

For EX3200 switches:

**Range:** 0.0 through 18.6

**Default:** 15.4 W

**NOTE:** EX4600 switches support PoE only when operating in a mixed Virtual Chassis with EX4300 switches.

For ACX2000 routers:

**Range:** 1 through 65 W

**Default:** 32 W

**NOTE:** The `maximum-power` setting permitted by the CLI might be greater than the maximum power a given PoE port can deliver. For example, the CLI permits you to set any PoE port on an EX8200 line card to 30 W; however, only ports 0 through 11 support 30 W. Similarly, the CLI permits you to set any PoE port on an EX4200 switch to 30 W, but some models of EX4200 switch support only 18.6 W per port. If you configure a `maximum-power` value that is greater than the maximum power supported by a port, the power allocated to the port will be the maximum supported.

If you use the all option to set maximum-power to a value greater than 15.4 W on all interfaces on an EX8200 line card, the maximum power allocated to all ports is 15.4 W.

**NOTE:** Support for a maximum of 18.6 W per port instead of 15.4 W per port on EX3200 switches and P and T models of EX4200 switch requires Junos OS Release 11.1 or later. In addition to requiring an upgrade of Junos OS to Release 11.1 or later, switches that are running an earlier release of Junos OS release require the PoE controller software be upgraded as described in [“Upgrading the PoE Controller Software” on page 4467](#). If the controller software is not upgraded and you set maximum-power to a value greater than 15.4 W, the configuration is accepted when you commit it, but the actual power allocated to the port will be 15.4 W.

**NOTE:** On ACX2000 routers, the power sourcing equipment (PSE) delivers up to 65 W per port, provided the management mode is set to high-power mode, by using the high-power option at the [edit poe management] hierarchy level. By default, the management mode is set to static. In the static mode, the PSE can deliver power up to 32 W.

## notification-control

---

**Syntax**    notification-control {  
              **fpc** *slot-number* {  
                  disable;  
              }  
          }

**Hierarchy Level**    [edit **poe**]

**Release Information**    Statement introduced in Junos OS Release 9.0 for EX Series switches.

**Description**    Enable or disable the generation of PoE SNMP traps. If PoE SNMP traps are enabled, an SNMP trap is sent whenever a PoE interface is enabled or disabled.

The remaining statements are explained separately.

**Required Privilege Level**    system—To view this statement in the configuration.  
                                  system-control—To add this statement to the configuration.

## poe

**Syntax** For switches other than EX6200 and EX8200 switches:

```
poe {
  guard-band watts;
  interface (all | interface-name) {
    disable;
    maximum-power watts;
    priority (high | low);
    telemetries {
      disable;
      duration hours;
      interval minutes;
    }
  }
  lldp-priority;
  management (class | static);
  notification-control {
    fpc slot-number {
      disable;
    }
  }
}
```

For EX6200 and EX8200 switches:

```
poe {
  fpc (all | slot-number) {
    guard-band watts;
    lldp-priority;
    management (class | static);
    maximum-power watts;
  }
  interface (all | interface-name) {
    af-mode;
    disable;
    maximum-power watts;
    priority (high | low);
    telemetries {
      disable;
      duration hours;
      interval minutes;
    }
  }
  notification-control {
    fpc slot-number {
      disable;
    }
  }
}
```

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | Set the power priority for individual interfaces when there is insufficient power for all PoE interfaces. If the switch needs to shut down powered devices because PoE demand exceeds the PoE budget, low-priority devices are shut down before high-priority devices. Among interfaces that have the same assigned priority, priority is determined by port number, with lower-numbered ports having higher priority.                                                                                                                                                                                                    |
| <b>Default</b>                  | low                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Options</b>                  | <p><b>high</b>—Specifies that this interface is to be treated as high-priority in terms of power allocation. If the switch needs to shut down powered devices because PoE demand exceeds the PoE budget, power is not shut down on this interface until it has been shut down on all the low-priority interfaces.</p> <p><b>low</b>—Specifies that this interface is to be treated as low-priority in terms of power allocation. If the switch needs to shut down powered devices because PoE demand exceeds the PoE budget, power is shut down on this interface before it is shut down on high-priority interfaces.</p> |
| <b>Required Privilege Level</b> | system—To view this statement in the configuration.<br>system-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"><li>• <a href="#">Example: Configuring PoE Interfaces with Different Priorities on an EX Series Switch on page 4435</a></li><li>• <a href="#">Configuring PoE on EX Series Switches (CLI Procedure) on page 4440</a></li></ul>                                                                                                                                                                                                                                                                                                                                                          |

## telemetries

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Upgrading

---

- [Upgrading the PoE Controller Software on page 4467](#)

### Upgrading the PoE Controller Software

Each Junos OS image for an EX Series switch that supports PoE contains the most recent version of the PoE controller software at the time the Junos OS image was built. When you upgrade Junos OS on your switch, the new image might contain a more recent version of the PoE controller software than is currently running on the PoE controller. You can upgrade your PoE controller software by requesting that the more recent version of the software contained in the Junos OS image be downloaded to the controller.

**NOTE:** Powered devices are not guaranteed to receive power while the new software is being downloaded to the PoE controller, a process that can take up to 10 minutes. In addition, during the software download, some PoE operational commands, such as [show poe interface](#), might not show correct output. We recommend that you upgrade your PoE controller software during a regularly scheduled maintenance window.

**NOTE:** On an EX8200 Virtual Chassis, you cannot execute PoE commands on the XRE200 External Routing Engine. You can execute PoE commands only on the member EX8200 switches. Use the [request session member member-id](#) command to open a CLI session on a member switch.

This topic covers:

- [Determining Whether the PoE Controller Software Needs Upgrading on page 4468](#)
- [Upgrading the PoE Controller Software on page 4468](#)
- [Monitoring the Upgrade Progress on page 4469](#)

---

### Determining Whether the PoE Controller Software Needs Upgrading

To determine whether the version of the PoE controller software supplied with Junos OS is more recent than the version of the software currently running on the PoE controller, enter the following command:

```
user@switch> show poe controller
Controller Maximum Power Guard Management Status Lldp
index power consumption band Class AF_MODE Priority
0** 130.00W 0.00W 0W Class AF_MODE Disabled
**New PoE software upgrade available.
Use 'request system firmware upgrade poe fpc-slot <slot>'
This procedure will take around 10 minutes (recommended to be performed during
maintenance)
```

The **New PoE software upgrade available** text in the output indicates that the PoE controller software is out-of-date and needs to be upgraded.

For Virtual Chassis or switches with PoE line cards, the output of the **show poe controller** command indicates which members of a Virtual Chassis or which PoE line cards have out-of-date PoE controller software:

```
user@switch> show poe controller
Controller Maximum Power Guard Management Status Lldp
index power consumption band Class AF_MODE Priority
2 130.00W 120.34W 0W Class AF_ENHANCE Disabled
4** 410.00W 182.80W 0W Class AF_MODE Disabled
**New PoE software upgrade available.
Use 'request system firmware upgrade poe fpc-slot slot'
This procedure will take around 10 minutes (recommended to be performed during
maintenance)
```

In the preceding example, member 4 of the Virtual Chassis has an out-of-date PoE controller software.

**NOTE:** We recommend that all member switches of a Virtual Chassis or all line cards in a switch run the same version of the PoE controller software.

---

---

### Upgrading the PoE Controller Software

To upgrade the PoE controller software for a standalone switch with built-in PoE interfaces, enter:

```
user@switch> request system firmware upgrade poe fpc-slot 0
Firmware upgrade initiated. Poe Upgrade takes about 10 minutes
Use 'show poe controller' to get the download status
```

To upgrade the PoE controller software on a specific Virtual Chassis member or line card on a switch, enter:

```
user@switch> request system firmware upgrade poe fpc-slot 8
Firmware upgrade initiated. Poe Upgrade takes about 10 minutes
Use 'show poe controller' to get the download status
```

To upgrade the PoE controller software on all members of a Virtual Chassis or all line cards on a switch, enter:

```
user@switch> request system firmware upgrade poe fpc-slot all-members
Firmware upgrade initiated. Poe Upgrade takes about 10 minutes
Use 'show poe controller' to get the download status
```

### Monitoring the Upgrade Progress

Use the **show poe controller** command to monitor the progress of the controller software upgrade:

```
user@switch> show poe controller
```

| Controller index | Maximum power | Power consumption | Guard band | Management | Status           | Lldp Priority |
|------------------|---------------|-------------------|------------|------------|------------------|---------------|
| 0**              | 130.00W       | 0.00W             | 0W         |            | SW_DOWNLOAD(14%) | Disabled      |

\*\*New PoE software upgrade available.

Use 'request system firmware upgrade poe fpc-slot <slot>'

This procedure will take around 10 minutes (recommended to be performed during maintenance)

The **Status** field is updated during the download process to show the following stages of the download:

- DOWNLOAD\_INIT
- SW\_DOWNLOAD (n%)

When the software upgrade is complete, the **New PoE software upgrade available** text is no longer displayed for the particular FPC.

**NOTE:** If you are upgrading the PoE controller software to enable enhanced PoE, the Status field for the controller shows AF\_ENHANCE after the upgrade completes, indicating that the controller now supports enhanced PoE. The default maximum power per port is not automatically increased as a result of the upgrade—it is still 15.4 W per port. You must explicitly set the maximum power for a port to 18.6 W. Enhanced PoE is supported in Junos OS Release 11.1 or later on EX3200 switches and on EX4200-P or EX4200-T model switches.

- [Verifying PoE Configuration and Status \(CLI Procedure\) on page 4474](#)

### Monitoring PoE

#### Purpose

**NOTE:** This topic applies only to the J-Web Application package.

Use the monitoring functionality to view real-time data of the power consumed by each PoE interface, and to enable and configure telemetry values. When telemetry is enabled, the software measures the power consumed by each interface and stores the data for future reference.

**NOTE:** If you are configuring a Virtual Chassis, the PoE monitoring option is displayed if any member of the Virtual Chassis supports PoE, even if the Virtual Chassis master does not support PoE.

**Action** To monitor PoE using the J-Web interface, select **Monitor > Power over Ethernet**.

To monitor PoE power consumption with CLI commands in the CLI Terminal in the J-Web interface:

1. Select **Troubleshoot > CLI Terminal**.
2. Type a CLI command:

- [show poe controller](#)
- [show poe interface](#)
- [show poe telemetries](#)

For detailed information about using these CLI commands to monitor PoE power consumption, see [Monitoring PoE Power Consumption \(CLI Procedure\)](#) in the EX Series documentation at <http://www.juniper.net/techpubs>.

**Meaning** In the J-Web interface the PoE Monitoring screen is divided into two parts. The top half of the screen displays real-time data of the power consumed by each PoE-capable interface and a list of ports that utilize maximum power.

Select a particular interface to view a graph of the power consumed by the selected interface.

The bottom half of the screen displays telemetry information for interfaces. The Telemetry Status field displays whether telemetry has been enabled on the interface. Click the **Show Graph** button to view a graph of the telemetries. The graph can be based on power or voltage. To modify telemetry values, click **Edit**. Specify Interval in minutes, Duration in hours, and select **Log Telemetries** to enable telemetry on the selected interface.

## Monitoring PoE Power Consumption (CLI Procedure)

You can monitor Power over Ethernet (PoE) power consumption, both for the switch as a whole and for individual PoE interfaces.

This topic describes how to monitor:

- [PoE Power Consumption on a Switch on page 4471](#)
- [Current Power Consumption for PoE Interfaces on page 4471](#)
- [Power Consumption for PoE Interfaces over Time on page 4473](#)

### PoE Power Consumption on a Switch

**Purpose** Determine the current PoE power consumption on a switch.

**Action** Enter the following command:

```
user@switch> show poe controller
Controller  Maximum   Power      Guard    Management  Status  Lldp
index      power     consumption band      Class       AT_MODE  Priority
0          405.00W   130.00W    0W       Class       AT_MODE  Disabled
```

**Meaning** At the time the command was executed, the PoE interfaces on the switch were consuming 130 W out of the PoE power budget of 405 W.

### Current Power Consumption for PoE Interfaces

**Purpose** Determine the current power consumption for individual PoE interfaces.

**Action** To monitor the power consumption of all PoE interfaces on the switch, use the following command:

```
user@switch> show poe interface
```

| Interface | Admin status | Oper status | Max power | Priority | Power consumption | Class          |
|-----------|--------------|-------------|-----------|----------|-------------------|----------------|
| ge-0/0/0  | Enabled      | ON          | 15.4W     | Low      | 7.4W              | 0              |
| ge-0/0/1  | Enabled      | ON          | 15.4W     | High     | 12.0W             | 0              |
| ge-0/0/2  | Enabled      | ON          | 15.4W     | Low      | 12.4W             | 0              |
| ge-0/0/3  | Enabled      | ON          | 7.0W      | Low      | 5.3W              | 2              |
| ge-0/0/4  | Enabled      | ON          | 4.0W      | Low      | 4.0W              | 1              |
| ge-0/0/5  | Enabled      | ON          | 7.0W      | Low      | 6.1W              | 2              |
| ge-0/0/6  | Enabled      | ON          | 15.4W     | Low      | 12.3W             | 3              |
| ge-0/0/7  | Disabled     | Disabled    | 0.0W      | Low      | 0.0W              | not-applicable |

To monitor the power consumption of the PoE interfaces on a specific EX6200 or EX8200 line card, use the following command:

```
user@switch> show poe interface fpc-slot 3
```

| Interface | Admin status | Oper status | Max power | Priority | Power consumption | Class |
|-----------|--------------|-------------|-----------|----------|-------------------|-------|
| ge-3/0/0  | Enabled      | ON          | 30.0W     | Low      | 20.3W             | 4     |
| ge-3/0/1  | Enabled      | ON          | 30.0W     | Low      | 17.8W             | 4     |
| ge-3/0/2  | Enabled      | ON          | 30.0W     | High     | 16.3W             | 4     |
| ge-3/0/3  | Enabled      | ON          | 30.0W     | High     | 16.2W             | 4     |
| ge-3/0/4  | Enabled      | ON          | 30.0W     | Low      | 25.9W             | 4     |
| ge-3/0/5  | Enabled      | ON          | 30.0W     | Low      | 10.1W             | 4     |
| ge-3/0/6  | Enabled      | ON          | 30.0W     | Low      | 16.2W             | 4     |
| ge-3/0/7  | Enabled      | ON          | 30.0W     | Low      | 6.4W              | 4     |
| ge-3/0/8  | Enabled      | ON          | 30.0W     | Low      | 5.2W              | 4     |
| ge-3/0/9  | Enabled      | ON          | 30.0W     | Low      | 5.2W              | 4     |
| ge-3/0/10 | Enabled      | ON          | 30.0W     | Low      | 21.5W             | 4     |
| ge-3/0/11 | Enabled      | ON          | 30.0W     | Low      | 21.7W             | 4     |
| ge-3/0/12 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/13 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/14 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/15 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/16 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/17 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/18 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/19 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/20 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/21 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/22 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/23 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/24 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/25 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/26 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/27 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/28 | Enabled      | ON          | 15.4W     | Low      | 7.0W              | 0     |
| ge-3/0/29 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/30 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/31 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/32 | Enabled      | ON          | 15.4W     | Low      | 2.0W              | 1     |
| ge-3/0/33 | Enabled      | ON          | 15.4W     | Low      | 2.0W              | 1     |
| ge-3/0/34 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/35 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/36 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/37 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/38 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |
| ge-3/0/39 | Enabled      | ON          | 15.4W     | Low      | 2.2W              | 1     |

To monitor the power consumption of an individual PoE interface (for example, ge-0/0/3), use the following command:

```
user@switch> show poe interface ge-0/0/3
PoE interface status:
PoE interface           : ge-0/0/3
Administrative status    : Enabled
Operational status      : ON
Power limit on the interface : 7.0W
Priority                 : Low
Power consumed           : 5.3W
Class of power device    : 2
PoE Mode                 : 802.3at
```

**Meaning** At the time the command was executed, the individual PoE ports were consuming the amount of power shown. For example, interface ge-0/0/3 was consuming 5.3 W at the time the command was executed.

### Power Consumption for PoE Interfaces over Time

**Purpose** Monitor the power consumption of a PoE interface over a period of time. The records collected remain available for future viewing.

You can specify the intervals at which power consumption data is collected, from once every minute to once every 30 minutes. The default is once every 5 minutes. You can also specify the duration over which the records are collected, from 1 hour (default) to 24 hours.

**Action** To collect historical records of PoE interface power consumption and display those records:

1. Add the **telemetries** statement to the PoE interface configuration:

```
[edit]
user@switch# set poe interface ge-0/0/5 telemetries interval 10
When you commit the configuration, record collection begins.
```

2. Display the collected records:

```
user@switch> show poe telemetries interface ge-0/0/5 count all
SI No    Timestamp                Power    Voltage
1        03-19-2010 13:00:07 UTC   3.9W    50.9V
2        03-19-2010 12:50:07 UTC   3.9W    50.9V
3        03-19-2010 12:40:07 UTC   3.9W    50.9V
4        03-19-2010 12:30:07 UTC   3.9W    50.9V
5        03-19-2010 12:20:07 UTC   3.9W    50.9V
6        03-19-2010 12:10:07 UTC   3.9W    50.9V
```

To start another session of record collection on the interface, you must delete the existing telemetries configuration on the interface and then reconfigure telemetries. Deleting the telemetries configuration also clears the power consumption history data.

To clear the history of PoE power consumption without deleting the telemetries configuration, use the command **clear poe telemetries interface**.

**Meaning** Over the hour in which the PoE power consumption data on ge-0/0/5 was collected, the connected powered device consistently consumed 3.9 W.

## Verifying PoE Configuration and Status (CLI Procedure)

You can verify the Power over Ethernet (PoE) configuration and status on an EX Series switch.

This topic describes how to verify:

- [PoE Controller Configuration and Status on page 4474](#)
- [PoE Interface Configuration and Status on page 4475](#)
- [PoE SNMP Trap Generation Status on page 4476](#)
- [PoE Line Card Configuration and Status on page 4477](#)

### PoE Controller Configuration and Status

---

**Purpose** Verify the PoE controller configuration and status, such as the PoE power budget, total PoE power consumption, power management mode, and the supported PoE standard.

**Action** Enter the following command:

```
user@switch> show poe controller
```

Example output for an EX2200 switch:

| Controller index | Maximum power | Power consumption | Guard band | Management | Status  | Lldp Priority |
|------------------|---------------|-------------------|------------|------------|---------|---------------|
| 0                | 405.00W       | 130.00W           | 19W        | Class      | AT_MODE | Disabled      |

Example output for an EX8200 switch:

| Controller index | Maximum power | Power consumption | Guard band | Management | Status      | Lldp Priority |
|------------------|---------------|-------------------|------------|------------|-------------|---------------|
| 3                | 540.00W       | 435.25W           | 0W         | Static     | AT/AF COMBO | Disabled      |
| 4                | 915.00W       | 627.01W           | 15W        | Class      | AT/AF COMBO | Disabled      |

**Meaning**

- For the EX2200 switch—The switch has a PoE power budget of 405 W, of which 130 W were being used by the PoE ports at the time the command was executed. The **Guard band** field shows that 19 W is reserved out of the PoE power budget to protect against spikes in power demand. The power management mode is class. The PoE ports on the switch support PoE+ (IEEE 802.3at).

- For the EX8200 switch—Line card 3 has a PoE power budget of 540 W, of which 435.25 W were being used by the PoE ports on the line card at the time the command was executed. The management mode for line card 3 is static and the line card has a mix of PoE (IEEE 802.3af) and PoE+ (IEEE 802.3at) ports.

Line card 4 has a PoE power budget of 915 W, of which 627.01 W were being used by the PoE ports on the line card at the time the command was executed. The **Guard band** field shows that 15 W is reserved out of the PoE power budget to protect against spikes in power demand. The management mode for line card 4 is class and the line card has a mix of PoE (IEEE 802.3af) and PoE+ (IEEE 802.3at) ports.

### PoE Interface Configuration and Status

**Purpose** Verify that PoE interfaces are enabled and set to the correct maximum power and priority settings. Also verify current operational status and power consumption.

**Action** To view configuration and status for all PoE interfaces, enter:

```
user@switch> show poe interface
```

| Interface | Admin status | Oper status | Max power | Priority | Power consumption | Class          |
|-----------|--------------|-------------|-----------|----------|-------------------|----------------|
| ge-0/0/0  | Enabled      | ON          | 15.4W     | Low      | 7.9W              | 3              |
| ge-0/0/1  | Enabled      | ON          | 30.0W     | High     | 4.8W              | 0              |
| ge-0/0/2  | Enabled      | ON          | 30.0W     | High     | 4.8W              | 0              |
| ge-0/0/3  | Enabled      | ON          | 7.0W      | High     | 3.3W              | 2              |
| ge-0/0/4  | Enabled      | ON          | 7.0W      | Low      | 3.3W              | 2              |
| ge-0/0/5  | Enabled      | ON          | 7.0W      | Low      | 3.2W              | 2              |
| ge-0/0/6  | Enabled      | ON          | 7.0W      | Low      | 3.3W              | 2              |
| ge-0/0/7  | Enabled      | OFF         | 30.0W     | Low      | 0.0W              | not-applicable |

To view the configuration and status for the PoE interfaces on an EX6200 or EX8200 line card:

```
user@switch> show poe interface fpc-slot 3
```

| Interface | Admin status | Oper status | Max power | Priority | Power consumption | Class |
|-----------|--------------|-------------|-----------|----------|-------------------|-------|
| ge-3/0/0  | Enabled      | ON          | 30.0W     | Low      | 20.3W             | 4     |
| ge-3/0/1  | Enabled      | ON          | 30.0W     | Low      | 17.8W             | 4     |
| ge-3/0/2  | Enabled      | ON          | 30.0W     | High     | 16.3W             | 4     |
| ge-3/0/3  | Enabled      | ON          | 30.0W     | High     | 16.2W             | 4     |
| ge-3/0/4  | Enabled      | ON          | 30.0W     | Low      | 25.9W             | 4     |
| ge-3/0/5  | Enabled      | ON          | 30.0W     | Low      | 10.1W             | 4     |
| ge-3/0/6  | Enabled      | ON          | 30.0W     | Low      | 16.2W             | 4     |
| ge-3/0/7  | Enabled      | ON          | 30.0W     | Low      | 6.4W              | 4     |
| ge-3/0/8  | Enabled      | ON          | 30.0W     | Low      | 5.2W              | 4     |
| ge-3/0/9  | Enabled      | ON          | 30.0W     | Low      | 5.2W              | 4     |
| ge-3/0/10 | Enabled      | ON          | 30.0W     | Low      | 21.5W             | 4     |
| ge-3/0/11 | Enabled      | ON          | 30.0W     | Low      | 21.7W             | 4     |
| ge-3/0/12 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/13 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/14 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/15 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/16 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/17 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/18 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/19 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |
| ge-3/0/20 | Enabled      | ON          | 15.4W     | Low      | 9.4W              | 0     |

|           |         |    |       |     |      |   |
|-----------|---------|----|-------|-----|------|---|

| ge-3/0/38 | Enabled | ON | 15.4W | Low | 2.2W | 1 |
| ge-3/0/39 | Enabled | ON | 15.4W | Low | 2.2W | 1 |

To view configuration and status for a single PoE interface, enter:

```

user@switch> show poe interface ge-0/0/3
PoE interface status:
PoE interface           : ge-0/0/3
Administrative status   : Enabled
Operational status      : ON
Power limit on the interface : 7.0W
Priority                 : High
Power consumed          : 3.3W
Class of power device    : 2
PoE Mode                : 802.3at

```

**Meaning** The command output shows the status and configuration of interfaces. For example, the interface ge-0/0/3 is administratively enabled. Its operational status is **ON**; that is, the interface is currently delivering power to a connected powered device. The maximum power allocated to the interface is 7.0 W. The interface has a high power priority. At the time the command was executed, the powered device was consuming 3.3 W. The IEEE 802.3af class of the powered device is class 2. If the PoE power management mode is class, the class of the powered device determines the maximum power allocated to the interface, which is 7 W in the case of class 2 devices.

The PoE Mode field indicates that the interface supports IEEE 802.3at.

### PoE SNMP Trap Generation Status

**Purpose** Verify the status of the **notification-control** option, which determines whether or not PoE SNMP traps are enabled.

**Action** Enter the following command:

```

user@switch> show poe notification-control
FPC slot      Notification-control-status
0              OFF

```

**Meaning** PoE SNMP traps are not enabled.

## PoE Line Card Configuration and Status

**Purpose** Verify the PoE configuration and status for line cards on an EX6200 or EX8200 switch, such as the PoE power allocation and priority for each line card.

**Action** Enter the following command:

```
user@switch> show chassis power-budget-statistics
```

Example output for an EX6200 switch:

```

PSU 0      (EX6200-PWR-AC2500)           :   2500 W   Online
PSU 1      (EX6200-PWR-AC2500)           :   2500 W   Online
PSU 2      (EX6200-PWR-AC2500)           :   2500 W   Online
PSU 3      (EX6200-PWR-AC2500)           :   2500 W   Online
Total Power supplied by all Online PSUs : 10000 W
Power Redundancy Configuration          :   N+1
Power Reserved for the Chassis           :    500 W

```

- Meaning**
- For the EX6200 switch—The total of the PoE power budgets allocated to the line cards in the switch is 5920 W. This figure includes the 37 W of PoE power always included in the base allocation for each line card that supports PoE. For line cards with PoE ports, the **PoE power** field shows the PoE power budget allocated to each line card, along with the line card priority.
  - For the EX8200 switch—The total of the PoE power budgets allocated to the line cards in the switch is 1707 W. This figure includes the 37 W of PoE power always included in the base allocation for each line card that supports PoE. For line cards with PoE ports, the **PoE power** field shows the PoE power budget allocated to each line card, along with the line card priority.

| <b>Release Information</b>      | Command introduced in Junos OS Release 12.1 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | <p>Upgrade the PoE controller software on switches and line cards.</p> <p>The Junos OS image running on the switch contains a copy of the PoE controller software. This command compares the Junos OS version with the version of the software running on the PoE controller. If the Junos OS version is a more recent version, the command downloads the more recent version to the controller.</p> <p>For all Virtual Chassis except EX8200 Virtual Chassis, execute this command on the master. The master itself need not support PoE for this command to work—for example, you can execute this command on the master of a mixed EX4200 and EX4500 Virtual Chassis when the master is an EX4500 switch, which does not support PoE. On an EX8200 Virtual Chassis, you must execute this command on the member switch, not the master XRE200 External Routing Engine.</p> <p>We recommend that all members of a Virtual Chassis run the same version of the PoE controller software.</p> <p>Upgrading the controller software can take up to 10 minutes. Use the <a href="#">show poe controller</a> command to monitor the progress of the software download.</p> <p>You cannot downgrade the PoE controller software.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <b>NOTE:</b> When you enter the <code>request system firmware upgrade poe</code> command, a message advises you that the controller software upgrade has started and that it will take about 10 minutes to complete. This message appears even if the FPC you have specified does not have a PoE controller or if the PoE controller software is up-to-date. To determine whether or not the controller software upgrade has actually started, use the <code>show poe controller</code> command.</p> </div> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <b>NOTE:</b> While the upgrade is in progress, power to the powered devices is not guaranteed. We recommend that you upgrade the controller software during a regularly scheduled maintenance window.</p> </div> |
| <b>Options</b>                  | fpc-slot ( <i>number</i>   all-members)—Upgrade the PoE controller firmware for the Virtual Chassis member or line card specified by <i>number</i> , or for all Virtual Chassis members and line cards, specified by <b>all-members</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**List of Sample Output**    [request system firmware upgrade poe \(Specific FPC Slot\) on page 4480](#)

**Output Fields**    When you enter this command, you are provided feedback on the status of your request.

## Sample Output

### [request system firmware upgrade poe \(Specific FPC Slot\)](#)

```
user@switch> request system firmware upgrade poe fpc-slot 8
Firmware upgrade initiated. Poe Upgrade takes about 10 minutes
Use 'show poe controller' to get the download status
```

## show poe controller

| <b>Controller index</b>  | PoE controller number: <ul style="list-style-type: none"> <li>• 0 for EX2200, EX3200, standalone EX3300, standalone EX4200 switches, standalone EX4300 switches, and ACX2000 routers.</li> <li>• Member ID for switches in an EX3300 Virtual Chassis, EX4200 Virtual Chassis, EX4300 Virtual Chassis, a mixed EX4200 and EX4500 Virtual Chassis, or a mixed EX4300 and EX4600 Virtual Chassis.</li> <li>• Slot number for line cards with a PoE controller in an EX6200 or EX8200 switch.</li> </ul> |
| <b>Maximum power</b>     | The PoE power budget for the switch or line card. The PoE controller allocates power to the PoE ports from this budget.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Power consumption</b> | Total amount of power being used by the PoE ports at the time the command is executed.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Guard Band</b>        | Amount of power that has been placed in reserve for power demand spikes and that cannot be allocated to a PoE interface.                                                                                                                                                                                                                                                                                                                                                                             |

Table 490: show poe controller Output Fields (*continued*)

| Field Name    | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Management    | Power management mode: <b>class</b> or <b>static</b> or <b>high-power</b> .<br><br><b>NOTE:</b> The mode <b>high-power</b> is available on only ACX2000 routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Status        | Status of the PoE controller: <ul style="list-style-type: none"> <li>• <b>AF_ENHANCE</b>—Controller supports enhanced PoE. The maximum power per PoE port is 18.6 W in static mode (15.4 W in class mode).</li> <li>• <b>DEVICE FAIL</b>—Software download to the controller has failed or the PoE controller is not initialized because of a hardware failure.</li> <li>• <b>DOWNLOAD_INIT</b>—Software download to the controller is in the initial phase.</li> <li>• <b>AF_MODE</b>—Controller supports standard IEEE 802.3af. The maximum power per PoE port is 15.4 W.</li> <li>• <b>AT/AF COMBO</b>—Controller supports a mix of standard IEEE 802.3af and IEEE 802.3at (PoE+) ports. The maximum power per port is 30 W for IEEE 802.3at (PoE+) ports and 15.4 W for the IEEE 802.3af ports.</li> <li>• <b>AT_MODE</b>—Controller supports IEEE 802.3at (PoE+). The maximum power per PoE port is 30 W.</li> <li>• <b>SW_DOWNLOAD (n%)</b>—Software download to the controller is in progress.</li> </ul> |
| Lldp Priority | Link Layer Discovery Protocol (LLDP) priority operating state. The state can be <b>Enabled</b> or <b>Disabled</b> .<br><br>LLDP priority enables the PoE controller to assign interfaces the power priority provided by the connected powered device by using LLDP power negotiation rather than the power priority configured on the switch interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Sample Output

### show poe controller (EX3200 Switch)

```

user@switch> show poe controller
Controller Maximum Power Guard Management Status Lldp
index      power  consumption band    ment     Status  Priority
0          130.00W  81.20W    10W     Static   AF_ENHANCE Disabled

```

### show poe controller (EX8200 Switch)

```

user@switch> show poe controller
Controller Maximum Power Guard Management Status Lldp
index      power  consumption band    ment     Status  Priority
0          792.00W  603.50W    0W      Class    AT/AF COMBO Disabled
4          915.00W  781.00W    0W      Class    AT/AF COMBO Disabled
7          915.00W   0.00W     0W      Class    AT/AF COMBO Disabled

```

### show poe controller (Controller Software Upgrade in Progress)

```

user@switch> show poe controller
Controller Maximum Power Guard Management Status Lldp
index      power  consumption band    ment     Status  Priority
0          130.00W   0.00W     0W     Static   AF_ENHANCE Disabled

```

```
8**      130.00W  0.00W      0W   Static      SW_DOWNLOAD(10%) Disabled
```

```
**New PoE software upgrade available.
```

```
Use 'request system firmware upgrade poe fpc-slot <slot>'
```

```
This procedure will take around 10 minutes (recommended to be performed during  
maintenance)
```

#### show poe controller (ACX2000 Router)

```
user@host> show poe controller
```

| Controller<br>index | Maximum<br>power | Power<br>consumption | Guard<br>band | Management | Status | Lldp<br>Priority |
|---------------------|------------------|----------------------|---------------|------------|--------|------------------|
| 0                   | 130.0 W          | 14.2 W               | 0 W           | high-power | UP     |                  |

## show poe interface

|                                 |                                                                                                                                                                                                                                                                                                                                                                                       |

## Sample Output

### show poe interface

```

user@switch> show poe interface
Interface Admin    Oper    Max    Priority Power    Class
           status    status  power                consumption
ge-0/0/0 Enabled    ON      15.4W  Low     7.9W     0
ge-0/0/1 Enabled    ON      15.4W  Low     3.2W     2
ge-0/0/2 Enabled    ON      15.4W  Low     3.2W     2
ge-0/0/3 Enabled    ON      15.4W  Low     3.2W     2
ge-0/0/4 Enabled    ON      15.4W  Low     3.2W     2
ge-0/0/5 Enabled    ON      15.4W  Low     3.2W     2
ge-0/0/6 Enabled    ON      15.4W  Low     3.2W     2
ge-0/0/7 Enabled    ON      15.4W  Low     3.2W     2

```

### show poe interface (with LLDP Negotiation)

```

user@switch> show poe interface
Interface Admin    Oper    Max    Priority Power    Class
           status    status  power                consumption
ge-0/0/0 Enabled    ON      17.5W(L) Low(L)    16.2W     4
ge-0/0/1 Enabled    ON      17.5W(L) Low(L)    16.0W     4
ge-0/0/2 Enabled    ON      17.5W(L) High(L)   16.0W     4
ge-0/0/3 Enabled    ON      17.5W(L) Low(L)    16.0W     4
ge-0/0/4 Enabled    ON      10.1W(L) Low(L)    10.0W     3

```

```

ge-0/0/5    Enabled    ON    3.5W(L)    High(L)    3.0W    2
(L) LLDP-negotiated value on the port.

```

### show poe interface (Specific Interface)

```

user@switch> show poe interface ge-0/0/3
PoE interface status:
PoE interface           : ge-0/0/3
Administrative status    : Enabled
Operational status      : ON
Power limit on the interface : 7.0W
Priority                 : Low
Power consumed           : 5.3W
Class of power device    : 2
PoE Mode                : 802.3af

```

### show poe interface (Specific FPC Slot)

```

user@switch> show poe interface fpc-slot 3

```

| Interface | Admin status | Oper status | Max power | Priority | Power consumption | Class |
|-----------|--------------|-------------|-----------|----------|-------------------|-------|
| ge-3/0/0  | Enabled      | ON          | 30.0W     | Low      | 20.3W             | 4     |

# Troubleshooting Procedures

- [Troubleshooting PoE Interfaces on page 4493](#)

## Troubleshooting PoE Interfaces

**Problem**    **Description:** A Power over Ethernet (PoE) interface is not supplying power to the powered device.

**Solution**    Check for the items shown in [Table 494 on page 4493](#).

**Table 494: Troubleshooting a PoE Interface**

| Items to Check                                                                                                        | Explanation                                                                                                       |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Is the switch a full PoE model or a partial PoE model?                                                                | If you are using a partial PoE model, only interfaces ge-0/0/0 through ge-0/0/7 can function as PoE ports.        |
| Has PoE capability been disabled for that interface?                                                                  | Use the <a href="#">show poe interface</a> command to check PoE interface status.                                 |
| Is the cable properly seated in the port socket?                                                                      | Check the hardware.                                                                                               |
| Has the PoE power budget been exceeded for the switch?                                                                | Use the <a href="#">show poe controller</a> command to check the PoE power budget and consumption for the switch. |

### Understanding Port Security

Ethernet LANs are vulnerable to attacks such as address spoofing (forging) and Layer 2 denial of service (DoS) on network devices. Port security features help protect the access ports on your device against the loss of information and productivity that such attacks can cause.

The Juniper Networks Junos operating system (Junos OS) provides features to help secure ports on a device. Ports can be categorized as either trusted or untrusted. You apply policies appropriate to each category to protect ports against various types of attacks.

Basic port security features are enabled in the device's default configuration. You can configure additional features with minimal configuration steps.

Depending on the particular feature, you can configure the feature either on VLANs or bridge domain interfaces.

Port security features supported on switching devices are:

- DHCP snooping—Filters and blocks ingress Dynamic Host Configuration Protocol (DHCP) server messages on untrusted ports; builds and maintains a database of DHCP lease information, which is called the DHCP snooping database.

**NOTE:** DHCP snooping is not enabled in the default configuration of the switching device. DHCP snooping is enabled on a VLAN or bridge domain. The details of enabling DHCP snooping depend on the particular device.

- DHCPv6 snooping—DHCP snooping for IPv6.
- DHCP option 82—Also known as the DHCP Relay Agent Information option. This DHCPv4 feature helps protect the switching device against attacks such as spoofing of IP addresses and MAC addresses and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.
- DHCPv6 option 37—Option 37 is the remote ID option for DHCPv6 and is used to insert information about the network location of the remote host into DHCPv6 packets. You enable option 37 on a VLAN.

**NOTE:** DHCPv6 snooping with option 37 is not supported on the MX Series.

- DHCPv6 option 18—Option 18 is the circuit ID option for DHCPv6 and is used to insert information about the client port into DHCPv6 packets. This option includes other details that can be optionally configured, such as the prefix and the interface description.
- DHCPv6 option 16—Option 16 is the vendor ID option for DHCPv6 and is used to insert information about the vendor of the client hardware into DHCPv6 packets.
- Dynamic ARP inspection (DAI)—Prevents Address Resolution Protocol (ARP) spoofing attacks. ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made on the basis of the results of those comparisons. You enable DAI on a VLAN.
- IPv6 neighbor discovery inspection—Prevents IPv6 address spoofing attacks. Neighbor discovery requests and replies are compared against entries in the DHCPv6 snooping database, and filtering decisions are made on the basis of the results of those comparisons. You enable neighbor discovery inspection on a VLAN.
- IP source guard—Mitigates the effects of IP address spoofing attacks on the Ethernet LAN. With IP source guard enabled, the source IP address in the packet sent from an untrusted access interface is validated against the DHCP snooping database. If the packet cannot be validated, it is discarded. You enable IP source guard on a VLAN or bridge domain.

**NOTE:** IP source guard is not supported on the QFX Series.

- IPv6 source guard—IP source guard for IPv6.

**NOTE:** IPv6 source guard is not supported on the QFX Series.

- MAC limiting—Protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You can enable MAC limiting on an interface.
- MAC move limiting—(Not supported on EX9200) Tracks MAC movement and detects MAC spoofing on access ports. You enable this feature on a VLAN or bridge domain.
- Persistent MAC learning—Also known as sticky MAC. Persistent MAC learning enables interfaces to retain dynamically learned MAC addresses across switch reboots. You enable this feature on an interface.
- Trusted DHCP server—Configuring the DHCP server on a trusted port protects against rogue DHCP servers sending leases. You enable this feature on an interface (port). By default, access ports are untrusted, and trunk ports are trusted. (Access ports are the switch ports that connect to Ethernet endpoints such as user PCs and laptops, servers, and printers. Trunk ports are the switch ports that connect an Ethernet switch to other switches or to routers.)

## Understanding DAI for Port Security

Dynamic ARP inspection (DAI) protects switching devices against ARP spoofing.

DAI inspects Address Resolution Protocol (ARP) packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP spoofing (also known as ARP poisoning or ARP cache poisoning). ARP requests and replies are compared against entries in the DHCP snooping database, and filtering decisions are made based on the results of those comparisons. When an attacker tries to use a forged ARP packet to spoof an address, the switch compares the address with entries in the database. If the media access control (MAC) address or IP address in the ARP packet does not match a valid entry in the DHCP snooping database, the packet is dropped.

ARP packets are sent to the Routing Engine and are rate-limited to protect the switching device from CPU overload.

- [Address Resolution Protocol on page 4500](#)
- [ARP Spoofing on page 4500](#)
- [Dynamic ARP Inspection on page 4501](#)
- [Prioritizing Inspected Packets on page 4502](#)

---

### Address Resolution Protocol

Sending IP packets on a multi-access network requires mapping an IP address to an Ethernet MAC address.

Ethernet LANs use ARP to map MAC addresses to IP addresses.

The switching device maintains this mapping in a cache that it consults when forwarding packets to network devices. If the ARP cache does not contain an entry for the destination device, the host (the DHCP client) broadcasts an ARP request for that device's address and stores the response in the cache.

---

### ARP Spoofing

ARP spoofing is one way to initiate man-in-the-middle attacks. The attacker sends an ARP packet that spoofs the MAC address of another device on the LAN. Instead of the switching device sending traffic to the proper network device, it sends the traffic to the device with the spoofed address that is impersonating the proper device. If the impersonating device is the attacker's machine, the attacker receives all the traffic from the switch that must have gone to another device. The result is that traffic from the switching device is misdirected and cannot reach its proper destination.

One type of ARP spoofing is gratuitous ARP, which is when a network device sends an ARP request to resolve its own IP address. In normal LAN operation, gratuitous ARP messages indicate that two devices have the same MAC address. They are also broadcast when a network interface card (NIC) in a device is changed and the device is rebooted, so that other devices on the LAN update their ARP caches. In malicious situations, an attacker can poison the ARP cache of a network device by sending an ARP response to

the device that directs all packets destined for a certain IP address to go to a different MAC address instead.

To prevent MAC spoofing through gratuitous ARP and through other types of spoofing, the switches examine ARP responses through DAI.

### Dynamic ARP Inspection

DAI examines ARP requests and responses on the LAN and validates ARP packets. The switch intercepts ARP packets from an access port and validates them against the DHCP snooping database. If no IP-MAC entry in the database corresponds to the information in the ARP packet, DAI drops the ARP packet and the local ARP cache is not updated with the information in that packet. DAI also drops ARP packets when the IP address in the packet is invalid. ARP probe packets are not subjected to dynamic ARP inspection. The switch always forwards such packets.

Junos OS for EX Series switches and the QFX Series uses DAI for ARP packets received on access ports because these ports are untrusted by default. Trunk ports are trusted by default, and therefore ARP packets bypass DAI on them.

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs.

If you set an interface to be a DHCP trusted port, it is also trusted for ARP packets.

#### NOTE:

- If your switching device is an EX Series switch and uses Junos OS with support for the Enhanced Layer 2 Software (ELS) configuration style, see [“Enabling a Trusted DHCP Server \(CLI Procedure\)” on page 4573](#) for information about configuring an access interface to be a DHCP trusted port.
- If your switching device is an EX Series switch and is *not* using Junos OS with support for the Enhanced Layer 2 Software (ELS) configuration style, see *Enabling a Trusted DHCP Server (CLI Procedure)* for information about configuring an access interface to be a DHCP trusted port.

For packets directed to the switching device to which a network device is connected, ARP queries are broadcast on the VLAN. The ARP responses to those queries are subjected to the DAI check.

For DAI, all ARP packets are trapped to the Packet Forwarding Engine. To prevent CPU overloading, ARP packets destined for the Routing Engine are rate-limited.

If the DHCP server goes down and the lease time for an IP-MAC entry for a previously valid ARP packet runs out, that packet is blocked.

## Prioritizing Inspected Packets

---

**NOTE:** Prioritizing inspected packets is not supported on the QFX Series and the EX4600 switch.

---

You can use class-of-service (CoS) forwarding classes and queues to prioritize DAI packets for a specified VLAN. This type of configuration places inspected packets for that VLAN in the egress queue, that you specify, ensuring that the security procedure does not interfere with the transmission of high-priority traffic.

## Understanding DHCP Option 82 for Port Security on Switching Devices

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect Juniper Networks EX Series Ethernet Switches and MX Series 3D Universal Edge Routers against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Hosts on untrusted access interfaces on an Ethernet LAN switching device send requests for IP addresses to access the Internet. The switching device forwards or relays these requests to DHCP servers, and the servers send offers for IP address leases in response. Attackers can use these messages to penetrate the network by address spoofing.

Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client. The Junos OS implementation of DHCP option 82 supports RFC 3046, *DHCP Relay Agent Information Option*, at <http://tools.ietf.org/html/rfc3046>.

This topic covers:

- [DHCP Option 82 Processing on page 4503](#)
- [Suboption Components of Option 82 on page 4504](#)
- [Switching Device Configurations That Support Option 82 on page 4505](#)
- [DHCPv6 Options on page 4506](#)

### DHCP Option 82 Processing

If DHCP option 82 is enabled on a VLAN or bridge domain, then when a network device—a DHCP client—that is connected to the VLAN or bridge domain on an untrusted interface sends a DHCP request, the switching device inserts information about the client's network location into the packet header of that request. The switching device then sends the request to the DHCP server. The DHCP server reads the option 82 information in the packet header and uses it to implement the IP address or another parameter for the client. See “[Suboption Components of Option 82](#)” on [page 4504](#) for more information about option 82.

#### NOTE:

- If your switching device is an EX Series switch and uses Junos OS with Enhanced Layer 2 Software (ELS) configuration style, you can enable DHCP option 82 only for a specific VLAN. See “[Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server \(CLI Procedure\)](#)” on [page 4577](#).
- If your switching device is an EX Series switch and does *not* use Junos OS with Enhanced Layer 2 Software (ELS) configuration style, you can enable DHCP option 82 either for a specific VLAN or for all VLANs. See *Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)*.

If option 82 is enabled on a VLAN or bridge domain, the following sequence of events occurs when a DHCP client sends a DHCP request:

1. The switching device receives the request and inserts the option 82 information in the packet header.
2. The switching device forwards (or relays) the request to the DHCP server.
3. The server uses the DHCP option 82 information to formulate its reply and sends a response to the switching device. It does not alter the option 82 information.
4. The switching device strips the option 82 information from the response packet.
5. The switching device forwards the response packet to the client.

**NOTE:** To use the DHCP option 82 feature, you must ensure that the DHCP server is configured to accept option 82. If the DHCP server is not configured to accept option 82, then when it receives requests containing option 82 information, it does not use the information for setting parameters and it does not echo the information in its response message.

---

### Suboption Components of Option 82

---

Option 82 as implemented on a switching device comprises the suboptions circuit ID, remote ID, and vendor ID. These suboptions are fields in the packet header:

- circuit ID—Identifies the circuit (interface or VLAN) on the switching device on which the request was received. The circuit ID contains the interface name and VLAN name, with the two elements separated by a colon—for example, `ge-0/0/10:vlan1`, where `ge-0/0/10` is the interface name and `vlan1` is the VLAN name. If the request packet is received on a Layer 3 interface, the circuit ID is just the interface name—for example, `ge-0/0/10`.

Use the prefix option to add an optional prefix to the circuit ID. If you enable the prefix option, the hostname for the switching device is used as the prefix; for example, `device1:ge-0/0/10:vlan1`, where `device1` is the hostname.

You can also specify that the interface description be used rather than the interface name or that the VLAN ID be used rather than the VLAN name.

- remote ID—Identifies the remote host. See [remote-id](#) for details.
- vendor ID—Identifies the vendor of the host. If you specify the **vendor-id** option but do not enter a value, the default value Juniper is used. To specify a value, you type a character string.

## Switching Device Configurations That Support Option 82

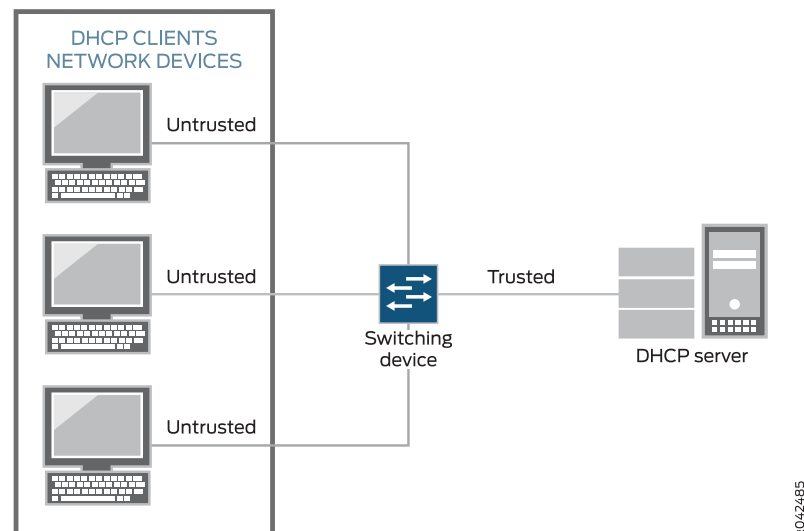

Switching device configurations that support option 82 are:

- [Switching Device, DHCP Clients, and the DHCP Server Are on the Same VLAN or Bridge Domain on page 4505](#)
- [Switching Device Acts as a Relay Agent on page 4505](#)

### ***Switching Device, DHCP Clients, and the DHCP Server Are on the Same VLAN or Bridge Domain***

If the switching device, the DHCP clients, and the DHCP server are all on the same VLAN or bridge domain, the switching device forwards the requests from the clients on untrusted access interfaces to the server on a trusted interface. See [Figure 58 on page 4505](#).

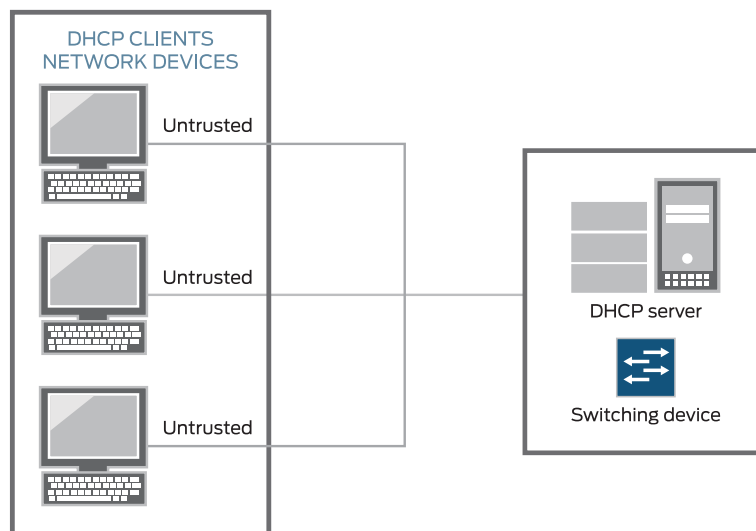

**Figure 58: DHCP Clients, Switching Device, and the DHCP Server Are All on the Same VLAN or Bridge Domain**

### ***Switching Device Acts as a Relay Agent***

The switching device functions as a relay agent (extended relay server) when the DHCP clients or the DHCP server is connected to the switching device through a Layer 3 interface. On the switching device, these interfaces are configured as routed VLAN interfaces (RVIs). [Figure 59 on page 4506](#) illustrates a scenario for the switching device acting as an extended relay server; in this instance, the switching device relays requests to the server.

Figure 59: Switching Device Acting as an Extended Relay Server

8042486

## DHCPv6 Options

**NOTE:** MX Series routers do not support DHCPv6.

DHCPv6 provides several options that can be used to insert information into the DHCPv6 request packets that are relayed to a server from a client. These options are equivalent to the sub-options of DHCP option 82.

- Option 37—Identifies the remote host. Option 37 is equivalent to the **remote-id** sub-option of DHCP option 82.
- Option 18—Identifies the interface on which the DHCP request packet was received from the client. Option 18 is equivalent to the **circuit-id** sub-option of DHCP option 82.
- Option 16—Identifies the vendor of the hardware on which the client is hosted. Option 16 is equivalent to the **vendor-id** sub-option of DHCP option 82.

DHCPv6 options are not enabled automatically when DHCPv6 snooping is enabled on a VLAN. They must be configured using the **dhcpv6-options** statement.

### Related Documentation

## Understanding DHCP Snooping for Port Security

**NOTE:** This topic includes information about enabling DHCP snooping when using Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Understanding DHCP Snooping for Port Security*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 3.

DHCP snooping enables the switch to monitor and control DHCP messages received from untrusted devices connected to the switch. When DHCP snooping is enabled on a VLAN, the system snoops the DHCP messages to view DHCP lease information and build and maintain a database of valid IP address to MAC address (IP-MAC) bindings called the DHCP snooping database. Only clients with valid bindings are allowed access to the network.

- [DHCP Snooping Basics on page 4507](#)
- [Enabling DHCP Snooping on page 4508](#)
- [DHCP Snooping Process on page 4508](#)
- [DHCPv6 Snooping on page 4509](#)
- [Rapid Commit for DHCPv6 on page 4509](#)
- [DHCP Server Access on page 4510](#)
- [Static IP Address Additions to the DHCP Snooping Database on page 4513](#)
- [Snooping DHCP Packets That Have Invalid IP Addresses on page 4513](#)

### DHCP Snooping Basics

Dynamic Host Configuration Protocol (DHCP) allocates IP addresses dynamically, *leasing* addresses to devices so that the addresses can be reused when no longer needed. Hosts and end devices that require IP addresses obtained through DHCP must communicate with a DHCP server across the LAN.

DHCP snooping acts as a guardian of network security by keeping track of valid IP addresses assigned to downstream network devices by a trusted DHCP server (the server is connected to a trusted network port).

By default, all trunk ports on the switch are trusted and all access ports are untrusted for DHCP snooping.

When DHCP snooping is enabled, the lease information from the server is used to create the DHCP snooping table, also known as the binding table. The table shows current IP-MAC bindings, as well as lease time, type of binding, names of associated VLANs, and associated interface.

Entries in the DHCP snooping table are updated in these events:

- When a DHCP client releases an IP address (sends a DHCPRELEASE message). In this event, the associated mapping entry is deleted from the database.

- If you move a network device from one VLAN to another. In this event, typically the device needs to acquire a new IP address. Therefore, its entry in the database, including the VLAN ID, is updated.
- When the lease time (timeout value) assigned by the DHCP server expires. In this event, the associated entry is deleted from the database.

**TIP:** By default, the IP-MAC bindings are lost when the switch is rebooted and DHCP clients (the network devices, or hosts) must reacquire bindings. However, you can configure the bindings to persist by setting the `dhcp-snooping-file` statement to store the database file either locally or remotely.

You can configure the switch to snoop DHCP server responses only from specific VLANs. Doing this prevents spoofing of DHCP server messages.

### Enabling DHCP Snooping

---

DHCP snooping is not enabled in the default switch configuration. DHCP snooping is enabled automatically by Junos OS software when you configure any port security features at the `[edit vlans vlan-name forwarding-options dhcp-security]` hierarchy level. You enable DHCP snooping per VLAN, not per interface (port). For additional information about enabling DHCP snooping, see [“Configuring Port Security \(CLI Procedure\)” on page 4539](#).

### DHCP Snooping Process

---

The basic process of DHCP snooping consists of the following steps:

**NOTE:** When DHCP snooping is enabled for a VLAN, all DHCP packets sent from that network devices in that VLAN are subjected to DHCP snooping. The final IP-MAC binding occurs when the DHCP server sends a DHCPACK packet to the DHCP client.

1. The network device sends a DHCPDISCOVER packet to request an IP address.
2. The switch forwards the packet to the DHCP server.
3. The server sends a DHCPOFFER packet to offer an address. If the DHCPOFFER packet is from a trusted interface, the switch forwards the packet to the DHCP client.
4. The network device sends a DHCPREQUEST packet to accept the IP address. The switch adds an IP-MAC placeholder binding to the database. The entry is considered a placeholder until a DHCPACK packet is received from the server. Until then, the IP address could still be assigned to some other host.
5. The server sends a DHCPACK packet to assign the IP address or a DHCPNAK packet to deny the address request.
6. The switch updates the DHCP database in accordance with the type of packet received:

- Upon receipt of a DHCPACK packet, the switch updates lease information for the IP-MAC binding in its database.
- Upon receipt of a DHCPNACK packet, the switch deletes the placeholder.

**NOTE:** The DHCP database is updated only after the DHCPREQUEST packet has been sent.

For general information about the messages that the DHCP client and DHCP server exchange during the assignment of an IP address for the client, see the [Junos OS System Basics Configuration Guide](#).

### DHCPv6 Snooping

DHCP snooping is also supported for IPv6 packets. The process for DHCPv6 snooping is similar to that for DHCP snooping, but uses different names for the messages exchanged between the client and server to assign IPv6 addresses. [Table 495 on page 4509](#) shows DHCPv6 messages and their DHCPv4 equivalents.

**Table 495: DHCPv6 Messages and DHCPv4 Equivalent Messages**

| Sent by | DHCPv6 Messages         | DHCPv4 Equivalent Messages |
|---------|-------------------------|----------------------------|
| Client  | SOLICIT                 | DHCPDISCOVER               |
| Server  | ADVERTISE               | DHCPOFFER                  |
| Client  | REQUEST, RENEW, REBIND  | DHCPREQUEST                |
| Server  | REPLY                   | DHCPACK/DHCPNACK           |
| Client  | RELEASE                 | DHCPRELEASE                |
| Client  | INFORMATION-REQUEST     | DHCPINFORM                 |
| Client  | DECLINE                 | DHCPDECLINE                |
| Client  | CONFIRM                 | none                       |
| Server  | RECONFIGURE             | DHCPFORCERENEW             |
| Client  | RELAY-FORW, RELAY-REPLY | none                       |

### Rapid Commit for DHCPv6

DHCPv6 provides for a Rapid Commit option, which, when supported by the server and set by the client, shortens the exchange from a four-way relay to a two-message handshake. For more information about enabling Rapid Commit, see [“Enabling DHCPv6 Rapid Commit Support” on page 1428](#).

In the Rapid Commit process:

1. The DHCPv6 client sends out a SOLICIT message that contains a Rapid Commit option, requesting that rapid assignment of address/prefix and other configuration parameters are preferred.
2. If the DHCPv6 server supports rapid assignment, it responds with a REPLY message containing the assigned IPv6 address and prefix and other configuration parameters.

## DHCP Server Access

---

A switch's access to the DHCP server can be configured in three ways:

- [Switch, DHCP Clients, and DHCP Server Are All on the Same VLAN on page 4510](#)
- [Switch Acts as DHCP Server on page 4511](#)
- [Switch Acts as Relay Agent on page 4512](#)

### **Switch, DHCP Clients, and DHCP Server Are All on the Same VLAN**

When the switch, DHCP clients, and DHCP server are *all members of the same VLAN*, the DHCP server can be connected to the switch in one of two ways:

**NOTE:** To enable DHCP snooping on the VLAN, set `[edit vlans vlan-name forwarding-options] dhcp-security`.

- (See [Figure 60 on page 4511](#).) The server is directly connected to the same switch as the one connected to the DHCP clients (the hosts, or network devices, that are requesting IP addresses from the server). The VLAN is enabled for DHCP snooping to protect the untrusted access ports. The trunk port is configured by default as a trusted port.
- (See [Figure 61 on page 4511](#).) The server is connected to an intermediary switch (Switch 2) that is connected through a trunk port to the switch (Switch 1) that the DHCP clients are connected to. Switch 2 is being used as a transit switch. The VLAN is enabled for DHCP snooping to protect the untrusted access ports of Switch 1. The trunk port is configured by default as a trusted port. In [Figure 61 on page 4511](#)—, ge-0/0/11 is a trusted trunk port.

Figure 60: DHCP Server Connected Directly to Switch

Figure 61: DHCP Server Connected Directly to Switch 2, with Switch 2 Connected to Switch 1 Through a Trusted Trunk Port

**Switch Acts as DHCP Server**

You can configure DHCP local server options on the switch, which enables the switch to function as an extended DHCP local server. In [Figure 62 on page 4512](#), the DHCP clients are connected to the extended DHCP local server through untrusted access ports..

Figure 62: Switch Is the DHCP Server

**Switch Acts as Relay Agent**

The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. The Layer 3 interfaces on the switch are configured as routed VLAN interfaces (RVIs)—also called integrated routing and bridging (IRB) interfaces. The trunk interfaces are trusted by default.

The switch can act as relay agent in these two scenarios:

- The DHCP server and clients are in different VLANs.
- The switch is connected to a router that is in turn connected to the DHCP server. See [Figure 63 on page 4513](#).

Figure 63: Switch Acting as Relay Agent Through Router to DHCP Server

### Static IP Address Additions to the DHCP Snooping Database

You can add specific static IP addresses to the database as well as have the addresses dynamically assigned through DHCP snooping. To add static IP addresses, you provide the IP address, the MAC address of the device, the interface on which the device is connected, and the VLAN with which the interface is associated. You do not assign a lease time to the entry. The statically configured entry never expires.

### Snooping DHCP Packets That Have Invalid IP Addresses

If you enable DHCP snooping on a VLAN and then devices on that VLAN send DHCP packets that request invalid IP addresses, these invalid IP addresses are stored in the DHCP snooping database until they are deleted when their default timeout is reached. To eliminate this unnecessary consumption of space in the DHCP snooping database, the switch drops the DHCP packets that request invalid IP addresses. The invalid IP addresses are:

- 0.0.0.0
- 128.0.x.x
- 191.255.x.x

## Understanding IP Source Guard for Port Security on EX Series Switches

Ethernet LAN switches are vulnerable to attacks that involve spoofing (forging) of source IP addresses or source MAC addresses. You can use the IP source guard access port security feature on Juniper Networks EX Series Ethernet Switches to mitigate the effects of these attacks.

- [IP Address Spoofing on page 4514](#)
- [How IP Source Guard Works on page 4514](#)
- [IPv6 Source Guard on page 4515](#)
- [The DHCP Snooping Table on page 4515](#)
- [Typical Uses of Other Junos OS Features with IP Source Guard on page 4516](#)

### IP Address Spoofing

---

Hosts on access interfaces can spoof source IP addresses and source MAC addresses by flooding the switch with packets containing invalid addresses. Such attacks combined with other techniques such as TCP SYN flood attacks can cause denial-of-service (DoS) attacks. With source IP address or source MAC address spoofing, the system administrator cannot identify the source of the attack. The attacker can spoof addresses on the same subnet or on a different subnet.

### How IP Source Guard Works

---

IP source guard checks the IP source address and MAC source address in a packet sent from a host attached to an untrusted access interface on the switch against entries stored in the DHCP snooping database. If IP source guard determines that the packet header contains an invalid source IP address or source MAC address, it ensures that the switch does not forward the packet—that is, the packet is discarded.

**NOTE:**

- If your switch uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, DHCP snooping is enabled automatically when you enable IP source guard on a VLAN. See [“Configuring IP Source Guard \(CLI Procedure\)”](#) on page 4546.
- If your switch is *not* using Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style and you enable IP source guard on a VLAN, you must also explicitly enable DHCP snooping on that VLAN. Otherwise, the default value of no DHCP snooping applies to the VLAN. See *Configuring IP Source Guard (CLI Procedure)*.

IP source guard applies its checking rules to packets sent from untrusted access interfaces on those VLANs. By default, on EX Series switches, access interfaces are untrusted and trunk interfaces are trusted. IP source guard does not check packets that have been sent to the switch by devices connected to either trunk interfaces or to trusted access interfaces so that a DHCP server can be connected to that interface to provide dynamic IP addresses.

**NOTE:** IP source guard is not supported on trunk interfaces regardless of whether the trunk interface is trusted or untrusted.

## IPv6 Source Guard

IPv6 source guard is available on switches that support DHCPv6 snooping. To determine whether your switch supports DHCPv6 snooping, see the *EX Series Switch Software Features Overview*.

## The DHCP Snooping Table

IP source guard obtains information about IP address to MAC address bindings (IP-MAC binding) from the DHCP snooping table, also known as the DHCP binding table. The DHCP snooping table is populated either through dynamic DHCP snooping or through configuration of specific static IP address to MAC address bindings. For more information about the DHCP snooping table, see [“Understanding DHCP Snooping for Port Security”](#) on page 4507.

To display the DHCP snooping table, issue the operational mode command that appears in the switch CLI.

For DHCP snooping:

- (For non-ELS switches) **show ip-source-guard**
- (EX4300 switches only) **show dhcp-security binding ip-source-guard**

For DHCPv6 snooping:

- (For non-ELS switches) **show dhcpv6 snooping binding**

- (EX4300 switches only) [show dhcp-security ipv6 binding](#)

### Typical Uses of Other Junos OS Features with IP Source Guard

---

You can configure IP source guard with various other features on the EX Series switch to provide access port security, including:

- VLAN tagging (used for voice VLANs)
- GRES (graceful Routing Engine switchover)
- Virtual Chassis configurations (See *EX Series Switch Software Features Overview* for list of models that support IP Source Guard.)
- Link aggregation groups (LAGs)
- 802.1X user authentication in single supplicant, single-secure supplicant, or multiple supplicant mode.

**NOTE:** While implementing 801.X user authentication in single-secure supplicant or multiple supplicant mode, use the following configuration guidelines:

- If the 802.1X interface is part of an untagged MAC-based VLAN and you want to enable IP source guard and DHCP snooping on that VLAN, you must enable IP source guard and DHCP snooping on all dynamic VLANs in which the interface has untagged membership. This also applies to IPv6 source guard and DHCPv6 snooping.
- If the 802.1X interface is part of a tagged MAC-based VLAN and you want to enable IP source guard and DHCP snooping on that VLAN, you must enable IP source guard and DHCP snooping on all dynamic VLANs in which the interface has tagged membership. This also applies to IPv6 source guard and DHCPv6 snooping.

### Understanding IPv6 Neighbor Discovery Inspection

IPv6 nodes (hosts and routers) use Neighbor Discovery Protocol (NDP) to discover the presence and link-layer addresses of other nodes residing on the same link. Hosts use

NDP to find neighboring routers that are willing to forward packets on their behalf, while routers use it to advertise their presence. Nodes also use NDP to maintain reachability information about the paths to active neighbors. When a router or the path to a router fails, a host can search for alternate paths.

IPv6 nodes use NDP exchange neighbor solicitation and advertisement messages to learn the link-layer addresses of their neighbors. This process makes NDP susceptible to attacks that involve the spoofing (or forging) of link-layer addresses. An attacking node can cause packets for legitimate nodes to be sent to some other link-layer address by either sending a neighbor solicitation message with a spoofed source MAC address, or by sending a neighbor advertisement address with a spoofed target MAC address. The spoofed MAC address is then associated with a legitimate network IPv6 address by the other nodes.

IPv6 neighbor discovery inspection prevents NDP security vulnerabilities by inspecting neighbor discovery messages and verifying them against the DHCPv6 binding table. The DHCPv6 binding table is a database of valid matches, or bindings, of IP addresses to MAC addresses, also known as the DHCPv6 snooping table. With neighbor discovery inspection, the source IP address and source MAC address of the ICMPv6 packet carrying the neighbor discovery message are compared against the entries in the binding table. If no match is found, the packet is dropped.

The neighbor discovery process uses five types of ICMPv6 packets for the purposes of advertisement, solicitation, or redirection: Neighbor Solicit, Neighbor Advertise, Router Solicit, Router Advertise, and Router Redirect. Neighbor discovery inspection checks all Neighbor or Router Solicit messages and Neighbor or Router Advertise messages for their source IPv6 address and MAC address, and also checks that Router Redirect messages are sent only by trusted routers. These checks can prevent the following types of attacks:

Cache poisoning attacks—Neighbor Discovery cache poisoning is the IPv6 equivalent of ARP spoofing, in which an attacker sends an unsolicited advertisement to other hosts on the network with a forged address, to associate its own MAC address with a legitimate network IP address. These bindings between IPv6 addresses and MAC addresses are stored by each node in its neighbor cache. When the caches are updated with the malicious binding, the attacker can initiate a man-in-the-middle attack, intercepting traffic that was intended for a legitimate host.

Routing denial-of-service (DoS) attacks—An attacker could cause a host to disable its first-hop router by spoofing the address of a router and sending a neighbor advertisement message with the *router* flag cleared. The victim host assumes that the device that used to be its first-hop router is no longer a router.

Redirect attacks—Routers use ICMPv6 redirect requests to inform a host of a more efficient route to a destination. Hosts can be redirected to a better first-hop router but can also be informed by a Router Redirect message that the destination is in fact a neighbor. An attacker using this provision can achieve an effect similar to cache poisoning and intercept all traffic from the victim host.

## Understanding MAC Limiting and MAC Move Limiting for Port Security on EX Series Switches

MAC limiting for port security protects against flooding of the Ethernet switching table (also known as the MAC forwarding table or Layer 2 forwarding table). You enable this feature on interfaces (ports).

MAC move limiting detects MAC movement and MAC spoofing on access interfaces. You enable this feature on VLANs.

This topic describes the various method of MAC limiting and MAC move limiting for port security:

- [MAC Limiting for Port Security by Limiting the Number of MAC Addresses That Can be Learned on Interfaces on page 4518](#)
- [MAC Limiting for Port Security by Specifying MAC Addresses That Are Allowed to Access Interfaces on page 4519](#)
- [MAC Move Limiting for Port Security by Monitoring MAC Address Moves within VLANs on page 4519](#)

### MAC Limiting for Port Security by Limiting the Number of MAC Addresses That Can be Learned on Interfaces

One method to enhance port security is to set the maximum number of MAC addresses that can be learned (added to the Ethernet switching table) on any of the following:

- A specific access interface (port)
- All access interfaces
- A specific access interface on the basis of its membership within a specific virtual LAN (VLAN membership MAC limit)

**NOTE:** Static MAC addresses do not count toward the limit you specify for dynamic MAC addresses.

---

When you are configuring the maximum MAC limit for an interface, you can choose the action that occurs on incoming packets when the MAC limit is exceeded. For additional information about configuring MAC limit for an interface, see *Configuring MAC Limiting (CLI Procedure)* or [“Configuring MAC Limiting \(CLI Procedure\)” on page 2361](#).

### MAC Limiting for Port Security by Specifying MAC Addresses That Are Allowed to Access Interfaces

Another method to enhance port security is to configure specific MAC addresses as *allowed MAC addresses* for specific access interfaces. Any MAC address that is not in the list of the configured addresses is not learned and the switch logs a message.

Allowed MAC binds MAC addresses to a VLAN so that the address does not get registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

### MAC Move Limiting for Port Security by Monitoring MAC Address Moves within VLANs

MAC move limiting causes the switch to limit and track the frequency with which a MAC address can move to a new interface (port). It can help prevent MAC spoofing, and it can also detect and prevent loops.

**NOTE:** MAC move limiting is not supported on EX9200.

If a MAC address moves more than the configured number of times within one second, the switch performs the configured action. You can configure MAC move limiting to apply to all VLANs or to a specific VLAN.

## Understanding Media Access Control Security (MACsec)

Media Access Control Security (MACsec) is an industry-standard security technology that provides secure communication for all traffic on Ethernet links. MACsec provides point-to-point security on Ethernet links between directly connected nodes and is capable of identifying and preventing most security threats, including denial of service, intrusion, man-in-the-middle, masquerading, passive wiretapping, and playback attacks. MACsec is standardized in IEEE 802.1AE.

MACsec allows you to secure an Ethernet link for almost all traffic, including frames from the Link Layer Discovery Protocol (LLDP), Link Aggregation Control Protocol (LACP), Dynamic Host Configuration Protocol (DHCP), Address Resolution Protocol (ARP), and other protocols that are not typically secured on an Ethernet link because of limitations with other security solutions. MACsec can be used in combination with other security protocols such as IP Security (IPsec) and Secure Sockets Layer (SSL) to provide end-to-end network security.

This topic contains the following sections:

---

### How MACsec Works

MACsec provides industry-standard security through the use of secured point-to-point Ethernet links. The point-to-point links are secured after matching security keys—a user-configured pre-shared key when you enable MACsec using static connectivity association key (CAK) security mode, a user-configured static secure association key when you enable MACsec using static secure association key (SAK) security mode, or a dynamic key included as part of the AAA handshake with the RADIUS server when you enable MACsec using dynamic security mode—are exchanged and verified between the interfaces at each end of the point-to-point Ethernet link. Other user-configurable parameters, such as MAC address or port, must also match on the interfaces on each side of the link to enable MACsec. See [“Configuring Media Access Control Security \(MACsec\)” on page 4548](#).

Once MACsec is enabled on a point-to-point Ethernet link, all traffic traversing the link is MACsec-secured through the use of data integrity checks and, if configured, encryption.

The data integrity checks verify the integrity of the data. MACsec appends an 8-byte header and a 16-byte tail to all Ethernet frames traversing the MACsec-secured point-to-point Ethernet link, and the header and tail are checked by the receiving interface to ensure that the data was not compromised while traversing the link. If the data integrity check detects anything irregular about the traffic, the traffic is dropped.

MACsec can also be used to encrypt all traffic on the Ethernet link. The encryption used by MACsec ensures that the data in the Ethernet frame cannot be viewed by anybody monitoring traffic on the link. MACsec encryption is optional and user-configurable; you can enable MACsec to ensure the data integrity checks are performed while still sending unencrypted data “in the clear” over the MACsec-secured link, if desired.

MACsec is configured on point-to-point Ethernet links between MACsec-capable interfaces. If you want to enable MACsec on multiple Ethernet links, you must configure MACsec individually on each point-to-point Ethernet link.

### Understanding Connectivity Associations and Secure Channels

MACsec is configured in connectivity associations. MACsec is enabled when a connectivity association is assigned to an interface.

When you are configuring MACsec using static secure association key (SAK) security mode, you must configure secure channels within a connectivity association. The secure channels are responsible for transmitting and receiving data on the MACsec-enabled link, and also responsible for transmitting SAKs across the link to enable and maintain MACsec. A single secure channel is uni-directional—it can only be used to apply MACsec to inbound or outbound traffic. A typical connectivity association when MACsec is enabled using SAK security mode contains two secure channels—one secure channel for inbound traffic and another secure channel for outbound traffic.

When you enable MACsec using static CAK or dynamic security mode, you have to create and configure a connectivity association. Two secure channels—one secure channel for inbound traffic and another secure channel for outbound traffic—are automatically created. The automatically-created secure channels do not have any user-configurable parameters; all configuration is done in the connectivity association outside of the secure channels.

### Understanding MACsec Security Modes

#### ***Understanding Static Connectivity Association Key Security Mode (Recommended Security Mode for Switch-to-Switch Links)***

When you enable MACsec using static connectivity association key (CAK) security mode, two security keys—a connectivity association key (CAK) that secures control plane traffic and a randomly-generated secure association key (SAK) that secures data plane traffic—are used to secure the point-to-point Ethernet link. Both keys are regularly exchanged between both devices on each end of the point-to-point Ethernet link to ensure link security.

You initially establish a MACsec-secured link using a pre-shared key when you are using static CAK security mode to enable MACsec. A pre-shared key includes a connectivity association name (CKN) and its own connectivity association key (CAK). The CKN and

CAK are configured by the user in the connectivity association and must match on both ends of the link to initially enable MACsec.

Once matching pre-shared keys are successfully exchanged, the MACsec Key Agreement (MKA) protocol is enabled. The MKA protocol is responsible for maintaining MACsec on the link, and decides which switch on the point-to-point link becomes the key server. The key server then creates an SAK that is shared with the switch at the other end of the point-to-point link only, and that SAK is used to secure all data traffic traversing the link. The key server will continue to periodically create and share a randomly-created SAK over the point-to-point link for as long as MACsec is enabled.

You enable MACsec using static CAK security mode by configuring a connectivity association on both ends of the link. All configuration is done within the connectivity association but outside of the secure channel. Two secure channels—one for inbound traffic and one for outbound traffic—are automatically created when using static CAK security mode. The automatically-created secure channels do not have any user-configurable parameters that cannot already be configured in the connectivity association.

We recommend enabling MACsec on switch-to-switch links using static CAK security mode. Static CAK security mode ensures security by frequently refreshing to a new random security key and by only sharing the security key between the two devices on the MACsec-secured point-to-point link. Additionally, some optional MACsec features—replay protection, SCI tagging, and the ability to exclude traffic from MACsec—are only available when you enable MACsec using static CAK security mode.

See [“Configuring Media Access Control Security \(MACsec\)” on page 4548](#) for step-by-step instructions on enabling MACsec using static CAK security mode.

### ***Understanding Dynamic Secure Association Key Security Mode (Switch-to-Host Links)***

Dynamic secure association key security mode is used to enable MACsec on a switch-to-host link.

To enable MACsec on a link connecting an endpoint device—such as a server, phone, or personal computer—to a switch, the endpoint device must support MACsec and must be running software that allows it to enable a MACsec-secured connection. When configuring MACsec on a switch-to-host link, the MACsec Key Agreement (MKA) keys, which are included as part of 802.1X authentication, are retrieved from a RADIUS server as part of the AAA handshake. A master key is passed from the RADIUS server to the switch and from the RADIUS server to the host in independent authentication transactions. The master key is then passed between the switch and the host to create a MACsec-secured connection.

A secure association using dynamic secure association security mode must be configured on the switch's Ethernet interface that connects to the host in order for the switch to create a MACsec-secured connection after receiving the MKA keys from the RADIUS server.

The RADIUS server must be using Extensible Authentication Protocol-Transport Layer Security (EAP-TLS) in order to support MACsec. The RADIUS servers that support other widely-used authentication frameworks, such as password-only or md5, cannot be used

to support MACsec. In order to enable MACsec on a switch to secure a connection to a host, you must be using 802.1X authentication on the RADIUS server. MACsec must be configured into dynamic mode. MACsec is still enabled using connectivity associations when enabled on a switch-to-host link, as it is on a switch-to-switch link.

### ***Understanding Static Secure Association Key Security Mode (Supported for Switch-to-Switch Links)***

When you enable MACsec using static secure association key (SAK) security mode, one of up to two manually configured SAKs is used to secure data traffic on the point-to-point Ethernet link. All SAK names and values are configured by the user; there is no key server or other tool that creates SAKs. Security is maintained on the point-to-point Ethernet link by periodically rotating between the two security keys. Each security key name and value must have a corresponding matching value on the interface at the other end of the point-to-point Ethernet link to maintain MACsec on the link.

You configure SAKs within secure channels when you enable MACsec using static SAK security mode. You configure secure channels within connectivity associations. A typical connectivity association for MACsec using static SAK security mode contains two secure channels—one for inbound traffic and one for outbound traffic—that have each been configured with two manually-configured SAKs. You must attach the connectivity association with the secure channel configurations to an interface to enable MACsec using static SAK security mode.

We recommend enabling MACsec using static CAK security mode. You should only use static SAK security mode if you have a compelling reason to use it instead of static CAK security mode.

See [“Configuring Media Access Control Security \(MACsec\)” on page 4548](#) for step-by-step instructions on enabling MACsec using SAKs.

### **Understanding the Requirements to Enable MACsec on a Switch-to-Host Link**

When configuring MACsec on a switch-to-host link, the MACsec Key Agreement (MKA) keys, which are included as part of 802.1X authentication, are retrieved from a RADIUS server as part of the AAA handshake. A master key is passed from the RADIUS server to the switch and from the RADIUS server to the host in independent authentication transactions. The master key is then passed between the switch and the host to create a MACsec-secured connection.

The following requirements must be met in order to enable MACsec on a link connecting a host device to a switch.

The host device:

- must support MACsec and must be running software that allows it to enable a MACsec-secured connection with the switch.

The switch:

- must be an EX4200, EX4300, or EX4550 switch running Junos OS Release 14.1X53-D10 or later

- must be configured into dynamic secure association key security mode.
- must be using 802.1X authentication to communicate with the RADIUS server.

The RADIUS server:

- must be using the Extensible Authentication Protocol-Transport Layer Security (EAP-TLS) authentication framework.

**NOTE:** RADIUS servers that support other widely-used authentication frameworks, such as password-only or md5, cannot be used to support MACsec.

- must be using 802.1X authentication.
- can be multiple hops from the switch and the host device.

---

### Understanding MACsec Hardware Requirements for EX Series and QFX Series Switches

---

MACsec is currently supported on the following EX Series and QFX Series switch interfaces:

- The uplink port connections on the SFP+ MACsec uplink module that can be installed on EX4200 series switches.
- All access and uplink ports on EX4300 switches.
- All EX4550 optical interfaces that use the LC connection type. See *Pluggable Transceivers Supported on EX4550 Switches*.
- All twenty-four fixed SFP+ interfaces on an EX4600 switch.
- All eight SFP+ interfaces on the EX4600-EM-8F expansion module, when installed in an EX4600 or QFX5100-24Q switch.

MACsec can be configured on supported switch interfaces when those switches are configured in a Virtual Chassis or Virtual Chassis Fabric (VCF), including when MACsec-supported interfaces are on member switches in a mixed Virtual Chassis or VCF that includes switch interfaces that do not support MACsec. MACsec, however, cannot be enabled on Virtual Chassis ports (VCPs) to secure traffic travelling between member switches in a Virtual Chassis or VCF.

---

### Understanding MACsec Software Requirements for EX Series and QFX Series Switches

---

MACsec was initially released on EX4200, EX4300, and EX4550 switches in Junos OS Release 13.2X50-D15.

MACsec support for dynamic security mode, which allows MACsec to be configured on switch-to-host links, for EX4200, EX4300, and EX4550 switches was introduced in Junos OS Release 14.1X53-D10.

MACsec support for EX4600 switches and QFX5100-24Q switches was introduced in Junos OS Release 14.1X53-D15. The EX4600 and QFX5100-24Q switches supports MACsec on switch-to-switch links only.

The switches on each end of a MACsec-secured switch-to-switch link must either both be using Junos OS Release 14.1X53-D10 or later, or must both be using an earlier version of Junos, in order to establish a MACsec-secured connection when using static CAK security mode.

You must download the controlled version of your Junos OS software to enable MACsec. MACsec software support is not available in the domestic version of your Junos OS software. The controlled version of Junos OS software includes all features and functionality available in the domestic version of Junos OS, while also supporting MACsec. The domestic version of Junos OS software is shipped on all switches that support MACsec, so you must download and install a controlled version of Junos OS software for your switch before you can enable MACsec.

The controlled version of Junos OS software contains encryption and is, therefore, not available to customers in all geographies. The export and re-export of the controlled version of Junos OS software is strictly controlled under United States export laws. The export, import, and use of the controlled version of Junos OS software is also subject to controls imposed under the laws of other countries. If you have questions about acquiring the controlled version of your Junos OS software, contact Juniper Networks Trade Compliance group at [compliance\\_helpdesk@juniper.net](mailto:compliance_helpdesk@juniper.net).

The process for installing a controlled version of Junos OS software on your switch is identical to installing the domestic version. See *Downloading Software Packages from Juniper Networks*.

### Understanding the MACsec Feature License Requirement

A feature license is required to configure MACsec on a switch.

To purchase a feature license for MACsec, contact your Juniper Networks sales representative (<http://www.juniper.net/us/en/contact-us/sales-offices>). The Juniper sales representative will provide you with a feature license file and a license key. You will be asked to supply the chassis serial number of your switch; you can obtain the serial number by running the **show chassis hardware** command.

The MACsec feature license is an independent feature license; the enhanced feature licenses (EFLs) or advanced feature licenses (AFLs) that must be purchased to enable some features on your switches cannot be purchased to enable MACsec.

### MACsec Limitations

All types of Spanning Tree Protocol frames cannot currently be encrypted using MACsec.

#### Related Documentation

- [Configuring Media Access Control Security \(MACsec\) on page 4548](#)

## Understanding Persistent MAC Learning (Sticky MAC)

Persistent MAC learning, also known as sticky MAC, is a port security feature that enables an interface to retain dynamically learned MAC addresses when the switch is restarted or if the interface goes down and is brought back online.

Persistent MAC address learning is disabled by default. You can enable persistent MAC address learning in conjunction with MAC limiting to restrict the number of persistent MAC addresses. You enable this feature on interfaces.

Configure persistent MAC learning on an interface to:

- Prevent traffic losses for trusted workstations and servers because the interface does not have to relearn the addresses from ingress traffic after a restart.
- Protect the switch against security attacks. Use persistent MAC learning in combination with MAC limiting to protect against attacks, such as Layer 2 denial-of-service (DoS) attacks, overflow attacks on the Ethernet switching table, and DHCP starvation attacks, by limiting the MAC addresses allowed while still allowing the interface to dynamically learn a specified number of MAC addresses. The interface is secured because after the limit has been reached, additional devices cannot connect to the port.

By configuring persistent MAC learning along with MAC limiting, you enable interfaces to learn MAC addresses of trusted workstations and servers from the time when you connect the interface to your network until the limit for MAC addresses is reached, and ensure that after this limit is reached, new devices will not be allowed to connect to the interface even if the switch restarts. As an alternative to using persistent MAC learning with MAC limiting, you can statically configure each MAC address on each port or allow the port to continuously learn new MAC addresses after restarts or interface-down events. Allowing the port to continuously learn MAC addresses represents a security risk.

**NOTE:** While a switch is restarting or an interface is coming back up, there might be a short delay before the interface can learn more MAC addresses. This delay occurs while the system re-enters previously learned persistent MAC addresses into the forwarding database for the interface.

**TIP:** If you move a device within your network that has a persistent MAC address entry on the switch, use the `clear ethernet-switching table persistent-mac` command to clear the persistent MAC address entry from the interface. If you move the device and do not clear the persistent MAC address from the original port it was learned on, then the new port will not learn the MAC address of the device and the device will not be able to connect.

If the original port is down when you move the device, then the new port will learn the MAC address and the device can connect. However, if you do not clear the persistent MAC address on the original port, then when the port restarts, the system reinstalls the persistent MAC address in the forwarding

table for that port. If this occurs, the persistent MAC address is removed from the new port and the device loses connectivity.

Consider the following configuration guidelines when configuring persistent MAC learning:

- Interfaces must be configured in access mode (use the **port-mode** configuration statement or, for switches operating on the Enhanced Layer 2 Software (ELS) configuration style, the **interface-mode** configuration statement).
- You cannot enable persistent MAC learning on an interface on which 802.1x authentication is configured.
- You cannot enable persistent MAC learning on an interface that is part of a redundant trunk group.
- You cannot enable persistent MAC learning on an interface on which **no-mac-learning** is enabled.

## Understanding Trusted DHCP Servers for Port Security

Any interface on the switching device that connects to a DHCP server can be configured as a trusted port. Configuring a DHCP server on a trusted port protects against rogue DHCP servers sending leases.

Ensure that the DHCP server interface is physically secure—that is, that access to the server is monitored and controlled at the site—before you configure the port as trusted.

- [Example: Configuring IPv6 Source Guard and Neighbor Discovery Inspection to Protect the Switch from IPv6 Address Spoofing on page 4534](#)

### Example: Configuring IP Source Guard and Dynamic ARP Inspection to Protect the Switch from IP Spoofing and ARP Spoofing

NOTE: This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks*. For ELS details, see “Getting Started with Enhanced Layer 2 Software” on page 3.

NOTE: On EX9200 switches, DHCP snooping, DAI, and IP source guard are not supported in an MC-LAG scenario.

This example describes how to enable IP source guard and Dynamic ARP Inspection (DAI) on a specified VLAN to protect the switch against spoofed IP/MAC addresses and ARP spoofing attacks. When you enable either IP source guard or DAI, the configuration automatically enables DHCP snooping for the same VLAN.

- [Requirements on page 4530](#)
- [Overview and Topology on page 4530](#)
- [Configuration on page 4532](#)
- [Verification on page 4532](#)

## Requirements

---

This example uses the following hardware and software components:

- One EX4300 switch or EX9200 switch
- Junos OS Release 13.2X50-D10 or later for EX Series switches
- A DHCP server to provide IP addresses to network devices on the switch

Before you configure IP source guard to prevent IP/MAC spoofing or DAI to mitigate ARP spoofing attacks, be sure you have:

- Connected the DHCP server to the switch.
- Configured the VLAN to which you are adding DHCP security features. See [“Configuring VLANs for EX Series Switches \(CLI Procedure\)” on page 2337](#).

## Overview and Topology

---

Ethernet LAN switches are vulnerable to attacks on security that involve spoofing (forging) of source MAC addresses or source IP addresses. These spoofed packets are sent from hosts connected to untrusted access interfaces on the switch. These spoofed packets are sent from hosts connected to untrusted access interfaces on the switch. IP source guard checks the IP source address and MAC source address in a packet sent from a host attached to an untrusted access interface on the switch against entries stored in the DHCP snooping database. If IP source guard determines that the packet header contains an invalid source IP address or source MAC address, it ensures that the switch does not forward the packet—that is, the packet is discarded.

Another type of security attack is ARP spoofing (also known as ARP poisoning or ARP cache poisoning). ARP-spoofing is a way to initiate man-in-the-middle attacks. The attacker sends an ARP packet that spoofs the MAC address of another device on the LAN. Instead of the switch sending traffic to the proper network device, it sends it to the device with the spoofed address that is impersonating the proper device. If the impersonating device is the attacker's machine, the attacker receives all the traffic from the switch that should have gone to another device. The result is that traffic from the switch is misdirected and cannot reach its proper destination.

**NOTE:** When dynamic ARP inspection (DAI) is enabled, the switch logs the number of invalid ARP packets that it receives on each interface, along with the sender's IP and MAC addresses. You can use these log messages to discover ARP spoofing on the network.

This example shows how to configure these important port security features on a switch that is connected to a DHCP server. The setup for this example includes the VLAN **employee-vlan** on the switch. [Figure 64 on page 4531](#) illustrates the topology for this example.

**NOTE:**

The trunk interface connecting to the DHCP server interface is a trusted port by default.

**Figure 64: Network Topology for Basic Port Security**

The components of the topology for this example are shown in [Table 496 on page 4531](#).

**Table 496: Components of the Port Security Topology**

| Properties                          | Settings                                                                                       |
|-------------------------------------|------------------------------------------------------------------------------------------------|
| Switchhardware                      | One EX4300 or EX9200 switch                                                                    |
| VLAN name and ID                    | <b>employee-vlan</b> , tag 20                                                                  |
| VLAN subnets                        | 192.0.2.16/28<br>192.0.2.17 through 192.0.2.30<br>192.0.2.31 is the subnet's broadcast address |
| Interfaces in <b>employee-vlan</b>  | ge-0/0/1, ge-0/0/2, ge-0/0/3, ge-0/0/8                                                         |
| Interface connecting to DHCP server | ge-0/0/8                                                                                       |

In this example, the switch has already been configured as follows:

- All access ports are untrusted, which is the default setting.
- The trunk port (**ge-0/0/8**) is trusted, which is the default setting.

- The VLAN (**employee-vlan**) has been configured to include the specified interfaces.

---

### Configuration

To configure IP source guard and DAI (and thereby, also automatically configure DHCP snooping) to protect the switch against IP spoofing and ARP attacks:

**CLI Quick Configuration** To quickly configure IP source guard and DAI (and thereby, also automatically configure DHCP snooping), copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans employee-vlan forwarding-options dhcp-security ip-source-guard
set vlans employee-vlan forwarding-options dhcp-security arp-inspection
```

**Step-by-Step Procedure** Configure IP source guard and DAI (and thereby, also automatically configure DHCP snooping) on the VLAN:

1. Configure IP source guard on the VLAN:  

```
[edit vlans employee-vlan forwarding-options dhcp-security]
user@switch# set ip-source-guard
```
2. Enable DAI on the VLAN:  

```
[edit vlans employee-vlan forwarding-options dhcp-security]
user@switch# set arp-inspection
```

**Results** Check the results of the configuration:

```
user@switch> show vlans employee-vlan forwarding-options
employee-vlan {
  forwarding-options {
    dhcp-security {
      arp-inspection;
      ip-source-guard;
    }
  }
}
```

---

### Verification

Confirm that the configuration is working properly.

- [Verifying That DHCP Snooping Is Working Correctly on the Switch on page 4532](#)
- [Verifying That IP Source Guard is Working on the VLAN on page 4533](#)
- [Verifying That DAI Is Working Correctly on the Switch on page 4533](#)

#### ***Verifying That DHCP Snooping Is Working Correctly on the Switch***

**Purpose** Verify that DHCP snooping is working on the switch.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the port on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

user@switch> **show dhcp-security binding**

| IP Address | MAC Address       | Vlan          | Expires | State | Interface  |
|------------|-------------------|---------------|---------|-------|------------|
| 192.0.2.17 | 00:05:85:3A:82:77 | employee-vlan | 86265   | BOUND | ge-0/0/1.0 |
| 192.0.2.18 | 00:05:85:3A:82:79 | employee-vlan | 86265   | BOUND | ge-0/0/1.0 |
| 192.0.2.19 | 00:05:85:3A:82:80 | employee-vlan | 86287   | BOUND | ge-0/0/2.0 |
| 192.0.2.20 | 00:05:85:3A:82:81 | employee-vlan | 86287   | BOUND | ge-0/0/2.0 |
| 192.0.2.21 | 00:05:85:3A:82:83 | employee-vlan | 86287   | BOUND | ge-0/0/2.0 |
| 192.0.2.22 | 00:05:85:27:32:88 | employee-vlan | 86254   | BOUND | ge-0/0/3.0 |

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for the assigned IP address, the device's MAC address, the VLAN name, and the time, in seconds, remaining before the lease expires.

#### *Verifying That IP Source Guard is Working on the VLAN*

**Purpose** Verify that IP source guard is enabled and working on the VLAN.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch. View the IP source guard information for the data VLAN.

user@switch> **show dhcp-security binding ip-source-guard**

| IP Address | MAC Address       | Vlan          | Expires | State | Interface  |
|------------|-------------------|---------------|---------|-------|------------|
| 192.0.2.17 | 00:05:85:3A:82:77 | employee-vlan | 86265   | BOUND | ge-0/0/1.0 |
| 192.0.2.18 | 00:05:85:3A:82:79 | employee-vlan | 86265   | BOUND | ge-0/0/1.0 |
| 192.0.2.19 | 00:05:85:3A:82:80 | employee-vlan | 86287   | BOUND | ge-0/0/2.0 |
| 192.0.2.20 | 00:05:85:3A:82:81 | employee-vlan | 86287   | BOUND | ge-0/0/2.0 |
| 192.0.2.21 | 00:05:85:3A:82:83 | employee-vlan | 86287   | BOUND | ge-0/0/2.0 |
| 192.0.2.22 | 00:05:85:27:32:88 | employee-vlan | 86254   | BOUND | ge-0/0/3.0 |

**Meaning** The IP source guard database table contains the VLANs enabled for IP source guard.

#### *Verifying That DAI Is Working Correctly on the Switch*

**Purpose** Verify that DAI is working on the switch.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show dhcp-security arp inspection statistics
```

ARP inspection statistics:

| Interface  | Packets received | ARP inspection pass | ARP inspection failed |
|------------|------------------|---------------------|-----------------------|
| ge-0/0/1.0 | 7                | 5                   | 2                     |
| ge-0/0/2.0 | 10               | 10                  | 0                     |
| ge-0/0/3.0 | 12               | 12                  | 0                     |

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

- Related Documentation**
- [Configuring IP Source Guard \(CLI Procedure\) on page 4546](#)
  - [Enabling Dynamic ARP Inspection \(CLI Procedure\) on page 4572](#)
  - [Enabling Dynamic ARP Inspection \(J-Web Procedure\) on page 4572](#)

## Example: Configuring IPv6 Source Guard and Neighbor Discovery Inspection to Protect the Switch from IPv6 Address Spoofing

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Example: Configuring DHCP Snooping and DAI to Protect the Switch from ARP Spoofing Attacks*. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 3](#).

This example describes how to enable IPv6 source guard and Neighbor Discovery inspection on a specified VLAN to protect the switch against IPv6 address spoofing attacks. When you enable either IPv6 source guard or Neighbor Discovery inspection, DHCPv6 snooping is automatically enabled on the same VLAN.

- [Requirements on page 4534](#)
- [Overview and Topology on page 4535](#)
- [Configuration on page 4537](#)
- [Verification on page 4537](#)

### Requirements

---

This example uses the following hardware and software components:

- One EX4300 switch
- Junos OS Release 13.2X51-D20 or later for EX Series switches

- A DHCPv6 server to provide IPv6 addresses to network devices on the switch

Before you configure IPv6 source guard and Neighbor Discovery inspection to prevent IPv6 address spoofing attacks, be sure you have:

- Connected the DHCPv6 server to the switch.
- Configured the VLAN to which you are adding DHCPv6 security features. See [“Configuring VLANs for EX Series Switches \(CLI Procedure\)” on page 2337](#).

### Overview and Topology

Ethernet LAN switches are vulnerable to attacks on security that involve spoofing (forging) of source MAC addresses or source IPv6 addresses. These spoofed packets are sent from hosts connected to untrusted access interfaces on the switch. For more information on IPv6 address spoofing attacks, see [“Understanding IPv6 Neighbor Discovery Inspection” on page 4516](#).

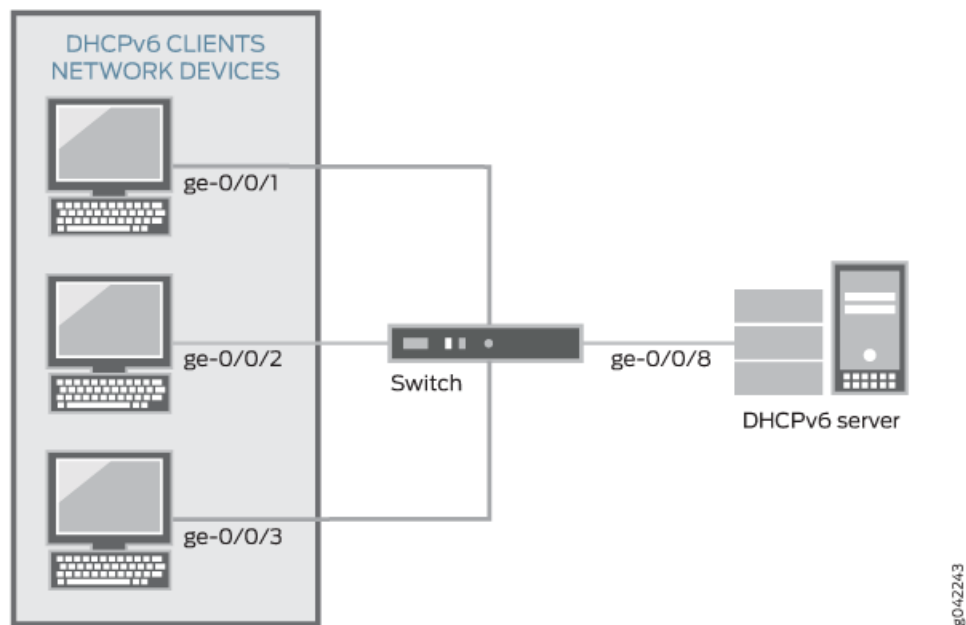

IPv6 source guard and Neighbor Discovery inspection mitigate the risk of IPv6 spoofing attacks by using the DHCPv6 snooping table. Also known as the binding table, the DHCPv6 snooping table contains the valid bindings of IPv6 addresses to MAC addresses. When a packet is sent from a host attached to an untrusted access interface on the switch, IPv6 source guard verifies the source IPv6 address and MAC address of the packet against the DHCPv6 snooping table. If there is no match in the table, the switch does not forward the packet—that is, the packet is discarded. Neighbor Discovery inspection verifies neighbor discovery messages sent between IPv6 nodes on the same network link against the DHCPv6 snooping table, and also discards the packet if no match is found.

This example shows how to configure these important port security features on a switch that is connected to a DHCPv6 server. The setup for this example includes the VLAN **sales** on the switch. [Figure 64 on page 4531](#) illustrates the topology for this example.

**NOTE:** The trunk interface connecting to the DHCPv6 server interface is a trusted port by default.

Figure 65: Network Topology for Basic Port Security

The components of the topology for this example are shown in [Table 496 on page 4531](#).

Table 497: Components of the Port Security Topology

| Properties                            | Settings                                                                                       |
|---------------------------------------|------------------------------------------------------------------------------------------------|
| Switch hardware                       | One EX4300 switch                                                                              |
| VLAN name and ID                      | <b>sales</b> , tag 20                                                                          |
| VLAN subnets                          | 192.0.2.16/28<br>192.0.2.17 through 192.0.2.30<br>192.0.2.31 is the subnet's broadcast address |
| Interfaces in <b>sales</b>            | <code>ge-0/0/1</code> , <code>ge-0/0/2</code> , <code>ge-0/0/3</code> , <code>ge-0/0/8</code>  |
| Interface connecting to DHCPv6 server | <code>ge-0/0/8</code>                                                                          |

In this example, the switch has already been configured as follows:

- All access ports are untrusted, which is the default setting.
- The trunk port (`ge-0/0/8`) is trusted, which is the default setting.
- The VLAN (**sales**) has been configured to include the specified interfaces.

## Configuration

**CLI Quick Configuration** To quickly configure IPv6 source guard and Neighbor Discovery inspection (and thereby, also automatically configure DHCPv6 snooping), copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans sales forwarding-options dhcp-security ipv6-source-guard
set vlans sales forwarding-options dhcp-security nd-inspection
```

**Step-by-Step Procedure** Configure IPv6 source guard and Neighbor Discovery inspection (and thereby, also automatically configure DHCPv6 snooping) on the VLAN:

1. Configure IPv6 source guard on the VLAN:

```
[edit vlans sales forwarding-options dhcp-security]
user@switch# set ipv6-source-guard
```

2. Enable Neighbor Discovery inspection on the VLAN:

```
[edit vlans sales forwarding-options dhcp-security]
user@switch# set neighbor-discovery-inspection
```

**Results** Check the results of the configuration:

```
user@switch> show vlans sales forwarding-options
dhcp-security {
  nd-inspection;
  ipv6-source-guard;
}
```

## Verification

Confirm that the configuration is working properly.

- [Verifying That DHCPv6 Snooping Is Working Correctly on the Switch on page 4537](#)
- [Verifying That Neighbor Discovery Inspection Is Working Correctly on the Switch on page 4538](#)

### *Verifying That DHCPv6 Snooping Is Working Correctly on the Switch*

**Purpose** Verify that DHCPv6 snooping is working on the switch.

**Action** Send DHCPv6 requests from network devices (in this example, they are DHCPv6 clients) connected to the switch.

Display the DHCPv6 snooping information when the port on which the DHCPv6 server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IPv6 addresses and leases:

```
user@switch> show dhcp-security ipv6 binding
```

| IPv6 address             | MAC address       | Vlan  | Expires | State | Interface  |
|--------------------------|-------------------|-------|---------|-------|------------|
| 2001::10:10:0:1          | 00:10:94:00:55:0b | sales | 86265   | BOUND | ge-0/0/1.0 |
| fe80::210:94ff:fe00:550b | 00:10:94:00:55:0b | sales | 86265   | BOUND | ge-0/0/1.0 |
| 2000::10:10:0:2          | 00:10:94:00:00:34 | sales | 86265   | BOUND | ge-0/0/2.0 |
| fe80::210:94ff:fe00:0034 | 00:10:94:00:00:34 | sales | 86265   | BOUND | ge-0/0/2.0 |
| 2000::10:10:0:3          | 00:10:94:00:00:55 | sales | 86265   | BOUND | ge-0/0/3.0 |
| fe80::210:94ff:fe00:0055 | 00:10:94:00:00:55 | sales | 86265   | BOUND | ge-0/0/3.0 |

**Meaning** The output shows the assigned IPv6 addresses, the MAC address, the VLAN name, and the time, in seconds, remaining before the lease expires. Because IPv6 hosts usually have more than one IPv6 address assigned to each of their IPv6-enabled network interfaces, there are two entries added for each client: one with the link-local IPv6 address, which is used by the client for DHCP transactions, and another with the IPv6 address assigned by the server. The link-local address always has the prefix **fe80::/10**.

#### *Verifying That Neighbor Discovery Inspection Is Working Correctly on the Switch*

**Purpose** Verify that Neighbor Discovery inspection is working on the switch.

**Action** Send Neighbor Discovery packets from network devices connected to the switch.

Display the Neighbor Discovery information:

```
user@switch> show dhcp-security nd-inspection statistics
```

ND inspection statistics:

| Interface  | ND Packets received | ND inspection pass | ND inspection failed |
|------------|---------------------|--------------------|----------------------|
| ge-0/0/1.0 | 7                   | 5                  | 2                    |
| ge-0/0/2.0 | 10                  | 10                 | 0                    |
| ge-0/0/3.0 | 12                  | 12                 | 0                    |

**Meaning** The sample output shows the number of Neighbor Discovery packets received and inspected per interface, with a list of how many packets passed and how many failed the inspection on each interface. The switch compares the Neighbor Discovery requests and replies against the entries in the DHCPv6 snooping database. If a MAC address or IPv6 address in the Neighbor Discovery packet does not match a valid entry in the database, the packet is dropped.

## Configuring Port Security (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring Port Security (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 3.

Ethernet LANs are vulnerable to attacks such as address spoofing and Layer 2 denial of service (DoS) on network devices. DHCP port security features help protect the access

ports on the switch against the loss of information and productivity that can result from such attacks.

The following port security features are supported for DHCPv4:

- DHCP snooping
- DAI (dynamic ARP inspection)
- IP source guard
- DHCP option 82

The following port security features are supported for DHCPv6:

- DHCPv6 snooping
- Neighbor Discovery inspection
- IPv6 source guard
- DHCPv6 option 37

DHCP snooping for DHCPv4 and DHCPv6 is disabled in the default configuration. There is no explicit configuration for enabling DHCP snooping. If you configure any other port security features for a VLAN at the **[edit vlans *vlan-name* forwarding-options dhcp-security]** hierarchy level, then DHCP snooping and DHCPv6 snooping are automatically enabled on that VLAN.

DAI, Neighbor Discovery inspection, IP source guard and IPv6 source guard, and DHCP option 82 are configured per VLAN. You must configure a VLAN before configuring these DHCP port security features. See [“Configuring VLANs for EX Series Switches \(CLI Procedure\)” on page 2337](#).

The DHCP port security features that you specify for the VLAN apply to all the interfaces included within that VLAN. However, you can create a specific group of access interfaces within the VLAN to have different attributes, such as:

- Specifying an interface to have a static IP-MAC address (**static-ip** or **static-ipv6**)
- Specifying an access interface to act as a trusted interface to a DHCP server (**trusted**)
- Specifying an interface not to transmit DHCP Relay Option (**no-option-82** or **no-option37**)

NOTE:

- If you configure any of these DHCP port security features—including configuring a group of access interfaces—for a specific VLAN, the switch automatically enables DHCP snooping for that VLAN.

NOTE: Trunk interfaces are trusted by default. However, on an EX9200 switch, you can override this default behavior and set a trunk interface as **untrusted**.

---

For additional details, see:

- [Enabling Dynamic ARP Inspection \(CLI Procedure\) on page 4572](#)
- [Enabling IPv6 Neighbor Discovery Inspection on page 4547](#)
- [Configuring IP Source Guard \(CLI Procedure\) on page 4546](#)
- [Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server \(CLI Procedure\) on page 4577](#)

You can override the general port security settings for the VLAN by configuring a group of access interfaces within that VLAN. For details, see:

- [Configuring Static IP Addresses for DHCP and DHCPv6 Bindings on Access Ports \(CLI Procedure\) on page 4571](#)
- [Enabling a Trusted DHCP Server \(CLI Procedure\) on page 4573](#)

- [Understanding DHCP Snooping for Port Security](#)

## Configuring Port Security (J-Web Procedure)

**NOTE:** This topic applies only to the J-Web Application package.

To configure port security on an EX Series switch using the J-Web interface:

1. Select **Configure > Security > Port Security**.

The VLAN List table lists all the VLAN names, VLAN identifiers, port members, and port security VLAN features.

The Interface List table lists all the ports and indicates whether security features have been enabled on the ports.

**NOTE:** After you make changes to the configuration on this page, you must commit the changes for them to take effect. To commit all changes to the active configuration, select **Commit Options > Commit**. See [Using the Commit Options to Commit Configuration Changes](#) for details about all commit options.

2. Click one of the following options:

- **Edit**—Click this option to modify the security features for the selected port or VLAN.

Enter information as specified in [Table 498 on page 4542](#) to modify port security settings on VLANs.

Enter information as specified in [Table 499 on page 4544](#) to modify port security settings on interfaces.

- **Activate/Deactivate**—Click this option to enable or disable security on the switch.

**NOTE:** This option is not supported on EX4300 switches.

- **Delete**—Click this option to delete the security features of the selected port or VLAN.

**NOTE:** This option is supported only on EX4300 switches.

**Table 498: Port Security Settings on VLANs**

| Field                                                                                                                                                                              | Function                                                                                                                                                                                                                                                          | Your Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Enable DHCP Snooping on VLAN<br><br><b>NOTE:</b> On EX4300 switches, DHCP snooping is enabled implicitly for all VLANs if you configure <b>dhcp-security</b> on one or more VLANs. | Allows the switch to monitor and control DHCP messages received from untrusted devices connected to the switch. Builds and maintains a database of valid IP addresses/MAC address bindings. (By default, access ports are untrusted and trunk ports are trusted.) | Select to enable DHCP snooping on a specified VLAN or all VLANs.<br><br><b>TIP:</b> For private VLANs (P-VLANs), enable DHCP snooping on the primary VLAN. If you enable DHCP snooping only on a community VLAN, DHCP messages coming from P-VLAN trunk ports are not snooped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Enable ARP Inspection on VLAN                                                                                                                                                      | Uses information in the DHCP snooping database to validate ARP packets on the LAN and protect against ARP cache poisoning.                                                                                                                                        | Select to enable ARP inspection on a specified VLAN or all VLANs. (Configure any port on which you do not want ARP inspection to occur as a trusted DHCP server port.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| MAC movement                                                                                                                                                                       | Number of MAC movements allowed on the given VLAN.                                                                                                                                                                                                                | Enter a number. The default is unlimited.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| MAC movement action                                                                                                                                                                | Specifies the action to be taken if the MAC movement limit is exceeded.                                                                                                                                                                                           | Select one of the following options: <ul style="list-style-type: none"> <li>• <b>log</b>—Generate a system log entry, an SNMP trap, or an alarm.</li> <li>• <b>drop</b>—Drop the packets and generate a system log entry, an SNMP trap, or an alarm (default).</li> <li>• <b>shutdown</b>—Shut down the VLAN and generate an alarm. You can mitigate the effect of this option by configuring autorecovery from the disabled state and specifying a <b>disable timeout</b> value. See <i>Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces (CLI Procedure)</i>.</li> <li>• <b>none</b>—Take no action.</li> </ul> EX4300 switches have an additional option: <ul style="list-style-type: none"> <li>• <b>drop-and-log</b>—Drop the packet and generate an alarm, an SNMP trap, or a system log entry.</li> </ul> |
| DHCP Groups                                                                                                                                                                        |                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 498: Port Security Settings on VLANs (*continued*)

## Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces (CLI Procedure)

**NOTE:** This example uses Junos OS with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switching device is an EX Series switch and runs software that does not support ELS, see *Understanding Storm Control on EX Series Switches*. If your switching device is an EX Series switch and runs software that does support ELS, see [“Getting Started with Enhanced Layer 2 Software” on page 3](#).

An Ethernet switching access interface on a switching device might shut down or be disabled as a result of one of the following port-security or storm-control configurations:

- MAC limiting—(Not supported for MX Series routers) The **mac-limit** statement is configured with the **action-shutdown** statement.
- MAC move limiting—(Not supported on EX9200 switches or MX Series routers) The **mac-move-limit** statement is configured with the **action-shutdown** statement.
- Storm control—The **storm-control** statement is configured with the **action-shutdown** statement.

You can configure the switching device to automatically restore the disabled interfaces to service after a specified period of time. The specified time configured in the **recovery-timeout** statement applies to all the interfaces that have been disabled due to MAC limiting, MAC move limiting, or storm control errors.

**NOTE:** To enable autorecovery, specify the recovery timeout value for the interfaces to recover automatically. There is no default recovery timeout. If you do not specify a timeout value, you need to use the [clear ethernet-switching recovery-timeout](#) command for EX Series switches and the [clear bridge recovery-timeout](#) command for MX Series routers to clear the errors and restore the interfaces to service.

To specify the recovery timeout period for the interface:

- Set the **recovery-timeout** statement.

For EX Series switches:

```
[edit interfaces interface-name family unit 0 ethernet-switching]
user@switch# set recovery-timeout seconds
```

For MX Series routers:

```
[edit interfaces interface-name family unit 0 bridge]
user@switch# set recovery-timeout seconds
```

## Configuring IP Source Guard (CLI Procedure)

---

**NOTE:** This example uses Junos OS for MX Series routers and EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switching device runs software that does not support ELS, see [Configuring IP Source Guard \(CLI Procedure\)](#). For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 3](#).

---

**NOTE:** On EX9200 switches, IP source guard is not supported in an MC-LAG scenario.

---

You can use the IP source guard access port security feature on EX Series switches to mitigate the effects of source IP address spoofing and source MAC address spoofing. If IP source guard determines that a host connected to an access interface has sent a packet with an invalid source IP address or source MAC address in the packet header, then IP source guard ensures that the switch does not forward the packet—that is, the packet is discarded.

You configure the IP source guard feature on a specific VLAN. When you configure IP source guard on a VLAN, the switch automatically enables DHCP snooping on that VLAN.

IPv6 source guard is supported on switches with support for DHCPv6 snooping. On these switches, configuring IP source guard or IPv6 source guard on a VLAN automatically enables DHCP snooping and DHCPv6 snooping on that VLAN.

IP source guard and IPv6 source guard can be applied only to untrusted interfaces. Access interfaces are untrusted by default.

IP source guard and IPv6 source guard can be used together with 802.1X user authentication in single supplicant, single-secure supplicant, or multiple supplicant mode.

Before you can configure IP source guard or IPv6 source guard on a VLAN, you must configure the VLAN. See [“Configuring VLANs for EX Series Switches \(CLI Procedure\)” on page 2337](#).

To configure IP source guard on a specific VLAN by using the CLI:

```
[edit vlans vlan-name forwarding-options dhcp-security]
user@switch# set ip-source-guard
```

To configure IPv6 source guard on a specific VLAN by using the CLI:

```
[edit vlans vlan-name forwarding-options dhcp-security]
user@switch# set ipv6-source-guard
```

#### Related Documentation

- [Understanding IP Source Guard for Port Security on EX Series Switches on page 4514](#)

## Enabling IPv6 Neighbor Discovery Inspection

**NOTE:** This procedure uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch uses software that does not support ELS, see [Configuring Port Security \(CLI Procedure\)](#). For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 3](#).

IPv6 Neighbor Discovery inspection protects switches against IPv6 address spoofing. Neighbor Discovery inspection validates IPv6 packets carrying Neighbor Discovery messages against the DHCPv6 binding table. The source IP address and source MAC address of each packet are checked against the table, and if a valid match is not found, the packet is dropped.

Before you can enable Neighbor Discovery inspection on a VLAN, you must configure the VLAN. See [“Configuring VLANs for EX Series Switches \(CLI Procedure\)” on page 2337](#).

To enable Neighbor Discovery inspection on a VLAN:

```
[edit vlans vlan-name forwarding-options dhcp-security]
user@switch# set neighbor-discovery-inspection
```

**NOTE:** DHCPv6 snooping is enabled automatically when Neighbor Discovery inspection is configured. There is no explicit configuration required for DHCPv6 snooping.

## Configuring Media Access Control Security (MACsec)

Media Access Control Security (MACsec) is an industry-standard security technology that provides secure communication for almost all types of traffic on Ethernet links. MACsec provides point-to-point security on Ethernet links between directly-connected nodes and is capable of identifying and preventing most security threats, including denial of service, intrusion, man-in-the-middle, masquerading, passive wiretapping, and playback attacks. MACsec is standardized in IEEE 802.1AE.

You can configure MACsec to secure point-to-point Ethernet links connecting EX Series or QFX Series switches, or on Ethernet links connecting a switch to a host device such as a PC, phone, or server. Each point-to-point Ethernet link that you want to secure using MACsec must be configured independently. You can enable MACsec on switch-to-switch links using static secure association key (SAK) security mode or static connectivity association key (CAK) security mode. Both processes are provided in this document.

**BEST PRACTICE:** We recommend enabling MACsec using static CAK security mode on switch-to-switch links. Static CAK security mode ensures security by frequently refreshing to a new random secure association key (SAK) and by only sharing the SAK between the two devices on the MACsec-secured point-to-point link. Additionally, some optional MACsec features—replay protection, SCI tagging, and the ability to exclude traffic from MACsec—are only available for MACsec-secured switch-to-switch connections that are enabled using static CAK security mode.

The configuration steps for both processes are provided in this document.

### Acquiring and Downloading the Junos OS Software

---

MACsec was initially released on EX Series switches in Junos OS Release 13.2X50-D15. MACsec was released on EX4600 and QFX5100-24Q switches in Junos OS Release 14.1X53-D15. The switches on each end of a MACsec-secured switch-to-switch link must either both be using Junos OS Release 14.1X51-D10 or later, or must both be using an earlier version of Junos, in order to establish a MACsec-secured connection when using static CAK security mode.

You must download the controlled version of your Junos OS software to enable MACsec. MACsec software support is not available in the domestic version of your Junos OS software. The controlled version of Junos OS software includes all features and functionality available in the domestic version of Junos OS, while also supporting MACsec. The domestic version of Junos OS software is shipped on all EX Series and QFX Series switches, so you must download and install a controlled version of Junos OS software on your switch before you can enable MACsec.

You can identify whether a software package is the controlled or domestic version of Junos OS by viewing the package name. A software package for a controlled version of Junos OS is named using the following format:

***package-name-m.nZx.y-controlled-signed.tgz***

A software package for a domestic version of Junos OS is named using the following format:

***package-name-m.nZx.y-domestic-signed.tgz***

If you are unsure which version of Junos OS is running on your switch, enter the **show version** command. If the “JUNOS Crypto Software Suite” description appears in the output, you are running the controlled version of Junos OS.

The controlled version of Junos OS software contains encryption and is, therefore, not available to customers in all geographies. The export and re-export of the controlled version of Junos OS software is strictly controlled under United States export laws. The export, import, and use of the controlled version of Junos OS software is also subject to controls imposed under the laws of other countries. If you have questions about acquiring the controlled version of your Junos OS software, contact Juniper Networks Trade Compliance group at [compliance\\_helpdesk@juniper.net](mailto:compliance_helpdesk@juniper.net).

The process for installing the controlled version of Junos OS software on your switch is identical to installing the domestic version of Junos OS software. You must enter the **request system software add** statement to download the Junos OS image, and the **request system reboot** statement to reboot the switch to complete the upgrade procedure. See *Downloading Software Packages from Juniper Networks, Installing Software on an EX Series Switch with a Single Routing Engine (CLI Procedure)*, and *Installing Software on an EX Series Switch with Redundant Routing Engines (CLI Procedure)* for detailed information about acquiring and installing Junos OS software images for your switches.

### Acquiring and Downloading the MACsec Feature License

A feature license is required to configure MACsec on an EX Series or a QFX Series switch.

The MACsec feature license is an independent feature license; the enhanced feature licenses (EFLs) or advanced feature licenses (AFLs) that must be purchased to enable some features on EX Series or QFX Series switches cannot be purchased to enable MACsec.

To purchase a software license for MACsec, contact your Juniper Networks sales representative (<http://www.juniper.net/us/en/contact-us/sales-offices>). The Juniper sales representative will provide you with a feature license file and a license key. You will be

asked to supply the chassis serial number of your switch; you can obtain the serial number by running the **show chassis hardware** command.

For a Virtual Chassis deployment, two MACsec license keys are recommended for redundancy—one for the device in the master role and the other for the device in the backup role

To add one or more new MACsec license keys on the switch, follow this procedure:

1. Add the license key or keys:
  - To add one or more license keys from a file or URL, specify the filename of the file or the URL where the key is located:

```
user@switch> request system license add filename |url
```

- To add a license key from the terminal:

```
user@switch> request system license add terminal
```

2. When prompted, enter the license key, separating multiple license keys with a blank line.

If the license key you enter is invalid, an error appears in the CLI output when you press Ctrl+d to exit the license entry mode.

A MACsec feature license is installed and maintained like any other switch license. See [“Managing Licenses for the EX Series Switch \(CLI Procedure\)” on page 714](#) or *Adding New Licenses (CLI Procedure)* for more detailed information on configuring and managing your MACsec software license.

### Configuring the PIC Mode of the MACsec-capable Interfaces (EX4200 switches only)

---

To configure MACsec on an EX4200 switch, you must install the SFP+ MACsec uplink module. The interfaces on the SFP+ MACsec uplink module are the only MACsec-capable interfaces available for EX4200 switches. All four ports on the uplink module are MACsec-capable.

The SFP+ MACsec uplink module provides two ports for 10-gigabit small form-factor pluggable (SFP+) transceivers when configured to operate in 10-gigabit mode or four ports for 1-gigabit small form-factor pluggable (SFP) transceivers when configured to operate in 1-gigabit mode.

The PIC mode is set to **10g**, by default. You only need to perform this procedure if you want to operate your uplink in 1-gigabit mode, or if you previously set the uplink module to 1-gigabit mode and would like to return it to 10-gigabit mode.

To configure the PIC mode:

```
[edit chassis]
```

```
user@switch# set fpc fpc-slot-number pic 1 sfpplus pic-mode (1g | 10g)
```

where *fpc-slot-number* is the FPC slot number, *pic-slot-number* is the PIC slot number, and the **[1g | 10g]** option configures the MACsec capability of the four SFP+ ports on the MACsec uplink module.

The **fpc-slot-number** is always 0 on standalone EX4200 switches, and is the member ID of the member switch in an EX4200 Virtual Chassis.

The PIC slot number is always 1 for the uplink module port slot on an EX4200 switch, so **pic 1** is always the specified PIC slot number.

The PIC mode is set to **10g** by default. When the PIC mode is set to **10g**, uplink ports 0 and 2 on the MACsec uplink module support MACsec at 10-Gbps speeds. Ports 1 and 3 cannot be used to send any traffic.

When the PIC mode is set to **1g**, all four SFP+ ports on the MACsec uplink module support MACsec at 1-Gbps speeds.

### Configuring MACsec Using Static Connectivity Association Key Security Mode (Recommended for Enabling MACsec on Switch-to-Switch Links)

---

You can enable MACsec using static connectivity association key (CAK) security mode or static secure association keys (SAK) security mode on a point-to-point Ethernet link connecting switches. This procedure shows you how to configure MACsec using static CAK security mode.

**BEST PRACTICE:** We recommend enabling MACsec using static CAK security mode on switch-to-switch links. Static CAK security mode ensures security by frequently refreshing to a new random secure association key (SAK) and by only sharing the SAK between the two devices on the MACsec-secured point-to-point link. Additionally, some optional MACsec features—replay protection, SCI tagging, and the ability to exclude traffic from MACsec—are only available for MACsec-secured switch-to-switch connections that are enabled using static CAK security mode.

When you enable MACsec using static CAK security mode, a pre-shared key is exchanged between the switches on each end of the point-to-point Ethernet link. The pre-shared key includes a connectivity association name (CKN) and a connectivity association key (CAK). The CKN and CAK are configured by the user in the connectivity association and must match on both ends of the link to initially enable MACsec.

After the pre-shared keys are exchanged and verified, the MACsec Key Agreement (MKA) protocol, which enables and maintains MACsec on the link, is enabled. The MKA is responsible for selecting one of the two switches on the point-to-point link as the key server. The key server then creates a randomized security key that is shared only with the other device over the MACsec-secured link. The randomized security key enables and maintains MACsec on the point-to-point link. The key server will continue to periodically create and share a randomly-created security key over the point-to-point link for as long as MACsec is enabled.

You enable MACsec using static CAK security mode by configuring a connectivity association on both ends of the link. All configuration is done within the connectivity association but outside of the secure channel. Two secure channels—one for inbound traffic and one for outbound traffic—are automatically created when using static CAK security mode. The automatically-created secure channels do not have any user-configurable parameters that cannot already be configured in the connectivity association.

To configure MACsec using static CAK security mode to secure a switch-to-switch Ethernet link:

1. Create a connectivity association. You can skip this step if you are configuring an existing connectivity association.

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name
```

For instance, to create a connectivity association named **ca1**, enter:

```
[edit security macsec]
user@switch# set connectivity-association ca1
```

2. Configure the MACsec security mode as **static-cak** for the connectivity association:

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name security-mode
static-cak
```

For instance, to configure the MACsec security mode to **static-cak** on connectivity association **ca1**:

```
[edit security macsec]
user@switch# set connectivity-association ca1 security-mode static-cak
```

3. Create the pre-shared key by configuring the connectivity association key name (CKN) and connectivity association key (CAK):

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name pre-shared-key
ckn hexadecimal-number
user@switch# set connectivity-association connectivity-association-name pre-shared-key
cak hexadecimal-number
```

A pre-shared key is exchanged between directly-connected links to establish a MACsec-secure link. The pre-shared-key includes the CKN and the CAK. The CKN is a 64-digit hexadecimal number and the CAK is a 32-digit hexadecimal number. The CKN and the CAK must match on both ends of a link to create a MACsec-secured link.

**NOTE:** To maximize security, we recommend configuring all 64 digits of a CKN and all 32 digits of a CAK.

If you do not configure all 64 digits of a CKN or all 32 digits of a CAK, however, all remaining digits will be auto-configured to 0.

After the pre-shared keys are successfully exchanged and verified by both ends of the link, the MACsec Key Agreement (MKA) protocol is enabled and manages the secure link. The MKA protocol then elects one of the two directly-connected switches as the key server. The key server then shares a random security with the other device over the MACsec-secure point-to-point link. The key server will continue to periodically create and share a random security key with the other device over the MACsec-secured point-to-point link as long as MACsec is enabled.

To configure a CKN of **37c9c2c45ddd012aa5bc8ef284aa23ff6729ee2e4acb66e91fe34ba2cd9fe311** and CAK of **228ef255aa23ff6729ee664acb66e91f** on connectivity association **ca1**:

```
[edit security macsec]
user@switch# set connectivity-association ca1 pre-shared-key ckn
37c9c2c45ddd012aa5bc8ef284aa23ff6729ee2e4acb66e91fe34ba2cd9fe311
user@switch# set connectivity-association ca1 pre-shared-key cak
228ef255aa23ff6729ee664acb66e91f
```

**NOTE:** MACsec is not enabled until a connectivity association is attached to an interface. See the final step of this procedure to attach a connectivity association to an interface.

4. (Required on switches when connecting to EX4300 switches only) Enable SCI tagging:

```
[edit security macsec connectivity-association connectivity-association-name]  
user@switch# set include-sci
```

You must enable SCI tagging on a switch that is enabling MACsec on an Ethernet link connecting to an EX4300 switch.

SCI tags are automatically appended to packets leaving a MACsec-enabled interface on an EX4300 switch. This option is, therefore, not available on EX4300 switches.

You should only use this option when enabling MACsec on a link to an EX4300 switch. SCI tags are eight octets long, so appending an SCI tag to all traffic on the link adds a significant amount of unneeded overhead.

5. (Optional) Set the MKA key server priority:

```
[edit security macsec connectivity-association connectivity-association-name]  
user@switch# set mka key-server-priority priority-number
```

Specifies the key server priority used by the MKA protocol to select the key server. The switch with the lower *priority-number* is selected as the key server.

The default *priority-number* is 16.

If the **key-server-priority** is identical on both sides of the point-to-point link, the MKA protocol selects the interface with the lower MAC address as the key server. Therefore, if this statement is not configured in the connectivity associations at each end of a MACsec-secured point-to-point link, the interface with the lower MAC address becomes the key server.

To change the key server priority to 0 to increase the likelihood that the current device is selected as the key server when MACsec is enabled on the interface using connectivity association **ca1**:

```
[edit security macsec connectivity-association ca1]  
user@switch# set mka key-server-priority 0
```

To change the key server priority to 255 to decrease the likelihood that the current device is selected as the key server in connectivity association **ca1**:

```
[edit security macsec connectivity-association ca1]  
user@switch# set mka key-server-priority 255
```

6. (Optional) Set the MKA transmit interval:

```
[edit security macsec connectivity-association connectivity-association-name]  
user@switch# set mka transmit-interval interval
```

The MKA transmit interval setting sets the frequency for how often the MKA protocol data unit (PDU) is sent to the directly connected device to maintain MACsec connectivity on the link. A lower *interval* increases bandwidth overhead on the link; a higher *interval* optimizes MKA protocol communication.

The default *interval* is 2000ms. We recommend increasing the interval to 6000 ms in high-traffic load environments. The transmit interval settings must be identical on both ends of the link when MACsec using static CAK security mode is enabled.

For instance, if you wanted to increase the MKA transmit interval to 6000 milliseconds when connectivity association *ca1* is attached to an interface:

```
[edit security macsec connectivity-association ca1]
user@switch# set mka transmit-interval 6000
```

7. (Optional) Disable MACsec encryption:

```
[edit security macsec connectivity-association connectivity-association-name]
user@switch# set no-encryption
```

Encryption is enabled for all traffic entering or leaving the interface when MACsec is enabled using static CAK security mode, by default.

When encryption is disabled, traffic is forwarded across the Ethernet link in clear text. You are able to view unencrypted data in the Ethernet frame traversing the link when you are monitoring it. The MACsec header is still applied to the frame, however, and all MACsec data integrity checks are run on both ends of the link to ensure the traffic sent or received on the link has not been tampered with and does not represent a security threat.

8. (Optional) Set an offset for all packets traversing the link:

```
[edit security macsec connectivity-association connectivity-association-name]
user@switch# set offset (0 | 30 | 50)
```

For instance, if you wanted to set the offset to 30 in the connectivity association named *ca1*:

```
[edit security macsec connectivity-association ca1]
user@switch# set offset 30
```

The default offset is 0. All traffic in the connectivity association is encrypted when encryption is enabled and an **offset** is not set.

When the offset is set to 30, the IPv4 header and the TCP/UDP header are unencrypted while encrypting the rest of the traffic. When the offset is set to 50, the IPv6 header and the TCP/UDP header are unencrypted while encrypting the rest of the traffic.

You would typically forward traffic with the first 30 or 50 octets unencrypted if a feature needed to see the data in the octets to perform a function, but you otherwise prefer to encrypt the remaining data in the frames traversing the link. Load balancing features, in particular, typically need to see the IP and TCP/UDP headers in the first 30 or 50 octets to properly load balance traffic.

9. (Optional) Enable replay protection.

```
[edit security macsec connectivity-association connectivity-association-name]
user@switch# set replay-protect replay-window-size number-of-packets
```

When MACsec is enabled on a link, an ID number is assigned to each packet on the MACsec-secured link.

When replay protection is enabled, the receiving interface checks the ID number of all packets that have traversed the MACsec-secured link. If a packet arrives out of sequence and the difference between the packet numbers exceeds the replay protection window size, the packet is dropped by the receiving interface. For instance,

if the replay protection window size is set to five and a packet assigned the ID of 1006 arrives on the receiving link immediately after the packet assigned the ID of 1000, the packet that is assigned the ID of 1006 is dropped because it falls outside the parameters of the replay protection window.

Replay protection is especially useful for fighting man-in-the-middle attacks. A packet that is replayed by a man-in-the-middle attacker on the Ethernet link will arrive on the receiving link out of sequence, so replay protection helps ensure the replayed packet is dropped instead of forwarded through the network.

Replay protection should not be enabled in cases where packets are expected to arrive out of order.

You can require that all packets arrive in order by setting the replay window size to 0.

To enable replay protection with a window size of five on connectivity association **ca1**:

```
[edit security macsec connectivity-association ca1]
user@switch# set replay-protect replay-window-size 5
```

10. (Optional) Exclude a protocol from MACsec:

```
[edit security macsec connectivity-association connectivity-association-name]
user@switch# set exclude-protocol protocol-name
```

For instance, if you did not want Link Level Discovery Protocol (LLDP) to be secured using MACsec:

```
[edit security macsec connectivity-association connectivity-association-name]
user@switch# set exclude-protocol lldp
```

When this option is enabled, MACsec is disabled for all packets of the specified protocol—in this case, LLDP—that are sent or received on the link.

11. Assign the connectivity association to an interface:

```
[edit security macsec]
user@switch# set interfaces interface-names connectivity-association
connectivity-association-name
```

Assigning the connectivity association to an interface is the final configuration step to enabling MACsec on an interface.

For instance, to assign connectivity association **ca1** to interface **xe-0/0/1**:

```
[edit security macsec]
user@switch# set interfaces xe-0/1/0 connectivity-association ca1
```

MACsec using static CAK security mode is not enabled until a connectivity association on the opposite end of the link is also configured, and contains pre-shared keys that match on both ends of the link.

---

### Configuring MACsec on the Switch Using Dynamic Secure Association Key Security Mode to Secure a Switch-to-Host Link

---

Before you begin to enable MACsec on a switch-to-host link:

- Configure a RADIUS server. The RADIUS server:
  - must be configured as the user database for 802.1X authentication.
  - must be using the Extensible Authentication Protocol-Transport Layer Security (EAP-TLS) authentication framework.

- must have connectivity to the switch and to the host. The RADIUS server can be multiple hops from the switch or the host.

See [“Example: Connecting a RADIUS Server for 802.1X to an EX Series Switch” on page 1843](#).

- Enable MACsec on the host device.

The procedures for enabling MACsec on the host device varies by host device, and is beyond the scope of this document.

To configure MACsec using dynamic security mode to secure a switch-to-host Ethernet link:

1. Create a connectivity association. You can skip this step if you are configuring an existing connectivity association.

```
[edit security macsec]
```

```
user@switch# set connectivity-association connectivity-association-name
```

For instance, to create a connectivity association named `ca-dynamic1`, enter:

```
[edit security macsec]
```

```
user@switch# set connectivity-association ca-dynamic1
```

2. Configure the MACsec security mode as dynamic for the connectivity association:

```
[edit security macsec]
```

```
user@switch# set connectivity-association connectivity-association-name security-mode dynamic
```

For instance, to configure the MACsec security mode to dynamic on connectivity association `ca-dynamic1`:

```
[edit security macsec]
```

```
user@switch# set connectivity-association ca-dynamic1 security-mode dynamic
```

3. (Optional) Configure the **must-secure** option:

```
[edit security macsec]
```

```
user@switch# set connectivity-association connectivity-association-name mka must-secure
```

When the **must-secure** option is enabled, all traffic that is not MACsec-secured that is received on the interface is dropped.

When the **must-secure** option is disabled, all traffic from devices that support MACsec is MACsec-secured while traffic received from devices that do not support MACsec is forwarded through the network.

The **must-secure** option is particularly useful in scenarios where multiple devices, such as a phone and a PC, are accessing the network through the same Ethernet interface. If one of the devices supports MACsec while the other device does not support MACsec, the device that doesn't support MACsec can continue to send and receive traffic over the network—provided the **must-secure** option is disabled—while traffic to and from the device that supports MACsec is MACsec-secured. In this scenario, traffic to the device that is not MACsec-secured must be VLAN-tagged.

The **must-secure** option is disabled, by default.

4. (Required only if the host device requires SCI tagging) Enable SCI tagging:

```
[edit security macsec connectivity-association connectivity-association-name]
```

```
user@switch# set include-sci
```

You should only use this option when connecting a switch to a host that requires SCI tags. SCI tags are eight octets long, so appending an SCI tag to all traffic on the link adds a significant amount of unneeded overhead.

5. (Optional) Set the MKA key server priority:

```
[edit security macsec connectivity-association connectivity-association-name]  
user@switch# set mka key-server-priority priority-number
```

Specifies the key server priority used by the MKA protocol to select the key server. The switch with the lower *priority-number* is selected as the key server.

The default *priority-number* is 16. If the **key-server-priority** is identical on both sides of the point-to-point link, the MKA protocol selects the interface with the lower MAC address as the key server. Therefore, if this statement is not configured in the connectivity associations at each end of a MACsec-secured point-to-point link, the interface with the lower MAC address becomes the key server.

To change the key server priority to 0 to increase the likelihood that the current device is selected as the key server when MACsec is enabled on the interface using connectivity association *ca1*:

```
[edit security macsec connectivity-association ca-dynamic1]  
user@switch# set mka key-server-priority 0
```

To change the key server priority to 255 to decrease the likelihood that the current device is selected as the key server in connectivity association *ca-dynamic1*:

```
[edit security macsec connectivity-association ca-dynamic1]  
user@switch# set mka key-server-priority 255
```

6. (Optional) Set the MKA transmit interval:

```
[edit security macsec connectivity-association connectivity-association-name]  
user@switch# set mka transmit-interval interval
```

The MKA transmit interval setting sets the frequency for how often the MKA protocol data unit (PDU) is sent to the directly connected device to maintain MACsec connectivity on the link. A lower interval increases bandwidth overhead on the link; a higher interval optimizes MKA protocol communication.

The default interval is 2000ms. We recommend increasing the interval to 6000 ms in high-traffic load environments. The transmit interval settings must be identical on both ends of the link.

For instance, if you wanted to increase the MKA transmit interval to 6000 milliseconds when connectivity association *ca-dynamic1* is attached to an interface:

```
[edit security macsec connectivity-association ca-dynamic1]  
user@switch# set mka transmit-interval 6000
```

7. (Optional) Disable MACsec encryption:

```
[edit security macsec connectivity-association connectivity-association-name]  
user@switch# set no-encryption
```

Encryption is enabled for all traffic entering or leaving the interface when MACsec is enabled using dynamic security mode, by default. When encryption is disabled, traffic is forwarded across the Ethernet link in clear text. You are able to view unencrypted data in the Ethernet frame traversing the link when you are monitoring it. The MACsec header is still applied to the frame, however, and all MACsec data integrity checks are

run on both ends of the link to ensure the traffic sent or received on the link has not been tampered with and does not represent a security threat.

8. (Optional) Set an offset for all packets traversing the link:

```
[edit security macsec connectivity-association connectivity-association-name]
user@switch# set offset (0 | 30 | 50)
```

For instance, if you wanted to set the offset to 30 in the connectivity association named ca-dynamic1:

```
[edit security macsec connectivity-association ca-dynamic1]
user@switch# set offset 30
```

The default offset is 0. All traffic in the connectivity association is encrypted when encryption is enabled and an offset is not set.

When the offset is set to 30, the IPv4 header and the TCP/UDP header are unencrypted while encrypting the rest of the traffic. When the offset is set to 50, the IPv6 header and the TCP/UDP header are unencrypted while encrypting the rest of the traffic.

You would typically forward traffic with the first 30 or 50 octets unencrypted if a feature needed to see the data in the octets to perform a function, but you otherwise prefer to encrypt the remaining data in the frames traversing the link. Load balancing features, in particular, typically need to see the IP and TCP/UDP headers in the first 30 or 50 octets to properly load balance traffic.

9. (Optional) Enable replay protection.

```
[edit security macsec connectivity-association connectivity-association-name]
user@switch# set replay-protect replay-window-size number-of-packets
```

When MACsec is enabled on a link, an ID number is assigned to each packet on the MACsec-secured link. When replay protection is enabled, the receiving interface checks the ID number of all packets that have traversed the MACsec-secured link. If a packet arrives out of sequence and the difference between the packet numbers exceeds the replay protection window size, the packet is dropped by the receiving interface. For instance, if the replay protection window size is set to five and a packet assigned the ID of 1006 arrives on the receiving link immediately after the packet assigned the ID of 1000, the packet that is assigned the ID of 1006 is dropped because it falls outside the parameters of the replay protection window.

Replay protection is especially useful for fighting man-in-the-middle attacks. A packet that is replayed by a man-in-the-middle attacker on the Ethernet link will arrive on the receiving link out of sequence, so replay protection helps ensure the replayed packet is dropped instead of forwarded through the network.

Replay protection should not be enabled in cases where packets are expected to arrive out of order.

You can require that all packets arrive in order by setting the replay window size to 0.

To enable replay protection with a window size of five on connectivity association ca-dynamic1:

```
[edit security macsec connectivity-association ca-dynamic1]
user@switch# set replay-protect replay-window-size 5
```

10. (Optional) Exclude a protocol from MACsec:

```
[edit security macsec connectivity-association connectivity-association-name]
```

```
user@switch# set exclude-protocol protocol-name
```

For instance, if you did not want Link Level Discovery Protocol (LLDP) to be secured using MACsec:

```
[edit security macsec connectivity-association ca-dynamic1]
user@switch# set exclude-protocol lldp
```

When this option is enabled, MACsec is disabled for all packets of the specified protocol—in this case, LLDP—that are sent or received on the link.

11. Assign the connectivity association to an interface:

```
[edit security macsec]
user@switch# set interfaces interface-names connectivity-association
connectivity-association-name
```

Assigning the connectivity association to an interface is the final configuration step to enabling MACsec on an interface. For instance, to assign connectivity association `ca-dynamic1` to interface `xe-0/0/1`:

```
[edit security macsec]
user@switch# set interfaces xe-0/1/0 connectivity-association ca-dynamic1
```

### Configuring MACsec Using Static Secure Association Key Security Mode to Secure a Switch-to-Switch Link

---

When you enable MACsec using static secure association key (SAK) security mode, one of up to two manually configured security keys is used to secure the point-to-point Ethernet link between the switches. All security key names and values are configured by the user; there is no key server or other tool that creates security keys. Security is maintained on the point-to-point Ethernet link by periodically rotating the security keys. Each security key name and value must have a corresponding matching value on the interface at the other end of the point-to-point Ethernet link to maintain MACsec on the link.

You configure static SAKs within secure channels when you are enabling MACsec using static SAK security mode. You configure secure channels within connectivity associations. A typical connectivity association for MACsec using static SAK security mode contains two secure channels—one for inbound traffic and one for outbound traffic—that have each been configured with two static SAKs. You must attach the connectivity association with the secure channel configurations to an interface to enable MACsec using static SAK security mode.

To configure MACsec on a switch-to-switch Ethernet link using static SAK security mode:

1. Create a connectivity association. You can skip this step if you are configuring an existing connectivity association.

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name
```

For instance, to create a connectivity association named `ca1`, enter:

```
[edit security macsec]
user@switch# set connectivity-association ca1
```

2. Configure the MACsec security mode as **static-sak** for the connectivity association:

```
[edit security macsec]
```

```
user@switch# set connectivity-association connectivity-association-name security-mode
static-sak
```

For instance, to configure the MACsec security mode to **static-sak** on connectivity association **ca1**:

```
[edit security macsec]
user@switch# set connectivity-association ca1 security-mode static-sak
```

3. Create a secure channel within the connectivity association. You can skip this step if you are configuring an existing secure channel.

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name secure-channel
secure-channel-name
```

For instance, to create secure channel **sc1** in connectivity association **ca1**, enter:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc1
```

4. Define the security associations and the static SAKs for the secure channel:

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name secure-channel
secure-channel-name security-association number key key-string
```

where the **security-association number** is a number between 0 and 3, and the **key-string** is a 32-digit key defined statically by the network administrator.

The key string is a 32-digit hexadecimal number. The key string and the security association must match on both sides of an Ethernet connection to secure traffic using MACsec.

A secure channel must have at least two security associations with unique key strings. MACsec uses a security associations to establish a secure communications link, and periodically rotates to a new security association to keep the link secure. MACsec, therefore, must have at least one backup security association and key at all times.

To create one secure channel with two security associations and keys, for example:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc1 security-association 0 key
d183c4002fa6fe3d2d9a852c20ab8412
user@switch# set connectivity-association ca1 secure-channel sc1 security-association 1 key
b976c7494ab6fe2f2d4c432a90fd90a8
```

5. Specify whether the secure channel should be applied to traffic entering or leaving the switch:

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name secure-channel
secure-channel-name direction [inbound | outbound]
```

where **inbound** applies the secure channel to traffic entering the switch, and **outbound** applies the secure channel to traffic leaving the switch.

**NOTE:** A secure channel can only be applied to traffic entering (inbound) or leaving (outbound) an interface on the switch.

If you need to configure MACsec using SAKs on inbound and outbound traffic on the same interface, you must configure a connectivity association with one secure channel for inbound traffic and a second secure channel for outbound traffic. The connectivity association is assigned to an interface later in this process.

For instance, to configure secure channel **sc1** to apply MACsec to incoming traffic:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc1 direction inbound
```

To configure secure channel **sc2** to apply MACsec to outgoing traffic:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc2 direction outbound
```

6. Specify a MAC address:

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name secure-channel
secure-channel-name id mac-address mac-address
```

If you are configuring a MAC address on a secure channel in the outbound direction, you should specify the MAC address of the interface as the **mac-address**.

If you are configuring a MAC address on a secure channel in the inbound direction, you should specify the MAC address of the interface at the other end of the link as the **mac-address**.

The **mac-address** variables must match on the sending and receiving secure channel on each side of a link to enable MACsec using static SAK security mode.

**NOTE:** You can see the MAC address of an interface in the **show interfaces** output.

To configure MACsec to accept frames from MAC address **12:34:56:ab:cd:ef** on secure channel **sc1**:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc1 id mac-address
12:34:56:ab:cd:ef
```

7. Specify a port:

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name secure-channel
secure-channel-name id port-id port-id-number
```

The **port-id-number** variables must match on a sending and receiving secure channel on each side of a link to enable MACsec.

**NOTE:** The only requirement for port numbers in this implementation of MACsec is that they match on the sending and receiving ends of an Ethernet link. When the port numbers match, MACsec is enabled for all traffic on the connection.

To specify port ID 4 on secure channel **sc1**:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc1 id port-id 4
```

8. (Optional) Enable encryption:

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name secure-channel
secure-channel-name encryption
```

You can enable MACsec without enabling encryption. If a secure channel is configured on an interface without encryption, traffic is forwarded across the Ethernet link in clear text, and you will be able to view unencrypted data in the Ethernet frame traversing the link when you are monitoring it. The MACsec header is still applied to the frame, however, and all MACsec data integrity checks are run on both ends of the link to ensure the traffic on the link does not represent a security threat.

Encryption is disabled by default when you are enabling MACsec using static SAK security mode. To ensure all traffic traversing secure-channel **sc1** is encrypted:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc1 encryption
```

9. (Optional) Set an offset to send the first 30 or 50 octets in unencrypted plain text when encryption is enabled.

```
[edit security macsec]
user@switch# set connectivity-association connectivity-association-name secure-channel
secure-channel-name offset [0 | 30 | 50]
```

When the offset is set to 30, the IPv4 header and the TCP/UDP header are unencrypted while encrypting the rest of the traffic. When the offset is set to 50, the IPv6 header and the TCP/UDP header are unencrypted while encrypting the rest of the traffic.

You would typically forward traffic with the first 30 or 50 octets unencrypted if a feature needed to see the data in the octets to perform a function, but you otherwise prefer to encrypt the remaining data in the frames traversing the link. Load balancing features, in particular, typically need to see the IP and TCP/UDP headers in the first 30 or 50 octets to properly load balance traffic.

The default offset is 0, so all traffic on the link is encrypted when the **encryption** option is enabled and an **offset** is not set.

To change the offset to 30 for secure channel **sc1**:

```
[edit security macsec]
user@switch# set connectivity-association ca1 secure-channel sc1 offset 30
```

10. Assign the connectivity association to an interface:

```
[edit security macsec]
user@switch# set interfaces interface-names connectivity-association
connectivity-association-name
```

Assigning the connectivity association to an interface is the final configuration step to enabling MACsec on an interface.

For instance, to assign connectivity association `ca1` to interface `xe-0/0/1`:

```
[edit security macsec]
user@switch# set interfaces xe-0/1/0 connectivity-association ca1
```

MACsec using static SAK security mode is not enabled until a connectivity association on the opposite end of the link is also configured, and the configuration match on both ends of the link.

## Configuring MAC Limiting (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches and QFX3500 and QFX3600 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring MAC Limiting (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 3.

This topic describes various ways of configuring a limitation on MAC addresses in packets that are received and forwarded by the switch.

**NOTE:** On a QFX Series Virtual Chassis, if you include the `shutdown` option at the `[edit vlans vlan-name switch-options interface interface-name interface-mac-limit packet-action]` hierarchy level and issue the `commit` operation, the system generates a commit error. The system does not generate an error if you include the `shutdown` option at the `[edit switch-options interface interface-name interface-mac-limit packet-action]` hierarchy level.

The different ways of setting a MAC limit are described in the following sections:

- [Limiting the Number of MAC Addresses Learned by an Interface on page 4565](#)
- [Limiting the Number of MAC Addresses Learned by a VLAN on page 4565](#)

### Limiting the Number of MAC Addresses Learned by an Interface

To secure a port, you can set the maximum number of MAC addresses that can be learned by an interface:

- Set the MAC limit on an interface, and specify an action that the switch takes after the specified limit is exceeded:

```
[edit switch-options]
user@switch# set interface interface-name interface-mac-limit limit packet-action action
```

After you set a new MAC limit for the interface, the system clears existing entries in the MAC address forwarding table associated with the interface.

### Limiting the Number of MAC Addresses Learned by a VLAN

To limit the number of MAC addresses learned by a VLAN, perform both of the following steps:

- Set the maximum number of MAC addresses that can be learned by a VLAN, and specify an action that the switch takes after the specified limit is exceeded:

```
[edit vlans]
user@switch# set vlan-name switch-options mac-table-size limit packet-action action
```

- Set the maximum number of MAC addresses that can be learned by one or all interfaces in the VLAN, and specify an action that the switch takes after the specified limit is exceeded:

```
[edit vlans]
user@switch# set vlan-name switch-options interface interface-name
interface-mac-limit limit packet-action action
[edit vlans]
user@switch# set vlan-name switch-options interface-mac-limit limit packet-action action
```

**NOTE:** If you specify a MAC limit and packet action for all interfaces in the VLAN *and* a specific interface in the VLAN, the MAC limit and packet action specified at the specific interface level takes precedence. Also, at the VLAN interface level, only the drop and drop-and-log options are supported.

After you set new MAC limits for a VLAN by using the **mac-table-size** statement or for interfaces associated with a VLAN by using the **interface-mac-limit** statement, the system clears the corresponding existing entries in the MAC address forwarding table.

- [Configuring Persistent MAC Learning \(CLI Procedure\) on page 4569](#)

## Configuring MAC Limiting (J-Web Procedure)

MAC limiting protects against flooding of the Ethernet switching table on an EX Series switch. MAC limiting sets a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface (port).

Junos OS provides two MAC limiting methods:

- Maximum number of dynamic MAC addresses allowed per interface—If the limit is exceeded, incoming packets with new MAC addresses are dropped.
- Specific “allowed” MAC addresses for the access interface—Any MAC address that is not in the list of configured addresses is not learned.

You configure MAC limiting for each interface, not for each VLAN. You can specify the maximum number of dynamic MAC addresses that can be learned on a single Layer 2 access interface or on all Layer 2 access interfaces. The default action that the switch will take if that maximum number is exceeded is **drop**—drop the packet and generate an alarm, an SNMP trap, or a system log entry.

To enable MAC limiting on one or more interfaces using the J-Web interface:

1. Select **Configure>Security>Port Security**.
2. Select one or more interfaces from the **Interface List**.
3. Click the **Edit** button. If a message appears asking whether you want to enable port security, click **Yes**.
4. To set a dynamic MAC limit:
  1. Type a limit value in the **MAC Limit** box.
  2. Select an action from the **MAC Limit Action** box (optional). The switch takes this action when the MAC limit is exceeded. If you do not select an action, the switch applies the default action, **drop**.
    - Log—Generate a system log entry.
    - Drop—Drop the packets and generate a system log entry. (Default)
    - Shutdown—Shut down the VLAN and generate a system log entry. You can mitigate the effect of this option by configuring the switch for autorecovery from the disabled state and specifying a **disable timeout** value. See *Configuring Autorecovery From the Disabled State on Secure or Storm Control Interfaces (CLI Procedure)*. If you have not configured autorecovery from the disabled state, you can bring up the interfaces by running the **clear ethernet-switching port-error** command.
    - None— No action to be taken.
5. To add allowed MAC addresses:
  1. Click **Add**.
  2. Type the allowed MAC address and click **OK**.

Repeat this step to add more allowed MAC addresses.

6. Click **OK** when you have finished setting MAC limits.
7. Click **OK** after the configuration has been successfully delivered.

**NOTE:** You can enable or disable port security on the switch at any time by clicking the **Activate** or **Deactivate** button on the Port Security Configuration page. If security status is shown as **Disabled** when you try to edit settings for any VLANs or interfaces (ports), a message asking whether you want to enable port security appears.

- [Understanding MAC Limiting and MAC Move Limiting for Port Security on EX Series Switches on page 4518](#)

## Configuring MAC Move Limiting (CLI Procedure)

**NOTE:** This topic uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring MAC Move Limiting (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 3.

When MAC move limiting is configured, MAC address movements are tracked by the switch and, if a MAC address changes more than the configured number of times within one second, the changes to MAC addresses are dropped, logged or ignored, or the interface is shut down.

**NOTE:** Although you enable this feature on VLANs, the MAC move limitation pertains to the number of movements for each individual MAC address rather than the total number of MAC address moves in the VLAN. For example, if the MAC move limit is set to 1, the switch allows an unlimited number of MAC address movements within the VLAN as long as the same MAC address does not change more than once.

You configure MAC move limiting per VLAN, not per interface (port). In the default configuration, the number of MAC moves permitted is unlimited.

You can choose to have one of the following actions performed when the MAC move limit is exceeded:

**NOTE:** There is no default action.

- **drop**—Drop the packet and do not generate an alarm.
- **drop-and-log**—Drop the packet and generate an alarm, an SNMP trap, or system log entry.
- **log**—Do not drop the packet but generate an alarm, an SNMP trap, or a system log entry.
- **none**—Take no action.
- **shutdown**—Disable the interfaces in the VLAN and generate an alarm, an SNMP trap, or a system log entry. If you have configured an interface with the [recovery-timeout](#) statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the [clear ethernet-switching recovery-timeout](#) command.

To configure a MAC move limit for MAC addresses within a specific VLAN:

- To limit the number of MAC address movements that can be made by an individual MAC address within the specified VLAN:

```
[edit edit vlans vlan-name switch-options]
user@switch# set mac-move-limit limit
```

- To limit the number of MAC address movements that can be made by an individual MAC address and to specify the action to be taken when the limit is reached:

```
[edit edit vlans vlan-name switch-options]
user@switch# set mac-move-limit limit packet-action action
```

The switch performs the specified action if it tracks that an individual MAC address within the specified VLAN has moved more than the specified number of times within one second.

#### Related Documentation

- [Configuring MAC Move Limiting \(J-Web Procedure\)](#)
- [Configuring Persistent MAC Learning \(CLI Procedure\) on page 4569](#)

## Configuring Persistent MAC Learning (CLI Procedure)

**NOTE:** This topic uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see [Configuring Persistent MAC Learning \(CLI Procedure\)](#). For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 3](#).

Persistent MAC address learning is disabled by default. You can enable it to:

- Help prevent traffic losses for trusted workstations and servers because the interface does not have to relearn the addresses from ingress traffic after a restart.
- Protect the switch against security attacks—Use persistent MAC learning in combination with MAC limiting to protect against attacks while still avoiding the need to statically configure MAC addresses. When the initial learning of MAC addresses up to the number specified by the MAC limit is done, new addresses will not be allowed even after a restart. The port is secured because after the limit has been reached, additional devices cannot connect to the interface.

To configure persistent MAC learning on an interface and limit the number of allowed MAC addresses:

1. Enable persistent MAC learning on an interface **ge-x/y/z** where x, y, and z are variables:

```
[edit “switch-options” on page 2212]
user@switch# set interface ge-x/y/z persistent-learning
```

2. To configure a MAC move limit for MAC addresses within a specific VLAN:

- To limit the number of MAC address movements that can be made by an individual MAC address within the specified VLAN:

```
[edit vlans vlan-name switch-options]
user@switch# set mac-move-limit limit
```

The action is not specified, so the switch performs the default action **drop** if it tracks that an individual MAC address within the specified VLAN has moved more than the specified number of times within one second.

- To limit the number of MAC address movements that can be made by an individual MAC address and to specify the action to be taken when the limit is reached:

```
[edit vlans vlan-name switch-options]
user@switch# set mac-move-limit limit packet-action action
```

Values for *action* are:

**drop**—Drop packets with new source MAC addresses, and do not learn the new source MAC addresses.

**drop-and-log**—(EX Series switches only) Drop packets with new source MAC addresses, and generate an alarm, an SNMP trap, or a system log entry.

**log**—(EX Series switches only) Hold packets with new source MAC addresses, and generate an alarm, an SNMP trap, or a system log entry.

**none**—(EX Series switches only) Forward packets with new source MAC addresses, and learn the new source MAC address.

**shutdown**—(EX Series switches only) Disable the specified interface, and generate an alarm, an SNMP trap, or a system log entry.

**TIP:** If you move a device within your network that has a persistent MAC address entry on the switch, use the [clear ethernet-switching table persistent-mac](#) command to clear the persistent MAC address entry from the interface. If you move the device and do not clear the persistent MAC address from the original port it was learned on, then the new port will not learn the MAC address of the device and the device will not be able to connect.

If the original port is down when you move the device, then the new port will learn the MAC address and the device can connect. However, if you do not clear the persistent MAC address on the original port, then when the port restarts, the system reinstalls the persistent MAC address in the forwarding table for that port. If this occurs, the persistent MAC address is removed from the new port and the device loses connectivity.

## Configuring Static IP Addresses for DHCP and DHCPv6 Bindings on Access Ports (CLI Procedure)

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring Static IP Addresses for DHCP Bindings on Access Ports (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 3.

You can add static (fixed) IP addresses and bind them to fixed MAC addresses in the DHCP snooping database. These bindings are labeled as *static* in the database, while those bindings that have been added through the process of DHCP snooping are labeled *dynamic*. Static IPv6 address assignment is also available for DHCPv6.

Before you can perform this procedure, you must configure the VLAN. See “[Configuring VLANs for EX Series Switches \(CLI Procedure\)](#)” on page 2337.

To configure a static IP address to MAC address (IP-MAC) binding in the DHCP snooping database, you must first create a group of access interfaces under **[edit vlans *vlan-name* forwarding-options dhcp-security]**. Creating this group automatically enables DHCP snooping, which is a prerequisite for creating the DHCP snooping database. You can then configure a specific interface within the group to have a static IP address that is bound to a fixed MAC address. If you want to have multiple static IP addresses, configure additional interfaces within the same group.

**NOTE:** On switches that support DHCPv6, creating the group of interfaces will automatically enable both DHCP and DHCPv6 snooping.

To configure a static IP-MAC address binding in the DHCP snooping database:

- **[edit vlans *vlan-name* forwarding-options dhcp-security]**  
`user@switch# set group group-name interface interface-name static-ip ip-address mac mac-address`

To configure a static IPv6-MAC address binding in the DHCPv6 snooping database:

- **[edit vlans *vlan-name* forwarding-options dhcp-security]**  
`user@switch# set group group-name interface interface-name static-ipv6 ip-address mac mac-address`

## Enabling Dynamic ARP Inspection (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Enabling Dynamic ARP Inspection (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 3.

**NOTE:** On EX9200 switches, DHCP snooping, DAI, and IP source guard are not supported in an MC-LAG scenario.

Dynamic ARP inspection (DAI) protects switches against ARP spoofing. DAI inspects ARP packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP cache poisoning.

Before you can enable DAI on a VLAN, you must configure the VLAN. See “[Configuring VLANs for EX Series Switches \(CLI Procedure\)](#)” on page 2337.

To enable DAI on a VLAN by using the CLI:

```
[edit vlans vlan-name forwarding-options dhcp-security]  
user@switch# set arp-inspection
```

### Related Documentation

- [Enabling Dynamic ARP Inspection \(J-Web Procedure\) on page 4572](#)
- [Example: Configuring IP Source Guard and Dynamic ARP Inspection to Protect the Switch from IP Spoofing and ARP Spoofing on page 4529](#)
- [Understanding DAI for Port Security on page 4500](#)

## Enabling Dynamic ARP Inspection (J-Web Procedure)

Dynamic ARP inspection (DAI) protects EX Series switches against ARP spoofing. DAI inspects ARP packets on the LAN and uses the information in the DHCP snooping database on the switch to validate ARP packets and to protect against ARP cache poisoning.

You configure DAI for each VLAN, not for each interface (port). By default, DAI is disabled for all VLANs.

To enable DAI on one or more VLANs by using the J-Web interface:

1. Select **Configure>Security>Port Security**.
2. Select one or more VLANs from the VLAN list.
3. Click the **Edit** button. If a message appears asking if you want to enable port security, click **Yes**.

4. Select the **Enable ARP Inspection on VLAN** check box and then click **OK**.
5. Click **OK** after the command has been successfully delivered.

**NOTE:** You can enable or disable port security on the switch at any time by clicking the **Activate** or **Deactivate** button on the Port Security Configuration page. If security status is shown as **Disabled** when you try to edit settings for any VLANs or interfaces (ports), the message asking if you want to enable port security appears.

## Enabling a Trusted DHCP Server (CLI Procedure)

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see [Enabling a Trusted DHCP Server \(CLI Procedure\)](#). For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 3](#).

You can configure any interface on a switch that connects to a DHCP server as a trusted interface (port). Configuring a DHCP server on a trusted interface protects against rogue DHCP servers sending leases.

By default, all access interfaces are untrusted, and all trunk interfaces are trusted. However, you can override the default setting for access interfaces by configuring a group of access interfaces within a VLAN, specifying an interface to belong to that group, and then configuring the group as trusted.

Before you can configure a trusted DHCP server, you must configure a VLAN. See [“Configuring VLANs for EX Series Switches \(CLI Procedure\)” on page 2337](#).

To configure an untrusted access interface as a trusted interface for a DHCP server by using the CLI :

1. Configure a group within a VLAN with a specific access interface:

```
[edit vlans vlan-name forwarding-options dhcp-security ]  
user@switch# set group group-name interface interface-name
```

2. Configure that group as **trusted** to make the specified interface contained within the group a trusted interface:

```
[edit vlans vlan-name forwarding-options dhcp-security group group-name]  
user@switch# set overrides trusted
```

**Related  
Documentation**

- [Enabling a Trusted DHCP Server \(J-Web Procedure\) on page 4574](#)
- [Understanding Trusted DHCP Servers for Port Security on page 4527](#)

## Enabling a Trusted DHCP Server (J-Web Procedure)

You can configure any interface on the EX Series switch that connects to a DHCP server as a trusted interface (port). Configuring a DHCP server on a trusted interface protects against rogue DHCP servers sending leases.

You configure a trusted DHCP server on an interface, not on a VLAN. By default, all access interfaces are untrusted and all trunk interfaces are trusted.

To enable a trusted DHCP server on one or more interfaces by using the J-Web interface:

1. Select **Configure>Security>Port Security**.
2. Select one or more interfaces from the Port list.
3. Click the **Edit** button. If a message appears asking if you want to enable port security, click **Yes**.
4. Select the **Trust DHCP** check box and then click **OK**.
5. Click **OK** after the command has been successfully delivered.

**NOTE:** You can enable or disable port security on the switch at any time by clicking the **Activate** or **Deactivate** button on the Port Security Configuration page. If security status is shown as **Disabled** when you try to edit settings for any VLANs or interfaces (ports), the message asking if you want to enable port security appears.

## Configuring Persistent Bindings in the DHCP or DHCPv6 Snooping Database to Improve Performance (CLI Procedure)

**NOTE:** This task uses Junos OS for MX Series routers and EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Making IP-MAC Bindings in the DHCP Snooping Database Persistent (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 3.

By default, IP-MAC address bindings in the DHCP snooping database do not persist through device reboots. You can improve network performance by configuring the IP-MAC address bindings in the DHCP snooping database to persist through reboots so that the table does not need to be rebuilt after rebooting. Do this by configuring a storage location for the DHCP snooping database file, where you must specify how frequently the device writes the database entries into the DHCP snooping database file.

**NOTE:** You can also configure the IPv6-MAC address bindings to persist through reboots on devices that support DHCPv6 snooping.

DHCPv6 is not supported on the MX Series routers.

The DHCP snooping database of IP-MAC address bindings is created when you enable any of the port security features for a specific VLAN or bridge-domain in either hierarchy:

- [edit vlans *vlan-name* forwarding-options dhcp-security]
- [edit bridge-domains *bridge-domain-name* forwarding-options dhcp-security]

On devices that support DHCPv6, enabling any port security features also creates the DHCPv6 snooping database. DHCP snooping and DHCPv6 snooping are not enabled by default.

To configure a *local* storage location for the DHCP snooping database file:

- For DHCP snooping:

```
[edit system processes]
user@device# set dhcp-service dhcp-snooping-file local-pathname write-interval seconds
```

For example:

```
[edit system processes]
user@switch# set dhcp-service dhcp-snooping-file /var/tmp/test.log write-interval 60
```

- For DHCPv6 snooping (not supported on MX Series routers):

```
[edit system processes]
user@device# set dhcp-service dhcpv6-snooping-file local-pathname write-interval seconds
```

For example:

```
[edit system processes]
user@switch# set dhcp-service dhcpv6-snooping-file /var/tmp/test.log write-interval 60
```

To configure a *remote* storage location for IP-MAC bindings, use **tftp://ip-address** or **ftp://hostname/path** as the remote URL or the local pathname for the storage location of the DHCP or DHCPv6 snooping database file:

- For DHCP snooping:

```
[edit system processes]
user@switch# set dhcp-service dhcp-snooping-file remote_url write-interval seconds
```

For example:

```
[edit system processes]
user@switch# set dhcp-service dhcp-snooping-file tftp://test:Test123@14.1.2.1 write-interval 60
```

- For DHCPv6 snooping (not supported on MX Series routers):

```
[edit system processes]
user@switch# set dhcp-service dhcpv6-snooping-file remote_url write-interval seconds
```

For example:

```
[edit system processes]
user@switch# set dhcp-service dhcpv6-snooping-file tftp://test:Test123@14.1.2.1 write-interval 60
```

**NOTE:** Specify any requisite user credentials for the FTP server before you specify the IP address or hostname. In this example, **test** is the username and **Test123** is the password for FTP server 14.1.2.1.

---

Documentation**

- *Understanding DHCP Snooping for Port Security*

## Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Setting Up DHCP Option 82 on the Switch with No Relay Agent Between Clients and DHCP Server (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on [page 3](#).

You can use DHCP option 82, also known as the DHCP relay agent information option, to help protect the switch against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation. Option 82 provides information about the network location of a DHCP client, and the DHCP server uses this information to implement IP addresses or other parameters for the client.

You can configure the DHCP option 82 feature in two topologies:

- The switch, DHCP clients, and DHCP server are all on the same VLAN. The switch forwards the clients' requests to the server and forwards the server's responses to the clients. This topic describes this configuration.
- The switch functions as a relay agent when the DHCP clients or the DHCP server is connected to the switch through a Layer 3 interface. On the switch, these interfaces are configured as integrated routing and bridging (IRB) interfaces. The switch relays the clients' requests to the server and then forwards the server's responses to the clients. This configuration is described in *Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure)*.

Before you configure DHCP option 82 on the switch, perform these tasks:

- Connect and configure the DHCP server.

**NOTE:** Your DHCP server must be configured to accept DHCP option 82. If the server is not configured for DHCP option 82, the server does not use the DHCP option 82 information in the requests sent to it when it formulates its reply messages.

- Configure a VLAN on the switch and associate the interfaces on which the clients and the server connect to the switch with that VLAN. See “[Configuring VLANs for EX Series Switches \(CLI Procedure\)](#)” on [page 2337](#)

To configure DHCP option 82:

1. Specify DHCP option 82 for the VLAN that you configured.

```
[edit vlans vlan-name forwarding-options dhcp-security]  
user@switch# set option-82
```

**NOTE:** If you want to enable DHCP option 82 on all VLANs, you must configure it separately for each specific VLAN.

The remaining steps are optional.

2. Configure the prefix for the circuit ID suboption to include the switch's hostname or the routing instance name for the VLAN:

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set circuit-id prefix (host-name | routing-instance-name)
```

3. Specify that the circuit ID suboption value contains the interface description rather than the interface name (the default):

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set circuit-id use-interface-description
```

4. Specify that the circuit ID suboption value contains the VLAN ID rather than the VLAN name (the default):

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set circuit-id use-vlan-id
```

5. Specify that the remote ID suboption is included in the DHCP option 82 information:

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set remote-id
```

**NOTE:** If you do not specify a keyword after *remote-id*, the default value for the *remote-id* suboption is the interface name.

6. Specify that the remote ID suboption is the hostname of the switch:

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set remote-id host-name
```

7. Specify that the remote ID suboption value contains the interface description:

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set remote-id use-interface-description
```

8. Specify that the remote ID suboption value contains a character string:

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set remote-id use-string mystring
```

9. Configure a vendor ID suboption:

- To use the default value (the default value is **Juniper**), do not type a character string after the **vendor-id** option keyword:

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]  
user@switch# set vendor-id
```

- To configure that the vendor ID suboption value contains a character string value that you specify rather than **Juniper** (the default):

```
[edit vlans vlan-name forwarding-options dhcp-security option-82]
user@switch# set vendor-id use-string mystring
```

## Enabling DHCPv6 Rapid Commit Support

You can configure the extended DHCPv6 local server to support the DHCPv6 Rapid Commit option (DHCPv6 option 14). When rapid commit is enabled on the extended DHCPv6 local server, the server recognizes the Rapid Commit option in Solicit messages sent from the DHCPv6 client. (DHCPv6 clients are configured separately to include the DHCPv6 Rapid Commit option in the Solicit messages.) The server and client then use a two-message exchange (Solicit and Reply) to configure clients, rather than the default four-method exchange (Solicit, Advertise, Request, and Reply). The two-message exchange provides faster client configuration, and is beneficial in environments in which networks are under a heavy load.

You can configure the DHCPv6 local server to support the Rapid Commit option globally, for a specific group, or for a specific interface. By default, rapid commit support is disabled on the DHCPv6 local server.

To configure the DHCPv6 local server to support the DHCPv6 Rapid Commit option:

1. Specify that you want to configure the **overrides** options.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

2. Enable rapid commit support.

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set rapid-commit
```

## [edit vlans] Configuration Statement Hierarchy on EX Series Switches

This topic lists supported and unsupported configuration statements in the **[edit vlans]** hierarchy level on EX Series switches.

- *Supported* statements are those that you can use to configure some aspect of a software feature on the switch.
- *Unsupported* statements are those that appear in the command-line interface (CLI) on the switch, but that have no effect on switch operation if you configure them.
- Not all features are supported on all switch platforms. For detailed information about feature support on specific EX Series switch platforms, see *EX Series Switch Software Features Overview*.

This topic lists:

- [Supported Statements in the \[edit vlans\] Hierarchy Level on page 4582](#)
- [Unsupported Statements in the \[edit vlans\] Hierarchy Level on page 4584](#)

### Supported Statements in the [edit vlans] Hierarchy Level

The following hierarchy shows the **[edit vlans]** configuration statements supported on one or more of the EX Series switches:

```
vlans {
  vlan-name {
    description text-description;
    domain-type bridge;
    forwarding-options {
      dhcp-security {
        arp-inspection;
        group group-name {
          interface interface-name {
            static-ip ip-address {
              mac mac-address;
            }
          }
        }
        overrides {
          no-option82;
          trusted;
        }
      }
    }
    ip-source-guard;
    no-dhcp-snooping;
    option-82 {
      circuit-id {
        prefix {
          host-name;
          logical-system-name;
          routing-instance-name;
        }
        use-interface-description (device | logical);
        use-vlan-id;
      }
      remote-id {
        host-name;
        use-interface-description (device | logical);
        use-string string;
      }
      vendor-id {
        use-string string;
      }
    }
  }
  filter {
    input filter-name;
    output filter-name;
  }
  flood {
```

```

        input filter-name;
    }
}
!3-interface irb.logical-unit-number;
multicast-snooping-options {
    flood-groups [group-names];
    forwarding-cache {
        threshold {
            reuse threshold;
            suppress threshold;
        }
    }
    graceful-restart {
        disable;
        restart-duration duration;
    }
    host-outbound-traffic {
        dot1p bits;
        forwarding-class forwarding-class;
    }
    multichassis-lag-replicate-state;
    nexthop-hold-time time;
    options {
        syslog {
            level level;
            mark interval;
            upto level;
        }
    }
}
traceoptions {
    file filename {
        files number;
        no-world-readable;
        size file-size;
        world-readable;
    }
    flag flag {
        disable;
    }
}
}
switch-options {
    interface interface-name {
        interface-mac-limit limit {
            packet-action action;
        }
        static-mac mac-address;
    }
    interface-mac-limit limit {
        packet-action action;
    }
    mac-move-limit limit {
        packet-action action;
    }
    mac-table-size limit {
        packet-action drop;
    }
}

```

```

    }
    no-mac-learning;
  }
  vlan-id number;
  vlan-id-list [vlan-id | vlan-id-vlan-id];
}

```

### Unsupported Statements in the [edit vlans] Hierarchy Level

All statements in the **[edit vlans]** hierarchy level that are displayed in the command-line interface (CLI) on the switch are supported on the switch and operate as documented with the following exceptions:

**Table 500: Unsupported [edit vlans] Configuration Statements on EX Series Switches**

| Statement                                                                                         | Hierarchy Level |
|---------------------------------------------------------------------------------------------------|-----------------|
| <b>NOTE:</b> Variables, such as <i>filename</i> , are not shown in the statements or hierarchies. |                 |
| mcae-mac-synchronize                                                                              | [edit vlans]    |
| no-irb-layer-2-copy                                                                               | [edit vlans]    |

| <b>Description</b>              | <p>Specifies the connectivity association key (CAK) for a pre-shared key.</p> <p>A pre-shared key includes a connectivity association key name (CKN) and a CAK. A pre-shared key is exchanged between two devices at each end of a point-to-point link to enable MACsec using dynamic security keys. The MACsec Key Agreement (MKA) protocol is enabled once the pre-shared keys are successfully exchanged. The pre-shared key—the CKN and CAK—must match on both ends of a link</p> |
| <b>Default</b>                  | No CAK exists, by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

```

**Hierarchy Level** [edit security *macsec*]

**Release Information** Statement introduced in Junos OS Release 13.2X50-D15 for EX Series switches.  
Statement introduced in Junos OS Release 14.1X53-D15 for the QFX Series.

**Description** Create or configure a MACsec connectivity association.

A connectivity association is not applying MACsec to traffic until it is associated with an interface. MACsec connectivity associations are associated with interfaces using the *interfaces* statement in the [edit security macsec] hierarchy.

**Default** No connectivity associations are present, by default.

**Options** The remaining statements are explained separately.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 13.2X50-D15 for EX Series switches.<br>Statement introduced in Junos OS Release 14.1X53-D15 for QFX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>              | <p>Configure whether the secure channel applies MACsec security to traffic entering or leaving an interface.</p> <p>If you need to apply MACsec on traffic entering and leaving an interface, you need to create one secure channel to apply MACsec on incoming traffic and another secure channel to apply MACsec on outgoing traffic within the same connectivity association. When you associate the connectivity association with an interface, MACsec is applied on traffic entering and leaving that interface.</p> <p>You only use this configuration option when you are configuring MACsec using static secure association keys (SAK) security mode. When you are configuring MACsec using static connectivity association keys (CAK) security mode, two secure channels that are not user-configurable—one inbound secure channel and one outbound secure channel—are automatically created within the connectivity association.</p> |
| <b>Default</b>                  | <p>This statement does not have a default value.</p> <p>If you have configured a secure channel to enable MACsec using static SAK security mode, you must specify whether the secure channel applies MACsec to traffic entering or leaving an interface. A candidate configuration that contains a secure channel that has not configured a direction cannot be committed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <p><b>inbound</b>—Enable MACsec security on traffic entering the interface that has applied the secure channel.</p> <p><b>outbound</b>—Enable MACsec security on traffic leaving the interface that has applied the secure channel.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

 use-interface-description (device | logical);  
 use-vlan-id;  
 }  
 remote-id {  
 host-name hostname;  
 use-interface-description (device | logical);  
 mac;  
 use-string string;  
 }  
 vendor-id {  
 use-string string;  
 }  
}`

**Hierarchy Level** [edit vlans *vlan-name* forwarding-options]

**Release Information** Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement introduced in Junos OS Release 13.2 for the QFX series. Support for **static-ipv6**, **nd-inspection**, **ipv6-source-guard**, **no-dhcpv6-snooping**, and **no-option-37** introduced in Junos OS Release 13.2X51-D20 for EX Series switches.

**Description** Configure port security features on the switch. DHCP snooping is enabled automatically if you configure any of the following port security features within this hierarchy:

- Dynamic ARP inspection (DAI)
- IP source guard

- DHCP option 82
- Static IP

For switches that support DHCPv6, both DHCP snooping and DHCPv6 snooping are enabled automatically if you configure any of the features listed above or any of the following IPv6 features:

- IPv6 Neighbor Discovery inspection
- IPv6 source guard
- Static IPv6

**NOTE:** On EX9200 switches, DHCP snooping, DAI, and IP source guard are not supported in an MC-LAG scenario.

The remaining statements are explained separately.

| <b>Description</b>              | <p>Enable DHCP services on the device. DHCP services automate network-parameter assignment to network devices. The DHCP service process is enabled by default. However, by default, IP-MAC bindings in the DHCP snooping database do not persist through device reboots. You can improve performance after rebooting by configuring the IP-MAC bindings to persist, by configuring a storage location for the DHCP database file. When specifying the location for the DHCP database, you must also specify how frequently the switch writes the database entries into the DHCP snooping database file.</p> <p>The remaining statements are explained separately.</p> |

| <b>Description</b>              | <p>Enable MACsec encryption within a secure channel.</p> <p>You can enable MACsec without enabling encryption. If a connectivity association with a secure channel that has not enabled MACsec encryption is associated with an interface, traffic is forwarded across the Ethernet link in clear text. You are, therefore, able to view this unencrypted traffic when you are monitoring the link. The MACsec header is still applied to the frame, however, and all MACsec data integrity checks are run on both ends of the link to ensure the traffic has not been tampered with and does not represent a security threat.</p> <p>Traffic traversing a MAC-enabled point-to-point Ethernet link traverses the link at the same speed regardless of whether encryption is enabled or disabled. You cannot increase the speed of traffic traversing a MACsec-enabled Ethernet link by disabling encryption.</p> <p>This command is used to enable encryption when MACsec is configured using secure association key (SAK) security mode only. When MACsec is configuring using static connectivity association key (CAK) security mode, the encryption setting is configured outside of the secure channel using the <b>no-encryption</b> configuration statement.</p> |
| <b>Default</b>                  | MACsec encryption is disabled when MACsec is configured using static SAK security mode, by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## group (DHCP Security)

---

**Syntax**    `group group-name {  
          interface interface-name {  
            static-ip ip-address {  
              mac mac-address;  
            }  
            static-ipv6 ip-address {  
              mac mac-address;  
            }  
          }  
          overrides {  
            no-option37;  
            no-option82;  
            trusted;  
            untrusted;  
          }  
        }`

**Hierarchy Level**    [edit vlans *vlan-name* forwarding-options [dhcp-security](#)]

**Release Information**    Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.  
Statement introduced in Junos OS Release 13.2 for the QFX series.  
Support for the **static-ipv6** and **no-option37** statements introduced in Junos OS Release 13.2X51-D20 for EX Series switches.

**Description**    Specify the name of a group of access interfaces that you want to configure for DHCP security attributes that are different from the attributes set for other interfaces in the VLAN. A group must contain at least one interface.

The remaining statements are explained separately.

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                  interface-control—To add this statement to the configuration.

| <b>Description</b>         | (MX Series routers or EX Series switches only) Configure a limit to the number of MAC addresses that can be learned from a bridge domain, VLAN, virtual switch, or set of bridge domains or VLANs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**NOTE:** For multichassis link aggregation (MC-LAG) peers in active-active mode, configuring the `interface-mac-limit` statement or changing the `interface-mac-limit` configuration when traffic is flowing can cause the MAC entries to be out of synchronization between the two MC-LAG peers, which might result in flooding. To avoid flooding, you must either halt traffic forwarding and then configure the `interface-mac-limit` statement or use the `commit at configuration` statement to commit the changes at the same time in both the peer nodes.

Alternatively, if flooding does occur, you can clear the bridge MAC table on both the routers by using the `clear bridge mac-table` command. Running this command ensures that the MAC entries are re-learned and in synchronization between both the peers.

**Default** For an access port, the default MAC limit is 1024 MAC addresses. For a trunk port, the default MAC limit is 8192 MAC addresses.

**Options** *limit*—Maximum number of MAC addresses learned from an interface.

**Range:** 1 through 131,071 MAC addresses per interface

The remaining statement is explained separately.

**Required Privilege** routing—To view this statement in the configuration.

**Level** routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 13.2X50-D15 for EX Series switches.<br>Statement introduced in Junos OS Release 14.1X53-D15 for QFX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | <p>Applies the specified connectivity association to the specified interface to enable MACsec.</p> <p>One connectivity association can be applied to multiple interfaces.</p> <p>You must always use this statement to apply a connectivity association to an interface to enable MACsec. You must complete this configuration step regardless of whether MACsec is enabled using static connectivity association key (CAK) security mode or static secure association key (SAK) security mode.</p> <p>If you are enabling MACsec using static SAK security mode and need to configure MACsec on inbound and outbound traffic on the same interface, you must configure a connectivity association with one secure channel for inbound traffic and a second secure channel for outbound traffic. The connectivity association is then applied to the interface using this statement to enable MACsec for traffic entering and leaving the interface.</p> |
| <b>Default</b>                  | Interfaces are not associated with any connectivity associations, by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
