| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | <p>Configure a policer to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. If you use a filter-specific policer in multiple terms, both of the following are true:</p> <ul style="list-style-type: none"> <li>• Traffic is policed at the aggregate rate. For example, if you create a policer that has a bandwidth limit of 100 Mbps and use the policer in two terms, the total allowed bandwidth for both terms is 100 Mbps—not 100 Mbps for each term.</li> <li>• The implicit counter counts all the packets are that matched by any of the terms. For example, if you reference the same filter-specific policer in term1 and term2, and term1 matches 1000 packets and term2 matches 500 packets, the implicit counter shows 1500 matches for the policer.</li> </ul> |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

```

Hierarchy Level [edit]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure firewall filters and policers.

The remaining statements are explained separately.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | <p>Configure policer rate limits and actions. To activate a policer, you must include the <b>policer</b> action modifier in the <b>then</b> statement in a firewall filter term.</p> <p>Each policer that you configure includes an implicit counter that counts the number of packets that exceed the rate limits that are specified for the policer. If you use the same policer in multiple terms—either within the same filter or across filters—the policer's implicit counter is used to count packets that are policed in all of these terms. If you want to obtain separate packet counts for each term, use these approaches:</p> <ul style="list-style-type: none"> <li>• Configure a unique policer for each term.</li> <li>• Configure only one policer, but use a unique, explicit counter in each term.</li> </ul> |
| <b>Options</b>                  | <p><b><i>policer-name</i></b>—Name that identifies the policer. The name can contain letters, numbers, hyphens (-), and can be up to 64 characters long.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Required Privilege Level</b> | <p>firewall—To view this statement in the configuration.</p> <p>firewall-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>              | <p>Configure a single-rate three-color policer in which marking is based on the committed information rate (CIR), committed burst size (CBS), and excess burst size (EBS).</p> <p>Packets that conform to the CIR or the CBS are assigned low loss priority (green). Packets that exceed the CIR and the CBS but are within the EBS are assigned medium-high loss priority (yellow). Packets that exceed the EBS are assigned high loss priority (red).</p> <p>Green and yellow packets are always forwarded; this action is not configurable. You can configure red packets to be discarded. By default, red packets are forwarded.</p> <p>The remaining statements are explained separately.</p> |
| <b>Options</b>                  | <b><i>policer-name</i></b> —Name of the three-color policer. Use this name when you apply the policer to an interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Required Privilege Level</b> | <b>firewall</b> —To view this statement in the configuration.<br><b>firewall-control</b> —To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | <p>Configure a two-rate three-color policer in which marking is based on the committed information rate (CIR), committed burst size (CBS), peak information rate (PIR), and peak burst size (PBS).</p> <p>Packets that conform to the CIR or the CBS are assigned low loss priority (green). Packets that exceed the CIR and the CBS but are within the PIR or the PBS are assigned medium-high loss priority (yellow). Packets that exceed the PIR and the PBS are assigned high loss priority (red).</p> <p>Green and yellow packets are always forwarded; this action is not configurable. You can configure red packets to be discarded. By default, red packets are forwarded.</p> <p>The remaining statements are explained separately.</p> |
| <b>Required Privilege Level</b> | <p><b>firewall</b>—To view this statement in the configuration.</p> <p><b>firewall-control</b>—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## allowed-mac

|                            |                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>allowed-mac <i>mac-address-list</i></code>                                                              |
| <b>Hierarchy Level</b>     | [edit <a href="#">ethernet-switching-options secure-access-port interface</a> (all   <i>interface-name</i> )] |
| <b>Release Information</b> | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                             |
| <b>Description</b>         | Specify particular MAC addresses to be added to the MAC address cache.                                        |

**NOTE:** Although this configuration restricts the addresses that can be added to the MAC address cache, it does not block the switch from receiving Layer 2 control packets—such as Link Layer Discovery Protocol (LLDP) packets—transmitted from MAC addresses that are not specified in the list of allowed MAC addresses. Control packets do not undergo the MAC address check, and they are therefore included in the statistics of packets received, though, they are not forwarded to another destination.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>                  | Allowed MAC addresses take precedence over dynamic MAC values. For example, if the <b>mac-limit</b> statement is set to four and three allowed MACs are configured, only one dynamic MAC can be learned on that interface.                                                                                                                                                                                              |
| <b>Options</b>                  | <b><i>mac-address-list</i></b> —One or more MAC addresses configured as allowed MAC addresses for a specified interface or all interfaces.                                                                                                                                                                                                                                                                              |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing—control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                     |

| <b>Description</b>              | <p>When the switch receives a DHCP request from a DHCP client connected on one of the switch's interfaces, have the switch insert DHCP option 82 (also known as the DHCP relay agent information option) information in the DHCP request packet header before it forwards or relays the request to a DHCP server. The server uses the option 82 information, which provides details about the circuit and host the request came from, in formulating the reply; the server does not, however, make any changes to the option 82 information in the packet header. The switch receives the reply and then removes the DHCP option 82 information before forwarding the reply to the client.</p> <p>The remaining statements are explained separately.</p> |
| <b>Default</b>                  | <p>Insertion of DHCP option 82 information is not enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## fc-map

**Syntax** `fc-map fc-map-value;`

**Hierarchy Level** Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) [examine-fip](#)]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security]

**NOTE:** The `fc-map` configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

[edit [fc-fabrics](#) *fc-fabric-name* [protocols fip](#)]

**Release Information** Statement introduced in Junos OS Release 10.4 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

**Description** Set the FCoE mapped address prefix (FC-MAP) value for the FCoE VLAN to match the FC switch (or FCoE forwarder) FC-MAP value for the FC fabric. The FC-MAP value is a unique MAC address prefix an FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN).

You can configure the FC-MAP value or use the default value. The default FC-MAP value is different for VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping (0x0EFC00) than for VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping.

The FC switch provides the FC-MAP value to FCoE nodes (ENodes) in the FIP discovery advertisement message. If the EX Series switch or the QFX Series FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, neither device discovers the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. The FC switch accepts only FCoE traffic that uses the correct FC-MAP value as part of the VN\_Port MAC address.

When the QFX Series acts as an FCoE-FC gateway, the FC-MAP value for the gateway and the FCoE devices must match the FC switch FC-MAP value in order to communicate with the FC switch.

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

**Options** `fc-map-value`—FC-MAP value, hexadecimal value preceded by “0x”.

**Range:** 0x0EFC00 through 0x0EFCFF

**Default:** 0x0EFC00 for VN2VF\_Port FIP snooping 0x0EFD00 for VN2VN\_Port FIP snooping

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Configure the specified 10-Gigabit Ethernet interface to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.</p> <p>(QFX Series FCoE-FC gateway) Configure the specified local Fibre Channel fabric to trust FCoE traffic on all ports in the fabric. Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted by removing the <b>fcoe-trusted</b> configuration from the fabric forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters.</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## forwarding-class (for DHCP Snooping or DAI Packets)

---

|                            |                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>forwarding-class class <i>class-name</i>;</code>                                                                                          |
| <b>Hierarchy Level</b>     | <code>[edit ethernet-switching-options secure-access-port vlan (all   <i>vlan-name</i>) (examine-dhcp   arp-inspection)]</code>                 |
| <b>Release Information</b> | Statement introduced in Junos OS Release 11.2 for EX Series switches.<br>Statement introduced in Junos OS Release 12.1 for the QFX Series.      |
| <b>Description</b>         | Assign a user-defined or a predefined forwarding class to the packets that have been checked for DHCP snooping or dynamic ARP inspection (DAI). |

**NOTE:** To assign a user-defined class, you must first configure the user-defined class by using the *forwarding-classes* configuration statement at the `[edit class-of-service]` hierarchy level.

| <b>Description</b>              | Specify the number of times a MAC address can move to a new interface (port) in 1 second and the action to be taken by the switch if the MAC address move limit is exceeded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                 | <div>  <p><b>CAUTION:</b> Mac move limiting does not work properly on a QFX5100 switch used as a Node device in a QFabric system. Do not use this feature on a QFX5100 switch in a QFabric system.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>                  | The default move limit is unlimited. The default action is <b>drop</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>                  | <p><b>fabric-limit</b>—Specify the maximum number of moves in a QFabric system. If you do not specify a fabric limit, the value for <b>mac-move-limit</b> applies to the QFabric system.</p> <p><b>limit</b>—Maximum number of moves to a new interface per second.</p> <p><b>action <i>action</i></b>—(Optional) Action to take when the MAC address move limit is reached:</p> <ul style="list-style-type: none"> <li>• <b>drop</b>—Drop the packet and generate an alarm, an SNMP trap, or a system log entry. This is the default.</li> <li>• <b>log</b>—Do not drop the packet but generate an alarm, an SNMP trap, or a system log entry.</li> <li>• <b>none</b>—No action.</li> <li>• <b>shutdown</b>—Disable the interface and generate an alarm. If you have configured the switch with the <b>port-error-disable</b> statement, the disabled interfaces recover automatically upon expiration of the specified disable timeout. If you have not configured the switch for autorecovery from port error disabled conditions, you can bring up the disabled interfaces by running the <b>clear-ethernet-switch-port</b> command.</li> </ul> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 on the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>              | Disable rather than block an interface when enforcing MAC limiting, MAC move limiting, and storm control, and allow the interface to recover automatically from the error condition after a specified period of time:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                 | <div> <b>NOTE:</b> The <code>port-error-disable</code> configuration does not apply to preexisting error conditions. It affects only error conditions that are detected after you enable and commit the <code>port-error-disable</code> statement. To clear a preexisting error condition and restore the interface to service, use the <a href="#">clear ethernet-switching port-error</a> command.</div>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                 | <ul style="list-style-type: none"><li>If you enable the <a href="#">mac-limit</a> statement with the <code>shutdown</code> option and also enable the <code>port-error-disable</code> statement, the switch disables (rather than shuts down) the interface when the MAC address limit is reached.</li><li>If you have enabled the <a href="#">mac-move-limit</a> statement with the <code>shutdown</code> option and you enable the <code>port-error-disable</code> statement, the switch disables (rather than shuts down) the interface when the maximum number of moves to a new interface is reached.</li><li>If you enable the <a href="#">storm-control</a> statement with the <code>action-shutdown</code> option and you also enable <code>port-error-disable</code>, the switch disables (rather than shuts down) the interface when broadcast traffic and unknown unicast traffic exceed the specified levels.</li></ul> |
| <b>Default</b>                  | Not enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## remote-id

---

**Syntax**    `remote-id {  
          host-name host-name;  
          mac;  
          prefix ( hostname | mac | none );  
          use-interface-description ( logical | device );  
          use-string string;  
          }`

- Hierarchy Level**
- For platforms with Enhanced Level 2 Software (ELS):  
[edit vlans *vlan-name* forwarding-options dhcp-security option-82]
  - For platforms without ELS:  
[edit ethernet-switching-options secure-access-port vlan (all | *vlan-name*) dhcp-option82],  
[edit forwarding-options helpers bootp dhcp-option82],  
[edit forwarding-options helpers bootp interface *interface-name* dhcp-option82]

**Release Information**    Statement introduced in Junos OS Release 9.3 for EX Series switches.  
Statement introduced in Junos OS Release 11.3 for the QFX Series.  
Hierarchy level [edit vlans *vlan-name* forwarding-options dhcp-security option-82] introduced in Junos OS Release 13.2X50-D10. (See *Getting Started with Enhanced Layer 2 Software* for information about ELS.)

**Description**    Insert the **remote-id** suboption of DHCP option 82 (also known as the DHCP relay agent information option) in DHCP request packet headers before forwarding or relaying requests to a DHCP server. This suboption provides a trusted identifier for the host system that has forwarded or relayed requests to the server.

The remaining statements are explained separately, and their availability depends on the hierarchy level at which the **remote-id** suboption is specified, as follows:

- The statement **prefix**, is *not* supported at the [edit vlans *vlan-name* forwarding-options dhcp-security option-82] hierarchy level.
- The statement **host-name** is supported *only* at the [edit vlans *vlan-name* forwarding-options dhcp-security option-82] hierarchy level.

**Default**    If the **remote-id** statement is not explicitly set, no remote ID value is inserted in the DHCP request packet header.

If the **remote-id** statement is explicitly set, but is not qualified by a keyword, the following are true:

- At the [edit vlans *vlan-name* forwarding-options dhcp-security] hierarchy level, the default keyword value is *interface-name*.
- At all other hierarchy levels, the default value of the **remote-id** keyword is the MAC address of the switch.

mac-move-limit limit action action;
}
```

**Hierarchy Level** [edit [ethernet-switching-options secure-access-port](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Apply DHCP snooping, dynamic ARP inspection (DAI), DHCP option 82, and MAC move limiting.

**TIP:** To display a list of all configured VLANs on the system, including VLANs that are configured but not committed, type ? after vlan or vlans in your configuration mode command line. Note that only one VLAN is displayed for a VLAN range.

The remaining statements are explained separately.

## bandwidth

|                            |                                                                                                                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>bandwidth <i>bandwidth</i>;</code>                                                                                                                                                                                                                   |
| <b>Hierarchy Level</b>     | [edit <code>ethernet-switching-options storm-control interface</code> (all   <i>interface-name</i> )]                                                                                                                                                      |
| <b>Release Information</b> | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                          |
| <b>Description</b>         | For interfaces configured for storm control, configure the storm control level as the bandwidth in kilobits per second (Kbps). If the combination of broadcast and unknown unicast traffic exceeds this level, the switch performs the appropriate action. |
| <b>Default</b>             | None.                                                                                                                                                                                                                                                      |
| <b>Options</b>             | <b>bandwidth</b> —Broadcast and unknown unicast traffic rate in Kbps.<br><b>Range:</b> 100 through 10000000 Kbps<br><b>Default:</b> None                                                                                                                   |

**NOTE:** When you configure storm control bandwidth, the value you configure is rounded off internally to the closest multiple of 64 Kbps, and the rounded-off value represents the bandwidth that is actually enforced. For example, if you configure a bandwidth limit of 150 Kbps, storm control enforces a bandwidth limit of 128 Kbps.

**CAUTION:** Junos OS allows you to configure a storm control value that exceeds the bandwidth of the interface. If you configure an interface with such a value, storm control does not drop broadcast or unknown unicast packets even if they consume all the available bandwidth.

## storm-control

**Syntax**

```
storm-control {
    action-shutdown;
    interface (all | interface-name) {
        bandwidth bandwidth;
        no-broadcast;
        no-multicast;
        no-unknown-unicast;
    }
}
```

**Hierarchy Level** [edit [ethernet-switching-options](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Apply storm control to all interfaces or to the specified interfaces on switches running non-ELS software. (For the equivalent statement for switches running ELS software, see *storm-control*.)

The statements are explained separately.

**NOTE:** The **no-multicast** option is not supported on QFabric systems.

**Default** On switches running non-ELS software, storm control is disabled by default on all switch interfaces. If you enable storm control and do not specify a storm control level, the default level is 80 percent of the available bandwidth for ingress traffic. You can change the storm control level by configuring it as a specific bandwidth value.

When you configure storm control bandwidth on an aggregated Ethernet interface, each member of the aggregated interface is assigned that bandwidth. For example, if you configure 7000000 Kbps on aggregated interface **ae1**, and **ae1** has two members, **xe-2:0/0/0** and **xe-2:0/0/1**, each member is allowed a bandwidth level of 7000000 Kbps. Thus, the storm control bandwidth on **ae1** could be as much as 14000000 Kbps of combined broadcast and unknown unicast traffic.

**Required Privilege Level**

|                                                             |
|-------------------------------------------------------------|
| routing—To view this statement in the configuration.        |
| routing-control—To add this statement to the configuration. |

- [Verifying That Two-Color Policers Are Operational on page 5165](#)

### Monitoring Firewall Filter Traffic

You can use operational mode commands to monitor firewall filter traffic.

- [Monitoring Traffic for All Firewall Filters and Policers That Are Configured on page 5153](#)
- [Monitoring Traffic for a Specific Firewall Filter on page 5154](#)
- [Monitoring Traffic for a Specific Policer on page 5154](#)

#### Monitoring Traffic for All Firewall Filters and Policers That Are Configured

**Purpose** Monitor the number of packets and bytes that matched the firewall filters and monitor the number of packets that exceeded policer rate limits:

**Action** Use the **show firewall** operational mode command:

```
user@switch> show firewall
Filter: egress-vlan-watch-employee
Counters:
```

|                                     |         |         |
|-------------------------------------|---------|---------|
| Name                                | Bytes   | Packets |
| counter-employee-web                | 3348    | 27      |
| Filter: ingress-port-limit-tcp-icmp |         |         |
| Counters:                           |         |         |
| Name                                | Bytes   | Packets |
| icmp-counter                        | 560     | 10      |
| Policers:                           |         |         |
| Name                                | Packets |         |
| icmp-connection-policer             | 10      |         |
| tcp-connection-policer              | 0       |         |
| Filter: ingress-vlan-rogue-block    |         |         |
| Filter: ingress-vlan-limit-guest    |         |         |

**Meaning** The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits.

#### Monitoring Traffic for a Specific Firewall Filter

**Purpose** Monitor the number of packets and bytes that matched a firewall filter and monitor the number of packets that exceeded policer rate limits.

**Action** Use the **show firewall filter *filter-name*** operational mode command:

```
user@switch> show firewall filter ingress-port-limit-tcp-icmp
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                      Bytes      Packets
icmp-counter              560         10
```

**Meaning** The **show firewall filter *filter-name*** command limits the display information to the counters and policers that are defined for the specified filter.

#### Monitoring Traffic for a Specific Policer

**Purpose** Monitor the number of packets that exceeded the rate limits of a policer:

**Action** Use the **show firewall policer *policer-name*** operational mode command:

```
user@switch> show firewall policer icmp-connection-policer
Filter: ingress-port-limit-tcp-icmp
Policers:
Name                      Packets
icmp-connection-policer  10
```

**Meaning** The **show firewall policer *policer-name*** command displays the number of packets that exceeded the rate limits for the specified policer.

## Monitoring Port Security

### Purpose

**NOTE:** This topic applies only to the J-Web Application package.

Use the monitoring functionality to view these port security details:

- DHCP snooping database for a VLAN or all VLANs
- ARP inspection details for all interfaces

### Action

To monitor port security in the J-Web interface, select **Monitor > Security > Port Security**.

To monitor and manipulate the DHCP snooping database and ARP inspection statistics in the CLI, enter the following commands:

- **show dhcp snooping binding**
- **clear dhcp snooping binding**—In addition to clearing the whole database, you can clear database entries for specified VLANs or MAC addresses.
- **show arp inspection statistics**
- **clear arp inspection statistics**

**NOTE:** On EX4300 switches, to monitor and manipulate the DHCP snooping database and ARP inspection statistics in the CLI, enter the following commands:

- **show dhcp-security binding**
- **clear dhcp-security binding**—In addition to clearing the whole database, you can clear database entries for specified VLANs or IP Address.
- **show dhcp-security arp inspection statistics**
- **clear arp inspection statistics**

### Meaning

The J-Web Port Security Monitoring page comprises two sections:

- **DHCP Snooping Details**—Displays the DHCP snooping database for all the VLANs for which DHCP snooping is enabled. To view the DHCP snooping database for a specific VLAN, select the specific VLAN from the list.
- **ARP Inspection Details**—Displays the ARP inspection details for all interfaces. The information includes details of the number of packets that passed ARP inspection and the number of packets that failed the inspection. The pie chart graphically represents

these statistics when you select an interface. To view ARP inspection statistics for a specific interface, select the interface from the list.

You can use the following options on the page to clear DHCP snooping and ARP inspection details:

- **Clear All**—Clears the DHCP snooping database, either for all VLANs if the option **ALL** has been selected in the Select VLANs list or for the specific VLAN that has been selected in that list.
- **Clear**—Deletes a specific IP address from the DHCP snooping database.

To clear ARP inspection details on the page, click **Clear All** in the ARP inspection details section.

**NOTE:** Clear All button in the ARP inspection details section is not supported on EX4300 switches.

Use the CLI commands to show and clear DHCP snooping database and ARP inspection statistics details.

  - [Configuring Port Security \(J-Web Procedure\)](#)
  - [Example: Configuring Basic Port Security Features on page 5006](#)

## Verifying That Firewall Filters Are Operational

**Purpose** Verify that firewall filters are working properly after you apply them to ports, VLANs, or Layer 3 interfaces.

**Action** Use the **show firewall** operational mode command to verify that the firewall filters are working properly:

```
user@switch> show firewall
Filter: egress-vlan-watch-employee
Counters:
Name                               Bytes      Packets
counter-employee-web              0           0
Filter: ingress-port-limit-tcp-icmp
Counters:
Name                               Bytes      Packets
icmp-counter                      560        10
Policers:
Name                               Packets
icmp-connection-policer          10
tcp-connection-policer           0
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The **show firewall** command displays the names of all firewall filters, counters, and policers that are configured. For each counter that is specified in a filter configuration, the output field shows the byte count and packet count for the term in which the counter is specified. In the above example, the **icmp-counter** in the filter **ingress-port-limit-tcp-icmp** shows that the filter matched 10 packets. For each policer that is specified in a filter configuration, the output field shows the packet count for packets that exceed the specified rate limits. The policer **icmp-connection-policer** shows that 10 ICMP packets were policed.

  - [Monitoring Firewall Filter Traffic on page 5153](#)

## Verifying That DAI Is Working Correctly

**Purpose** Verify that dynamic ARP inspection (DAI) is working on the switch.

**Action** Send some ARP requests from network devices connected to the switch.

Display the DAI information:

```
user@switch> show arp inspection statistics
ARP inspection statistics:
Interface          Packets received  ARP inspection pass  ARP inspection failed
-----
ge-0/0/1.0          7                 5                    2
ge-0/0/2.0          10                10                   0
ge-0/0/3.0          12                12                   0
```

**Meaning** The sample output shows the number of ARP packets received and inspected per interface, with a listing of how many packets passed and how many failed the inspection on each interface. The switch compares the ARP requests and replies against the entries in the DHCP snooping database. If a MAC address or IP address in the ARP packet does not match a valid entry in the database, the packet is dropped.

  - [Monitoring Port Security on page 5155](#)

## Verifying That DHCP Snooping Is Working Correctly

**Purpose** Verify that DHCP snooping is working on the switch and that the DHCP snooping database is correctly populated with both dynamic and static bindings.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
DHCP Snooping Information:
MAC address          IP address  Lease (seconds)  Type      VLAN    Interface
00:05:85:3A:82:77    192.0.2.17  600              dynamic   employee ge-0/0/1.0
00:05:85:3A:82:79    192.0.2.18  653              dynamic   employee ge-0/0/1.0
00:05:85:3A:82:80    192.0.2.19  720              dynamic   employee ge-0/0/2.0
00:05:85:3A:82:81    192.0.2.20  932              dynamic   employee ge-0/0/2.0
00:05:85:3A:82:83    192.0.2.21  1230             dynamic   employee ge-0/0/2.0
00:05:85:27:32:88    192.0.2.22  -                static    data     ge-0/0/4.0
```

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires. Static IP addresses have no assigned lease time. The statically configured entry never expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

## Verifying That MAC Limiting Is Working Correctly

MAC limiting protects against flooding of the Ethernet switching table by setting a limit on the number of MAC addresses that can be learned on a single Layer 2 access interface (port).

Junos OS provides two MAC limiting methods:

- **Maximum number of MAC addresses**—You configure the maximum number of dynamic MAC addresses allowed per interface. When the limit is exceeded, incoming packets with new MAC addresses can be ignored, dropped, or logged. You can also specify that the interface be shut down or temporarily disabled.
- **Allowed MAC addresses**—You configure specific “allowed” MAC addresses for the access interface. Any MAC address that is not in the list of configured addresses is not learned, and the switch logs an appropriate message. The allowed MAC method binds MAC addresses to a VLAN so that the address is not registered outside the VLAN. If an allowed MAC setting conflicts with a dynamic MAC setting, the allowed MAC setting takes precedence.

This topic includes the following tasks:

1. [Verifying That MAC Limiting for Dynamic MAC Addresses Is Working Correctly on page 5159](#)
2. [Verifying That Allowed MAC Addresses Are Working Correctly on page 5160](#)
3. [Verifying That Interfaces Are Shut Down on page 5160](#)
4. [Customizing the Ethernet Switching Table Display to View Information for a Specific Interface on page 5161](#)

### Verifying That MAC Limiting for Dynamic MAC Addresses Is Working Correctly

**Purpose** Verify that MAC limiting for dynamic MAC addresses is working.

**Action** Display the MAC addresses that have been learned. The following sample output shows the results of sending two packets from hosts connected to **xe-1:0/0/1** and five packets from hosts connected to **xe-1:0/0/2**, with both interfaces configured with a MAC limit of **4** and the action **drop**:

```
user@switch> show ethernet-switching table
Ethernet-switching table: 7 entries, 6 learned
```

| VLAN          | MAC address       | Type  | Age | Interfaces   |
|---------------|-------------------|-------|-----|--------------|
| employee-vlan | *                 | Flood | -   | xe-1:0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:77 | Learn | 0   | xe-1:0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:79 | Learn | 0   | xe-1:0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:80 | Learn | 0   | xe-1:0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:81 | Learn | 0   | xe-1:0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:83 | Learn | 0   | xe-1:0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:85 | Learn | 0   | xe-1:0/0/2.0 |

**Meaning** The output shows that the fifth packet received on the **xe-1:0/0/2** interface was dropped because it exceeded the MAC limit for that interface. The address was not learned, and thus an asterisk (\*) rather than an address appears in the MAC address column in the first line of the sample output.

---

### Verifying That Allowed MAC Addresses Are Working Correctly

**Purpose** Verify that allowed MAC addresses are working.

**Action** Display the MAC cache information after allowed MAC addresses have been configured on an interface. The following sample shows the MAC cache after four allowed MAC addresses had been configured on interface **xe-1:0/0/2** and a fifth MAC address appeared on the interface.

```
user@switch> show ethernet-switching table
Ethernet-switching table: 5 entries, 4 learned
```

| VLAN          | MAC address       | Type  | Age | Interfaces   |
|---------------|-------------------|-------|-----|--------------|
| employee-vlan | 00:05:85:3A:82:80 | Learn | 0   | xe-1:0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:81 | Learn | 0   | xe-1:0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:83 | Learn | 0   | xe-1:0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:85 | Learn | 0   | xe-1:0/0/2.0 |
| employee-vlan | *                 | Flood | -   | xe-1:0/0/2.0 |

**Meaning** Because the fifth address was not allowed it was not learned, and an asterisk (\*) rather than an address appears in the MAC address column in the last line of the sample output.

---

### Verifying That Interfaces Are Shut Down

**Purpose** Verify that an interface is shut down when the MAC limit is exceeded.

**Action** For more information about interfaces that have been shut down because the MAC limit was exceeded, use the **show ethernet-switching interfaces** command.

```
user@switch> show ethernet-switching interfaces
Interface      State  VLAN members      Tag  Tagging  Blocking

bme0.32770     down   mgmt              untagged unblocked
xe-0/0/0.0     down   v1                untagged MAC limit exceeded
xe- 0/0/1.0    up     v1                untagged unblocked
xe-0/0/2.0     up     v1                untagged unblocked
me0.0          up     mgmt              untagged unblocked
```

**NOTE:** You can configure interfaces to recover automatically when the MAC limit has been exceeded by specifying the **port-error-disable** statement with a **disable timeout** value. The switch automatically restores the disabled interface to service when the disable timeout expires. The **port-error-disable** configuration does not apply to preexisting error conditions—it affects only error conditions that are detected after the **port-error-disable** statement has been enabled and the configuration has been committed. To clear a preexisting error condition and restore the interface to service, use the **clear ethernet-switching port-error** command.

### Customizing the Ethernet Switching Table Display to View Information for a Specific Interface

**Purpose** You can use the **show ethernet-switching table** command to view information for a specific interface.

**Action** For example, to display the MAC addresses that have been learned on the **xe-0/0/2** interface, enter:

```
user@switch> show ethernet-switching table interface xe-0/0/2.0
Ethernet-switching table: 1 unicast entries
```

| VLAN | MAC address       | Type  | Age | Interfaces  |
|------|-------------------|-------|-----|-------------|
| v1   | *                 | Flood | -   | All-members |
| v1   | 00:00:06:00:00:00 | Learn | 0   | xe-0/0/2.0  |

**Meaning** The MAC limit value for the **xe-0/0/2** interface had been set to 1, and the output shows that only one MAC address was learned and added to the MAC cache.

## Verifying That MAC Move Limiting Is Working Correctly

**Purpose** Verify that MAC move limiting is working on the switch.

**Action** Display the MAC addresses in the Ethernet switching table when MAC move limiting has been configured for a VLAN. The following sample shows the results after two of the hosts on **ge-0/0/2** sent packets after the MAC addresses for those hosts had moved to other interfaces more than five times in 1 second. The VLAN, **employee-vlan**, was set to a MAC move limit of **5** with the action **drop**:

```
user@switch> show ethernet-switching table
```

```
Ethernet-switching table: 7 entries, 4 learned
```

| VLAN          | MAC address       | Type  | Age | Interfaces |
|---------------|-------------------|-------|-----|------------|
| employee-vlan | 00:05:85:3A:82:77 | Learn | 0   | ge-0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:79 | Learn | 0   | ge-0/0/1.0 |
| employee-vlan | 00:05:85:3A:82:80 | Learn | 0   | ge-0/0/2.0 |
| employee-vlan | 00:05:85:3A:82:81 | Learn | 0   | ge-0/0/2.0 |
| employee-vlan | *                 | Flood | -   | ge-0/0/2.0 |
| employee-vlan | *                 | Flood | -   | ge-0/0/2.0 |

**Meaning** The last two lines of the sample output show that MAC addresses for two hosts on **ge-0/0/2** were not learned, because the hosts had been moved back and forth from the original interfaces more than five times in 1 second.

  - [Monitoring Port Security on page 5155](#)

## Verifying That the Port Error Disable Setting Is Working Correctly

**Purpose** Verify that the port error disable setting is working as expected for MAC limited and storm control interfaces.

**Action** Display information about interfaces:

```
user@switch> show ethernet-switching interfaces
```

| Interface    | State | VLAN members | Blocking                |
|--------------|-------|--------------|-------------------------|
| xe-2:0/0/0.0 | up    | T1122        | unblocked               |
| xe-2:0/0/1.0 | down  | default      | MAC limit exceeded      |
| xe-2:0/0/2.0 | down  | default      | Storm control in effect |
| xe-2:0/0/3.0 | down  | default      | unblocked               |
| xe-2:0/0/4.0 | down  | default      | unblocked               |
| xe-2:0/0/5.0 | down  | default      | unblocked               |
| xe-2:0/0/6.0 | down  | default      | unblocked               |

**Meaning** For interfaces disabled by port security features, the sample output from the **show ethernet-switching interfaces** command specifies the reasons that the interfaces are disabled:

- **MAC limit exceeded**—The interface is temporarily disabled because of a **mac-limit** error. The disabled interface is automatically restored to service when the **disable-timeout (Port Error Disable)** expires.
- **MAC move limit exceeded**—The interface is temporarily disabled because of a **mac-move-limit** error. The disabled interface is automatically restored to service when the **disable-timeout** expires.
- **Storm control in effect**—The interface is temporarily disabled because of a **storm-control** error. The disabled interface is automatically restored to service when the **disable-timeout (Port Error Disable)** expires.

## Verifying That a Trusted DHCP Server Is Working Correctly

**Purpose** Verify that a DHCP trusted server is working on the switch. See what happens when the DHCP server is trusted and then untrusted.

**Action** Send some DHCP requests from network devices (here they are DHCP clients) connected to the switch.

Display the DHCP snooping information when the interface on which the DHCP server connects to the switch is trusted. The following output results when requests are sent from the MAC addresses and the server has provided the IP addresses and leases:

```
user@switch> show dhcp snooping binding
```

DHCP Snooping Information:

| MAC Address       | IP Address | Lease | Type    | VLAN          | Interface  |
|-------------------|------------|-------|---------|---------------|------------|
| 00:05:85:3A:82:77 | 192.0.2.17 | 600   | dynamic | employee-vlan | ge-0/0/1.0 |
| 00:05:85:3A:82:79 | 192.0.2.18 | 653   | dynamic | employee-vlan | ge-0/0/1.0 |
| 00:05:85:3A:82:80 | 192.0.2.19 | 720   | dynamic | employee-vlan | ge-0/0/2.0 |
| 00:05:85:3A:82:81 | 192.0.2.20 | 932   | dynamic | employee-vlan | ge-0/0/2.0 |
| 00:05:85:3A:82:83 | 192.0.2.21 | 1230  | dynamic | employee-vlan | ge-0/0/2.0 |
| 00:05:85:27:32:88 | 192.0.2.22 | 3200  | dynamic | employee-vlan | ge-0/0/2.0 |

**Meaning** When the interface on which the DHCP server connects to the switch has been set to trusted, the output (see preceding sample) shows, for each MAC address, the assigned IP address and lease time—that is, the time, in seconds, remaining before the lease expires.

If the DHCP server had been configured as untrusted, no entries would be added to the DHCP snooping database and nothing would be shown in the output of the **show dhcp snooping binding** command.

## Verifying That Three-Color Policers Are Operational

**Purpose** Verify that three-color policers in firewall filter configurations are working properly.

**Action** Use the following operational mode commands to verify that a three-color policer is working properly:

- **show class-of-service forwarding-table classifiers**
- **show interfaces *interface-name* extensive**

- `show interfaces queue interface-name`

- Related Documentation**
- [Overview of Policers on page 4967](#)
  - [Configuring Two-Color and Three-Color Policers to Control Traffic Rates on page 5054](#)

## Verifying That Two-Color Policers Are Operational

**Purpose** Verify that two-color policers in firewall filter configurations are working properly.

**Action** Use the `show firewall policer` operational mode command to verify that the policers are working properly:

```
user@switch> show firewall policer
Filter: egress-vlan-watch-employee
Filter: ingress-port-filter
Filter: ingress-port-limit-tcp-icmp
Policers:
Name                               Packets
icmp-connection-policer            10
tcp-connection-policer             539
Filter: ingress-vlan-rogue-block
Filter: ingress-vlan-limit-guest
```

**Meaning** The `show firewall policer` command displays the names of all firewall filters and policers that are configured. For each policer that is specified in a filter configuration, the output field shows the current packet count for all packets that exceed the specified rate limits.

## Sample Output

`clear firewall all`

```
user@switch> clear firewall all
```

`clear firewall counter`

```
user@switch> clear firewall counter port-filter-counter
```

`clear firewall filter`

```
user@switch> clear firewall filter ingress-port-filter
```

### Firewall Filter Configuration Returns a No Space Available in TCAM Message

**Problem**    **Description:** When a firewall filter configuration exceeds the amount of available Ternary Content Addressable Memory (TCAM) space, the system returns the following **syslogd** message:

No space available in tcam.  
Rules for filter *filter-name* will not be installed.

A switch returns this message during the commit operation if the firewall filter that has been applied to a port, VLAN, or Layer 3 interface exceeds the amount of space available

in the TCAM table. The filter is not applied, but the commit operation for the firewall filter configuration is completed in the CLI module.

**Solution** When a firewall filter configuration exceeds the amount of available TCAM table space, you must configure a new firewall filter with fewer filter terms so that the space requirements for the filter do not exceed the available space in the TCAM table.

You can perform either of the following procedures to correct the problem:

To delete the filter and its binding and apply the new smaller firewall filter to the same binding:

1. Delete the filter and its binding to ports, VLANs, or Layer 3 interfaces. For example:

```
[edit]
user@switch# delete firewall family ethernet-switching filter ingress-vlan-rogue-block
user@switch# delete vlans employee-vlan description "filter to block rogue devices on
employee-vlan"
user@switch# delete vlans employee-vlan filter input ingress-vlan-rogue-block
```

2. Commit the changes:

```
[edit]
user@switch# commit
```

3. Configure a smaller filter with fewer terms that does not exceed the amount of available TCAM space. For example:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block ...
```

4. Apply (bind) the new firewall filter to a port, VLAN, or Layer 3 interface. For example:

```
[edit]
user@switch# set vlans employee-vlan description "filter to block rogue devices on
employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

5. Commit the changes:

```
[edit]
user@switch# commit
```

To apply a new firewall filter and overwrite the existing binding but not delete the original filter:

1. Configure a firewall filter with fewer terms than the original filter:

```
[edit]
user@switch# set firewall family ethernet-switching filter new-ingress-vlan-rogue-block...
```

2. Apply the firewall filter to the port, VLAN, or Layer 3 interfaces to overwrite the binding of the original filter—for example:

```
[edit]
user@switch# set vlans employee-vlan description "smaller filter to block rogue devices on
employee-vlan"
user@switch# set vlans employee-vlan filter input new-ingress-vlan-rogue-block
```

Because you can apply no more than one firewall filter per VLAN per direction, the binding of the original firewall filter to the VLAN is overwritten with the new firewall filter **new-ingress-vlan-rogue-block**.

3. Commit the changes:

```
[edit]
user@switch# commit
```

**NOTE:** The original filter is not deleted and is still available in the configuration.

### Filter Counts Previously Dropped Packet

- Problem**    **Description:** If you configure two or more filters in the same direction for a physical interface and one of the filters includes a counter, the counter will be incorrect if the following circumstances apply:
- You configure the filter that is applied to packets first to discard certain packets. For example, imagine that you have a VLAN filter that accepts packets sent to 10.10.1.0/24 addresses and implicitly discards packets sent to any other addresses. You apply the filter to the **admin** VLAN in the output direction, and interface xe-0/0/1 is a member of that VLAN.
  - You configure a subsequent filter to accept and count packets that are dropped by the first filter. In this example, you have a port filter that accepts and counts packets sent to 192.168.1.0/24 addresses that is also applied to xe-0/0/1 in the output direction.

The egress VLAN filter is applied first and correctly discards packets sent to 192.168.1.0/24 addresses. The egress port filter is applied next and counts the discarded packets as matched packets. The packets are not forwarded, but the counter displayed by the egress port filter is incorrect.

Remember that the order in which filters are applied depends on the direction in which they are applied, as indicated here:

Ingress filters:

1. Port (Layer 2) filter
2. VLAN filter
3. Router (Layer 3) filter

Egress filters:

1. Router (Layer 3) filter
2. VLAN filter
3. Port (Layer 2) filter

**Solution**    This is expected behavior.

### Matching Packets Not Counted

---

**Problem** **Description:** If you configure two egress filters with counters for a physical interface and a packet matches both of the filters, only one of the counters includes that packet. For example:

- You configure an egress port filter with a counter for interface xe-0/0/1.
- You configure an egress VLAN filter with a counter for the **adminVLAN**, and interface xe-0/0/1 is a member of that VLAN.
- A packet matches both filters.

In this case, the packet is counted by only one of the counters even though it matched both filters.

**Solution** This is expected behavior.

### Counter Reset When Editing Filter

---

**Problem** **Description:** If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

**Solution** This is expected behavior.

### Cannot Include loss-priority and policer Actions in Same Term

---

**Problem** **Description:** You cannot include both of the following actions in the same firewall filter term in a QFX Series switch:

- **loss-priority**
- **policer**

If you do so, you see the following error message when you attempt to commit the configuration: "cannot support policer action if loss-priority is configured."

**Solution** This is expected behavior.

### Cannot Egress Filter Certain Traffic Originating on QFX Switch

**Problem** **Description:** On a QFX Series switch, you cannot filter certain traffic with a firewall filter applied in the output direction if the traffic originates on the QFX switch. This limitation applies to control traffic for protocols such as ICMP (ping), STP, LACP, and so on.

**Solution** This is expected behavior.

### Firewall Filter Match Condition Not Working with Q-in-Q Tunneling

**Problem** **Description:** If you create a firewall filter that includes a match condition of **dot1q-tag** or **dot1q-user-priority** and apply the filter on input to a trunk port that participates in a service VLAN, the match condition does not work if the Q-in-Q EtherType is not 0x8100. (When Q-in-Q tunneling is enabled, trunk interfaces are assumed to be part of the service provider or data center network and therefore participate in service VLANs.)

**Solution** This is expected behavior. To set the Q-in-Q EtherType to 0x8100, enter the **set dot1q-tunneling ethertype 0x8100** statement at the **[edit ethernet-switching-options]** hierarchy level. You must also configure the other end of the link to use the same Ethertype.

### Egress Firewall Filters with Private VLANs

**Problem** **Description:** If you apply a firewall filter in the output direction to a primary VLAN, the filter also applies to the secondary VLANs that are members of the primary VLAN when the traffic egresses with the primary VLAN tag or isolated VLAN tag, as listed below:

- Traffic forwarded from a secondary VLAN trunk port to a promiscuous port (trunk or access)
- Traffic forwarded from a secondary VLAN trunk port that carries an isolated VLAN to a PVLAN trunk port.
- Traffic forwarded from a promiscuous port (trunk or access) to a secondary VLAN trunk port
- Traffic forwarded from a PVLAN trunk port. to a secondary VLAN trunk port
- Traffic forwarded from a community port to a promiscuous port (trunk or access)

If you apply a firewall filter in the output direction to a primary VLAN, the filter does *not* apply to traffic that egresses with a community VLAN tag, as listed below:

- Traffic forwarded from a community trunk port to a PVLAN trunk port
- Traffic forwarded from a secondary VLAN trunk port that carries a community VLAN to a PVLAN trunk port
- Traffic forwarded from a promiscuous port (trunk or access) to a community trunk port
- Traffic forwarded from a PVLAN trunk port. to a community trunk port

If you apply a firewall filter in the output direction to a community VLAN, the following behaviors apply:

- The filter is applied to traffic forwarded from a promiscuous port (trunk or access) to a community trunk port (because the traffic egresses with the community VLAN tag).
- The filter is applied to traffic forwarded from a community port to a PVLAN trunk port (because the traffic egresses with the community VLAN tag).
- The filter is *not* applied to traffic forwarded from a community port to a promiscuous port (because the traffic egresses with the primary VLAN tag or untagged).

**Solution** These are expected behaviors. They occur only if you apply a firewall filter to a private VLAN in the output direction and do not occur if you apply a firewall filter to a private VLAN in the input direction.

---

#### Egress Filtering of L2PT Traffic Not Supported

**Problem** **Description:** Egress filtering of L2PT traffic is not supported on the QFX3500 switch. That is, if you configure L2PT to tunnel a protocol on an interface, you cannot also use a firewall filter to filter traffic for that protocol on that interface in the output direction. If you commit a configuration for this purpose, the firewall filter is not applied to the L2PT-tunneled traffic.

**Solution** This is expected behavior.

---

#### Cannot Drop BGP Packets in Certain Circumstances

**Problem** **Description:** BGP packets with a time-to-live (TTL) value greater than 1 cannot be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface. BGP packets with TTL value of 1 or 0 can be discarded using a firewall filter applied to a loopback interface or applied on input to a Layer 3 interface.

**Solution** This is expected behavior.

---

#### Invalid Statistics for Policer

**Problem** **Description:** If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

**Solution** This is expected behavior.

---

#### Policers can Limit Egress Filters

**Problem** **Description:** The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume

two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters.

Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.
  - Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

**Solution** You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

- [Policers Can Limit Egress Filters on page 5190](#)

---

### Incomplete Count of Packet Drops

**Problem**    **Description:** Under certain circumstances, Junos OS might display a misleading number of packets dropped by an ingress policer.

If packets are dropped because of ingress admission control, policer statistics might not show the number of packet drops you would expect by calculating the difference between ingress and egress packet counts. This might happen if you apply an ingress policer to multiple interfaces, and the aggregate ingress rate of those interfaces exceeds the line rate of a common egress interface. In this case, packets might be dropped from the ingress buffer. These drops are not included in the count of packets dropped by the policer, which causes policer statistics to underreport the total number of drops.

**Solution**    This is expected behavior.

---

### Counter Reset When Editing Filter

**Problem**    **Description:** If you edit a firewall filter term, the value of any counter associated with any term in the same filter is set to 0, including the implicit counter for any policer referenced by the filter. Consider the following examples:

- Assume that your filter has **term1**, **term2**, and **term3**, and each term has a counter that has already counted matching packets. If you edit any of the terms in any way, the counters for all the terms are reset to 0.
- Assume that your filter has **term1** and **term2**. Also assume that **term2** has a **policer** action modifier and the implicit counter of the policer has already counted 1000 matching packets. If you edit **term1** or **term2** in any way, the counter for the policer referenced by **term2** is reset to 0.

**Solution**    This is expected behavior.

---

### Invalid Statistics for Policer

**Problem**    **Description:** If you apply a single-rate two-color policer in more than 128 terms in a firewall filter, the output of the **show firewall** command displays incorrect data for the policer.

**Solution** This is expected behavior.

### Egress Policers on QFX3500 Devices Might Allow More Throughput Than Is Configured

**Problem** **Description:** If you configure a policer to rate-limit throughput and apply it on egress to multiple interfaces on a QFX3500 switch or Node, the measured aggregate policed rate might be twice the configured rate, depending on which interfaces you apply the policer to. The doubling of the policed rate occurs if you apply a policer to multiple interfaces and *both* of the following are true:

- There is at least one policed interface in the range xe-0/0/0 to xe-0/0/23 or the range xe-0/1/1 to xe-0/1/7.
- There is at least one policed interface in the range xe-0/0/24 to xe-0/0/47 or the range xe-0/1/8 to xe-0/1/15.

For example, if you configure a policer to rate-limit traffic at 1 Gbps and apply the policer (by using a firewall filter) to xe-0/0/0 and xe-0/0/24 in the output direction, each interface is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps. The same behavior occurs if you apply the policer to xe-0/1/1 and xe-0/0/24—each interface is rate-limited at 1 Gbps.

If you apply the same policer on egress to multiple interfaces in these groups, each *group* is rate-limited at 1 Gbps. For example, if you apply the policer to xe-0/0/0 through xe-0/0/4 (five interfaces) and xe-0/0/24 through xe-0/0/33 (ten interfaces), each group is rate-limited at 1 Gbps, for a total allowed throughput of 2 Gbps.

Here is another example: If you apply the policer to xe-0/0/0 through xe-0/0/4 and xe-0/1/1 through xe-0/1/5 (a total of ten interfaces), that group is rate-limited at 1 Gbps in aggregate. If you also apply the policer to xe-0/0/24, that one interface is rate-limited at 1 Gbps while the other ten are still rate-limited at 1 Gbps in aggregate.

Interfaces xe-0/1/1 through xe-0/1/15 are physically located on the QSFP+ uplink ports, according to the following scheme:

- xe-0/1/1 through xe-0/1/3 are on Q0.
- xe-0/1/4 through xe-0/1/7 are on Q1.
- xe-0/1/8 through xe-0/1/11 are on Q2.
- xe-0/1/12 through xe-0/1/15 are on Q3.

The doubling of the policed rate occurs only if the policer is applied in the output direction. If you configure a policer as described above but apply it in the input direction, the total allowed throughput for all interfaces is 1 Gbps.

**Solution** This is expected behavior.

### Filter-Specific Egress Policers on QFX3500 Devices Might Allow More Throughput Than Is Configured

---

**Problem** **Description:** You can configure policers to be filter-specific, which means that Junos OS creates only one policer instance regardless of how many times the policer is referenced. When you do this, rate limiting is applied in aggregate, so if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms, the total bandwidth allowed by the filter is 1 Gbps. However, the behavior of a filter-specific policer is affected by how the firewall filter terms that reference the policer are stored in ternary content addressable memory (TCAM). If you create a filter-specific policer and reference it in multiple firewall filter terms, the policer allows more traffic than expected if the terms are stored in different TCAM slices. For example, if you configure a policer to discard traffic that exceeds 1 Gbps and reference that policer in three different terms that are stored in three separate memory slices, the total bandwidth allowed by the filter is 3 Gbps, not 1 Gbps.

**Solution** To prevent this unexpected behavior, use the information about TCAM slices presented in [“Planning the Number of Firewall Filters to Create” on page 4961](#) to organize your configuration file so that all the firewall filter terms that reference a given filter-specific policer are stored in the same TCAM slice.

### Policers Can Limit Egress Filters

---

**Problem** **Description:** The number of egress policers that you configure can affect the total number of allowed egress firewall filters. Every policer has two implicit counters that consume two entries in a 1024-entry TCAM that is used for counters, including counters that are configured as action modifiers in firewall filter terms. (Policers consume two entries because one is used for green packets and one is used for nongreen packets regardless of policer type.) If the TCAM becomes full, you cannot commit any more egress firewall filters that have terms with counters. For example, if you configure and commit 512 egress policers (two-color, three-color, or a combination of both policer types), all of the memory entries for counters are used up. If later in your configuration file you insert additional egress firewall filters with terms that also include counters, *none* of the terms in those filters are committed because there is no available memory space for the counters. Here are some additional examples:

- Assume that you configure egress filters that include a total of 512 policers and no counters. Later in your configuration file you include another egress filter with 10 terms, 1 of which has a counter action modifier. None of the terms in this filter are committed because there is not enough TCAM space for the counter.
- Assume that you configure egress filters that include a total of 500 policers, so 1000 TCAM entries are occupied. Later in your configuration file you include the following two egress filters:
  - Filter A with 20 terms and 20 counters. All the terms in this filter are committed because there is enough TCAM space for all the counters.

- Filter B comes after Filter A and has five terms and five counters. *None* of the terms in this filter are committed because there is not enough memory space for *all* the counters. (Five TCAM entries are required but only four are available.)

**Solution** You can prevent this problem by ensuring that egress firewall filter terms with counter actions are placed earlier in your configuration file than terms that include policers. In this circumstance, Junos OS commits policers even if there is not enough TCAM space for the implicit counters. For example, assume the following:

- You have 1024 egress firewall filter terms with counter actions.
- Later in your configuration file you have an egress filter with 10 terms. None of the terms have counters but one has a policer action modifier.

You can successfully commit the filter with 10 terms even though there is not enough TCAM space for the implicit counters of the policer. The policer is committed without the counters.

### Port Mirroring Overview

---

Port mirroring copies packets entering or exiting a port or entering a VLAN and sends the copies to a local interface for local monitoring or to a VLAN for remote monitoring. Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on.

Port mirroring is needed for traffic analysis on a switch because a switch normally sends packets only to the port to which the destination device is connected. You configure port mirroring on the switch to send copies of unicast traffic to a local interface or a VLAN and run an analyzer application on a device connected to the interface or VLAN. You configure port mirroring by using the **analyzer** statement.

Keep performance in mind when configuring port mirroring. For example, If you mirror traffic from multiple ports, the mirrored traffic may exceed the capacity of the output interface. We recommend that you limit the amount of copied traffic by selecting specific interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter to send specific traffic to a port mirroring instance. Mirroring only the necessary packets reduces the possibility of a performance impact.

You can use port mirroring to copy any of the following:

- All packets entering or exiting an interface (in any combination)—For example, you can send copies of the packets entering some interfaces and the packets exiting other interfaces to the same local interface or VLAN. If you configure port mirroring to copy packets exiting an interface, traffic that originates on that switch or Node device (in a QFabric system) is not copied when it egresses. Only switched traffic is copied on egress. (See the limitation on egress mirroring below.)
- All packets entering a VLAN—You cannot use port mirroring to copy packets exiting a VLAN.
- Firewall-filtered sample—Sample of packets entering a port or VLAN. Configure a firewall filter to select certain packets for mirroring.

**NOTE:** Firewall filters are not supported on egress ports; therefore, you cannot specify policy-based sampling of packets exiting an interface.

### Port Mirroring Instance Types

To configure port mirroring, you configure an instance of one of the following types:

- Analyzer instance: You must specify the input and output for the instance. This instance type is useful for ensuring that all traffic transiting an interface or VLAN is mirrored and sent to the analyzer device.
- Port-mirroring instance: You do not specify an input for this instance type. Instead, you create a firewall filter that specifies the required traffic and directs it to the mirror. This instance type is useful for controlling which types of traffic should be mirrored. When you use a port-mirroring instance, you can direct traffic to it in the following ways:
  - Specify the name of the port-mirroring instance in the firewall filter using the **port-mirror-instance *instance-name*** action. You should use this approach if there are multiple port-mirroring instances defined.
  - Configure the filter to send the mirrored packets to the output interface defined in the instance using the **port-mirror** action. You can use this approach if there is only one port-mirroring instance defined.

### Port-Mirroring Terminology

Table 372 on page 5196 lists the terms used in the documentation about port mirroring and provides definitions.

**Table 372: Port Mirroring Terms and Definitions**

| Term              | Description                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Analyzer instance | Port-mirroring configuration that includes a name, source interfaces or source VLAN, and a destination for mirrored packets (either a local access interface or a VLAN). |

Table 372: Port Mirroring Terms and Definitions (*continued*)

|                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Port mirroring instance                                         | A port-mirroring configuration that does not specify an input.. A firewall filter must be used to send traffic to the port mirror. Use the action <b>port-mirror-instance</b> <i>instance-name</i> in the firewall filter configuration to send packets to the port mirror.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Output interface (also known as monitor interface)              | <p>Access interface to which packet copies are sent and to which a device running an analyzer application is connected.</p> <p>The following limitations apply to an output interface:</p> <ul style="list-style-type: none"> <li>• Cannot also be a source port.</li> <li>• Cannot be used for switching.</li> <li>• Cannot be an aggregated Ethernet interface (LAG).</li> <li>• Does not participate in Layer 2 protocols, such as Spanning Tree Protocol (STP).</li> <li>• Loses any existing VLAN associations when you configure it as an analyzer output interface.</li> </ul> <p>If the capacity of the output interface is insufficient to handle the traffic from the source ports, overflow packets are dropped.</p>                                                                            |
| Output IP address                                               | <p>IP address of the device running an analyzer application. The device can be on a remote network. When you use this feature, the mirrored packets are GRE-encapsulated. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)</p> <ul style="list-style-type: none"> <li>• An output IP address cannot be in the same subnetwork as any of the switch's management interfaces.</li> <li>• If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).</li> </ul> |
| Output VLAN (also known as monitor or analyzer VLAN)            | <p>VLAN to which copies are sent and to which a device running an analyzer application is connected. The analyzer VLAN can span multiple switches.</p> <p>The following limitations apply to an output VLAN:</p> <ul style="list-style-type: none"> <li>• Cannot be a private VLAN or VLAN range.</li> <li>• Cannot be shared by multiple <b>analyzer</b> statements.</li> <li>• An output VLAN interface cannot be a member of any other VLAN.</li> <li>• An output VLAN interface cannot be an aggregated Ethernet interface (LAG).</li> <li>• On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.</li> </ul>                                                                                                                                                     |
| Input interface (also known as mirrored or monitored interface) | Interface that provides traffic to be mirrored. This traffic can be entering or exiting the interface. (Ingress or egress traffic can be mirrored.) An input interface cannot also be an output interface for an analyzer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Monitoring station                                              | Computer running an analyzer application.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Local port mirroring                                            | Port-mirroring configuration in which the mirrored packets are sent to an interface on the same switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Remote port mirroring                                           | Flooding mirrored packets to an analyzer VLAN that you create to receive mirror traffic or sending the mirrored packets to a remote IP address. (You cannot send mirrored packets to a remote IP address on a QFabric system.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 372: Port Mirroring Terms and Definitions (*continued*)

|                        |                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Policy-based mirroring | Mirroring of packets that match the match a firewall filter term. The action <b>analyzer analyzer-name</b> is used in the firewall filter to send the packets to the analyzer. |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Port Mirroring and STP

The behavior of STP in a port-mirroring configuration depends on the version of Junos OS you are using:

- Junos OS 13.2X50, Junos OS 13.2X51-D25 or earlier, Junos OS 13.2X52: If you enable STP, port mirroring might not work because STP might block the mirrored packets.
- Junos OS 13.2X51-D30, Junos OS 14.1X53: STP is disabled for mirrored traffic. You must ensure that your topology prevents loops for this traffic.

### Port Mirroring Constraints and Limitations

- [Local and Remote Port Mirroring on page 5198](#)
- [Remote Port Mirroring Only on page 5200](#)

#### Local and Remote Port Mirroring

The following constraints and limitations apply to local and remote port mirroring:

- You can create a total of four port-mirroring configurations.
- You can create a total of four port-mirroring configurations on each Node group in a QFabric system, subject to the following constraints:
  - As many as four of the configurations can be for local port mirroring.
  - As many as three of the configurations can be for remote port mirroring.
- Regardless of whether you are configuring a standalone switch or a Node group, the following limits apply:
  - There can be no more than two configurations that mirror ingress traffic. (If you configure a firewall filter to send traffic to a port mirror—that is, you use the **analyzer** action modifier in a filter term—this counts as an ingress mirroring configuration for switch or Node group on which the filter is applied.)
  - There can be no more than two configurations that mirror egress traffic.

**NOTE:** On QFabric systems, there is no system-wide limit on the total number of mirror sessions.

- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer name output** statement:
  - **interface**
  - **ip-address**

- **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a standalone switch or QFabric system. If you do so, some VLAN packets might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.
- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
  - Dedicated Virtual Chassis interfaces
  - Management interfaces (me0 or vme0)
  - Fibre Channel interfaces
  - Routed VLAN interfaces
- An aggregated Ethernet interface cannot be an output interface if the input is a VLAN or if traffic is sent to the analyzer by a firewall filter.
- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- CPU-generated packets (such as ARP, ICMP, BPDU, and LACP packets) cannot be mirrored on egress.
- VLAN-based mirroring is not supported for STP traffic.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

### **Remote Port Mirroring Only**

The following constraints and limitations apply to remote port mirroring:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.
- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

## **Understanding Layer 3 Logical Interfaces**

A Layer 3 logical interface is a logical division of a physical interface that operates at the network level and therefore can receive and forward 802.1Q VLAN tags. You can use Layer 3 logical interfaces to route traffic among multiple VLANs along a single trunk line that connects a Juniper Networks switch to a Layer 2 switch. Only one physical connection is required between the switches. You can also use Layer 3 logical interfaces to provide alternative gateway addresses for smart DHCP relay.

To create Layer 3 logical interfaces on a switch, enable VLAN tagging, partition the physical interface into logical partitions, and bind the VLAN ID to the logical interface.

We recommend that you use the VLAN ID as the logical interface number when you configure the logical interface. QFX Series and EX4600 switches support a maximum of 4089 VLANs, which includes the default VLAN. You can, however, assign a VLAN ID in the range of 1 to 4094, but five of these VLAN IDs are reserved for internal use.

VLAN tagging places the VLAN ID in the frame header, allowing each physical interface to handle multiple VLANs. When you configure multiple VLANs on an interface, you must also enable tagging on that interface. Junos OS on switches supports a subset of the 802.1Q standard for receiving and forwarding routed or bridged Ethernet frames with single VLAN tags and running Virtual Router Redundancy Protocol (VRRP) over 802.1Q-tagged interfaces.

## DHCP Relay

---

- [DHCP and BOOTP Relay Overview on page 5201](#)

### DHCP and BOOTP Relay Overview

You can configure a Juniper Networks switch to act as a Dynamic Host Configuration Protocol (DHCP) or Bootstrap Protocol (BOOTP) relay agent. This means that if the switch receives a broadcast DHCP or BOOTP request from a locally attached host (client), it relays the message to a specified DHCP or BOOTP server. You should configure the switch to be a DHCP/BOOTP relay agent if you have locally attached hosts and a distant DHCP or BOOTP server.

If you configure a switch to be a DHCP relay agent, you can also enable smart DHCP relay, which enables you to configure alternative gateway addresses for a DHCP server so that if the server fails to reply to the requests sent to the primary gateway address, the switch can resend the requests to the alternative gateway addresses. To use this feature, you must configure a routed VLAN interface or Layer 3 subinterface with multiple IP addresses and configure that interface to be a relay agent.

**NOTE:** Because DHCP and BOOTP messages are broadcast and are not directed to a specific server, switch, or router, Juniper switches cannot function as both a DHCP server and a DHCP/BOOTP relay agent at the same time. The Junos operating system (Junos OS) generates a commit error if both options are configured at the same time, and the commit operation does not succeed until one of the options is removed.

### Example: Configuring Port Mirroring for Local Analysis

Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on. Port mirroring copies packets entering or exiting an interface or entering a VLAN and sends the copies to a local interface for local monitoring.

**NOTE:** This example uses a release of Junos OS that does not support the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Examples: Configuring Port Mirroring for Local Analysis*. For ELS details, see *Getting Started with Enhanced Layer 2 Software*.

This example describes how to configure port mirroring to copy traffic sent by employee computers to a switch to an access interface on the same switch.

- [Overview and Topology on page 5204](#)
- [Mirroring All Employee Traffic for Local Analysis on page 5204](#)
- [Mirroring Employee-to-Web Traffic for Local Analysis on page 5205](#)
- [Verification on page 5207](#)

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 11.1
- A switch

## Overview and Topology

This topic includes two related examples that describe how to mirror traffic entering interfaces on the switch to an access interface on the same switch. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

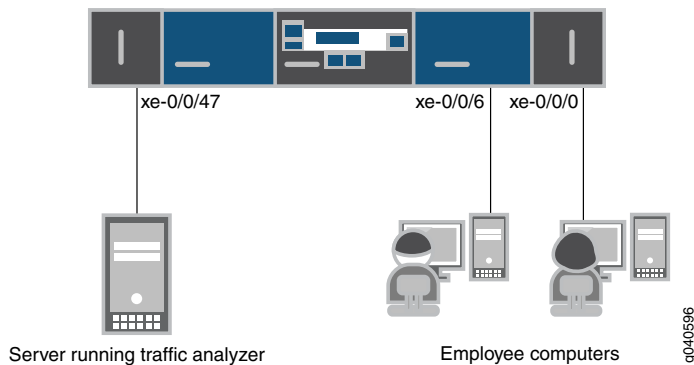

In this example, **xe-0/0/0** and **xe-0/0/6** serve as connections for employee computers. Interface **xe-0/0/47** is connected to a device running an analyzer application.

**NOTE:** Multiple ports mirrored to one interface can cause buffer overflow and dropped packets.

Figure 202 on page 5204 shows the network topology for this example.

Figure 202: Network Topology for Local Port Mirroring Example

## Mirroring All Employee Traffic for Local Analysis

To configure port mirroring for all traffic sent by employee computers for local analysis, perform the tasks explained in this section.

### CLI Quick Configuration

To quickly configure local port mirroring for ingress traffic to the two ports connected to employee computers, copy the following commands and paste them into a switch terminal window:

```
[edit]
set interfaces xe-0/0/0 unit 0 family ethernet-switching
set interfaces xe-0/0/6 unit 0 family ethernet-switching
set interfaces xe-0/0/47 unit 0 family ethernet-switching
set ethernet-switching-options analyzer employee-monitor input ingress interface xe-0/0/0.0
```

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | <pre>set ethernet-switching-options analyzer employee-monitor input ingress interface xe-0/0/6.0 set ethernet-switching-options analyzer employee-monitor output interface xe-0/0/47.0</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step-by-Step Procedure</b> | <p>To configure an analyzer called <b>employee-monitor</b> and specify the input (source) interfaces and the output interface:</p> <ol style="list-style-type: none"> <li>1. Configure the interfaces connected to employee computers as input interfaces for the port-mirror analyzer <b>employee-monitor</b>: <pre>[edit ethernet-switching-options] user@switch# set analyzer employee-monitor input ingress interface xe-0/0/0.0 user@switch# set analyzer employee-monitor input ingress interface xe-0/0/6.0</pre> </li> <li>2. Configure the output analyzer interface for the <b>employee-monitor</b> analyzer. This will be the destination interface for the mirrored packets: <pre>[edit ethernet-switching-options] user@switch# set analyzer employee-monitor output interface xe-0/0/47.0</pre> </li> </ol> |

**Results** Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
analyzer employee-monitor {
  input {
    ingress {
      interface xe-0/0/0.0;
      interface xe-0/0/6.0;
    }
  }
  output {
    interface {
      xe-0/0/47.0;
    }
  }
}
```

### Mirroring Employee-to-Web Traffic for Local Analysis

To mirror only traffic sent by employees to the Web for local analysis, perform the tasks explained in this section.

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CLI Quick Configuration</b> | <p>To quickly configure local port mirroring of traffic from employee computers that is destined for the Web, copy the following commands and paste them into a switch terminal window:</p> <pre>[edit] set ethernet-switching-options analyzer employee-web-monitor output interface xe-0/0/47.0 set firewall family ethernet-switching filter watch-employee term employee-to-corp from destination-address 192.0.2.16/28 set firewall family ethernet-switching filter watch-employee term employee-to-corp from source-address 192.0.2.16/28 set firewall family ethernet-switching filter watch-employee term employee-to-corp then accept set firewall family ethernet-switching filter watch-employee term employee-to-web from destination-port 80 set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer employee-web-monitor set interfaces xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee</pre> |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Step-by-Step Procedure** `set interfaces xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee`

To configure local port mirroring of employee-to-web traffic from the two ports connected to employee computers:

1. Configure the output interface:
 

```
[edit interfaces]
user@switch# set xe-0/0/47 unit 0 family ethernet-switching
```
2. Configure the **employee-web-monitor** analyzer output. (Configure only the output—the input comes from the filter.)
 

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-web-monitor output interface xe-0/0/47.0
```
3. Configure a firewall filter called **watch-employee** that includes a term to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**. Traffic to and from the corporate subnet (destination or source address of **192.0.2.16/28**) does not need to be copied, so create another term to accept that traffic before it reaches the term that sends Web traffic to the analyzer:
 

```
[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-corp from destination-address 192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp from source-address 192.0.2.16/28
user@switch# set filter watch-employee term employee-to-corp then accept
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer employee-web-monitor
```
4. Apply the firewall filter to the appropriate interfaces as an ingress filter (egress filters do not allow analyzers):
 

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family ethernet-switching filter input watch-employee
user@switch# set xe-0/0/6 unit 0 family ethernet-switching filter input watch-employee
```

**Results** Check the results of the configuration:

```
[edit]
user@switch# show ethernet-switching-options
  analyzer employee-web-monitor {
    output {
      interface xe-0/0/47.0;
    }
  }
...
firewall family ethernet-switching {
  filter watch-employee {
    term employee-to-web {
      from {
        destination-port 80;
      }
      then analyzer employee-web-monitor;
    }
  }
}
```

```

interfaces {
  xe-0/0/0 {
    unit 0 {
      family ethernet-switching {
        filter {
          input watch-employee;
        }
      }
    }
  }
  xe-0/0/6 {
    family ethernet-switching {
      filter {
        input watch-employee;
      }
    }
  }
}

```

### Verification

#### *Verifying That the Analyzer Has Been Correctly Created*

**Purpose** Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.

**Action** You can verify that the port mirror analyzer has been configured as expected using the **show analyzer** command.

```

user@switch> show analyzer
Analyzer name           : employee-monitor
Output interface        : xe-0/0/47.0
Mirror ratio            : 1
Loss priority           : Low
Ingress monitored interfaces : xe-0/0/0.0
Ingress monitored interfaces : xe-0/0/6.0
Egress monitored interfaces : None

```

**Meaning** This output shows that the **employee-monitor** analyzer:

- Has a ratio of 1 (mirroring every packet, the default setting)
- Has a loss priority of low (set this option to high only when the analyzer output is to a VLAN)
- Is mirroring the traffic entering the **xe-0/0/0** and **xe-0/0/6** interfaces
- Is sending the mirrored traffic to the **xe-0/0/47** interface

**Related Documentation**

- [Understanding Port Mirroring on page 5195](#)
- [Configuring Port Mirroring on page 5212](#)

- [Example: Configuring Port Mirroring for Remote Analysis on page 5208](#)

## Example: Configuring Port Mirroring for Remote Analysis

Use port mirroring to send traffic to applications that analyze traffic for purposes such as monitoring compliance, enforcing policies, detecting intrusions, monitoring and predicting traffic patterns, correlating events, and so on. Port mirroring copies packets entering or exiting an interface or entering a VLAN and sends the copies either to a local interface for local monitoring or to a VLAN for remote monitoring. This example describes how to configure port mirroring for remote analysis.

**NOTE:** This example uses a release of Junos OS that does not support the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Example: Configuring Port Mirroring for Remote Analysis*. For ELS details, see *Getting Started with Enhanced Layer 2 Software*.

---

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 12.1 for the QFX Series
- A switch

---

### Overview and Topology

This topic includes two related examples that describe how to mirror traffic entering ports on the switch to an analyzer VLAN so that you can perform analysis using a remote device. The first example shows how to mirror all traffic sent by employee computers to the switch. The second example includes a filter to mirror only the employee traffic going to the Web.

In this example:

- Interfaces **ge-0/0/0** and **ge-0/0/1** are Layer 2 interfaces that connect to employee computers.
- Interface **ge-0/0/10** is a Layer 2 interface that connects to another switch.
- VLAN **remote-analyzer** is configured on all switches in the topology to carry the mirrored traffic.

**NOTE:** In addition to performing the configuration steps described here, you must also configure the analyzer VLAN (remote-analyzer in this example) on the other switches that are used to connect the source switch (the one in this configuration) to the one that the monitoring station is connected to.

### Mirroring All Employee Traffic for Remote Analysis

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```
[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/0.0
set ethernet-switching-options analyzer employee-monitor input ingress interface ge-0/0/1.0
set ethernet-switching-options analyzer employee-monitor output vlan remote-analyzer
```

#### Step-by-Step Procedure

To configure basic remote port mirroring:

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):  

```
[edit vlans]
user@switch# set vlans remote-analyzer vlan-id 999
```
2. Configure the interface connected to another switch for trunk mode and associate it with the **remote-analyzer** VLAN:  

```
[edit interfaces]
user@switch# set ge-0/0/10 unit 0 family ethernet-switching port-mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999
```
3. Configure the **employee-monitor** analyzer:  

```
[edit ethernet-switching-options]
user@switch# set analyzer employee-monitor
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/0.0
user@switch# set analyzer employee-monitor input ingress interface ge-0/0/1.0
user@switch# set analyzer employee-monitor output vlan remote-analyzer
```
4. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

**Results** Check the results of the configuration:

```
[edit]
user@switch# show
ethernet-switching-options {
  analyzer employee-monitor {
    input {
      ingress {
        interface ge-0/0/0.0;
        interface ge-0/0/1.0;
      }
    }
  }
  output {
```

```

        vlan {
            remote-analyzer;
        }
    }
}

```

### Mirroring Employee-to-Web Traffic for Remote Analysis

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **edit** hierarchy level:

```

[edit]
set vlans remote-analyzer vlan-id 999
set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
set interfaces ge-0/0/10 unit 0 family ethernet-switching vlan members 999
set ethernet-switching-options analyzer employee-web-monitor loss-priority high output vlan 999
set firewall family ethernet-switching filter watch-employee term employee-to-web from destination-port 80
set firewall family ethernet-switching filter watch-employee term employee-to-web then analyzer employee-web-monitor
set ge-0/0/0 unit 0 family ethernet-switching filter input watch-employee
set interfaces ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee

```

#### Step-by-Step Procedure

1. Configure the analyzer VLAN (called **remote-analyzer** in this example):  

```

[edit vlans]
user@switch# set remote-analyzer vlan-id 999

```
2. Configure an interface to associate it with the **remote-analyzer** VLAN:  

```

[edit interfaces]
user@switch# set interfaces ge-0/0/10 unit 0 family ethernet-switching port mode trunk
user@switch# set ge-0/0/10 unit 0 family ethernet-switching vlan members 999

```
3. Configure the **employee-web-monitor** analyzer. (Configure only the output—the input comes from the filter.)  

```

[edit ethernet-switching-options]
user@switch# set ethernet-switching-options analyzer employee-web-monitor output vlan 999

```
4. Configure a firewall filter called **watch-employee** to match traffic sent to the Web and send it to the analyzer **employee-web-monitor**:  

```

[edit firewall family ethernet-switching]
user@switch# set filter watch-employee term employee-to-web from destination-port 80
user@switch# set filter watch-employee term employee-to-web then analyzer employee-web-monitor

```
5. Apply the firewall filter to the appropriate interfaces as an ingress filter:  

```

[edit interfaces]
user@switch# set ge-0/0/0 unit 0 family ethernet-switching filter input watch-employee
user@switch# set ge-0/0/1 unit 0 family ethernet-switching filter input watch-employee

```
6. Configure the **remote-analyzer** VLAN on the switches that connect this switch to the monitoring workstation.

**Results** Check the results of the configuration:

```

[edit]
user@switch# show
interfaces {
  ...
  ge-0/0/10 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members remote-analyzer;
        }
      }
    }
  }
  ge-0/0/0 {
    unit 0 {
      family ethernet-switching {
        filter {
          input watch-employee;
        }
      }
    }
  }
  ge-0/0/1 {
    unit 0 {
      family ethernet-switching {
        filter {
          input watch-employee;
        }
      }
    }
  }
}
...
firewall {
  family ethernet-switching {
    ...
    filter watch-employee {
      term employee-to-web {
        from {
          destination-port 80;
        }
        then analyzer employee-web-monitor;
      }
    }
  }
}
ethernet-switching-options {
  analyzer employee-web-monitor {
    output {
      vlan {
        999;
      }
    }
  }
}
vlangs {

```

```
remote-analyzer {  
    vlan-id 999;  
}  
}
```

---

### Verification

#### *Verifying That the Analyzer Has Been Correctly Created*

- Purpose** Verify that the analyzer named **employee-monitor** or **employee-web-monitor** has been created on the switch with the appropriate input interfaces and appropriate output interface.
- Action** You can verify the port mirror analyzer is configured as expected using the **show analyzer** command.
- ```
user@switch> show analyzer  
Analyzer name           : employee-monitor  
Output VLAN             : remote-analyzer  
Ingress monitored interfaces : ge-0/0/0.0  
Ingress monitored interfaces : ge-0/0/1.0
```
- Meaning** This output shows that the **employee-monitor** analyzer is mirroring the traffic entering **ge-0/0/0** and **ge-0/0/1** and is sending the mirror traffic to the analyzer **remote-analyzer**.

---

## Configuration Tasks

- [Configuring Port Mirroring on page 5212](#)
- [Configuring DHCP and BOOTP Relay on page 5215](#)

### Configuring Port Mirroring

You use port mirroring to copy packets and send the copies to a device running an application such as a network analyzer or intrusion detection application so that you can analyze traffic without delaying it. You can mirror traffic entering or exiting a port or entering a VLAN, and you can send the copies to a local access interface or to a VLAN through a trunk interface.

We recommend that you disable port mirroring when you are not using it. To avoid creating a performance issue if you do enable port mirroring, we recommend that you select specific input interfaces instead of using the **all** keyword. You can also limit the amount of mirrored traffic by using a firewall filter.

**NOTE:** This task uses a release of Junos OS that does not support the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Configuring Port Mirroring*. For ELS details, see *Getting Started with Enhanced Layer 2 Software*.

**NOTE:** If you want to create additional analyzers without deleting an existing analyzer, first disable the existing analyzer using the **disable analyzer analyzer-name** command.

**NOTE:** You must configure port mirroring output interfaces as **family ethernet-switching**.

- [Configuring Port Mirroring for Local Analysis on page 5213](#)
- [Configuring Port Mirroring for Remote Analysis on page 5214](#)
- [Filtering the Traffic Entering an Analyzer on page 5215](#)

### Configuring Port Mirroring for Local Analysis

To mirror interface traffic to a local interface on the switch:

1. If you want to mirror traffic that is ingressing or egressing specific interfaces, choose a name for the port-mirroring configuration and configure what traffic should be mirrored by specifying the interfaces and direction of traffic:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name input (ingress | egress) interface interface-name
```

**NOTE:** If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs. If you do so, some VLAN packets might contain incorrect VLAN IDs.

**NOTE:** If you configure mirroring for packets that egress an access interface, the original packets lose any VLAN tags when they exit the access interface, but the mirrored (copied) packets retain the VLAN tags when they are sent to the analyzer system.

2. If you want to specify that all traffic entering a VLAN should be mirrored, choose a name for the port-mirroring configuration and specify the VLAN:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name input ingress vlan vlan-name
```

**NOTE:** You cannot configure port mirroring to copy traffic that egresses a VLAN.

3. Configure the destination interface for the mirrored packets:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name output interface interface-name
```

---

### Configuring Port Mirroring for Remote Analysis

---

To mirror traffic to a VLAN for analysis at a remote location:

1. Configure a VLAN to carry the mirrored traffic:

```
[edit]
user@switch# set vlans vlan-name vlan-id number
```

2. Configure the interface that connects to another switch (the uplink interface) to trunk mode and associate it with the appropriate VLAN:

```
[edit]
user@switch# set interfaces interface-name unit 0 family ethernet-switching port-mode
trunk vlan members (vlan-name | vlan-id)
```

3. Configure the analyzer:

- a. Choose a name for the analyzer:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name
```

- b. Specify the interface to be mirrored and whether the traffic should be mirrored on ingress or egress:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name input (ingress | egress) interface interface-name
```

- c. Specify the appropriate IP address or VLAN as the output (a VLAN is specified in this example:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name output vlan (vlan-name | vlan-id)
```

If you specify an IP address as the output, note the following constraints:

- The address cannot be in the same subnet as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (**inet.0** routing table).
- The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.)

### Filtering the Traffic Entering an Analyzer

In addition to specifying which traffic to mirror by configuring an analyzer, you can also use a firewall filter to exercise more control over which packets are copied. For example, you might use a filter to specify that only traffic from certain applications be mirrored. The filter can use any of the available match conditions and must have an action of **analyzer *analyzer-name***. If you use the same analyzer in multiple filters or terms, the output packets are copied only once.

**NOTE:** You can include the action **analyzer** in ingress firewall filters only. You can apply ingress filters with this action to ports (Layer 2 interfaces), Layer 3 interfaces, and VLANs.

When you use a firewall filter as the input to an analyzer, you output the copied traffic to a local interface or a VLAN just as you do when a firewall is not involved.

To configure port mirroring with filters:

1. Configure an analyzer for local or remote analysis. Configure only the output. For example, for local analysis enter:

```
[edit ethernet-switching-options]
user@switch# set analyzer analyzer-name output interface interface-name
```

**NOTE:** Do not configure input to this analyzer.

2. Create a firewall filter using any of the available match conditions and specify the action as **analyzer *analyzer-name***.
3. Apply the firewall filter to the interfaces or VLAN that should provide the input to the analyzer:

```
[edit]
user@switch# set interfaces interface-name unit 0 family ethernet-switching filter input
filter-name
[edit]
user@switch# set vlan (vlan-name | vlan-id) filter input filter-name
```

### Configuring DHCP and BOOTP Relay

You can configure the QFX Series to act as a Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) relay agent. This means that if a locally attached host can issue a DHCP or BOOTP request as a broadcast message and the switch relays the

message to a specified DHCP or BOOTP server. You should configure a switch to be a DHCP and BOOTP relay agent if you have locally attached hosts and a remote DHCP or BOOTP server.

**NOTE:** This task uses a release of Junos OS that does not support the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Configuring DHCP and BOOTP*. For ELS details, see *Getting Started with Enhanced Layer 2 Software*.

If you configure a switch to be a DHCP relay agent, you can also enable smart DHCP relay, which allows you to configure alternative gateway addresses for a DHCP server so that if the server fails to reply to the requests sent using the primary gateway address, the switch can resend the requests via the alternative gateway addresses. To use this feature, you must configure a routed VLAN interface or Layer 3 logical interface with multiple IP addresses and configure that interface to be a relay agent.

- [Configuring a DHCP and BOOTP Relay Agent on page 5216](#)
- [Configuring DHCP Smart Relay on page 5217](#)

---

### Configuring a DHCP and BOOTP Relay Agent

---

To configure a switch to act as a DHCP and BOOTP relay agent, include the **bootp** statement at the **[edit forwarding-options helpers]** hierarchy level:

```
[edit forwarding-options helpers]
bootp {
  apply-secondary-as-giaddr text-description;
  client-response-ttl number;
  description text-description;
  interface (interface-name | interface-group) {
    client-response-ttl number;
    description text-description;
    maximum-hop-count number;
    minimum-wait-time seconds;
    no-listen;
    server address
    apply-secondary-as-giaddr
  }
  maximum-hop-count number;
  minimum-wait-time seconds;
  relay-agent-option;
  server server-identifier
}
```

To include a description of the BOOTP service, DHCP service, or interface, use the **description** statement.

To configure a logical interface or a group of logical interfaces with a specific DHCP relay or BOOTP configuration, include the **interface** statement.

To stop packets from being forwarded, include the **no-listen** statement.

To set the maximum allowed number in the hops field of the BOOTP message, include the **maximum-hop-count** statement. BOOTP messages that have a larger number in the hops field than the maximum allowed are not forwarded. If you omit the **maximum-hop-count** statement, the default maximum number of hops is four.

To set the minimum allowed number of seconds in the **secs** field of the BOOTP message, include the **minimum-wait-time** statement. This setting configures a minimum number of seconds since the client sent its first BOOTP request. BOOTP messages that have a smaller number in the **secs** field than the allowed minimum are not forwarded. The default value for the minimum wait time is zero (0).

To set the IP address that specify the DHCP or BOOTP server for the router, switch, or interface, include the **server** statement. You can include multiple **server** statements.

To set an IP time-to-live (TTL) value for DHCP response packets sent to a DHCP client, include the **client-response-ttl** statement.

The following example demonstrates a BOOTP relay agent configuration.

```
user@host# show forwarding-options
helpers {
  bootp {
    description "dhcp relay agent global parameters";
    server 192.168.55.44;
    server 172.16.0.3 routing-instance c3;
    maximum-hop-count 10;
    minimum-wait-time 8;
    interface {
      xe-0/0/1 {
        description "use this info for this interface";
        server 10.10.10.10;
        server 192.168.14.14;
        maximum-hop-count 11;
        minimum-wait-time 3;
      }
      xe-0/0/2 {
        no-listen; ###ignore DHCPDISCOVER messages on this interface
      }
    }
    all {
      description "globals apply to all other interfaces";
    }
  }
}
```

### Configuring DHCP Smart Relay

You can use DHCP smart relay to provide redundancy and resiliency to your DHCP relay configuration. Smart relay provides additional relay functionality and requires all of the configuration settings required by DHCP relay. To use DHCP smart relay, you also need an interface with multiple IP addresses assigned to it. You can achieve this by doing either of the following tasks:

- Create a routed VLAN interface and assign at least two IP addresses to it. See [“Configuring IRB Interfaces” on page 2240](#) and [“Example: Configuring Routing Between VLANs on One Switch” on page 2207](#) for information about this approach.
- Create a Layer 3 logical interface (by using VLAN tagging) and assign at least two IP addresses to it. See [“Understanding Layer 3 Logical Interfaces” on page 2613](#) and [“Configuring a Layer 3 Logical Interface” on page 2777](#) for information about this approach.

Once you have created an interface with multiple IP addresses, complete the smart relay configuration by entering one of the following statements:

- **set forwarding-options helpers bootp smart-relay-global:** Use this statement to enable smart relay on all the interfaces that are configured as relay agents.
- **set forwarding-options helpers bootp interface *interface-name* smart-relay-agent:** Use this statement to enable smart relay on a specific interface.

When smart relay is configured for an interface, the switch initially sends DHCP request (discover) messages out of that interface using the primary address of the interface as the gateway IP address (in the giaddr field) for the DHCP message. If no DHCP offer message is received from a server in reply, the switch allows the client to send as many as three more discover messages using the same gateway IP address. If no DHCP offer message is received after three retries, the switch resends the discover message using the alternate IP address as the gateway IP address. If you configure more than two IP addresses on the relay agent interface, the switch repeats this process until a DHCP offer message is received or all of the IP addresses have been used without success.

---

## Configuration Statements for Port Mirroring

---

- [analyzer on page 5219](#)

- [output on page 5227](#)
- [vlan \(Port Mirroring\) on page 5228](#)

## analyzer

```
Syntax analyzer {
    name {
        input {
            egress {
                interface (all | interface-name);
            }
            ingress {
                interface (all | interface-name);
                vlan (vlan-id | vlan-name);
            }
        }
        output {
            interface interface-name;
            ip-address ip-address;
            routing-instance
            vlan (vlan-id | vlan-name);
        }
    }
}
```

**Hierarchy Level** For platforms without ELS:

[edit [ethernet-switching-options](#)]

For platforms with ELS:

[edit forwarding-options]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.  
 Option **output vlan** added in Junos OS Release 12.1 for the QFX Series.  
 Option **output ip-address** added in Junos OS Release 12.3 for the QFX Series for non-ELS platforms and added in 14.1X53-D10 for ELS platforms.

**Description** Configure port mirroring. You can create a total of four port-mirroring configurations on the QFX Series, subject to the following limits:

- There can be no more than two configurations that mirror ingress traffic.
- There can be no more than two configurations that mirror egress traffic.

**Default** Port mirroring is disabled, and Junos OS creates no default analyzers.

**Options** **all**—Mirror all the access interfaces. Using this option does not cause the QSFP+ or management interfaces to be mirrored.

**CAUTION:** Configuring the **all** option in a QFabric system causes all the access interfaces on all the nodes to be mirrored. Be cautious about using this option on a QFabric system.

**name**—Name of the analyzer. The name can include as many as 125 characters; must begin with a letter; and can include uppercase letters, lowercase letters, numbers, dashes, and underscores. No other special characters are allowed.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## ip-address (Port Mirroring)

---

<b>Syntax</b>	<code>ip-address <i>ip-address</i>;</code>
<b>Hierarchy Level</b>	<code>[edit forwarding-options] <i>analyzer name</i> <i>output</i>]</code> <code>[edit forwarding-options port-mirroring [<i>instance name</i>] family ethernet-switching <i>output interface name</i>]</code>
<b>Release Information</b>	Statement introduced in Junos OS Release 14.1X53 for the QFX Series.
<b>Description</b>	Specify the IP address to which traffic should be mirrored (the IP address of the analyzer system). The device can be on a remote network. The analyzer device must be able to de-encapsulate GRE-encapsulated packets, or the GRE-encapsulated packets must be de-encapsulated before reaching the analyzer device. (You can use a network sniffer to de-encapsulate the packets.) This statement is not supported on QFabric systems.
<div><b>NOTE:</b> An output IP address cannot be in the same subnetwork as any of the switch's management interfaces.</div>	
<div><b>NOTE:</b> If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).</div>	
<b>Required Privilege Level</b>	routing—To view this statement in the configuration. routing-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Port Mirroring on page 5195</a></li><li>• <a href="#">Configuring Port Mirroring</a></li></ul>

## output

<b>Syntax</b>	<pre>output {   interface <i>interface-name</i>;   ip-address <i>ip-address</i>;   vlan (<i>vlan-id</i>   <i>vlan-name</i>);   routing-instance <i>instance-name</i> {     ip-address <i>address</i> { </pre>
<b>Hierarchy Level</b>	<p>For platforms without ELS:</p> <pre>[edit ethernet-switching-options analyzer <i>name</i>]</pre> <p>For platforms with ELS:</p> <pre>[edit forwarding-options analyzer <i>name</i>] [edit forwarding-options port-mirroring [instance <i>name</i>] family ethernet-switching ]</pre>
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 11.1 for the QFX Series.</p> <p>Option <b>output vlan</b> added in Junos OS Release 12.1 for the QFX Series.</p>
<b>Description</b>	<p>Configure the destination for mirrored traffic, either an interface on the switch (for local monitoring) or a VLAN (for remote monitoring).</p> <p>The statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Understanding Port Mirroring on page 5195</a></li> <li>• <a href="#">Configuring Port Mirroring</a></li> <li>• <a href="#">Examples: Configuring Port Mirroring for Local Analysis</a></li> </ul>

## vlan (Port Mirroring)

---

<b>Syntax</b>	<code>vlan (vlan-id   vlan-name);</code>
<b>Hierarchy Level</b>	For platforms without ELS:  [edit <code>ethernet-switching-options analyzer name input ingress</code> ], [edit <code>ethernet-switching-options analyzer name output</code> ]  For platforms with ELS:  [edit <code>forwarding-options analyzer name input (egress   ingress)</code> ] [edit <code>forwarding-options analyzer name output</code> ] [edit <code>forwarding-options port-mirroring[instance name] family ethernet-switching output</code> ]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.1 for the QFX Series. Option <code>output vlan</code> added in Junos OS Release 12.1 for the QFX Series.
<b>Description</b>	Specify that traffic entering into a VLAN should be mirrored. Configure mirrored traffic to be sent to a VLAN for remote monitoring (output).
<b>Options</b>	<code>vlan-id</code> —Numeric VLAN identifier.  <code>vlan-name</code> —Name of the VLAN.
<b>Required Privilege Level</b>	<code>routing</code> —To view this statement in the configuration. <code>routing-control</code> —To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Understanding Port Mirroring on page 5195</a></li><li>• <a href="#">Configuring Port Mirroring</a></li><li>• <a href="#">Examples: Configuring Port Mirroring for Local Analysis</a></li></ul>

## authentication-key-chains

---

<b>Syntax</b>	<pre>authentication-key-chains {   key-chain <i>key-chain-name</i> {     description <i>text-string</i>;     key <i>key</i> {       algorithm (md5   hmac-sha-1);       options (basic   isis-enhanced);       secret <i>secret-data</i>;       start-time <i>yyyy-mm-dd.hh:mm:ss</i>;     }     tolerance <i>seconds</i>;   } }</pre>
<b>Hierarchy Level</b>	[edit security]
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.</p> <p>Support for IS-IS introduced in JUNOS OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p>
<b>Description</b>	<p>Configure authentication key updates for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol. When the <b>authentication-key-chains</b> statement is configured at the <b>[edit security]</b> hierarchy level, and is associated with the BGP, LDP, or IS-IS protocols at the <b>[edit protocols]</b> hierarchy level or with the BFD protocol using the <b>bfd-liveness-detection</b> statement, authentication key updates can occur without interrupting routing and signaling protocols such as Open Shortest Path First (OSPF) and Resource Reservation Setup Protocol (RSVP).</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols</i></li><li>• <a href="#">Example: Configuring BFD Authentication for Static Routes on page 3109</a></li><li>• <a href="#">Example: Configuring Hitless Authentication Key Rollover for IS-IS on page 3935</a></li></ul>

## cache-size

---

<b>Syntax</b>	cache-size <i>bytes</i> ;
<b>Hierarchy Level</b>	[edit security <a href="#">certificates</a> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Configure the cache size for digital certificates.
<b>Options</b>	<b>bytes</b> —Cache size for digital certificates. <b>Range:</b> 64 through 4,294,967,295 <b>Default:</b> 2 megabytes (MB)

**NOTE:** We recommend that you limit your cache size to 4 MB.

---

<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Configuring Digital Certificates for an ES PIC</i></li> </ul>

## cache-timeout-negative

---

<b>Syntax</b>	cache-timeout-negative <i>seconds</i> ;
<b>Hierarchy Level</b>	[edit security <a href="#">certificates</a> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Configure a negative cache for digital certificates.
<b>Options</b>	<b>seconds</b> —Negative time to cache digital certificates, in seconds. <b>Range:</b> 10 through 4,294,967,295 <b>Default:</b> 20

**CAUTION:** Configuring a large negative cache value can lead to a denial-of-service attack.

---

<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring Digital Certificates for an ES PIC</i></li></ul>

## ca-name

---

<b>Syntax</b>	ca-name <i>ca-identity</i> ;
<b>Hierarchy Level</b>	[edit security certificates <a href="#">certification-authority</a> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Specify the certificate authority (CA) identity to use in the certificate request.
<b>Options</b>	<b>ca-identity</b> —CA identity to use in the certificate request.
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring Digital Certificates for an ES PIC</i></li></ul>

## certificates

<b>Syntax</b>	<pre> certificates {   cache-size bytes;   cache-timeout-negative seconds;   certification-authority ca-profile-name {     ca-name ca-identity;     crl file-name;     encoding (binary   pem);     enrollment-url url-name;     file certificate-filename;     ldap-url url-name;   }   enrollment-retry attempts;   local certificate-name {     certificate-key-string;     load-key-file URL filename;   }   maximum-certificates number;   path-length certificate-path-length; } </pre>
<b>Hierarchy Level</b>	[edit security]
<b>Release Information</b>	<p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.1 for the QFX Series.</p>
<b>Description</b>	<p>(Encryption interface on M Series and T Series routers and EX Series switches only)</p> <p>Configure the digital certificates for IPsec.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li><i>Configuring Digital Certificates for an ES PIC</i></li> </ul>

## certification-authority

---

<b>Syntax</b>	<code>certification-authority <i>ca-profile-name</i> {     <i>ca-name</i> <i>ca-identity</i>;     <i>crl</i> <i>file-name</i>;     <i>encoding</i> (binary   pem);     <i>enrollment-url</i> <i>url-name</i>;     <i>file</i> <i>certificate-filename</i>;     <i>ldap-url</i> <i>url-name</i>; }</code>
<b>Hierarchy Level</b>	[edit security <a href="#">certificates</a> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Configure a certificate authority profile name.  The remaining statements are explained separately.
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring Digital Certificates for an ES PIC</i></li></ul>

## crl (Encryption Interface)

---

<b>Syntax</b>	<code>crl <i>file-name</i>;</code>
<b>Hierarchy Level</b>	[edit security <a href="#">certificates</a> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Configure the certificate revocation list (CRL). A CRL is a time-stamped list identifying revoked certificates, which is signed by a CA and made available to the participating IPsec peers on a regular periodic basis.
<b>Options</b>	<i>file-name</i> —Specify the file from which to read the CRL.
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring Digital Certificates for an ES PIC</i></li></ul>

## encoding

<b>Syntax</b>	encoding (binary   pem);
<b>Hierarchy Level</b>	[edit security ike policy <i>ike-peer-address</i> ], [edit security certificates <b>certification-authority</b> <i>ca-profile-name</i> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Specify the file format used for the <b>local-certificate</b> and <b>local-key-pair</b> statements.
<b>Options</b>	<b>binary</b> —Binary file format.  <b>pem</b> —Privacy-enhanced mail (PEM), an ASCII base 64 encoded format. <b>Default:</b> binary
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Configuring Digital Certificates for an ES PIC</i></li> <li>• <i>Configuring an IKE Policy for Digital Certificates for an ES PIC</i></li> </ul>

## enrollment-retry

<b>Syntax</b>	enrollment-retry <i>attempts</i> ;
<b>Hierarchy Level</b>	[edit security <b>certificates</b> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Specify how many times a router or switch can resend a digital certificate request.
<b>Options</b>	<b>attempts</b> —Number of enrollment retries. <b>Range:</b> 0 through 100 <b>Default:</b> 0
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Configuring Digital Certificates for an ES PIC</i></li> </ul>

## enrollment-url

---

<b>Syntax</b>	<code>enrollment-url <i>url-name</i>;</code>
<b>Hierarchy Level</b>	[edit security certificates <a href="#">certification-authority</a> <i>ca-profile-name</i> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Specify where your router or switch sends Simple Certificate Enrollment Protocol-based (SCEP-based) certificate enrollment requests (certificate authority URL).
<b>Options</b>	<i>url-name</i> —Certificate authority URL.
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring Digital Certificates for an ES PIC</i></li></ul>

## file

---

<b>Syntax</b>	<code>file <i>certificate-filename</i>;</code>
<b>Hierarchy Level</b>	[edit security certificates <a href="#">certification-authority</a> <i>ca-profile-name</i> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Specify the file from which to read the digital certificate.
<b>Options</b>	<i>certificate-filename</i> —File from which to read the digital certificate.
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring Digital Certificates for an ES PIC</i></li></ul>

## key (Authentication Keychain)

<b>Syntax</b>	<pre>key key {   algorithm (md5   hmac-sha-1);   options (basic   isis-enhanced);   secret secret-data;   start-time yyyy-mm-dd.hh:mm:ss; }</pre>
<b>Hierarchy Level</b>	[edit security authentication-key-chains key-chain <i>key-chain-name</i> ]
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.</p> <p>Support for IS-IS introduced in JUNOS OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 11.3 for QFX Series switches.</p>
<b>Description</b>	Configure the authentication element.
<b>Options</b>	<p><b>key</b>—Each key within a keychain is identified by a unique integer value.</p> <p><b>Range:</b> 0 through 63</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	<p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols</a></li> <li>• <a href="#">Example: Configuring BFD Authentication for Static Routes on page 3109</a></li> <li>• <a href="#">Example: Configuring Hitless Authentication Key Rollover for IS-IS on page 3935</a></li> </ul>

## key-chain (Security)

---

<b>Syntax</b>	<pre>keychain <i>key-chain-name</i> {   description <i>text-string</i>;   key <i>key</i> {     algorithm (md5   hmac-sha-1);     options (basic   isis-enhanced);     secret <i>secret-data</i>;     start-time <i>yyyy-mm-dd.hh:mm:ss</i>;   }   tolerance <i>seconds</i>; }</pre>
<b>Hierarchy Level</b>	[edit security authentication-key-chains]
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.</p> <p>Support for IS-IS introduced in Junos OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 11.3 for the QFX Series.</p>
<b>Description</b>	Create the key-chain configuration for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol.
<b>Options</b>	<b><i>key-chain-name</i></b> —Authentication keychain name. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">authentication-key-chains on page 5230</a></li><li>• <a href="#">Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols</a></li><li>• <a href="#">Example: Configuring BFD Authentication for Static Routes on page 3109</a></li><li>• <a href="#">Example: Configuring Hitless Authentication Key Rollover for IS-IS on page 3935</a></li></ul>

---

## ldap-url

---

<b>Syntax</b>	<ldap-url <i>url-name</i> >;
<b>Hierarchy Level</b>	[edit security certificates <a href="#">certification-authority</a> <i>ca-profile-name</i> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) (Optional) Specify the Lightweight Directory Access Protocol (LDAP) URL for digital certificates.
<b>Options</b>	<i>url-name</i> —Name of the LDAP URL.
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring Digital Certificates for an ES PIC</i></li></ul>

## local

---

Syntax	<pre>local <i>certificate-name</i> {     <i>certificate-key-string</i>;     load-key-file <i>URL filename</i>; }</pre>
Hierarchy Level	[edit security <a href="#">certificates</a> ]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	Import a paired X.509 private key and authentication certificate, to enable Junos XML protocol client applications to establish Secure Sockets Layer (SSL) connections to the router or switch.
<div> <b>NOTE:</b> For FIPS mode, the digital security certificates must be compliant with the National Institute of Standards and Technology (NIST) SP 800-131A standard.</div>	
Options	<p><b><i>certificate-name</i></b><b><i>certificate-key-string</i></b>—String of alphanumeric characters that constitute the private key and certificate.</p> <p><b><i>certificate-name</i></b>—Name that uniquely identifies the certificate.</p> <p><b>load-key-file <i>URL filename</i></b>—File that contains the private key and certificate. It can be one of two types of values:</p> <ul style="list-style-type: none"><li>• Pathname of a file on the local disk (assuming you have already used another method to copy the certificate file to the router's or switch's local disk)</li><li>• URL to the certificate file location (for instance, on the computer where the Junos XML protocol client application runs)</li></ul>
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"><li>• <i>Importing SSL Certificates for Junos XML Protocol Support</i></li></ul>

## maximum-certificates

---

<b>Syntax</b>	maximum-certificates <i>number</i> ;
<b>Hierarchy Level</b>	[edit security <a href="#">certificates</a> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Configure the maximum number of peer digital certificates to be cached.
<b>Options</b>	<b>number</b> —Maximum number of peer digital certificates to be cached. <b>Range:</b> 64 through 4,294,967,295 peer certificates <b>Default:</b> 1024 peer certificates
<b>Required Privilege Level</b>	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Configuring Digital Certificates for an ES PIC</i></li> </ul>

## path-length

---

<b>Syntax</b>	path-length <i>certificate-path-length</i> ;
<b>Hierarchy Level</b>	[edit security <a href="#">certificates</a> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.1 for the QFX Series.
<b>Description</b>	(Encryption interface on M Series and T Series routers and EX Series switches only) Configure the digital certificate path length.
<b>Options</b>	<b>certificate-path-length</b> —Digital certificate path length. <b>Range:</b> 2 through 15 certificates <b>Default:</b> 15 certificates
<b>Required Privilege Level</b>	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Configuring Digital Certificates for an ES PIC</i></li> </ul>

## secret

---

<b>Syntax</b>	<code>secret <i>secret-data</i>;</code>
<b>Hierarchy Level</b>	[edit security authentication-key-chains key-chain <i>key-chain-name</i> key <i>key</i> ]
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.</p> <p>Support for IS-IS introduced in JUNOS OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 11.3 for QFX Series switches.</p>
<b>Description</b>	Specify a password in encrypted text or plain text format. The secret password always appears in encrypted format.
<b>Options</b>	<b><i>secret-data</i></b> —Password to use; it can include spaces if the character string is enclosed in quotation marks.
<b>Required Privilege Level</b>	<p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols</a></li><li>• <a href="#">Example: Configuring BFD Authentication for Static Routes on page 3109</a></li><li>• <a href="#">Example: Configuring Hitless Authentication Key Rollover for IS-IS on page 3935</a></li></ul>

## security

```
Syntax  security {
    authentication-key-chains {
        key-chain key-chain-name {
            key key {
                secret secret-data;

## ssh-known-hosts

---

Syntax	<pre>ssh-known-hosts {   host <i>host-name</i> {     fetch-from-server <i>host-name</i>;     load-key-file <i>file-name</i>;   } }</pre>
Hierarchy Level	[edit security ssh-known-hosts]
Release Information	Statement introduced in Junos OS Release 11.1 for the QFX Series.
Description	Configure SSH support for known hosts and for administering SSH host key updates.
Options	<p><b>host <i>host-name</i></b>—Hostname of the SSH known host entry. This option has the following suboptions:</p> <ul style="list-style-type: none"><li>• <b>fetch-from-server <i>host-name</i></b>—Retrieve SSH public host key information from a specified server.</li><li>• <b>load-key-file <i>filename</i></b>—Import SSH host key information from the <code>/var/tmp/ssh-known-hosts</code> file.</li></ul>
Required Privilege Level	<p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"><li>• <a href="#">Understanding Security Features on the QFabric System on page 1369</a></li><li>• <a href="#">Configuring SSH Host Keys for Secure Copying of Data on page 1851</a></li></ul>

## start-time (Authentication Key Transmission)

<b>Syntax</b>	<code>start-time (now   yyyy-mm-dd.hh:mm:ss);</code>
<b>Hierarchy Level</b>	[edit security authentication-key-chains key-chain <i>key-chain-name</i> key <i>key</i> ]
<b>Release Information</b>	<p>Statement introduced in Junos OS Release 7.6.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6.</p> <p>Support for the BFD protocol introduced in Junos OS Release 9.6 for EX Series switches.</p> <p>Support for IS-IS introduced in JUNOS OS Release 11.2.</p> <p>Statement introduced in Junos OS Release 11.3 for QFX Series switches.</p>
<b>Description</b>	<p>Specify a start time for key transmission. You do not need to specify an end time for the key. If a new key is present with a new start time, the keychain rolls over to the new one. The start time must be unique within the keychain.</p>
<b>Options</b>	<p><b>now</b>—Start time as the current year, month, day, hour, minute, and second.</p> <p><b>daydays</b>—Start time as the specified number of days after the current day. For example, if the current day is the 12th and you configure <b>start-time 2day</b>, the start time will be on the 14th, exactly two days after the configuration is entered.</p> <p><b>hourhours</b>—Start time as the specified number of hours after the current hour. For example, if the current hour is 9:00 and you configure <b>start-time 3hour</b>, the start time will be in 12:00, exactly three hours after the configuration is entered.</p> <p><b>minuteminutes</b>—Start time as the specified number of minutes after the current minute. For example, if the current minute is 27 minutes after the hour and you configure <b>start-time 5min</b>, the start time will be in 32 minutes after the hour, exactly five minutes after the configuration is entered.</p> <p><b>monthmonths</b>—Start time as the specified number of months after the current month. For example, if the current month is March and you configure <b>start-time 4month</b>, the start time will be in July, exactly four months after the configuration is entered.</p> <p><b>secondseconds</b>—Start time as the specified number of seconds after the current second. For example, if the current second is 10:20:40 and you configure <b>start-time 10seconds</b>, the start time will be 10:20:50, exactly 10 seconds after the configuration is entered.</p> <p><b>yearyears</b>—Start time as the specified number of years after the current year. For example, if the current year is 2011 and you configure <b>start-time 1year</b>, the start time will be in 2012, exactly one year after the configuration is entered.</p> <p><b>yyyy-mm-dd.hh:mm:ss</b>—Start time in UTC (Coordinated Universal Time). The start time must be unique within the keychain.</p>
<b>Required Privilege Level</b>	<p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>

## traceoptions

<b>Syntax</b>	<pre> traceoptions {   file <i>filename</i> &lt;files <i>number</i>&gt; &lt;size <i>size</i>&gt;;   flag all;   flag certificates;   flag database;   flag general;   flag ike;   flag parse;   flag policy-manager;   flag routing-socket;   flag timer;   level   no-remote-trace } </pre>
<b>Hierarchy Level</b>	<p>[edit security], [edit services ipsec-vpn]</p> <p>Trace options can be configured at either the <b>[edit security]</b> or the <b>[edit services ipsec-vpn]</b> hierarchy level, but not at both levels.</p>
<b>Release Information</b>	<p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 11.1 for the QFX Series.</p>
<b>Description</b>	<p>Configure security trace options.</p> <p>To specify more than one trace option, include multiple <b>flag</b> statements. Trace option output is recorded in the <code>/var/log/kmd</code> file.</p>
<div style="display: flex; align-items: center;">  <p><b>NOTE:</b> The <code>traceoptions</code> statement is not supported on QFabric systems.</p> </div>	
<b>Options</b>	<p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file (for example, <b>kmd</b>) reaches its maximum size, it is renamed <b>kmd.0</b>, then <b>kmd.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 0 files</p> <p><b>size <i>size</i></b>—(Optional) Maximum size of each trace file, in kilobytes (KB). When a trace file (for example, <b>kmd</b>) reaches this size, it is renamed, <b>kmd.0</b>, then <b>kmd.1</b> and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p><b>Default:</b> 1024 KB</p>

**flag flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.

- **all**—Trace all security events.
- **certificates**—Trace certificate events.
- **database**—Trace database events.
- **general**—Trace general events.
- **ike**—Trace IKE module processing.
- **parse**—Trace configuration processing.
- **policy-manager**—Trace policy manager processing.
- **routing-socket**—Trace routing socket messages.
- **timer**—Trace internal timer events.

**level level**—(Optional) Set traceoptions level.

- **all**—match all levels.
- **error**—Match error conditions.
- **info**—Match informational messages.
- **notice**—Match conditions that should be handled specially.
- **verbose**—Match verbose messages.
- **warning**—Match warning messages.

**no-remote-trace**—(Optional) Disable remote tracing

<b>Required Privilege</b>	admin—To view the configuration.
<b>Level</b>	admin-control—To add this statement to the configuration.

## broadcast

---

<b>Syntax</b>	<code>broadcast <i>number</i>;</code>
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp <a href="#">interface</a> ( <i>interface-name</i>   <i>interface-group</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 11.3 for QFX Series switches.
<b>Description</b>	If the specified interface is unavailable, broadcast DHCP and BOOTP packets.
<b>Options</b>	None
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring DHCP and BOOTP Relay on page 5215</a></li></ul>

## client-response-ttl

---

<b>Syntax</b>	<code>client-response-ttl <i>number</i>;</code>
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp], [edit forwarding-options helpers bootp <a href="#">interface</a> ( <i>interface-name</i>   <i>interface-group</i> )]
<b>Release Information</b>	Statement introduced in Junos OS Release 8.1. Statement introduced in Junos OS Release 11.3 for QFX Series switches.
<b>Description</b>	Set the IP time-to-live (TTL) value in DHCP response packets sent to a DHCP client.
<b>Options</b>	<i>number</i> —Decrement amount. <b>Default:</b> None
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Routers, Switches, and Interfaces as DHCP and BOOTP Relay Agents</a></li></ul>

## description (Forwarding Options)

<b>Syntax</b>	<code>description text-description;</code>
<b>Hierarchy Level</b>	<p>[edit forwarding-options helpers bootp],</p> <p>[edit forwarding-options helpers bootp <b>interface</b> (<i>interface-name</i>   <i>interface-group</i>)],</p> <p>[edit forwarding-options helpers domain],</p> <p>[edit forwarding-options helpers domain interface <i>interface-name</i>],</p> <p>[edit forwarding-options helpers tftp],</p> <p>[edit forwarding-options helpers tftp <b>interface</b> <i>interface-name</i>]</p>

## interface (BOOTP)

---

<b>Syntax</b>	<pre>interface (<i>interface-name</i>   <i>interface-group</i>) {     broadcast;     client-response-ttl <i>number</i>;     description <i>text-description</i>;     maximum-hop-count <i>number</i>;     minimum-wait-time <i>seconds</i>;     no-listen;     server <i>address</i> {         logical-system <i>logical-system-name</i> &lt;routing-instance [ &lt;default&gt;             <i>routing-instance-names</i> ]&gt;;         routing-instance [ &lt;default&gt; <i>routing-instance-names</i> ];     }     apply-secondary-as-giaddr (QFX platforms only) }</pre>
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.3 for QFX Series switches.
<b>Description</b>	Specify the interface for a DHCP and BOOTP relay agent.
<b>Options</b>	<p><b><i>interface-group</i></b>—Sets a logical interface or group of logical interfaces with a specific DHCP relay configuration.</p> <p>The remaining statements are explained separately.</p>
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Configuring Routers, Switches, and Interfaces as DHCP and BOOTP Relay Agents</a></li><li>• <a href="#">Setting Up DHCP Option 82 with the Switch as a Relay Agent Between Clients and DHCP Server (CLI Procedure) on page 5075</a></li></ul>

## maximum-hop-count

<b>Syntax</b>	<code>maximum-hop-count <i>number</i>;</code>
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp], [edit forwarding-options helpers bootp <code>interface</code> ( <i>interface-name</i>   <i>interface-group</i> )]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.3 for QFX Series switches.
<b>Description</b>	Specify the maximum number of hops allowed.
<b>Options</b>	<i>number</i> —Maximum number of hops. <b>Default:</b> 4 hops
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Configuring Routers, Switches, and Interfaces as DHCP and BOOTP Relay Agents</i></li> </ul>

## minimum-wait-time

<b>Syntax</b>	<code>minimum-wait-time <i>seconds</i>;</code>
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp], [edit forwarding-options helpers bootp <code>interface</code> ( <i>interface-name</i>   <i>interface-group</i> )]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.3 for QFX Series switches.
<b>Description</b>	Specify the minimum time allowed.
<b>Options</b>	<i>seconds</i> —Minimum time. <b>Default:</b> 0 seconds
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <i>Configuring Routers, Switches, and Interfaces as DHCP and BOOTP Relay Agents</i></li> </ul>

## no-listen

---

<b>Syntax</b>	no-listen;
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp <b>interface</b> ( <i>interface-name</i>   <i>interface-group</i> )], [edit forwarding-options helpers domain interface <i>interface-name</i> ], [edit forwarding-options helpers tftp interface <i>interface-name</i> ]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.3 for QFX Series switches.
<b>Description</b>	Disable recognition of DNS requests or stop packets from being forwarded on a logical interface, a group of logical interfaces, a router, or a switch.
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <i>Configuring DNS and TFTP Packet Forwarding</i></li><li>• <i>Configuring Routers, Switches, and Interfaces as DHCP and BOOTP Relay Agents</i></li></ul>

## server (DHCP and BOOTP Relay Agent)

---

<b>Syntax</b>	server <i>address</i> { logical-system <i>logical-system-name</i> <routing-instance [ <default> <i>routing-instance-names</i> ]>; routing-instance [ <default> <i>routing-instance-names</i> ]; }
<b>Hierarchy Level</b>	[edit forwarding-options helpers bootp], [edit forwarding-options helpers bootp <b>interface</b> ( <i>interface-name</i>   <i>interface-group</i> )]
<b>Release Information</b>	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches. Statement introduced in Junos OS Release 11.3 for QFX Series switches.
<b>Description</b>	Configure the router or switch to act as a DHCP and BOOTP relay agent.
<b>Options</b>	<ul style="list-style-type: none"><li>• <b>address</b>—One or more addresses of the server.</li><li>• <b>logical-system</b> <i>logical-system-name</i>—(Optional) Logical system of the server.</li><li>• <b>routing-instance</b> <i>routing-instance-names</i>—(Optional) Routing instance name that belong to the DHCP or BOOTP relay agent.</li></ul>
<b>Required Privilege Level</b>	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

### Monitoring Commands for Port Mirroring

---

- [show analyzer](#)

## show analyzer

**Syntax** `show analyzer <analyzer-name>`

**Release Information** Command introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Display information about port mirroring.

**Options** *analyzer-name*—(Optional) Displays the status of a specific analyzer (port-mirroring configuration).

**Required Privilege Level** view

**Related Documentation**

- [Layer 2 Port Mirroring Overview](#)
- [Port Mirroring Constraints and Limitations on page 5198](#)
- [Example: Configuring Port Mirroring for Local Analysis on page 5203](#)
- [Example: Configuring Port Mirroring for Remote Analysis on page 5208](#)

**List of Sample Output** [show analyzer on page 5256](#)

**Output Fields** [Table 373 on page 5256](#) describes the output fields for the **show analyzer** command. Output fields are listed in the approximate order in which they appear.

**Table 373: show analyzer Output Fields**

Field Name	Field Description
Analyzer name	Name of the analyzer.
Output interface	Local interface to which mirror packets are sent. If you configure an output interface, you cannot also configure an output VLAN.
Output VLAN	VLAN to which mirror packets are sent. If you configure an output VLAN, you cannot also configure an output interface.
Egress monitored interfaces	Interfaces for which egress traffic is mirrored.
Ingress monitored interfaces	Interfaces for which ingress traffic is mirrored.
Ingress monitored VLANs	VLANs for which ingress traffic is mirrored.

## Sample Output

### show analyzer

```

user@switch> show analyzer
Analyzer name      : employee-monitor
Output interface   : ge-0/0/10.0
Output VLAN        : remote-analyzer

```

```
Egress monitored interfaces : ge-0/0/7.0
Ingress monitored interfaces : ge-0/0/8.0
Ingress monitored interfaces : ge-0/0/9.0
```

- [Egress Port Mirroring with Private VLANs on page 5261](#)

### Port Mirroring Constraints and Limitations

---

- [Local and Remote Port Mirroring on page 5259](#)
- [Remote Port Mirroring Only on page 5261](#)

#### ***Local and Remote Port Mirroring***

The following constraints and limitations apply to local and remote port mirroring:

- You can create a total of four port-mirroring configurations.
- You can create a total of four port-mirroring configurations on each Node group in a QFabric system, subject to the following constraints:
  - As many as four of the configurations can be for local port mirroring.
  - As many as three of the configurations can be for remote port mirroring.
- Regardless of whether you are configuring a standalone switch or a Node group, the following limits apply:
  - There can be no more than two configurations that mirror ingress traffic. (If you configure a firewall filter to send traffic to a port mirror—that is, you use the **analyzer** action modifier in a filter term—this counts as an ingress mirroring configuration for switch or Node group on which the filter is applied.)
  - There can be no more than two configurations that mirror egress traffic.

**NOTE:** On QFabric systems, there is no system-wide limit on the total number of mirror sessions.

- You can configure no more than one type of output in one port-mirroring configuration. That is, you can use no more than one of the following to complete a **set analyzer name output** statement:
  - **interface**
  - **ip-address**
  - **vlan**
- If you configure Junos OS to mirror egress packets, do not configure more than 2000 VLANs on a standalone switch or QFabric system. If you do so, some VLAN packets might contain incorrect VLAN IDs. This applies to any VLAN packets—not only the mirrored copies.
- The **ratio** and **loss-priority** options are not supported.
- Packets with physical layer errors are filtered out and are not sent to the output port or VLAN.
- If you use sFlow monitoring to sample traffic, it does not sample the mirror copies when they exit from the output interface.
- You cannot mirror packets exiting or entering the following ports:
  - Dedicated Virtual Chassis interfaces
  - Management interfaces (me0 or vme0)
  - Fibre Channel interfaces
  - Routed VLAN interfaces
- An aggregated Ethernet interface cannot be an output interface if the input is a VLAN or if traffic is sent to the analyzer by a firewall filter.
- Do not include an 802.1Q subinterface that has a unit number other than 0 in a port mirroring configuration. Port mirroring does not work with subinterfaces if their unit number is not 0. (You configure 802.1Q subinterfaces using the **vlan-tagging** statement.)
- When packet copies are sent out the output interface, they are not modified for any changes that are normally applied on egress, such as CoS rewriting.
- An interface can be the input interface for only one mirroring configuration. Do not use the same interface as the input interface for multiple mirroring configurations.
- CPU-generated packets (such as ARP, ICMP, BPDU, and LACP packets) cannot be mirrored on egress.
- VLAN-based mirroring is not supported for STP traffic.
- (QFabric systems only) If you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on different Node devices, the mirrored copies have

incorrect VLAN IDs. This limitation does not apply if you configure a QFabric analyzer to mirror egress traffic and the input and output interfaces are on the *same* Node device. In this case the mirrored copies have the correct VLAN IDs (as long as you do not configure more than 2000 VLANs on the QFabric system).

### ***Remote Port Mirroring Only***

The following constraints and limitations apply to remote port mirroring:

- If you configure an output IP address, the address cannot be in the same subnetwork as any of the switch's management interfaces.
- If you create virtual routing instances and also create an analyzer configuration that includes an output IP address, the output address belongs to the default virtual routing instance (inet.0 routing table).
- An output VLAN cannot be a private VLAN or VLAN range.
- An output VLAN cannot be shared by multiple **analyzer** statements.
- An output VLAN interface cannot be a member of any other VLAN.
- An output VLAN interface cannot be an aggregated Ethernet interface.
- On the source (monitored) switch, only one interface can be a member of the analyzer VLAN.

### **Egress Port Mirroring with VLAN Translation**

**Problem** **Description:** If you create a port-mirroring configuration that mirrors customer VLAN (CVLAN) traffic on egress and the traffic undergoes VLAN translation before being mirrored, the VLAN translation does not apply to the mirrored packets. That is, the mirrored packets retain the service VLAN (SVLAN) tag that should be replaced by the CVLAN tag on egress. The original packets are unaffected—on these packets VLAN translation works properly, and the SVLAN tag is replaced with the CVLAN tag on egress.

**Solution** This is expected behavior.

### **Egress Port Mirroring with Private VLANs**

**Problem** **Description:** If you create a port-mirroring configuration that mirrors private VLAN (PVLAN) traffic on egress, the mirrored traffic (the traffic that is sent to the analyzer system) has the VLAN tag of the ingress VLAN instead of the egress VLAN. For example, assume the following PVLAN configuration:

- Promiscuous trunk port that carries primary VLANs pvlan100 and pvlan400.
- Isolated access port that carries secondary VLAN isolated200. This VLAN is a member of primary VLAN pvlan100.
- Community port that carries secondary VLAN comm300. This VLAN is also a member of primary VLAN pvlan100.
- Output interface (monitor interface) that connects to the analyzer system. This interface forwards the mirrored traffic to the analyzer.

If a packet for pvlan100 enters on the promiscuous trunk port and exits on the isolated access port, the original packet is untagged on egress because it is exiting on an access port. However, the mirror copy retains the tag for pvlan100 when it is sent to the analyzer.

Here is another example: If a packet for comm300 ingresses on the community port and egresses on the promiscuous trunk port, the original packet carries the tag for pvlan100 on egress, as expected. However, the mirrored copy retains the tag for comm300 when it is sent to the analyzer.

**Solution** This is expected behavior.

- [Learn About Technology on page 5424](#)

### Software Features Overview

---

- [Overview of Fibre Channel on page 5266](#)
- [Overview of FIP on page 5271](#)

## Overview of Fibre Channel

Fibre Channel (FC) is a high-speed network technology that interconnects network elements and allows them to communicate with one another. The International Committee for Information Technology Standards (INCITS) T11 Technical Committee sets FC standards.

FC networks provide high-performance characteristics such as lossless transport combined with flexible network topology. FC is primarily used in storage area networks (SANs) because it provides reliable, lossless, in-order frame transport between initiators and targets. FC components include initiators, targets, and FC-capable switches that interconnect FC devices and may also interconnect FC devices with Fibre Channel over Ethernet (FCoE) devices. Initiators originate I/O commands. Targets receive I/O commands. For example, a server can initiate an I/O request to a storage device target.

The Juniper Networks QFX3500 Switch has native FC ports as well as Ethernet access ports, and can function as an FCoE-FC gateway or as an FCoE transit switch. All other QFX Series switches and EX4600 switches have Ethernet access ports and can function as an FCoE transit switch.

FCoE transports native FC frames over an Ethernet network by encapsulating the unmodified frames in Ethernet. It also provides protocol extensions to discover FCoE devices through the Ethernet network. FCoE requires that the Ethernet network support data center bridging (DCB) extensions that ensure lossless transport and allow the Layer 2 Ethernet domain to meet the requirements of FC transport.

The FCoE-FC gateway functionality is a licensed feature on the QFX Series that is available only on QFX3500 switches. As an FCoE-FC gateway, the switch connects FCoE devices on an Ethernet network to a SAN FC switch.

You do not need a license to use the switch as an FCoE transit switch. As an FCoE transit switch, the switch:

- Is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames.
- Implements FCoE Initialization Protocol (FIP) snooping.
- Connects multiple FCoE endpoints to the FC network.

**NOTE:** Standalone switches support FCoE. Virtual Chassis (VC) and mixed-mode Virtual Chassis Fabric (VCF) configurations do not support FCoE. Pure QFX5100 switch VCFs (consisting of only QFX5100 switches) support FCoE.

---

This topic describes:

- [Fibre Channel Transport Protocol on page 5267](#)
- [How FC Works on the Switch on page 5267](#)

- [Supported FC Features and Functions on page 5270](#)
- [Lossless Transport Support on page 5270](#)

### Fibre Channel Transport Protocol

The Fibre Channel Protocol is a transport protocol that consists of five layers as shown in [Table 374 on page 5267](#):

**Table 374: Fibre Channel Protocol Layers**

FC Protocol Layer	Description
FC-0	Physical (cabling, connectors, and so on)
FC-1	Data link layer
FC-2	Network layer (defines the main protocols)
FC-3	Common services
FC-4	Protocol mapping

The FC protocol layers are generally split into three groups:

- FC-0 and FC-1 are the physical layers.
- FC-2 is the protocol layer, similar to OSI Layer 3.
- FC-3 and FC-4 are the services layers.

The FCoE-FC gateway operates the physical layers and the protocol layer, and provides FIP and service redirection at the services layer.

### How FC Works on the Switch

The switch connects devices that support FC and Ethernet (such as FCoE servers on an Ethernet network) to an FC SAN, thus converging the Ethernet and FC networks on a single physical network infrastructure. The switch provides the class-of-service (CoS) features needed to handle the different types of traffic appropriately.

To converge FC and Ethernet networks, you can configure the switch as an:

- [FCoE-FC Gateway on page 5267](#)
- [FCoE Transit Switch on page 5268](#)
- [FCoE VLANs on page 5268](#)

#### **FCoE-FC Gateway**

When the switch functions as an FCoE-FC gateway, the switch aggregates FCoE traffic and performs the encapsulation and de-encapsulation of native FC frames in Ethernet as it transports the frames between FCoE devices in the Ethernet network and the FC switch. In effect, the switch translates Ethernet to FC and FC to Ethernet.

The gateway receives FC frames encapsulated in Ethernet from FCoE devices through an FCoE VLAN interface composed of one or more 10-Gigabit Ethernet interfaces. The gateway removes the Ethernet encapsulation from the FC frames, and then sends the native FC frames to the FC switch through a native FC interface.

The gateway receives native FC frames from the FC switch on the gateway's native FC interfaces. The gateway encapsulates the native FC frames in Ethernet, and then sends the encapsulated frames to the appropriate FCoE device through the FCoE VLAN interface.

To FCoE devices, the gateway behaves like an FC switch and can present multiple virtual F\_Ports (VF\_Ports) on a single interface. To an FC switch, the gateway behaves like an FC node that is doing N\_Port ID virtualization (NPIV).

### ***FCoE Transit Switch***

When the switch functions as an FCoE transit switch, it forwards traffic (including FCoE traffic) based on Layer 2 media access control (MAC) forwarding and is a normal DCB-enabled Layer 2 switch that also performs FIP snooping. The switch aggregates FCoE traffic and passes it through to an FCF. The switch does not remove the Ethernet encapsulation from the FC frames, but it does preserve the class of service (CoS) required to transport FC frames.

The switch inspects (snoops) FIP information in order to create filters that permit only valid FCoE traffic to flow through the switch between FCoE devices and the FCF. The switch does not use native FC ports because the FC frames are encapsulated in Ethernet when they flow between the FCoE devices and the FCF. Virtual point-to-point links between each FCoE device and the FCF pass transparently through the switch, so the switch is not seen as a terminating point or an intermediate point by FCoE devices or by the FCF.

### ***FCoE VLANs***

All FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

**NOTE:** The same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

---

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

FCoE traffic cannot use a standard LAG because traffic might be hashed to different physical LAG links on different transmissions. This breaks the (virtual) point-to-point link that Fibre Channel traffic requires. If you configure a standard LAG interface for FCoE traffic, FCoE traffic might be rejected by the FC SAN.

QFabric systems support a special LAG called an FCoE LAG, which enables you to transport FCoE traffic and regular Ethernet traffic (traffic that is not FCoE traffic) across the same link aggregation bundle. Standard LAGs use a hashing algorithm to determine which physical link in the LAG is used for a transmission, so communication between two devices might use different physical links in the LAG for different transmissions. An FCoE LAG ensures that FCoE traffic uses the same physical link in the LAG for requests and replies in order to preserve the virtual point-to-point link between the FCoE device converged network adapter (CNA) and the FC SAN switch across the QFabric system Node device. An FCoE LAG does not provide load balancing or link redundancy for FCoE traffic. However, regular Ethernet traffic uses the standard hashing algorithm and receives the usual LAG benefits of load balancing and link redundancy in an FCoE LAG.

**NOTE:** IGMP snooping is enabled by default on all VLANs in all software versions before Junos OS R13.2. Disable IGMP snooping on FCoE VLANs if you are using software that is older than 13.2.

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

**NOTE:** All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

**BEST PRACTICE:** Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

## Supported FC Features and Functions

---

The following features and functionality are supported:

- As an FCoE-FC gateway:
  - DCB, including Data Center Bridging Capability Exchange protocol (DCBX), priority-based flow control (PFC), enhanced transmission service (ETS), and 10-Gigabit Ethernet interfaces
  - FCoE Initialization Protocol (FIP)
  - Proxy for FCoE devices when communicating with FC switches and acts as a proxy for FC switches when communicating with FCoE devices
  - Up to 12 native FC interfaces per QFX3500 switch (each interface can be configured as a 2-Gigabit, 4-Gigabit, or 8-Gigabit Ethernet interface)
- As an FCoE transit switch:
  - DCB functions
  - FIP snooping
  - Transparent Layer 2 MAC forwarding of FCoE frames

## Lossless Transport Support

---

Up to six lossless forwarding classes are supported. For lossless transport, you must enable PFC on the IEEE 802.1p code point of lossless forwarding classes. The following limitations apply to support lossless transport:

- The external cable length from a standalone switch or QFabric system Node device to other devices cannot exceed 300 meters.
- The internal cable length from a QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.
- For FCoE traffic, the interface maximum transmission unit (MTU) must be at least 2180 bytes to accommodate the packet payload, headers, and checks.

## Overview of FIP

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) is a Layer 2 protocol that establishes and maintains Fibre Channel (FC) virtual links between pairs of FCoE devices such as server FCoE Nodes (ENodes) and FC switches. FIP can also establish and maintain virtual links between FCoE devices and an FCoE-FC gateway (such as the QFX3500 switch), where the gateway acts on behalf of the FC switch.

FIP enables FCoE devices to discover one another and to initialize and maintain virtual links over a physical Ethernet network. This allows FCoE devices in the Ethernet network to access storage devices in the FC storage area network (SAN).

FIP solves the problem presented by the FC requirement for point-to-point connections (FC does not permit point-to-multipoint connections) by creating a unique virtual link for each connection between an ENode VN\_Port and an FC switch VF\_Port. Multiple virtual links can use a single physical link and virtual links can traverse Ethernet transit (passthrough) switches while appearing to be direct point-to-point connections to the FC switch.

FIP has its own EtherType (0x8914) to distinguish its traffic from payload-carrying FCoE traffic and other Ethernet traffic. FIP operations occur on a per-VLAN basis.

For more details about FIP, see the Technical Committee T11 organization document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* available at <http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf>.

## Understanding Fibre Channel

Fibre Channel (FC) is a serial I/O interconnect network technology capable of supporting multiple protocols. It is used primarily for storage area networks (SANs). The committee standardizing FC is the International Committee for Information Technology Standards (INCITS).

When configured as a Fibre Channel over Ethernet (FCoE)-FC gateway, the QFX3500 switch supports the transport of native FC traffic between FC switches and the gateway's native FC interfaces.

**NOTE:** Only the QFX3500 switch has native FC ports and supports native FC connection to the SAN. Only the QFX3500 can be configured as an FCoE-FC gateway, and only as a standalone switch or as a QFabric system Node device. FCoE-FC gateway configuration is not supported in Virtual Chassis or Virtual Chassis Fabric configurations.

FC concepts include:

- [FC Fabrics on page 5273](#)
- [FC Port Types on page 5274](#)
- [FC Switches on page 5274](#)
- [Adapters on page 5274](#)
- [N\\_Port ID Virtualization \(NPIV\) on page 5275](#)
- [FC Services on page 5275](#)

### FC Fabrics

An FC fabric is a switched network topology that interconnects FC devices using FC switches, usually to create a SAN. An FC switch is a Layer 3 network switch that is compatible with the FC protocol, forwards FC traffic, and provides FC services to the components of the FC fabric. FC devices are usually servers or storage devices such as disk arrays.

Switches called FCoE forwarders (FCFs) perform a subset of FC switch functions. An FCF is a Layer 3 network switch that is compatible with the FC protocol and forwards FC traffic, but does not provide network services.

When configured as an FCoE-FC gateway, the QFX3500 switch acts a proxy for the FCF functionality of an FC switch. The gateway provides FCoE devices on the Ethernet network access to the FC network without requiring the FC switches in the SAN to support Ethernet interfaces. The gateway is not an FCF and does not provide FC services.

FC network design often uses two fabrics (dual-rail topology) for redundancy. The two fabrics connect to edge devices but are otherwise unconnected, so that if one fabric goes down, the other fabric can continue to provide connectivity.

## FC Port Types

---

The QFX3500 switch supports the following FC port types:

- **N\_Port**—An N\_Port is a port on the node of an FC device such as a server or a storage device and is also known as a node port.
- **F\_Port**—An F\_Port is a port on an FC switch that connects to an FC device N\_Port in a point-to-point connection. F\_Ports are also known as fabric ports.

These port types are a subset of the existing FC port types that can be supported in an FC fabric.

## FC Switches

---

FC switches provide FC services to the FC network. FC switches forward Layer 3 traffic. They may transport a combination of native FC traffic and other traffic, such as Internet Small Computer Systems Interface (iSCSI) or FCoE, or they may transport only native FC traffic. When an FC switch supports FCoE, it combines FCoE termination functions with the FC stack on an FC switching element. This is also known as a dual-stack switch.

When FC switches support FCoE, they present virtual FC interfaces in the form of virtual F\_Ports (VF\_Ports) to the FCoE nodes (ENodes) on FCoE devices. A VF\_Port is an endpoint in a virtual point-to-point connection with an ENode virtual N\_Port (VN\_Port). A VF\_Port emulates a native FC F\_Port and performs similar functions. A VF\_Port is an intermediate port in a connection between an FCoE device such as a server in the Ethernet network and a storage device in the FC SAN.

FC switches that support FCoE contain at least one lossless Ethernet media access controller (MAC) paired with an FCoE controller. The lossless Ethernet MAC implements Ethernet extensions to avoid frame loss due to congestion. The FCoE controller instantiates and terminates virtual port instances as they are needed. Each VF\_Port instance has one unique virtual link to an ENode VN\_Port.

FCoE support also requires one FCoE Link End Point (LEP) for each VF\_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface. It transmits and receives FCoE frames on the virtual link, and handles FC frame encapsulation for traffic going from the FC switch to the FCoE device and frame de-encapsulation of traffic received from the FCoE device.

When you configure the QFX3500 switch as an FCoE-FC gateway, the gateway performs these FC-to-Ethernet and Ethernet-to-FC conversion functions so that the FC switch does not need Ethernet (FCoE) ports.

## Adapters

---

FC host bus adapters (HBAs) in FC switches and devices perform functions similar to those of Ethernet adapters in Ethernet switches and devices. Switches that perform FCoE functions and FCoE devices have converged network adapters (CNAs) that support both native FC and Ethernet functionality.

---

### N\_Port ID Virtualization (NPIV)

---

FC requires a unique point-to-point link between the FC switch (F\_Port) and each host N\_Port. In order to avoid using one physical link for each F\_Port to N\_Port connection, the port connections must be virtualized so that they can share a physical link while maintaining logical separation.

FC accomplishes this by enabling you to create an independent virtual link for each FC session by mapping each session to a virtualized N\_Port. This process is called N\_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link. In this way, multiple FC devices and multiple applications or virtual machines (VMs) on a single FC device can connect to an FC switch using one physical port instead of using a physical port for each connection. The virtual link creates a secure boundary between traffic from different sources on a single physical connection.

NPIV works by creating a unique virtual port identifier for each logical connection on a physical port. Conceptually, this is similar to splitting a single physical interface into multiple logical interfaces or subinterfaces. A virtual port identifier consists of the port's unique worldwide name (WWN) combined with a Fibre Channel ID (FCID) that the FC switch assigns to the virtual connection. This creates a virtual host bus adapter (HBA) for each virtual link that uniquely identifies the link to the FC switch.

---

### FC Services

---

When you configure the QFX3500 switch as an FCoE-FC gateway, the gateway connects FCoE devices in the Ethernet network to the FC fabric. The gateway does not provide FC services directly. The gateway logs in to the FC fabric and obtains FC services from the FC fabric, including:

- Management servers
  - Zone server—Defines which devices can connect to each other in the FC fabric.
  - Fabric configuration server—Discovers FC fabric topology and attributes.
  - Policy server—Distributes the rules for administering, managing, and controlling access to FC fabric resources.
  - HBA management server—Registers HBA information with the FC fabric.
- Domain manager—Allocates domain IDs to virtual switches.
- Fabric login server—Provides login services to the gateway so that the native FC ports on the gateway can perform initial fabric login (FLOGI) to the FC fabric and subsequent fabric discovery (FDISC) logins for the physical and virtual ports on the FCoE devices in the Ethernet network. This includes allocating Fibre Channel IDs (FCIDs) to ports.
- Name server—Discovers, registers, and unregisters N\_Port attributes, including the attributes of the native FC ports on the gateway that connect to the FC fabric.
- Event server—Validates incoming events to ensure transaction integrity.

- Time server—Maintains a common time for devices in the FC fabric.
- Fabric controller
  - Fabric Shortest Path First (FSPF)—The FC fabric provides link-state path selection to the gateway.
  - State change notification (SCN) / registered state change notification server (RSCN)—Notifies the appropriate nodes when new devices come online, when other nodes fail, or when changes on an online node affect system operation.

## Understanding DCB Features and Requirements

Data center bridging (DCB) is a set of enhancements to the IEEE 802.1 bridge specifications. DCB modifies and extends Ethernet behavior to support I/O convergence in the data center. I/O convergence includes but is not limited to the transport of Ethernet LAN traffic and Fibre Channel (FC) storage area network (SAN) traffic on the same physical Ethernet network infrastructure.

Video: [What is Data Center Bridging?](#)

A converged architecture saves cost by reducing the number of networks and switches required to support both types of traffic, reducing the number of interfaces required, reducing cable complexity, and reducing administration activities.

The Juniper Networks QFX Series and EX4600 switch support the DCB features required to transport converged Ethernet and FC traffic while providing the class-of-service (CoS) and other characteristics FC requires for transmitting storage traffic. To accommodate FC traffic, DCB specifications provide:

- A flow control mechanism called priority-based flow control (PFC, described in IEEE 802.1Qbb) to help provide lossless transport.
- A discovery and exchange protocol for conveying configuration and capabilities among neighbors to ensure consistent configuration across the network, called Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB).
- A bandwidth management mechanism called enhanced transmission selection (ETS, described in IEEE 802.1Qaz).
- A congestion management mechanism called quantized congestion notification (QCN, described in IEEE 802.1Qau).

The switch supports the PFC, DCBX, and ETS standards but does not support QCN. The switch also provides the high-bandwidth interfaces (10-Gbps minimum) required to support DCB and converged traffic.

This topic describes the DCB standards and requirements the switch supports:

- [Lossless Transport on page 5277](#)
- [ETS on page 5278](#)
- [DCBX on page 5279](#)

### Lossless Transport

FC traffic requires lossless transport (defined as no frames dropped because of congestion). Standard Ethernet does not support lossless transport, but the DCB extensions to Ethernet along with proper buffer management enable an Ethernet network to provide the level of class of service (CoS) necessary to transport FC frames encapsulated in Ethernet over an Ethernet network.

This section describes these factors in creating lossless transport over Ethernet:

- [PFC on page 5278](#)
- [Buffer Management on page 5278](#)
- [Physical Interfaces on page 5278](#)

### **PFC**

PFC is a link-level flow control mechanism similar to Ethernet PAUSE (described in IEEE 802.3x). Ethernet PAUSE stops all traffic on a link for a period of time. PFC enables you to divide traffic on a link into eight priorities and stop the traffic of a selected priority without stopping the traffic assigned to other priorities on the link.

Pausing the traffic of a selected priority enables you to provide lossless transport for traffic assigned that priority and at the same time use standard lossy Ethernet transport for the rest of the link traffic.

### **Buffer Management**

Buffer management is critical to the proper functioning of PFC, because if buffers are allowed to overflow, frames are dropped and transport is not lossless.

For each lossless flow priority, the switch requires sufficient buffer space to:

- Store frames sent during the time it takes to send the PFC pause frame across the cable between devices.
- Store the frames that are already on the wire when the sender receives the PFC pause frame.

The propagation delay due to cable length and speed, as well as processing speed, determines the amount of buffer space needed to prevent frame loss due to congestion.

The switch automatically sets the threshold for sending PFC pause frames to accommodate delay from cables as long as 150 meters (492 feet) and to accommodate large frames that might be on the wire when the switch sends the pause frame. This ensures that the switch sends pause frames early enough to allow the sender to stop transmitting before the receive buffers on the switch overflow.

### **Physical Interfaces**

The switch supports 10-Gbps, full-duplex interfaces. The switch enables DCB capability only on 10-Gbps (or faster) Ethernet interfaces.

---

### **ETS**

PFC divides traffic into up to eight separate streams (priorities, configured on the switch as forwarding classes) on a physical link. ETS enables you to manage the link bandwidth by:

- Grouping the priorities into priority groups (configured on the switch as forwarding class sets).
- Specifying the bandwidth available to each of the priority groups as a percentage of the total available link bandwidth.

- Allocating the bandwidth to the individual priorities in the priority group.

The available link bandwidth is the bandwidth remaining after servicing strict-high priority flows. We recommend that you always configure a shaping rate to limit the amount of bandwidth a strict-high priority flow can consume by including the [shaping-rate](#) statement in the [\[edit class-of-service schedulers\]](#) hierarchy on the strict-high priority scheduler. This prevents a strict-high priority from starving other queues on the port.

Managing link bandwidth with ETS provides several advantages:

- There is uniform management of all types of traffic on the link, both congestion-managed traffic and standard Ethernet traffic.
- When a priority group does not use all of its allocated bandwidth, other priority groups on the link can use that bandwidth as needed.

When a priority in a priority group does not use all of its allocated bandwidth, other priorities in the group can use that bandwidth.

The result is better bandwidth utilization, because priorities that consist of bursty traffic can share bandwidth during periods of low traffic transmission instead of consuming their entire bandwidth allocation when traffic loads are light.

- You can assign traffic types with different service needs to different priorities so that each traffic type receives appropriate treatment.
- Strict priority traffic retains its allocated bandwidth.

## DCBX

DCB devices use DCBX to exchange configuration information with directly connected peers (switches and endpoints such as servers). DCBX is an extension of LLDP. If you disable LLDP on an interface, that interface cannot run DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit fails.

DCBX can:

- Discover the DCB capabilities of peers.
- Detect DCB feature misconfiguration or mismatches between peers.
- Configure DCB features on peers.

You can configure DCBX operation for PFC, ETS, and for Layer 2 and Layer 4 applications such as FCoE and iSCSI. DCBX is enabled or disabled on a per-interface basis.

## Understanding FCoE

Fibre Channel over Ethernet (FCoE) is a method of supporting converged Fibre Channel (FC) and Ethernet traffic on a data center bridging (DCB) network. FCoE encapsulates unmodified FC frames in Ethernet to transport the FC frames over a physical Ethernet network. The T11 Technical Committee, which is the International Committee for Information Technology Standards (INCITS) committee responsible for FC interfaces, developed the FCoE standard to provide a method for transporting FC frames over a DCB network. The T11 document *Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00* at <http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf> provides details about the FCoE version 1 standard.

**NOTE:** The switch does not support T11 Annex F *FCoE Pre-FIP Virtual Link Instantiation Protocol*.

To the Ethernet network, an FCoE frame is the same as any other Ethernet frame because the Ethernet encapsulation provides the header information needed to forward the frames. However, to achieve the lossless behavior that FC transport requires, the Ethernet network must conform to DCB standards.

DCB standards create an environment over which FCoE can transport native FC traffic encapsulated in Ethernet while preserving the mandatory class of service (CoS) and other characteristics that FC traffic requires.

Supporting FCoE in a DCB network requires that the FCoE devices in the Ethernet network and the FC switches at the edge of the SAN network handle both Ethernet and native FC traffic. To handle Ethernet traffic, an FC switch does one of two things:

- Incorporates FCoE interfaces.
- Uses an FCoE-FC gateway such as a QFX3500 switch to de-encapsulate FCoE traffic from FCoE devices into native FC and to encapsulate native FC traffic from the FC switch into FCoE and forward it to FCoE devices through the Ethernet network.

**NOTE:** Standalone switches support FCoE. Virtual Chassis (VC) and mixed-mode Virtual Chassis Fabric (VCF) configurations do not support FCoE. Pure QFX5100 switch VCFs (consisting of only QFX5100 switches) support FCoE.

FCoE concepts include:

- [FCoE Devices on page 5281](#)
- [FCoE Frames on page 5282](#)

- [Virtual Links on page 5283](#)
- [FCoE VLANs on page 5283](#)

### FCoE Devices

Each FCoE device has a converged network adapter (CNA) that combines the functions of an FC host bus adapter (HBA) and a lossless Ethernet network interface card (NIC) with 10-Gbps Ethernet ports. The portion of the CNA that handles FCoE traffic is called an FCoE Node (ENode). An ENode combines FCoE termination functions and the client part of the FC stack on the CNA.

ENodes present virtual FC interfaces to FC switches in the form of virtual N\_Ports (VN\_Ports). A VN\_Port is an endpoint in a virtual point-to-point connection called a virtual link. The other endpoint of the virtual link is an FC switch (or FCF) port. A VN\_Port emulates a native FC N\_Port and performs similar functions: handling the creation, detection, and flow of messages to and from the FC switch. A single ENode can host multiple VN\_Ports. Each VN\_Port has a separate, unique virtual link with a FC switch.

ENodes contain at least one lossless Ethernet media access controller (MAC). Each Ethernet MAC is paired with an FCoE controller. The lossless Ethernet MAC is a full-duplex Ethernet MAC that implements Ethernet extensions to avoid frame loss due to congestion and supports frames of at least 2500 bytes. The FCoE controller instantiates and terminates VN\_Port instances dynamically as they are needed for FCoE sessions. Each VN\_Port instance has a unique virtual link to an FC switch.

**NOTE:** A *session* is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.

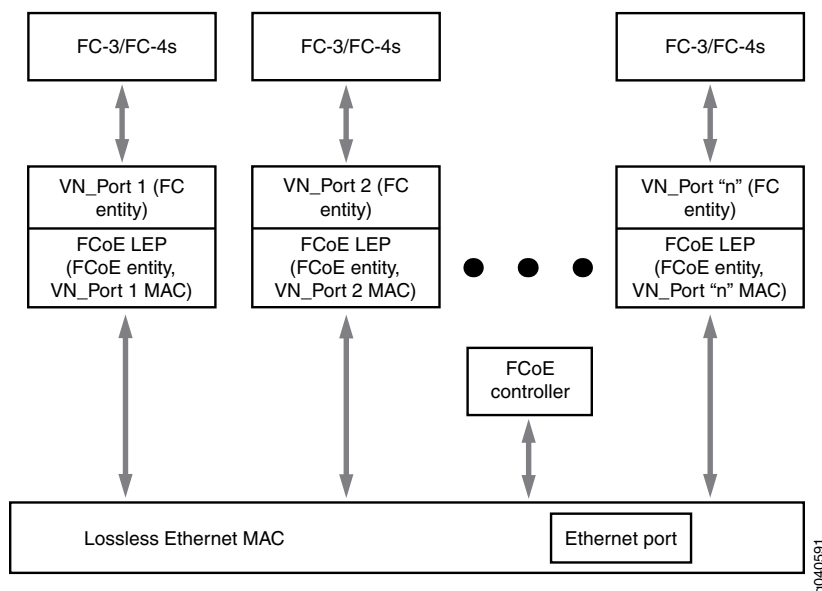

ENodes also contain one FCoE link end point (LEP) for each VN\_Port connection. An FCoE LEP is a virtual FC interface mapped onto the physical Ethernet interface.

An FCoE LEP:

- Transmits and receives FCoE frames on the virtual link.
- Handles FC frame encapsulation for traffic going from the server to the FC switch.
- Performs frame de-encapsulation of traffic received from the FC switch.

[Figure 203 on page 5282](#) shows a block diagram of the major ENode components.

Figure 203: ENode Components

### FCoE Frames

The FCoE protocol specification replaces the FC0 and FC1 layers of the FC stack with Ethernet, but retains the FC frame header. Retaining the FC frame header enables the FC frame to pass directly to a native FC SAN after de-encapsulation. The FCoE header carries the FC start of file (SOF) bits and end of file (EOF) bits in an encoded format. FCoE supports two frame types, control frames and data frames. FCoE Initialization Protocol (FIP) carries all of the discovery and fabric login frames.

FIP control frames handle FCoE device discovery, initializing communication, and maintaining communication. They do not carry a data payload. FIP has its own EtherType (0x8914) to distinguish FIP traffic from FCoE traffic and other Ethernet traffic. To establish communication, the ENode uses the globally unique MAC address assigned to it by the CNA manufacturer.

After FIP establishes a connection between FCoE devices, the FCoE data frames handle the transport of the FC frames encapsulated in Ethernet. FCoE also has its own EtherType (0x8906) to distinguish FCoE frames from other Ethernet traffic and ensure the in-order frame handling that FC requires. FCoE frames include:

- 2112 bytes FC payload
- 24 bytes FC header
- 14 bytes standard Ethernet header
- 14 bytes FCoE header
- 8 bytes cyclic redundancy check (CRC) plus EOF
- 4 bytes VLAN header
- 4 bytes frame check sequence (FCS)

The payload, headers, and checks add up to 2180 bytes. Therefore, interfaces that carry FCoE traffic should have a configured maximum transmission unit (MTU) of 2180 or larger. An MTU size of 2180 bytes is the minimum size; some network administrators prefer an MTU of 2240 or 2500 bytes.

### Virtual Links

Native FC uses point-to-point physical links between FC devices. In FCoE, virtual links replace the physical links. A virtual link emulates a point-to-point link between two FCoE device endpoints, such as a server VN\_Port and an FC switch (or FCF) VF\_Port.

Each FCoE interface can support multiple virtual links. The MAC addresses of the FCoE endpoints (the VN\_Port and the VF\_Port) uniquely identify each virtual link and allow traffic for multiple virtual links to share the same physical link while maintaining data separation and security.

A virtual link exists in one FCoE VLAN and cannot belong to more than one VLAN. Although the FC switch and the FCoE device detect a virtual link as a point-to-point connection, virtual links do not need to be direct connections between a VF\_Port and a VN\_Port. A virtual link can traverse one or more transit switches, also known as passthrough switches. A transit switch can transparently aggregate virtual links while still appearing and functioning as a point-to-point connection to the FCoE devices. However, a virtual link must remain within a single Layer 2 domain.

### FCoE VLANs

All FCoE traffic must travel in a VLAN dedicated to transporting only FCoE traffic. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE or FIP traffic must travel in a different VLAN.

**NOTE:** On a standalone switch or QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

FCoE traffic cannot use a standard LAG because traffic might be hashed to different physical LAG links on different transmissions. This breaks the (virtual) point-to-point link that Fibre Channel traffic requires. If you configure a standard LAG interface for FCoE traffic, FCoE traffic might be rejected by the FC SAN.

QFabric systems support a special LAG called an FCoE LAG, which enables you to transport FCoE traffic and regular Ethernet traffic (traffic that is not FCoE traffic) across the same link aggregation bundle. Standard LAGs use a hashing algorithm to determine which physical link in the LAG is used for a transmission, so communication between two devices might use different physical links in the LAG for different transmissions. An FCoE LAG ensures that FCoE traffic uses the same physical link in the LAG for requests and replies in order to preserve the virtual point-to-point link between the FCoE device converged network adapter (CNA) and the FC SAN switch across the QFabric system Node device. An FCoE LAG does not provide load balancing or link redundancy for FCoE traffic. However, regular Ethernet traffic uses the standard hashing algorithm and receives the usual LAG benefits of load balancing and link redundancy in an FCoE LAG.

**NOTE:** IGMP snooping is enabled by default on all VLANs in all software versions before Junos OS R13.2. Disable IGMP snooping on FCoE VLANs if you are using software that is older than 13.2.

You can configure more than one FCoE VLAN, but any given virtual link must be in only one FCoE VLAN.

**NOTE:** All 10-Gigabit Ethernet interfaces that connect to FCoE devices must have a native VLAN configured in order to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

On switches that use the Enhanced Layer 2 Software (ELS) CLI, it is not sufficient only to configure the native VLAN on the interface, the interface must also be configured as a member of the native VLAN. (This is because the ELS CLI does not support tagged-access interface mode, so interfaces that are members of FCoE VLANs must use trunk mode, and trunk port interfaces must be explicitly included as members of a native VLAN.)

In addition, the VLAN ID must match the native VLAN ID that you configure on the physical interface. For example, to configure a native VLAN with an ID of 20 on interface xe-0/0/15 that is a member of an FCoE VLAN, you must include both of the following statements in the configuration:

1. Configure the native VLAN on the interface:

```
user@switch# set interfaces xe-0/0/15 native-vlan-id 20
```

(The equivalent configuration statement on a non-ELS device switch would be `set interfaces xe-0/0/15 unit 0 family ethernet-switching native-vlan-id 20`.)

2. Configure the port as a member of the native VLAN (this step is not required on switches that do not use the ELS software):

```
user@switch# set interfaces xe-0/0/15 unit 0 family ethernet-switching vlan members 20
```

**BEST PRACTICE:** Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

## Understanding FCoE Transit Switch Functionality

You can use the switch as a Fibre Channel over Ethernet (FCoE) transit switch. An FCoE transit switch is a Layer 2 data center bridging (DCB) switch that can transport FCoE frames and implements FCoE Initialization Protocol (FIP) snooping. A DCB switch transports both FCoE and Ethernet LAN traffic over the same network infrastructure while preserving the class of service (CoS) that Fibre Channel (FC) traffic requires.

An FCoE transit switch does not encapsulate or de-encapsulate FC frames in Ethernet. It is an access switch that transports FC frames that have already been encapsulated in Ethernet between FCoE initiators such as servers and a storage area network (SAN) FC switch that supports both Ethernet and native FC traffic on its interfaces. The transit switch acts as a passthrough switch and is transparent to the FC switch, which detects each connection to an FCoE device as a direct point-to-point link.

When a switch acts as a transit switch, the VLANs you configure for FCoE traffic can use any of the switch ports because the traffic in both directions is standard Ethernet traffic, not native FC traffic.

.....

**NOTE:** The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets. It is a good practice to keep the native VLAN separate from the VLANs that carry FCoE traffic. FCoE VLANs should carry only FCoE traffic, but other types of untagged traffic might use the native VLAN.

Switches and QFabric system Node devices that use the original CLI (not the Enhanced Layer 2 (ELS) software) only require that you configure the native VLAN on the FCoE interfaces that belong to the FCoE VLAN by including the `[set interfaces interface-name unit unit family ethernet-switching native-vlan-id native-vlan-id]` statement in the configuration.

QFX5100 and EX4600 switches use ELS software and require that you include two statements in the configuration to configure a native VLAN on FCoE interfaces. Include the `[set interfaces interface-name native-vlan-id vlan-id]` statement in the configuration to configure the native VLAN on the interface, and also include the `[set interfaces interface-name unit unit family ethernet-switching native-vlan-id vlan-id]` statement in the configuration to configure the port as a member of the native VLAN.

.....

FCoE traffic should use a VLAN dedicated only to FCoE traffic. Do not mix FCoE traffic with standard Ethernet traffic on a VLAN on the switch.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

FCoE traffic cannot use a standard LAG because traffic might be hashed to different physical LAG links on different transmissions. This breaks the (virtual) point-to-point link that Fibre Channel traffic requires. If you configure a standard LAG interface for FCoE traffic, FCoE traffic might be rejected by the FC SAN.

QFabric systems support a special LAG called an FCoE LAG, which enables you to transport FCoE traffic and regular Ethernet traffic (traffic that is not FCoE traffic) across the same link aggregation bundle. Standard LAGs use a hashing algorithm to determine which physical link in the LAG is used for a transmission, so communication between two devices might use different physical links in the LAG for different transmissions. An FCoE LAG ensures that FCoE traffic uses the same physical link in the LAG for requests and replies in order to preserve the virtual point-to-point link between the FCoE device converged network adapter (CNA) and the FC SAN switch across the QFabric system Node device. An FCoE LAG does not provide load balancing or link redundancy for FCoE traffic. However, regular Ethernet traffic uses the standard hashing algorithm and receives the usual LAG benefits of load balancing and link redundancy in an FCoE LAG.

**NOTE:** IGMP snooping is enabled by default on all VLANs in all software versions before Junos OS R13.2. Disable IGMP snooping on FCoE VLANs if you are using software that is older than 13.2.

**NOTE:** On a QFX3500 switch or on a QFabric system Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode. (Only QFX3500 switches can be configured in FCoE-FC gateway mode.) If you configure both a transit switch and an FCoE-FC gateway on the same QFX3500 switch or QFabric system Node device, configure different FCoE VLANs for the transit switch and the FCoE-FC gateway.

Transit switch architecture differs from FCoE-FC gateway architecture. As an FCoE-FC gateway, the system transports traffic to the FC SAN as native FC frames, and the VLAN must use an FCoE VLAN interface and native FC interfaces to transport that traffic. As a transit switch, the system forwards Ethernet traffic, and requires DCB configuration for lossless transport of that traffic and FIP snooping at FCoE device access ports, but not the FCoE-FC gateway features necessary for transporting FC traffic.

With the exception of Virtual Chassis (VC) and mixed-mode Virtual Chassis Fabric (VCF) configurations, switches support the DCB standards for ensuring lossless transport and low latency, and provide 10-Gbps ports for FCoE traffic. VCF configurations that use only

QFX5100 switches support DCB standards. For lossless transport to function correctly, you must use priority-based flow control (PFC, described in IEEE 802.1Qbb) to create bandwidth reservations and ensure proper CoS for FCoE traffic.

FIP snooping adds security by filtering access so that only traffic from servers that have successfully logged in to the FC network passes through the transit switch and reaches the FC network. The Technical Committee T11 organization specifications describe two types of FIP snooping:

- The FC-BB-5 specification describes VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping, which provides security for communication between FCoE device VN\_Ports on the Ethernet network and FCF or FC switch VF\_Ports.
- The FC-BB-6 specification describes VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping, which provides security for communication between FCoE device VN\_Ports on the Ethernet network.

To accommodate the larger size of Ethernet-encapsulated frames, FCoE interfaces should be configured with a maximum transmission unit (MTU) size of at least 2180 bytes.

The transit switch transparently connects FCoE-capable devices such as servers in an Ethernet LAN to an FC switch or to a gateway switch (hereafter referred to as the FC switch), as shown in [Figure 204 on page 5288](#). The transit switch acts as a transparent DCB access layer between FCoE servers and the FC switch.

**Figure 204: FCoE Transit Switch Connecting FCoE Devices to an FC Switch**

The transit switch performs FIP snooping at the ports connected to the FCoE devices. For VN2VF\_Port FIP snooping, at the SAN edge, the FC switch must be able to convert the FCoE traffic to native FC traffic. (VN2VN\_Port FIP snooping switches traffic between

VN\_Ports directly through the transit switch, without going through the FC switch, so no conversion of FCoE traffic to native FC traffic is needed.)

Encapsulated FCoE traffic flows through the transit switch to the FCoE ports on the FC switch. The FC switch removes the Ethernet encapsulation from the FCoE frames to restore the native FC frames. Native FC traffic travels out native FC ports to storage devices in the FC SAN.

Native FC traffic from storage devices flows to the FC switch FC ports, and the FC switch encapsulates that traffic in Ethernet as FCoE traffic. The FCoE traffic flows through the transit switch to the appropriate FCoE device.

**NOTE:** The FC switch and FC fabric apply appropriate zoning checks on traffic to and from each ENode and provide FC services (for example, name server, fabric login server, or event server).

**NOTE:** VN\_Port to VN\_Port FIP snooping is supported to allow FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch. An FCoE VLAN can support either VN2VF\_Port FIP snooping (FC-BB-5) or VN2VN\_Port FIP snooping (FC-BB-6), but not both. The same switch can have multiple FCoE VLANs configured, some FCoE VLANs for VN2VF FIP snooping traffic and others for VN2VN FIP snooping traffic.

## Understanding an FCoE-FC Gateway

A Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway connects FCoE devices on an Ethernet network to an FC switch in an FC storage area network (SAN) as shown in [Figure 205 on page 5290](#). To FCoE devices such as servers, the FCoE-FC gateway presents virtual fabric ports (VF\_Ports) and appears to be an FCoE forwarder (FCF). To the FC switch, the FCoE-FC gateway presents a proxy node port (NP\_Port) and appears to be an FC device. Only the QFX3500 switch, both in standalone mode and as a QFabric system Node device, supports configuration as an FCoE-FC gateway.

**Figure 205: FCoE-FC Gateway Topology**

The FCoE-FC gateway handles FCoE Initialization Protocol (FIP) and FCoE traffic on the interfaces connected to FCoE devices. The gateway forwards native FC traffic on the interfaces to the FC switch. The gateway does not provide FC services (such as fabric login server or name server). It is a proxy for an FCF, not an FCF or an FC switch. The gateway transparently substitutes for the FC switch when communicating with FCoE devices and transparently substitutes for FCoE devices when communicating with the FC switch.

The gateway does not use an FC domain ID, so it extends the SAN fabric while saving domain resources. Using the gateway also means that the FC switch does not have to handle FCoE traffic (and therefore requires no FCoE blades or ports). The gateway converges Ethernet and FC backbones to leverage existing resources.

- [Gateway FC Fabric on page 5291](#)
- [Fabric Services on page 5292](#)
- [FCoE-FC Gateway Traffic Switching on page 5292](#)

## Gateway FC Fabric

A gateway FC fabric is a QFX3500 configuration construct. It is not the same thing as an FC fabric in the SAN; the gateway FC fabric is local to the switch. It creates associations that connect FCoE devices with converged network adapters (CNAs) on the Ethernet network to an FC switch on the Fibre Channel network. A gateway FC fabric consists of:

- A unique fabric name.
- A unique fabric ID.
- At least one dedicated VLAN for FCoE traffic. VLANs that carry FCoE traffic should not carry any other type of traffic.

**NOTE:** On a QFX3500 or QFabric system QFX3500 Node device, the same VLAN cannot be used in both transit switch mode and FCoE-FC gateway mode.

- At least one FCoE VLAN interface (Layer 3 VLAN interface) that includes one or more 10-Gigabit Ethernet interfaces connected to FCoE devices. The FCoE VLANs transport traffic between the FCoE servers and the FCoE-FC gateway. Each FCoE VLAN must carry only FCoE traffic. You cannot mix FCoE traffic and standard Ethernet traffic on the same VLAN.

The 10-Gigabit Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic because FIP VLAN discovery and notification frames are exchanged as untagged packets.

Each FCoE VLAN interface can present multiple VF\_Port interfaces to the FCoE network.

**NOTE:** Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

- One or more native FC interfaces. The native FC interfaces transport traffic between the gateway and the FC switch.

**TIP:** If the network does not use a dual-rail architecture for redundancy, configure more than one native FC interface for each FC fabric to create redundant connections between the FCoE devices and the FC switch. If one physical link goes down, any sessions it carried can log in again and connect to the FC switch on a different interface. Even in dual-rail architecture networks, creating redundant connections between the QFabric system and the FC switch is the best practice.

You can also configure FIP parameters for the fabric or accept the default FIP parameters. VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping is automatically enabled on all server-facing ports because all ports are untrusted by default. You can disable VN2VF\_Port

FIP snooping on a port-by-port basis by marking a port as an FCoE trusted interface. You can disable VN2VF\_Port FIP snooping on all Ethernet ports in an FC fabric by configuring the fabric as FCoE trusted.

Because the switch has 12 native FC ports and each FC fabric requires a minimum of one native FC port, the switch supports a maximum of 12 FC fabrics. However, as a best practice for redundancy, we recommend that you assign at least two native FC interfaces to each FC fabric.

On a QFabric system, all of the FC and FCoE traffic that belongs to a particular gateway FC fabric must ingress and egress the same gateway Node device. Gateway FC fabrics do not span across Node devices. All of the native FC interfaces and the Ethernet interfaces that belong to the FCoE VLAN must reside on the same gateway Node device to be included in an FC fabric on that Node device.

Traffic from FC and FCoE devices that are not in the same FC fabric remain separate and cannot communicate with each other through the gateway.

### Fabric Services

---

The FC switch provides all FC services (domain manager, name server, fabric login server, and so on) except FIP to the FCoE devices. The FC switch assigns all FCIDs (through N\_Port ID virtualization) and fabric attributes to FCoE device VN\_Ports.

The FCoE-FC gateway does not provide FC services (except FIP). The gateway relays communication between the FC switch and the FCoE devices, encapsulates and de-encapsulates native FC frames, converges Ethernet and FC backbones, and aggregates FCoE device VN\_Port sessions.

### FCoE-FC Gateway Traffic Switching

---

All traffic that flows through the gateway FC fabric is switched through the FC switch. Even if two hosts on the Ethernet FCoE network connect directly to the gateway, FCoE communication between them goes through the FC switch, as shown in [Figure 206 on page 5293](#).

**Figure 206: Traffic Switching Between FCoE Hosts Connected to the FC Network by an FCoE-FC Gateway**

For example, FCoE host server *Host1* sends frames destined for FCoE host server *Host2*. Both *Host1* and *Host2* are directly connected to the gateway. The communication path looks like this:

1. *Host1* sends FCoE frames destined for *Host2* to the gateway .
2. The gateway de-encapsulates the FCoE frames from *Host1* into native FC frames and switches them to the FC switch.
3. The FC switch processes the native FC frames and sends them back to the gateway destined for *Host2*.
4. The gateway encapsulates the FC frames in Ethernet and sends the resulting FCoE frames to *Host2*.
5. When *Host2* replies, the FCoE reply goes to the gateway. The gateway de-encapsulates the reply and switches it to the FC switch for processing. The FC switch then sends it back to the gateway, which encapsulates the FC frames and sends them to *Host1*.

## Understanding FCoE-FC Gateway Functions

When it functions as a Fibre Channel over Ethernet (FCoE)-Fibre Channel (FC) gateway, the QFX3500 switch provides the following functions:

- [Login and Logout on page 5294](#)
- [FCoE and FC Frame Handling on page 5294](#)
- [Data Center Bridging on page 5294](#)
- [Disabling the Fabric WWN Verification Check on page 5295](#)
- [Load Balancing on page 5296](#)

### Login and Logout

---

Each of the native FC interfaces on the gateway performs a fabric login (FLOGI) to the FC switch when each interface initializes. This establishes the link between each gateway FC interface and the FC switch.

When FCoE devices on the Ethernet network send an FCoE Initialization Protocol (FIP) login (FIP FLOGI) or FIP discovery (FIP FDISC) request to the gateway, the gateway acts on behalf of those devices and converts their FIP FLOGI and FIP FDISC requests to FC FDISC requests. The gateway then sends the FC FDISC requests to the FC switch. When the FC switch responds to an FDISC request, the gateway converts the FC response into a FIP response and sends it to the appropriate FCoE device.

The gateway also converts FIP logout (LOGO) requests from FCoE devices into FC LOGO requests to the FC switch, and converts the FC switch response into a FIP response for the FCoE device.

### FCoE and FC Frame Handling

---

When it receives FCoE frames from FCoE devices, the gateway strips away the Ethernet encapsulation from the FC frame before sending the native FC frame to the FC switch.

When it receives native FC frames from the FC switch, the gateway encapsulates the native FC frames in Ethernet before sending the resulting FCoE frames to the appropriate VN\_Port.

### Data Center Bridging

---

The Ethernet ports connected to the FCoE devices are 10-Gbps Ethernet ports and support data center bridging (DCB) specifications:

- Priority-based flow control (PFC, described in IEEE 802.1Qbb)
- Data Center Bridging Capability Exchange protocol (DCBX), which is an extension of Link Layer Data Protocol (LLDP, described in IEEE 802.1AB)
- Enhanced transmission selection (ETS, described in IEEE 802.1Qaz)
- 10-Gigabit Ethernet ports

---

### Disabling the Fabric WWN Verification Check

---

The gateway connects to a SAN fabric using the gateway NP\_Ports (native FC ports). When the NP\_Ports initialize, each port sends a FLOGI to the FC switch to which it is connected in the SAN fabric. The FC switch sends a FLOGI accept (FLOGI-ACC) message back to each NP\_Port. The FLOGI-ACC message includes the SAN fabric worldwide name (WWN). The gateway uses the SAN fabric WWN in the multicast discovery advertisement (MDA) that the gateway sends to the ENodes in the FCoE network.

Some FC switches substitute their own WWN (often the FC switch's virtual WWN) for the SAN fabric WWN in the FLOGI-ACC message. When the FC switch substitutes its own WWN for the fabric WWN, gateway NP\_Ports that log in to the same SAN fabric might receive different fabric WWNs in the FLOGI-ACC messages if the NP\_Ports are connected to different FC switches in that SAN fabric. This creates a problem, because different fabric WWNs indicate different SAN fabrics. But in this scenario, the different fabric WWNs come from different FC switches in the same SAN fabric.

If the gateway receives different fabric WWNs on NP\_Ports that are connected to the same SAN fabric, the gateway uses the first fabric WWN it receives in the MDA it sends to the ENodes. The gateway isolates the NP\_Ports connected to that fabric that receive a different fabric WWN in the FLOGI-ACC message. No ENode sessions are assigned to the isolated NP\_Ports. FC traffic is assigned only to NP\_Ports that receive a fabric WWN that matches the fabric WWN received by the first NP\_Port to log in to the FC fabric. (If an NP\_Port receives a fabric WWN that does not match the fabric WWN received by the first NP\_Port to log in to the FC fabric, it does not carry traffic to the SAN fabric.)

In summary, the scenario is:

1. The gateway has multiple NP\_Ports connected to more than one FC switch in a SAN fabric.
2. When the NP\_Ports initialize, each NP\_Port sends a FLOGI to the FC switch to which it is connected.
3. The FC switches substitute their own WWNs for the fabric WWN in the FLOGI-ACC message, so different NP\_Ports receive different fabric WWNs.
4. In the MDA the gateway sends to FCoE devices, the gateway uses the fabric WWN that the first NP\_Port to log in to the fabric receives in the FLOGI-ACC message. If other NP\_Ports receive a different fabric WWN from other FC switches in the SAN fabric, that fabric WWN is not advertised.
5. NP\_Ports that receive a fabric WWN that does not match the first received fabric WWN are isolated, and the ENode sessions cannot use those ports.

To prevent this from happening, you can disable the gateway fabric WWN verification check so that all NP\_Ports connected to a SAN fabric are used to carry traffic between the gateway and the FC switch, regardless of the fabric WWN the NP\_Port receives in the FLOGI-ACC message.

**NOTE:** Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.

---

## Load Balancing

The switch performs automatic link load balancing for the connections between the gateway and the FC SAN and can also perform load balancing for the connections between the gateway and the FCoE devices in the Ethernet network. On the native FC links (NP\_Ports) between the gateway and the FC SAN, the gateway can use one of the following three load-balancing algorithms:

- Simple load balancing—The switch assigns each ENode FLOGI session and VN\_Port FDISC session to the least-loaded link. The switch can place FDISC sessions on a different link than the parent FLOGI session (an ENode FLOGI session and its subsequent FDISC sessions can be placed on different links). Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- ENode-based load balancing—When an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP\_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- FLOGI-based load balancing—Similar to ENode-based load balancing; when an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

**NOTE:** Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out, then log in again.

## Understanding FCoE and FIP Session High Availability

High availability features maintain storage network sessions when a system process is terminated and during certain types of upgrades:

- [High Availability for Fibre Channel Process Termination \(FCoE-FC Gateway Mode\) on page 5297](#)
- [High Availability for FIP Snooping on page 5297](#)
- [Nonstop Software Upgrade \(QFabric Systems\) on page 5298](#)

### High Availability for Fibre Channel Process Termination (FCoE-FC Gateway Mode)

In FCoE-FC gateway mode, the QFX3500 switch provides high availability to restore the FCoE sessions running on the switch in case the Fibre Channel (FC) process is terminated. A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric, not an end-to-end server-to-storage session.

The switch stores FCoE session data in a persistent storage module. If the FC process terminates, the switch restores the existing FCoE sessions on the same interfaces that they were on before the FC process terminated. Data traffic for existing sessions is not affected during session restoration.

For a brief time, the system does not process control traffic because of the FC process restart and session restoration. During this brief time, no new FCoE sessions can be established, and no existing sessions can log out.

**NOTE:** During the restoration process, if the FC process does not receive an *interface up* notification from a particular interface within a certain time, the switch times out the restore operation and discards the data on that interface. The previously existing FCoE sessions on that interface are not restored, and the ENodes must log in again.

**NOTE:** An FC process restart and session restoration resets the Fibre Channel statistics.

If the FC process terminates repeatedly, the operating system disables the process until you manually restart it. To restart the FC process manually, issue the **restart fibre-channel** command.

### High Availability for FIP Snooping

You can configure the system to perform FIP snooping on Ethernet interfaces that are connected to FCoE devices that have ENodes. The high availability function restores running FIP snooping sessions in case the Ethernet switching process is terminated.

The Ethernet switching process stores the FIP snooping state in a persistent storage module. If the Ethernet switching process terminates, the switch restores the existing

FIP snooping sessions on the same interfaces that they were on before the Ethernet switching process terminated. The high availability features preserve:

- Logged in ENodes
- Discovered FCFs
- Existing sessions
- Existing FIP snooping filters

The complete restoration process, including reconciling all valid states, takes a maximum of 8 seconds. During the restoration process, the switch can learn a new FCF or a new FC switch, and new ENodes can log in to the FC network. However, FDISC messages from an ENode that is already logged in to the network might be dropped if the ENode has not yet been restored.

When the Ethernet switching process terminates ungracefully, the FIP keepalive timer is reset to the normal initial value, not the value at the time of the Ethernet switching process termination.

In the event of an Ethernet switching process termination, ENodes remain logged in, and existing sessions are not interrupted.

**NOTE:** An Ethernet switching process restart and session restoration resets the FIP snooping statistics.

---

### Nonstop Software Upgrade (QFabric Systems)

---

On QFabric system Node groups that have more than one Node device, nonstop software upgrade (NSSU) enables you to upgrade the Node devices with minimal packet loss and maximum uptime. NSSU automates software upgrades on the QFabric system components in an orderly and consistent manner to maximize system uptime.

The system upgrades components with redundant architectures, such as redundant server Node groups and network Node groups that have two or more members, in stages. While the system upgrades one component, the redundant component continues to function.

For example, while one member of a redundant server Node group is upgraded, the other member continues to forward traffic. When the first Node group member completes the upgrade, it comes online while the system upgrades the second member.

NSSU provides high availability for the lossless traffic forwarding required to support storage networks. If your system design includes redundancy (redundant Node devices in Node groups, LAGs, and so on) so that an alternate traffic path is available, when you upgrade a Node device, traffic is not impacted.

In fully redundant topologies, NSSU preserves FIP session, FIP snooping filter, VN2VF\_Port session, and VN2VN\_Port session information and prevents traffic loss in most cases.

An exception is that Node devices that are directly connected to ENodes experience momentary traffic loss when the Node device reboots.

## Understanding FIP Functions

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) performs four major functions:

- FIP VLAN discovery: FCoE device FCoE nodes (ENodes) discover the FCoE VLANs on which to transmit and receive FIP and FCoE traffic.
- FIP discovery: FCoE devices discover Fibre Channel (FC) switches to which they can connect.
- Initialization: FCoE devices perform fabric login (FLOGI) and fabric discovery (FDISC) to create a virtual link with an FC switch.
- Maintenance: The switch ensures that the virtual link between the FCoE device and the FC switch remains valid, and also that the link termination logout (LOGO) functions properly.

When you configure the switch as an FCoE-FC gateway (QFX3500 switch only, as a standalone switch or as a QFabric system Node device), it converts FIP requests and information from FCoE devices into FC requests and information and relays them to the FC switch. To FCoE devices, the gateway appears to be an FCoE forwarder (FCF) and presents virtual fabric port (VF\_Port) interfaces to the server ENode. To FC switches, the gateway appears to be an FC device that supports N\_Port ID virtualization (NPIV) and presents an N\_Port interface to the FC switch F\_Port interface. When you configure the switch as an FCoE transit switch, you do not configure FIP parameters on the switch.

FIP FLOGI, FDISC, and LOGO are similar to the same processes in the native FC protocol.

This topic describes:

- [FIP VLAN Discovery on page 5300](#)
- [FIP Discovery on page 5300](#)
- [FIP FLOGI on page 5301](#)
- [FIP FDISC on page 5302](#)
- [FIP Maintenance \(Keepalive Messages\) on page 5302](#)
- [FIP LOGO on page 5303](#)

## FIP VLAN Discovery

---

The gateway supports FIP VLAN discovery. Host ENodes use FIP VLAN discovery to discover the FCoE VLANs on which they will send and receive FIP and FCoE traffic and on which they will establish a virtual link with the FC switch. This means FCoE devices do not need manually configured FCoE VLANs.

FIP VLAN discovery and notification takes place on the native VLAN that the FCoE device uses for Ethernet traffic:

1. The ENode sends a FIP VLAN discovery request to a multicast address called *ALL-FCF-MACs* to which all FC switches and FCFs on the VLAN listen.
2. The FC switches and FCFs respond on the native VLAN with a list of the FCoE VLANs that are available for login.
3. The ENode selects an FCoE VLAN and continues the FIP process on that VLAN.

Except for FIP VLAN discovery, all other FIP and FCoE traffic runs on an FCoE VLAN.

**BEST PRACTICE:** Only FCoE traffic is permitted on the FCoE VLAN. A native VLAN might need to carry untagged traffic of different types and protocols. Therefore, it is a good practice to keep the native VLAN separate from FCoE VLANs.

---

## FIP Discovery

---

The FIP discovery process allows an FCoE device ENode MAC to locate (discover) the FC switches in the FCoE VLAN to which it belongs. The ENode selects an FC switch to log in to from the available FC switches. Either the ENode MAC or the FC switch can initiate the FIP discovery process.

Server ENode MACs initiate FIP discovery:

1. When an ENode MAC comes online, it sends a multicast discovery solicitation message on its FCoE VLAN to a multicast address called *ALL-FCF-MACs* to which all FCFs (including the FCF functionality of FC switches) on the VLAN listen. The discovery solicitation message includes the ENode's addressing mode and the maximum protocol data unit (PDU) size the ENode MAC uses for FCoE traffic.

The ENode uses the globally unique ENode MAC address assigned to it by the converged network adapter (CNA) manufacturer as an identifier in the FIP frame header.

2. The FCFs on the VLAN that have a similar supported addressing mode, match the maximum FCoE size, and can accept a login from the ENode reply to the discovery solicitation message by sending a solicited unicast discovery advertisement message to the soliciting ENode MAC.
3. The ENode MAC compiles a list of FCFs that are available for login, selects an FCF (the FCF with the highest priority setting), and is then ready to log in to the FCF.

The FIP discovery process is similar when the FC switch or FCF initiates discovery:

1. FCF MACs periodically send unsolicited multicast discovery advertisements on the FCoE VLAN to the *ALL-ENode-MACs* multicast address, to which all ENode MACs on the VLAN listen. The FIP keepalive advertisement period timer (FKA\_ADV\_PERIOD) controls the interval between multicast discovery advertisements. The multicast discovery advertisements inform ENodes on the VLAN that FCF VF\_Ports are available for establishing virtual links with ENode VN\_Ports.
2. ENodes on the FCoE VLAN create an entry for the FCF-MAC in their FCF-MAC lists.
3. An ENode can respond to the unsolicited multicast discovery advertisement with a unicast discovery solicitation message to the FCF.
4. Upon receiving the ENode's unicast discovery solicitation, the FCF replies with a unicast discovery advertisement sent to the ENode MAC.

After the ENode MAC selects an FCF to log in to, FIP initialization begins. To proceed from discovery to initialization, the server ENode addressing mode must match the FCF addressing mode and maximum FCoE size. In addition, the FCF must be configured to allow FIP FLOGI from that ENode.

### FIP FLOGI

FIP initialization is the server ENode login process to the FCF after the ENode discovers the FCFs (including FC switches) on the FCoE VLAN:

1. The ENode sends a fabric login (FLOGI) request message to the FCF.
2. The FCF replies to confirm the ENode login and provides the ENode a locally unique MAC address to use for FCoE frame transactions. The locally unique MAC address identifies the VN\_Port interface of the ENode for the session the login establishes. (The ENode continues to use the globally unique ENode MAC address for FIP frame transactions.)

The locally unique ENode MAC address for FCoE operations depends on whether the ENode address mode is configured as a fabric-provided MAC address (FPMA) or as a server-provided MAC address (SPMA; the gateway does not support ENodes in SPMA mode and rejects login attempts from ENodes in SPMA mode):

- For FPMA mode, the FCF provides a MAC address to the ENode during the FIP FLOGI exchange. The FPMA MAC address is a 48-bit value that is unique to the local fabric and consists of a 24-bit FCoE mapped address prefix (FC-MAP) and a 24-bit FC identifier (FCID). You can configure the FC-MAP value on the FCF or use the default value of 0EFC00h. The FCoE device must use the same FC-MAP value as the FCF, or else discovery and login fail.
- For SPMA mode, the server provides its MAC address to the FCF. The FCF compares the server MAC address to a list of addresses approved for FCoE access. The gateway does not support ENodes in SPMA mode.

Successful login instantiates a secure virtual link between the ENode and the FCF and terminates the FIP virtual link instantiation phase. The initiating server behind the ENode

can exchange FC payloads with storage devices in the FC SAN by sending FCoE frames over the virtual link.

### FIP FDISC

---

After an ENode successfully logs in to an FCF and establishes a virtual link, the ENode can request more virtual links (sessions) over the same physical link by sending a FIP fabric discovery (FDISC) request. FDISC allows the creation of multiple separate secure VN\_Port virtual links on one physical link. Each virtual link receives a locally unique identifier from the FCF to enable security and separation between the VN\_Port virtual links sharing a physical ENode port. This is called N\_Port ID virtualization (NPIV).

FDISC is similar to FLOGI in that it requests a login and a unique ID from the FCF. The difference is that FLOGI obtains the initial login and ID for the physical link, whereas FDISC obtains additional logins and IDs so that multiple virtual links can share one physical link securely.

After a VN\_Port FDISC is complete, the application using that VN\_Port can send FCoE frames over the virtual link.

### FIP Maintenance (Keepalive Messages)

---

Although FCoE protocol handles the payload communication between the initiating ENode and the target FC device, FIP continues to run in the background. FIP constantly updates ENode FCF lists by listening to the periodic FCF multicast discovery advertisements, and it verifies the ability to reach the FCF by transmitting periodic FIP keepalive advertisements.

The ENode sends periodic ENode FIP keepalive advertisements to the FCF with the ENode MAC address as the identifier. The ENode also sends periodic VN\_Port FIP keepalive advertisements on behalf of each VN\_Port on the ENode, using the VN\_Port MAC address as the source MAC. The VN\_Port FIP keepalive advertisements occur every 90 seconds. The keepalive advertisements reset the session timer for the virtual link connection to the FCF. If the FCF does not receive a keepalive advertisement for a logged-in ENode or VN\_Port before the session timer expires, the virtual link is terminated.

The periodic unsolicited multicast discovery advertisements the FCF sends to the *ALL-ENode-MACs* address continuously verify that the FCF is still reachable. The ENode and the FCF periodic unsolicited multicast discovery advertisements occur at the configured FIP keepalive advertisement period interval (FKA\_ADV\_PERIOD) plus or minus a random offset to prevent a flood of simultaneous keepalive advertisements.

If the FCF does not receive the ENode keepalive advertisements before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the ENode as "down" and terminates the virtual link to the ENode. The keepalive timer expires in 2.5 times the configured timer value. This also terminates any VN\_Port virtual links instantiated by that ENode.

If the FCF does not receive a VN\_Port keepalive advertisement before the FCF's FIP keepalive timer expires, the FCF considers the virtual link to the VN\_Port as "down" and terminates the virtual link to that VN\_Port. The VN\_Port keepalive timer expires in 2.5 times the configured timer value.

If the ENode does not receive the FCF unsolicited multicast discovery advertisement before the ENode's FIP keepalive timer expires, the ENode considers the virtual link to the FCF as "down" and all of the VN\_Port virtual links to that FCF on the ENode are terminated.

### FIP LOGO

FIP handles ENode and VN\_Port logout when a session is finished.

## Understanding FIP Implementation on an FCoE-FC Gateway

In a network that converges Fibre Channel (FC) and Ethernet traffic, when you configure a QFX3500 switch as a Fibre Channel over Ethernet (FCoE)-FC gateway, it translates FCoE Initialization Protocol (FIP) frames from FCoE nodes (ENodes) into native FC frames for FC switches and translates native FC frames from FC switches into FIP frames for ENodes. To an FCoE device, the gateway appears to be an FCoE forwarder (FCF) and presents a fabric port (F\_Port) interface to the FCoE device ENode. To an FC switch, the gateway appears to be an FC host capable of N\_Port ID virtualization (NPIV) and presents a node port (N\_Port) interface to the FC switch F\_Port interface.

**NOTE:** The N\_Ports that the gateway presents to the FC switch are called proxy N\_Ports (NP\_Ports). To the FC switch, the gateway NP\_Ports appear to be native FC N\_Ports that are capable of performing NPIV. The NP\_Ports are proxies for the FCoE devices in the Ethernet network. The NP\_Ports convert FCoE traffic from the FCoE devices into native FC traffic for the FC switch. The NP\_Ports also convert native FC traffic from the FC switch into FCoE traffic for the FCoE devices on the Ethernet network.

- [Proxy FIP Logout on page 5307](#)

### FIP Basics

FIP is enabled by default on all VLAN interfaces that belong to each FC fabric configured on the gateway. You can configure FIP parameters at a global level or on an individual

interface. When you configure a parameter on an interface, it overrides the global configuration only for that interface. If you do not explicitly configure a FIP parameter, the gateway uses the default value.

In order for the gateway to connect FCoE devices with FCFs, the FIP parameters you configure on the gateway must be compatible with the parameters configured on the FC switch (for example, the FC-MAP values of the FC switch and of the FC fabric FIP configuration on the gateway must match, or the FC switch drops the frames).

When the NP\_Ports on the gateway come up, they perform an FC FLOGI to the connected FC switch. Successful login establishes communication between the gateway and the FC switch, and gateway NP\_Ports are marked for sending FDISC messages. Successful login also creates a next-hop entry in the gateway for the FC switch. If the FC switch rejects the FLOGI request, no link is established. The gateway maintains a list of valid FCF-MACs with which ENodes can connect.

After establishing communication with an FC switch, the gateway can connect FCoE devices in the Ethernet network to the FC switch. All of the subsequent connections the gateway makes with FC switches as a proxy for ENodes (on behalf of ENodes) are virtualized (NPIV) connections.

### Fabric Login and FIP Login Overview

Figure 207 on page 5304 provides a brief overview of the FCoE-FC gateway fabric login to the FC switch and the FCoE device FIP login to the gateway.

**Figure 207: FCoE-FC Gateway Fabric Login and FIP Login**

The numbers in the following list correspond to the numbers in Figure 207 on page 5304 and briefly describe each step of the login process:

1. The FCoE-FC gateway NP\_Port sends an FC fabric login (FLOGI) request to the FC switch F\_Port.
2. The FC switch accepts the gateway FLOGI.
3. The gateway sends FIP multicast discovery advertisements on the FCoE VLAN (the gateway F\_Port interface) to all connected FCoE device ENodes.

4. The FCoE device ENode sends a discovery solicitation message to the gateway.
5. The gateway responds with a unicast discovery advertisement to the ENode.

**NOTE:** The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not respond to new discovery solicitations. Instead, the gateway drops new discovery solicitations and reports the number of dropped discovery solicitations in the **Dropped** field of the **show fibre-channel fip statistics** command output. When there are fewer than 100 outstanding discovery solicitations, the system responds to new requests as usual with a discovery advertisement.

6. The FCoE device sends a FIP FLOGI or FIP FDISC message to the gateway.
7. The gateway converts the FIP FLOGI or FIP FDISC to an FC FDISC and forwards it to the FC switch to obtain a login for the FCoE device.
8. The FC switch responds to the FC FDISC by sending a new ID for the NPIV session to the gateway.
9. The gateway converts the FC FDISC response from the FC switch to a FIP FDISC response and forwards it to the FCoE device.

The following sections describe some of these steps in greater detail.

### Proxy FIP Discovery

After the gateway establishes a connection with an FC switch:

1. The gateway sends periodic FIP multicast discovery advertisements on the FCoE VLAN so that ENodes can add the gateway to their FCF lists.
2. The ENode initializes and sends a multicast discovery solicitation message on the FCoE VLAN. If the ENode has already initialized and has a list of FCFs, it can send a unicast discovery solicitation message to a particular FCF such as the gateway.

**NOTE:** The gateway limits the number of discovery solicitations it accepts from FCoE devices to a maximum of 100 outstanding requests at any given time. If the gateway has 100 discovery solicitations outstanding, the gateway does not accept new discovery solicitations until there are fewer than 100 discovery solicitations outstanding.

3. When the gateway receives a multicast discovery solicitation from an ENode, it responds by sending a unicast discovery advertisement to that ENode.

When the gateway receives a unicast discovery solicitation from an ENode, it also responds with a unicast discovery advertisement to the ENode.

To the ENode, the gateway appears to be an FCF.

The FIP discovery process adds the ENode to the gateway ENode database.

### Proxy FIP Initialization

---

1. If the ENode chooses to log in to the gateway, it responds to the gateway's unicast discovery advertisement by sending a login request in the form of a FIP FLOGI if it is the initial connection to the gateway. If the ENode already has an established session with the gateway and another application or virtual machine wants to connect to the gateway, the ENode sends a FIP FDISC to the gateway.
2. The gateway receives the FIP FLOGI or FIP FDISC from the ENode, converts it into an FC FDISC, and sends it through the least-loaded NP\_Port to the FC switch on behalf of the ENode. The FC FDISC message requests an FCID for the new virtual link.

**NOTE:** The gateway converts both ENode FIP FLOGI and FIP FDISC messages into FC FDISC messages, because the gateway has already performed FC FLOGI with the FC switch, so all subsequent connection requests on the gateway NP\_Port are FDISC requests for virtual (NPIV) connections. FDISC messages request a virtual N\_Port connection over an existing physical N\_Port connection.

---

3. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and then sends the response to the gateway. If the FC switch rejects the FDISC request, no virtual link is established.
4. The gateway maps the FC switch response to the ENode VN\_Port, converts the FC acceptance message to a FIP FLOGI or FIP FDISC response, and sends it to the ENode VN\_Port.
5. The ENode VN\_Port accepts the FCID, and the virtual link is established.

If an ENode sends an FDISC, the proxy gateway switch checks whether the ENode has already performed a FLOGI to create the initial connection. If the ENode has not performed a FLOGI, the FDISC request is dropped.

The FC protocol does not recognize multipoint-to-point connections. Although the gateway can aggregate traffic from multiple FCoE servers on one NP\_Port, each virtual link appears to be an individual point-to-point link between an FCoE ENode VN\_Port and the FC switch, not as an aggregated multipoint-to-point link. The gateway is essentially invisible to the FC protocol, so the virtual link looks and acts like a point-to-point link from the FCoE device to the FC switch.

### Proxy FIP Maintenance

---

The gateway sends and receives periodic FIP keepalive messages to and from ENode VN\_Ports to maintain the connection between the gateway and the ENodes.

### Proxy FIP Logout

As with FIP discovery and FIP FLOGI, the gateway represents the FCoE device in transactions with the FC switch and represents the FC switch in transactions with the FCoE device:

1. An ENode VN\_Port sends a FIP LOGO message to log off and terminate the virtual link connection.
2. The gateway converts the FIP LOGO to an FC LOGO and relays it to the FC switch.
3. The FC switch responds to the LOGO request.
4. The gateway converts the FC LOGO response to a FIP LOGO response and relays it to the VN\_Port, completing the logout and terminating the virtual link.

### Understanding FIP Parameters on an FCoE-FC Gateway

By default, FIP is enabled, and the default FIP settings are valid on all FCoE interfaces that are part of the gateway FC fabric. You can configure some FIP parameters at a global level or on a specific interface. Some FIP parameters can be configured only at the global level or only at the individual interface level. When you configure a parameter at the interface level, the configuration overrides the global setting for that interface only.

- [Priority on page 5310](#)

#### FIP Keepalive Advertisement Period

The FIP keepalive advertisement period (fka-adv-period) is the time interval between messages that verify the connection is still valid and the device at the other end of the virtual link is still reachable. The ENode sends an ENode FIP keepalive advertisement to the gateway with the ENode MAC address as the source address to verify its reachability. The ENode also sends VN\_Port FIP keepalive messages for every VN\_Port on the ENode that is logged in to the gateway, with the VN\_Port MAC address as the source address.

The FIP keepalive advertisement period also determines the time interval between unsolicited multicast discovery advertisements from the gateway to the *ALL-ENode-MACs* multicast address. Unsolicited multicast discovery advertisements serve as keepalive messages from the gateway to the ENodes and also advertise the gateway's presence on the network.

The gateway sends the periodic unsolicited multicast discovery advertisements to the ENodes. On the gateway, you can configure a global FIP keepalive advertisement period for an FC fabric and you can configure a FIP keepalive advertisement period for individual interfaces to override the global setting.

### Addressing Mode

---

For FIP transactions, the ENode identifies itself using the globally unique MAC address assigned to the CNA by the manufacturer. After FIP has established a virtual link between an ENode VN\_Port and the gateway, for FCoE transactions, the VN\_Port identifies itself using a locally unique MAC address. The format of the locally unique MAC address depends on the addressing mode the fabric supports and the addressing mode the ENode is programmed to use.

The addressing mode is not a configurable parameter on the gateway. FC fabrics on the gateway support only the fabric provided MAC address (FPMA) addressing mode for FCoE transactions. The gateway does not support the server provided MAC address (SPMA) addressing mode. ENodes that use SPMA cannot log in to the gateway.

The FC switch assigns a locally unique FPMA to an ENode MAC through the FLOGI or FDISC process:

1. During the FIP discovery process, the ENode compiles a list of compatible FCFs (including the gateway) in the fabric. A compatible addressing mode is one of the criteria an FCF must meet to be added to an ENode's compatible FCFs list.
2. The ENode MAC transmits a FLOGI or FDISC to the FCF that includes the addressing modes the ENode supports.
3. If the FCF supports an addressing mode the ENode uses, the FCF accepts the FLOGI or FDISC and assigns the FPMA in the accept message (FIP FLOGI LS\_ACC or FIP NPIV FDISC LS\_ACC). If the ENode uses an addressing mode that is incompatible with the FCF, the FLOGI or FDISC is rejected.

The FPMA uniquely identifies a single VN\_Port at that ENode MAC in FCoE transactions with the FCF. Each VN\_Port connection receives its own unique FPMA to identify its virtual link connection. When an ENode uses NPIV to create multiple VN\_Ports, each VN\_Port virtual link receives its own unique FPMA to identify its traffic.

An FPMA consists of two concatenated 24-bit values:

1. The upper 24 bits are the FCF's FC-MAP value, which is a MAC address prefix that is unique to the fabric.
2. The lower 24 bits are the locally unique FCID that the FCF (FC switch) assigns to the VN\_Port.

The combination of these values guarantees that each FPMA is unique within a fabric.

### FC-MAP

The FCoE mapped address prefix (FC-MAP) value is a MAC address prefix used by the FCF that is unique within a given fabric. The FCF uses the FC-MAP for FCoE traffic within that fabric. The FCF rejects FCoE traffic that uses an FC-MAP value that does not match the FCF's FC-MAP value. In most cases, the FCF uses the default FC-MAP value (0EFC00), but a pool of 256 values is available (0EFC00 through 0EFCFF).

The gateway learns FC switches in the fabric that match the gateway fabric's FC-MAP value. To learn and communicate with an FC switch, the FC-MAP value for a fabric (or for the fabric's FCoE VLAN) on the gateway must match the FC switch's FC-MAP value. If the FC-MAP values do not match, no connection is established.

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

### FCoE Trusted Fabric

By default, all interfaces are untrusted interfaces. You can globally configure all of the ports in a specified gateway FC fabric to be FCoE trusted. This reduces system overhead by eliminating the need for filters. The total number of FCoE sessions (ENode to FCF sessions) the system can support is 2500 sessions. Sessions are defined as the combined number of VN\_Port to VF\_Port sessions and VN\_Port to VN\_Port sessions. (Although VN2VF and VN2VN sessions run in different FCoE VLANs, the session limit is a system limit, not a per-VLAN limit.)

**NOTE:** A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

**NOTE:** Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN\_Ports log in again, the switch can build the appropriate FIP snooping filters.

### Maximum Number of FCoE Sessions Per ENode

You can configure the maximum number of FCoE session logins from each ENode that are permitted on the gateway FC fabric. The number of sessions is the ENode FLOGI session plus the VN\_Port FDISC sessions on that ENode. Regardless of whether the fabric is trusted or untrusted, the maximum number of FCoE sessions per ENode is

2500 sessions. The total number of sessions cannot exceed the gateway fabric's maximum limit of 2500 sessions.

The maximum number of FCoE sessions per ENode is a global configuration for all members of the gateway FC fabric and cannot be configured on a per-interface basis.

**NOTE:** Session does not refer to end-to-end server-to-storage sessions. There is no limit to the number of end-to-end server-to-storage sessions.

---

### Priority

When the FIP discovery process offers an ENode the choice of more than one FCF-MAC on a given FCF to use for login, the ENode chooses the FCF-MAC to which to send a login request based on the FCF-MAC priority. The lower the priority number, the higher the FCF-MAC's priority. The ENode selects the highest-priority (lowest priority number) FCF-MAC for the login request.

An ENode can receive multiple FCF-MAC advertisements from the same FCF in two ways:

- During the FIP discovery process, an FCF can receive an ENode MAC's multicast discovery solicitation on multiple FCF-MACs. Each FCF-MAC replies with a unicast discovery advertisement to the ENode. The ENode determines that the advertisements are from the same FCF, because the value in the Name\_Identifier descriptor is the same in each advertisement.
- During the FIP discovery process, an ENode MAC can receive unsolicited multicast discovery advertisements from multiple FCF-MACs on the same FCF. The ENode determines that the advertisements are from the same FCF, because the value in the Name\_Identifier descriptor is the same in each advertisement.

On the gateway, you can configure the priority value for an entire fabric or for an individual interface. The default value for both the fabric and the individual interfaces is 128 (the highest priority is 0; the lowest priority is 255).

## Understanding Fibre Channel Virtual Links

A virtual link emulates a secure point-to-point connection between the virtual node port (VN\_Port) of a Fibre Channel over Ethernet (FCoE) node (ENode) and the virtual fabric port (VF\_Port) of an FCoE forwarder (FCF). The combination of the FCF media access control (MAC) address and the VN\_Port MAC address uniquely identifies each virtual

link. Uniquely identifying each virtual link enables the logical separation of traffic that belongs to each virtual link. A single physical link between an ENode and an FCF can carry multiple virtual links and maintain secure, separate transport of traffic on the different virtual links.

Virtual links are necessary because Fibre Channel protocol does not recognize multipoint-to-point connections. Even when multiple connections are aggregated on one physical port, FCoE Initialization Protocol (FIP) presents each virtual link as an individual point-to-point link between an ENode VN\_Port and an FCF VF\_Port.

## Understanding Interfaces on an FCoE-FC Gateway

When a QFX3500 switch functions as an FCoE-FC gateway to connect FCoE devices on an Ethernet network to a Fibre Channel (FC) switch in a storage area network (SAN), it handles FCoE traffic from hosts and native FC traffic from the FC switch. To support this architecture, each local FC fabric configured on the gateway (in the **fc-fabrics** configuration hierarchy) must have:

- An Ethernet-network-facing F\_Port interface for the FCoE VLAN to connect to FCoE device VN\_Ports in the form of an FCoE VLAN interface. Multiple VF\_Ports are initiated on the F\_Port interface, one VF\_Port for each ENode that logs in to the FC network.
- One or two blocks of six proxy N\_Port (NP\_Port) interfaces to connect to FC switch fabric ports (F\_Ports).

Each FC fabric is local to the gateway on which you configure it. This means that both the FC switch and the FCoE devices must be connected to the same gateway (QFX3500 switch or QFabric system Node device), and that all of the interfaces configured for the local fabric also must be on that gateway. FC fabric traffic does not flow between different Node devices in a QFabric system.

## Native FC Interfaces to the FC Switch

---

You must configure either 6 or 12 of the physical interfaces on the gateway as native FC NP\_Port interfaces to connect to FC switch F\_Port interfaces. By default, all of the gateway interfaces are Ethernet interfaces, so you must explicitly configure the interfaces that you want to use as FC interfaces.

You can configure the FC-capable ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You cannot configure ports xe-0/0/6 through xe-0/0/41 and ports xe-0/1/1 through xe-0/1/15 as native FC ports; they can only be Ethernet ports. Native FC ports do not handle Ethernet traffic (including FCoE traffic); they handle only native FC traffic and must connect to native FC ports.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.

Each native FC interface can belong to only one local FC fabric configured on the gateway. You can configure up to 12 FC fabrics on a gateway, but each FC fabric must use different native FC interfaces to connect to an FCF. (Although the native FC ports are configured in blocks, each individual port can belong to a different FC fabric.) Native FC interfaces can be configured as loopback interfaces.

- [Port Mode on page 5312](#)
- [NPIV on page 5313](#)
- [Port Speed on page 5313](#)

### Port Mode

The gateway presents a proxy N\_Port (NP\_Port) interface to the FC switch. An NP\_Port connects to a single FC switch F\_Port using a point-to-point link (in other architectures an N\_Port can also connect in a point-to-point link to another N\_Port, but that is not a valid configuration on the gateway).

You must explicitly configure each native FC interface connected to an FC switch as an NP\_Port. The gateway NP\_Ports act as a proxy for the FCoE device virtual N\_Ports (VN\_Ports) when the VN\_Ports attempt to connect to the FC switch.

When the FC switch is a trusted switch, configure the fabric as **fcoe-trusted** to reduce overhead caused by the VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping filters that are automatically installed on untrusted ports.

### ***NPIV***

FC requires a unique point-to-point link between the FC switch and each host N\_Port. The gateway creates an independent virtual link for each FCoE device session by mapping each FCoE device to a virtualized N\_Port through the gateway's proxy function. This process is called N\_Port ID virtualization (NPIV).

NPIV makes each virtual link look like a dedicated point-to-point link to the FC switch. In this way, multiple FCoE devices, multiple applications, and multiple virtual machines on an FCoE device can connect to an FC switch using one physical port instead of using a physical port for each host connection. The virtual link creates a secure boundary between traffic from different sources that are on a single physical port.

FCoE-FC gateway mode implements NPIV as follows:

1. An NP\_Port on the gateway comes up and logs in to the attached F\_Port on the FC switch. The FC switch sees the gateway port as a physical FC device N\_Port and assigns it a unique FCID. This establishes the physical point-to-point link between the gateway and the FC switch.
2. The gateway receives a FIP discovery message from an FCoE device that seeks to log in to the FC network. To the FCoE device, the gateway presents a virtual F\_Port (VF\_Port) interface and appears to be an FCF.
3. The gateway converts the FCoE device's message into an FC fabric discovery (FDISC) message and sends it through the least-loaded physical NP\_Port to the FC switch. The FDISC message requests an FCID for the new virtual link.
4. The FC switch processes the request, accepts it, assigns a unique FCID for the connection, and sends the response.
5. The gateway maps the FC switch response to the host FCoE device's VN\_Port and sends a FIP acceptance advertisement to the FCoE device.
6. The FCoE device accepts the FCID.

If the FC switch rejects the FDISC, the gateway relays the rejection to the FCoE device VN\_Port.

### ***Port Speed***

The gateway supports configuring FC port speeds of 2 Gbps, 4 Gbps, or 8 Gbps. FC ports can also autonegotiate the port speed to 2, 4, or 8 Gbps.

### ***FIP Login Session Limits***

A FIP login session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. (A session here does not refer to an end-to-end server-to-storage session; there is no limit to the number of end-to-end server-to-storage sessions.) You can limit the maximum number of FIP login sessions on each gateway Node device (QFX3500

switch or QFabric system Node device configured in FCoE-FC gateway mode), on each local gateway FC fabric, and on each individual NP\_Port interface in a local FC fabric:

- **Gateway Node devices and Node groups**—The total number of FIP login sessions on the gateway Node or Node group (the sum of the sessions on all of the NP\_Port interfaces in all of the local FC fabrics on the gateway Node or Nodes) cannot exceed the limit. When a gateway reaches the maximum session limit, the gateway sends subsequent multicast discovery advertisements (MDAs) with the availability bit set to 0 (zero) to prevent additional ENode login attempts. If the maximum number of sessions is running on the gateway, ENodes cannot use the gateway to log in new sessions to the FC switch. When the number of sessions falls below the maximum, the gateway sets the availability bit in MDAs to 1 so that ENodes can again log in new sessions. When a session slot becomes available, the system accepts the first session request to fill the slot.
- **FC fabric**—The total number of FIP login sessions on an FC fabric (the sum of the sessions on all of the NP\_Port interfaces that belong to the fabric) cannot exceed the limit. When a fabric reaches the maximum session limit, the gateway sends MDAs associated with that fabric with the availability bit set to 0 to prevent additional ENode login attempts.

**NOTE:** Other FC fabrics on the same gateway can still accept ENode logins as long as the maximum session limit for those fabrics and the maximum session limit for the gateway (the Node device) have not been met.

- **NP\_Port interfaces**—The total number of FIP login sessions cannot exceed the interface's limit. When an interface reaches the maximum session limit, the gateway removes it from the load-balancing list for that FC fabric to prevent the gateway from attempting to assign new sessions to the interface. Other interfaces in the FC fabric can still accept logins until the FC fabric or gateway reaches its maximum session limit. However, the interface that reached the maximum session limit cannot be assigned new sessions until the number of sessions on the interface falls below the limit.

**BEST PRACTICE:** Configure a maximum session limit for each NP\_Port interface that is less than or equal to the number of FIP sessions the directly connected FC switch port is configured to support. This prevents the gateway from attempting to assign new login sessions to an interface when the connected FC switch port reaches its maximum number of sessions.

- [Increasing Session Limits on page 5316](#)
- [Effect of Deactivating and Then Reactivating the Configuration on Session Limits on page 5316](#)

### ***FCoE Trusted and Untrusted Interface Session Limits***

The maximum number of VN2VF\_Port FCoE login sessions that each gateway can support is 2500 sessions, regardless of whether interfaces are trusted or untrusted. (In software releases earlier than Junos OS Release 12.3, the session limit on untrusted interfaces and untrusted fabrics was 376 sessions.)

**NOTE:** If you configure an FCoE LAG on interfaces that are members of an FCoE-FC gateway fabric, the number of supported sessions depends on whether the FC fabric (fc-fabric) is an FCoE trusted fabric or an FCoE untrusted fabric. If the FC fabric is a trusted fabric, then 2,500 sessions are supported.

However, if the FC fabric is an untrusted fabric, you must disable FIP snooping session scaling on the gateway, which decreases the number of supported sessions to 376 sessions. (Disable FIP snooping scaling by including the `no-fip-snooping-scaling` option in the `[edit fc-options]` hierarchy.)

### ***Configuring Consistent Session Limits***

The system does not perform commit checks to enforce consistent session limit configuration. For example, the system does not prevent you from configuring a higher limit for ENode sessions than the total session limit for the gateway Node device, or from configuring a higher limit on an interface than on the fabric to which the interface belongs.

To prevent unexpected FIP login rejections, you should configure consistent Node device, fabric, and interface session limits. For example:

- The session limit of an interface should not exceed the session limit of the fabric to which it belongs.
- For interfaces that belong to the same fabric, the sum of the interface session limits should not exceed the fabric session limit.
- The fabric session limit should not exceed the session limit of the gateway Node device.
- For fabrics that belong to the same gateway Node device, the sum of the fabric session limits should not exceed the Node device session limit.

Session limit configuration considerations include:

- The fabric session limit restricts how many sessions can run on the NP\_Port interfaces that belong to that fabric. If the combined session limits of the interfaces exceed the fabric session limit, the total number of sessions on the interfaces is the fabric limit.

For example, if a fabric has three NP\_Port interfaces, and each NP\_Port interface has a limit of 500 sessions (total of 1500 sessions for the three interfaces), but the fabric has a limit of 1000 sessions, the combined number of sessions on the three interfaces is limited to 1000 sessions.

- The gateway Node device session limit restricts how many sessions can run on the fabrics that belong to that gateway. If the combined session limits of the fabrics exceed

the gateway Node device session limit, the total number of sessions on the fabrics is the gateway Node device limit.

For example, if a gateway has two fabrics, and each fabric has a limit of 1000 sessions (total of 2000 sessions for the two fabrics), but the gateway has a limit of 1500 sessions, the combined number of sessions on the two fabrics is limited to 1500 sessions.

Hierarchically, the gateway Node device session limit is the maximum limit for all sessions on the gateway, regardless of fabric and interface session limits. In the same way, the fabric session limit supersedes the interface session limit.

When session limits are exceeded, no new logins are accepted until a session slot becomes free.

### ***Decreasing Session Limits***

If you decrease the session limit, the currently logged in sessions are terminated as follows:

- Gateway Node devices and Node groups—Decreasing the session limit terminates all of the sessions on the Node device (all sessions on all interfaces on all fabrics). If the gateway Node device is part of a Node group, all sessions on all members of the Node group are terminated.
- Fabric—Decreasing the session limit terminates all of the sessions on all of the interfaces that belong to the fabric.
- NP\_Port interfaces—Decreasing the session limit terminates all of the sessions on the interface and also terminates all of the sessions on any other interfaces that belong to the same fabric.

After you decrease a session limit, the sessions are terminated even if the new session limit is greater than the number of currently active sessions. For example:

- An interface has 300 active sessions.
- The current session limit is 1000 sessions.
- You decrease the session limit to 500 sessions and commit the new configuration.
- All 300 sessions are logged out, even though the new session limit is greater than the number of sessions running.

After the session limit change takes effect, the ENodes log in again and establish new sessions, up to the new session limits.

### ***Increasing Session Limits***

Increasing the session limits does not disrupt logged in sessions.

### ***Effect of Deactivating and Then Reactivating the Configuration on Session Limits***

If you decrease session limits, all ENodes are logged out. Deactivating and then reactivating the configuration can have the same effect as decreasing the session limit, which results in the ENodes being logged out.

The ENode logouts occur because when you deactivate the configuration, the system reverts to the default session limit of 2500 sessions (the maximum number of sessions). When you reactivate the configuration, the system uses the configured session limit. Unless the configured session limit is equal to the maximum session limit, reactivating the configuration decreases the session limit, which causes the ENodes to be logged out.

For example, if you:

1. Configure and commit a limit of 400 sessions.
2. Allow ENodes to log in and start sessions.
3. Deactivate the configuration.
4. Reactivate the configuration.
5. The ENode sessions are logged out because deactivating the session increased the session limit from 400 to 2500.

Because an increase in the session limit does not affect existing sessions, the running ENode sessions are not affected. However, reactivating the configuration decreased the session limit from 2500 back to 400. The session limit decrease causes the ENode sessions to be logged out.

### Trusted and Untrusted Interfaces

By default, gateway fabric interfaces are untrusted interfaces. If you do not configure a gateway fabric as an FCoE trusted fabric to set all of the gateway fabric interfaces as trusted interfaces, the gateway installs VN2VF\_Port FIP snooping filters on the fabric ports.

If you configure a gateway fabric as an FCoE trusted fabric, the gateway does not install VN2VF\_Port FIP snooping filters on the fabric interfaces. This is usually done when the gateway is connected to an FCoE transit switch that has VN2VF\_Port FIP snooping enabled.

Regardless of whether an interface is trusted or untrusted, the maximum session limit is 2500 sessions, unless the interface is a member of an FCoE LAG interface.

**NOTE:** If you configure an FCoE LAG on interfaces that are members of an FCoE-FC gateway fabric, the number of supported sessions depends on whether the FC fabric (fc-fabric) is an FCoE trusted fabric or an FCoE untrusted fabric. If the FC fabric is a trusted fabric, then 2,500 sessions are supported.

However, if the FC fabric is an untrusted fabric, you must disable FIP snooping session scaling on the gateway, which decreases the number of supported sessions to 376 sessions. (Disable FIP snooping scaling by including the `no-fip-snooping-scaling` option in the `[edit fc-options]` hierarchy.)

**NOTE:** The session limit for a Node group is the same as the session limit for an individual Node device, 2500 sessions. Even if more than one Node device in a Node group is acting as an FCoE-FC gateway, the total maximum number of sessions on all Node devices in the Node group is 2500 sessions.

The default maximum login session value for Node devices (on QFabric systems, the maximum applies to each Node device), FC fabrics, and interfaces in fabrics is 2500 sessions.

### Buffer-to-Buffer Credit Recovery

---

Buffer-to-buffer credits represent the number of receive buffers an interface can use to store FC frames. Buffer-to-buffer credit determines buffer-to-buffer flow control. When an interface transmits a frame, it decrements its buffer-to-buffer credit count by one. When the destination interface forwards the frame and frees a buffer, it sends a receiver ready (R\_RDY) primitive to the transmitting interface. Each R\_RDY primitive the transmitting interface receives increments its buffer-to-buffer credit count by one.

Both interfaces on an FC link track buffer-to-buffer credits. As long as buffer-to-buffer credits are available, the transmitter continues to send frames. If the number of buffer-to-buffer credits reaches zero (0), transmission stops until buffer-to-buffer credits are available, as indicated by the reception of an R\_RDY primitive. Buffer-to-buffer credits can compensate for long cable distances to limit throughput and prevent buffer overflow.

However, if frame corruption or errors transmitting R\_RDY primitives occur, the buffer-to-buffer credit counters on the sending and receiving interfaces do not have the same values. This causes the permanent loss of buffer-to-buffer credits. When credits are lost, the buffer credit count can decrement to zero and indicate that there is no available buffer space even if buffer space is actually available. This can result in unnecessary link idle time.

To recover lost buffer-to-buffer credits, you can configure a buffer-to-buffer credit state change number (BB\_SC\_N). BB\_SC\_N must be configured on both ends of the connection. If only one end of the connection is configured for BB\_SC\_N, the feature is disabled. The two directly connected FC interfaces communicate the BB\_SC\_N value during fabric login (FLOGI).

When you enable BB\_SC\_N on the interfaces on both ends of an FC link, the interfaces exchange buffer-to-buffer state change send (BB\_SCs) and buffer-to-buffer state change receive (BB\_SCr) primitives to track the number of frames sent and the number of R\_RDY primitives received. The state change number determines the number of frames and R\_RDY primitives the interfaces exchange between consecutive BB\_SCn primitives and between consecutive BB\_SCr primitives. The state change primitives inform each interface of the other interface's frame count and R\_RDY count states.

The state counters should match so that each interface knows and agrees with the other interface's state. If the interface at either end of the link detects a discrepancy, it knows that a frame or an R\_RDY primitive was corrupted or dropped.

For example, if a receiving interface has sent two R\_RDY primitives but the BB\_SCr that the interface receives from the sending interface only counts one R\_RDY primitive received, it reveals that one R\_RDY primitive was not delivered successfully and that one buffer-to-buffer credit was lost. When one of the interfaces on the link detects a discrepancy, the interfaces can take corrective action and recover the lost buffer-to-buffer credits.

Enabling the buffer-to-buffer credit recovery feature does not impact buffer resources and has an insignificant impact on processing resources.

If buffer-to-buffer credit recovery is not used, then when there is no buffer credit on a port, a timeout and recovery mechanism prevents buffer overflow.

### FCoE VLAN Interface to FCoE Devices

Each FC fabric configured on the gateway includes at least one FCoE VLAN interface to connect the FCoE devices on the FCoE VLAN to the FC switch. (Including the FCoE VLAN interface and the native FC interfaces in the FC fabric configuration connects them.) FCoE VLANs can include any Ethernet interface on the switch that is in tagged-access or trunk mode. The best practice is to configure Ethernet interfaces that belong to FCoE VLANs in **tagged-access** port mode.

**NOTE:** The Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets.

FCoE VLANs should carry only FCoE traffic. You should not mix FCoE traffic and standard Ethernet traffic on the same VLAN.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

FCoE traffic cannot use a standard LAG because traffic might be hashed to different physical LAG links on different transmissions. This breaks the (virtual) point-to-point link that Fibre Channel traffic requires. If you configure a standard LAG interface for FCoE traffic, FCoE traffic might be rejected by the FC SAN.

Beginning with Junos OS Release 13.2X52, QFabric systems support a special LAG called an FCoE LAG, which enables you to transport FCoE traffic and regular Ethernet traffic (traffic that is not FCoE traffic) across the same link aggregation bundle. An FCoE LAG ensures that FCoE traffic uses the same physical link in the LAG for requests and replies in order to preserve the virtual point-to-point link between the FCoE device converged network adapter (CNA) and the FC SAN switch across the QFabric system Node device. An FCoE LAG does not provide load balancing or link redundancy for FCoE traffic. However, regular Ethernet traffic uses the standard hashing algorithm and receives the usual LAG benefits of load balancing and link redundancy in an FCoE LAG.

On FCoE-FC gateway untrusted FC fabrics, you must disable FIP snooping session scaling on the gateway, which decreases the number of supported sessions from 2,500 to 376 sessions. (Disable FIP snooping scaling by including the `no-fip-snooping-scaling` option in the `[edit fc-options]` hierarchy.) On FCoE trusted FC fabrics, the session limit is 2,500 sessions.

Each FCoE VLAN interface can belong to only one FC fabric configured on the gateway. A gateway FC fabric can have more than one FCoE VLAN, but each FCoE VLAN in the FC fabric must belong only to that FC fabric. You can configure more than one FC fabric on a gateway; each FC fabric must use different FCoE VLAN interfaces to connect to FCoE devices.

**NOTE:** Storm control must be disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

- [Port Mode on page 5320](#)
- [Disabling Storm Control on FCoE Interfaces on page 5322](#)
- [NPIV Support on page 5323](#)
- [VN2VF\\_Port FIP Snooping on page 5323](#)

### **Port Mode**

You must explicitly configure the FCoE VLAN interface in F\_Port mode. All members of the FCoE VLAN use the FCoE VLAN interface as the connection to the gateway NP\_Port interfaces and ultimately to the FC switch.

All of the 10-Gigabit Ethernet interfaces that are members of an FCoE VLAN should be configured as **tagged-access** port mode interfaces. However, the system also supports configuring these interfaces in **trunk** port mode.

**BEST PRACTICE:** Use **tagged-access** port mode for Ethernet interfaces that are connected to converged network adapters (CNAs) in FCoE access devices.

Use **trunk** port mode when an Ethernet interface is an interswitch link (ISL)—that is, when the port is connected to another switch. For example, if a port is connected to a transit switch that is performing VN2VF\_Port FIP snooping, configure the port in **trunk** mode and as an FCoE trusted port.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and earlier releases. In Release 11.3 and earlier, only **trunk** port mode was used for Ethernet interfaces that belong to an FCoE VLAN. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** mode to **tagged-access** mode as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

There are several advantages of configuring Ethernet ports connected to FCoE devices in **tagged-access** mode instead of in **trunk** mode:

- It is standard practice to configure ISL ports as **trunk** ports.
- It is standard practice not to configure ports that connect to servers as **trunk** ports.
- When an interface goes down, if that interface is in **trunk** mode, then the FCoE sessions on that interface are terminated only after the gateway stops receiving FIP keepalive messages from the ENode and exceeds 2.5 times the FIP keepalive timeout advertisement value. If the interface is in **tagged-access** mode and the interface goes down, the gateway sends a FIP message to terminate the sessions on the interface.
- Similarly, if an ENode session moves from one interface to another interface, if the original interface is in **trunk** mode, the session is not removed from the interface until the gateway stops receiving FIP keepalive messages and exceeds 2.5 times the FIP keepalive advertisement timeout value. But if the interface is in **tagged-access** mode, the gateway detects that the session is no longer on the interface, does not refresh the FIP keepalive timer, and thus ages out the session.

**NOTE:** FIP is enabled on the FCoE VLAN, which is a Layer 3 interface. As with other Layer 3 interfaces under Junos OS, when the last member (10-Gigabit Ethernet interface) of the FCoE VLAN is deleted, the FCoE VLAN interface is internally marked as “down.” When the Layer 3 FCoE VLAN interface is marked as “down”, FIP stops running on it. When the last member interface is deleted from an FCoE VLAN and FIP stops running, the result could be an immediate timeout for the VN\_Ports that were connected on that interface, regardless of whether the port mode is tagged-access or trunk.

### ***Disabling Storm Control on FCoE Interfaces***

Storm control is not supported on the FCoE interfaces of an FCoE-FC gateway VLAN. Enabling storm control on an FCoE-FC gateway VLAN interface may cause FCoE packet loss. Storm control is disabled by default on all interfaces. However, if you enabled storm control globally on all switch interfaces or on any interfaces that are part of the FCoE VLAN interface, you must disable storm control on the Ethernet interfaces of the FCoE VLAN.

If storm control is enabled on only a few interfaces of the FCoE VLAN, you can disable storm control on individual interfaces by including the **delete ethernet-switching-options storm-control interface *interface-name*** statement in the configuration, where *interface-name* is the name of the interface on which you want to disable storm control.

If storm control is enabled globally on the switch when the switch is acting as an FCoE-FC gateway, it is often easiest to disable storm control on all interfaces, then enable storm control only on Ethernet interfaces that are not part of the FCoE VLAN interface.

If storm control is enabled globally, you can disable storm control in either of two ways:

- Disable storm control on all interfaces, then enable storm control on the interfaces you want to use storm control. (From the default configuration, you cannot disable storm control on individual interfaces because the default configuration enables storm control on **all** interfaces, not on individual interfaces.)

For example, if you want interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22 to use storm control, disable storm control on all interfaces, then enable storm control on those three interfaces:

1. Disable storm control on all interfaces:

```
user@switch# delete ethernet-switching-options storm-control interface all
```

2. Enable storm control on interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22:

```
user@switch# set ethernet-switching-options storm-control interface xe-0/0/20
user@switch# set ethernet-switching-options storm-control interface xe-0/0/21
user@switch# set ethernet-switching-options storm-control interface xe-0/0/22
```

- Disable storm control for all unknown unicast traffic on all interfaces by including the following statement in your configuration:

```
user@switch# set ethernet-switching-options storm-control interface all no-unknown-unicast
```

***NPIV Support***

The gateway supports FCoE device NPIV. For example, a single physical FCoE device can have multiple virtual machines running on it. Each virtual machine can instantiate a separate virtual connection to the gateway, which results in its own virtual link to the FC switch. In this way, an FCoE device can have multiple separate connections to the FC SAN on a single physical port.

This is similar to the NPIV function the gateway performs with the FC switch to support multiple virtual FCoE device connections on one physical NP\_Port.

The gateway presents multiple VF\_Port interfaces on each FCoE VLAN interface to support the requirement for unique, secure virtual links.

***VN2VF\_Port FIP Snooping***

The FCoE-facing ports that belong to an FCoE VLAN on a gateway are enabled for VN2VF\_Port FIP snooping automatically. You can disable VN2VF\_Port FIP snooping on any individual interface by configuring it as a trusted interface.

***Assigning Interfaces to a Fibre Channel Fabric***

You assign at least one FCoE VLAN interface and at least one native FC interface to each FC fabric you configure on the gateway. All of the interfaces that belong to an FC fabric must reside on the same gateway device. Interfaces on different gateways cannot belong to the same FC fabric, because an FC fabric is local to a single gateway device.

***Deleting a Fibre Channel Interface***

To delete an FC interface or an FCoE VLAN interface, you must delete the interface from the fabric first and then delete the interface from the switch.

## Understanding Load Balancing in an FCoE-FC Gateway Proxy Fabric

You can balance or rebalance the load on the ports in an FCoE-FC gateway proxy fabric in order to avoid overutilizing or underutilizing the links. Load balancing is distributing sessions across the available native Fibre Channel (FC) interfaces (NP\_Ports) that belong to a local gateway FC fabric to create a relatively equal load on all the fabric links. Load rebalancing is redistributing the existing sessions across the available NP\_Port links on a local gateway FC fabric.

**NOTE:** A session is a fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.

The fabric-facing NP\_Port links of an FCoE-FC gateway use different load-balancing methods than the FCoE-network-facing Ethernet links.

Balancing the load on FCoE-FC gateway NP\_Port links consists of two steps:

1. Choosing the algorithm used to balance and rebalance the link load
2. Choosing whether to rebalance link loads automatically or only when you explicitly request a rebalance (load-rebalancing method)

You can configure a different load-balancing algorithm and use a different rebalancing method for each local FC fabric on the FCoE-FC gateway. The load-balancing algorithm and automated rebalancing, if configured, apply to all NP\_Port interfaces in the local FC fabric.

This topic describes:

- [Load-Balancing Algorithms on page 5325](#)
- [Load-Rebalancing Methods on page 5329](#)

- [Load-Balancing Scenarios on page 5334](#)

## Load-Balancing Algorithms

You can choose one of three load-balancing algorithms to configure the way the switch balances the link loads. The switch uses the configured algorithm to balance the link loads when NP\_Ports are initialized and whenever link loads are rebalanced. Regardless of whether you configure automated load rebalancing or use on-demand load rebalancing, the switch uses the configured algorithm to balance the link load:

- **Simple load balancing**—The switch assigns each ENode FLOGI session and VN\_Port FDISC session to the least-loaded link. The switch can place FDISC sessions on a different link than the parent FLOGI session (an ENode FLOGI session and its subsequent FDISC sessions can be placed on different links). Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- **ENode-based load balancing**—When an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP\_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- **FLOGI-based load balancing**—Similar to ENode-based load balancing; when an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link.

One difference between ENode-based load balancing and FLOGI-based load balancing is that the switch calculates the link load based only on the number of FLOGIs on each NP\_Port link. The algorithm does not count FDISCs. Another difference is that instead of disrupting all sessions on a link load rebalance, the system disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).

**NOTE:** Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out and then log in again.

If you do not explicitly configure the load-balancing algorithm, the switch uses simple load balancing by default on the all NP\_Port interfaces that belong to a given local FC fabric.

The following sections describe how each algorithm works, its advantages and disadvantages, and what happens when NP\_Port links come up for the first time, when an NP\_Port link is added to existing links, and when you rebalance the link load:

- [Simple Load Balancing on page 5326](#)
- [ENode-Based Load Balancing on page 5327](#)
- [FLOGI-Based Load Balancing on page 5327](#)
- [Load-Balancing Algorithm Comparison on page 5328](#)

### **Simple Load Balancing**

Simple load balancing provides the most equal load balancing across links because each VN\_Port FDISC session can be assigned to the least-loaded link, regardless of whether the parent ENode FLOGI session is on that link. (The parent ENode is the ENode that originates the logins to the fabric. After the parent ENode logs in, the VN\_Ports on that ENode can log in to the fabric using FDISC.)

The FCoE-FC gateway performs simple load balancing by default on the NP\_Ports that connect the gateway to the FC SAN. When an ENode sends a FLOGI request to the gateway, the gateway checks the NP\_Ports that connect it to the FC SAN and assigns the new session to the least-loaded link.

Every time an ENode sends a FLOGI or an FDISC request, the gateway assigns the new session to the least-loaded NP\_Port link. After the gateway assigns an ENode FLOGI session to an NP\_Port, subsequent FDISC requests by the same ENode can result in sessions being assigned to different NP\_Ports, because the gateway always assigns the new session to the least-loaded interface.

**NOTE:** Because VN\_Port sessions might be placed on a different link than their parent ENode, if the link that contains the ENode goes down, only the ENode session and any of its VN\_Port sessions that are on that link go down. VN\_Port sessions on other links remain active as long as the link is up and the VN\_Port is not logged out.

---

When a new link comes up, the switch logs out enough sessions so that when the sessions log in again, they are placed on the new link and the link loads are balanced. The switch uses an algorithm to log out sessions in the least disruptive manner by first logging out FDISCs whose FLOGI is not on the same link, then the least-loaded FLOGIs (loaded in terms of related FDISC logins).

Similarly, when you rebalance an existing link load, the switch logs out only enough sessions so that when the sessions log in again, they balance the load on the existing links. In this case (rebalance without a new link up), the switch takes into account the dependencies between FLOGIs and FDISCs when selecting sessions to log out.

The simple load-balancing algorithm uses the sum of the FLOGI and FDISC sessions to determine the session load on each link for both initial load balancing and load rebalancing.

### ***ENode-Based Load Balancing***

ENode-based load balancing can result in a less balanced load across the NP\_Port links because the VN\_Port FDISC sessions are assigned to the same link as the parent ENode FLOGI session, regardless of how many FDISC sessions are associated with the ENode. However, ENode-based load balancing has the advantage of keeping all of the sessions associated with a particular ENode on one link, which provides better control and predictability.

When you use the ENode-based load-balancing algorithm, the gateway assigns the ENode to an NP\_Port link when the ENode sends its FLOGI message to the gateway. The gateway places the ENode session on the least-loaded link at that time. The VN\_Port FDISC sessions associated with an ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. Essentially, the ENode sessions are load-balanced, but the VN\_Port sessions are not.

ENode-based load balancing ensures that each ENode and its associated VN\_Port sessions are assigned to the same NP\_Port link. ENode-based load balancing provides more control and predictability and ensures that if the link carrying an ENode goes down, all of the ENodes associated VN\_Port sessions also go down.

The disadvantage of ENode-based load balancing is that if one ENode has a large number of sessions and the other ENodes do not, the link that carries the ENode with the large number of sessions might have a much larger load than the other NP\_Port links in the gateway proxy fabric.

For example, if a gateway fabric has two NP\_Ports connected to the FC fabric, and two ENodes log in to the fabric, one ENode session is placed on each link. If two VN\_Port sessions are initiated on one of the ENodes, those sessions are placed on the same link as the parent ENode. If 1000 VN\_Port sessions are initiated on the other ENode, all of the 1000 VN\_Port sessions are placed on the same link as that ENode. In this case, one link has 3 sessions (1 ENode FLOGI session and 2 VN\_Port FDISC sessions) and the other link has 1001 sessions (1 ENode FLOGI session and 1000 VN\_Port FDISC sessions).

When a new link comes up or when you rebalance an existing load, the switch logs out all sessions (FLOGIs and FDISCs) in the fabric. As the sessions log in again, the switch assigns them to NP\_Ports in a balanced manner, with all FDISCs assigned to the same link as the parent FLOGI. A new link coming up or a rebalance disrupts all of the existing sessions.

The ENode-based load-balancing algorithm uses the sum of the FLOGI and FDISC sessions to determine the session load on each link for both initial load balancing and load rebalancing.

### ***FLOGI-Based Load Balancing***

FLOGI-based load balancing is similar to ENode-based load balancing in most ways:

- It can result in a less balanced load across the NP\_Port links because the VN\_Port FDISC sessions are assigned to the same link as the parent ENode FLOGI session, regardless of how many FDISC sessions are associated with the ENode.
- When an ENode logs in with a FLOGI, the gateway places the session on the least-loaded link, and the FDISC logins associated with the FLOGI are placed on the same link, regardless of link load.
- Provides control and predictability because each ENode and its associated VN\_Port (FDISC) sessions are assigned to the same link, so if the link an ENode is on goes down, all of its associated sessions also go down.
- If one ENode has a large number of sessions and the other ENodes do not, the link that carries the ENode with the large number of sessions might have a much larger load than the other NP\_Port links in the gateway proxy fabric.

FLOGI-based load balancing differs from ENode-based load balancing in two important ways:

1. The switch uses the sum of the FLOGI sessions on a link to determine the link load. The switch does not use FDISC sessions when calculating the number of sessions on a link. (ENode-based load balancing uses the sum of the FLOGI and FDISC sessions to calculate the number of sessions on a link.)
2. When a new link comes up or when you rebalance an existing load, the switch logs out enough FLOGI (and FDISC) sessions so that when the FLOGI sessions log in again, the load is balanced. The switch balances the load based only on the number of FLOGI sessions, not the sum of FLOGI and FDISC sessions. However, the FDISC sessions associated with a FLOGI follow the FLOGI to the new link if the FLOGI session is part of the rebalancing.

The FLOGI-based load-balancing algorithm uses only the FLOGI sessions to determine the session load on each link for both initial load balancing and load rebalancing.

#### ***Load-Balancing Algorithm Comparison***

[Table 375 on page 5328](#) compares the three load-balancing algorithms and summarizes their differences, advantages, and disadvantages.

**Table 375: Load-Balancing Algorithm Comparison**

Load-Balancing Algorithm	Session Assignment	Session Disruption on Rebalance	Session Count Method	Advantages	Disadvantages
Simple (default algorithm)	FDISC sessions can be placed on different links than the parent FLOGI session	Minimum number of selected sessions logged out (FDISC sessions can be logged out independent of the parent FLOGI session)	Sum of FLOGI and FDISC sessions	<ul style="list-style-type: none"> <li>• Most equal session distribution across links</li> <li>• Minimum number of sessions logged out when rebalancing</li> <li>• Least disruptive algorithm</li> </ul>	<ul style="list-style-type: none"> <li>• Less session control and predictability</li> </ul>

Table 375: Load-Balancing Algorithm Comparison (*continued*)

Load-Balancing Algorithm	Session Assignment	Session Disruption on Rebalance	Session Count Method	Advantages	Disadvantages
ENode-based	FDISC sessions are always placed on the same link as the parent FLOGI session	All sessions are logged out	Sum of FLOGI and FDISC sessions	<ul style="list-style-type: none"> <li>Better session control and predictability (on link down, all sessions associated with an ENode go down)</li> </ul>	<ul style="list-style-type: none"> <li>Most disruptive algorithm; all sessions logged out on rebalance</li> <li>Might result in less balanced link load because FDISCs are placed on the same link as parent FLOGI</li> </ul>
FLOGI-based	FDISC sessions are always placed on the same link as the parent FLOGI session	Minimum number of selected sessions logged out (but FDISC sessions logged out when parent FLOGI session is logged out)	FLOGI sessions only (FDISC sessions not included in the session count)	<ul style="list-style-type: none"> <li>Better session control and predictability (on link down, all sessions associated with an ENode go down)</li> <li>Minimum number of sessions logged out when rebalancing</li> </ul>	<ul style="list-style-type: none"> <li>Might result in less balanced link load because FDISCs are placed on the same link as parent FLOGI</li> </ul>

### Load-Rebalancing Methods

The load-rebalancing method determines the way the system redistributes sessions to balance the load on the NP\_Ports that belong to a local FC fabric on an FCoE-FC gateway.

You can rebalance the existing load on existing NP\_Port links using either of two methods:

- Automated load rebalancing—When a load rebalancing trigger occurs, the switch automatically rebalances the link loads by redistributing the sessions across the active NP\_Port links. There are three possible load rebalancing triggers:

- When you enable automated load rebalancing, the switch checks the load balance on the existing NP\_Port links. If the links are already balanced, the switch does not rebalance the link load. If the links are not balanced, the switch rebalances the link loads using the configured load-balancing algorithm.

Enabling automated load rebalancing causes sessions to be logged out in accordance with the configured load-balancing algorithm if the link load is unbalanced. If the link load is already balanced when you enable automated load rebalancing, the links are not rebalanced. (Disabling automated load rebalancing is not disruptive because the link load is already balanced.)

- When a new NP\_Port link comes up on a local FCoE-FC gateway fabric, the switch rebalances the link load using the configured load-balancing algorithm if automated load balancing is enabled.
- When the port speed is changed (unless the port speed change does not change the actual port speed, for example, changing the port speed from auto to 8 Gbps).

Use automated load rebalancing if you want link loads to be rebalanced automatically when a load-balancing trigger occurs, instead of at times of your choosing. Keep in mind that load rebalancing is a disruptive event (sessions are logged out).

- On-demand load rebalancing—You choose when to rebalance the NP\_Port links by explicitly requesting a load rebalance using an operational command. The system rebalances the link load only when you issue the rebalancing command.

Use on-demand load rebalancing if you only want to rebalance the link load once or if you want to rebalance the link loads at controlled times instead of automatically.

You can also request a load rebalancing *dry run*. A dry run simulates rebalancing and lists the sessions that might be affected if you choose to perform an actual load-rebalancing operation. The link loads are not rebalanced when you request a dry run.

---

### NP\_Port Interface FIP Session Limit Effect on Load Balancing

The maximum number of FIP login sessions configured for each NP\_Port interface affects load balancing. When an interface reaches its maximum number of FIP login sessions, that interface is removed from the list of interfaces used for load balancing. The other interfaces in the gateway fabric continue to accept ENode login sessions until they reach their configured maximum session limit. Only interfaces that have not reached their maximum session limit are included in the load-balancing calculations.

**NOTE:** If all NP\_Port interfaces in a gateway fabric reach their FIP login session limits, the fabric sends subsequent multicast discovery advertisements (MDAs) with the availability bit set to 0 (zero) to prevent additional ENode login attempts. While the maximum number of sessions is running on the gateway fabric, ENodes cannot use that fabric to log in to the FC switch. When the number of sessions falls below the maximum, the gateway sets the availability bit in MDAs to 1 so that ENodes can log in to the fabric again.

---

---

### Load-Balancing Triggers and Timing

Several events trigger load balancing. Some of the events trigger load balancing only when automated load balancing is enabled. Other events trigger load rebalancing whether or not automated rebalancing is enabled.

This section describes the load-balancing triggers, what happens when the trigger action occurs, and how the switch determines if and when to balance the link load:

- [Load-Balancing Triggers on page 5330](#)
- [Load-Balancing Timer on page 5331](#)

#### **Load-Balancing Triggers**

[Table 376 on page 5331](#) describes the four different events can trigger load balancing or load rebalancing. In every case, link load rebalancing uses the configured load-balancing algorithm to determine the placement of sessions on links.

Table 376: Load-Balancing Triggers and Actions

Trigger Event	Action
New link comes up	<p>Triggers a load-rebalancing operation regardless of whether or not automated load rebalancing is enabled. (The new link has no sessions, so the sessions on other links must be redistributed to balance the load.)</p> <p>The link load is not rebalanced if there are no sessions on the existing links or if there are so few sessions on the existing links that they cannot be redistributed.</p>
On-demand load rebalancing request issued from CLI	<p>The switch checks the NP_Port link load. If the load is not balanced across the links, the switch rebalances the link load. If the load is already balanced, nothing happens.</p> <p><b>NOTE:</b> Requesting a dry run displays sessions that might be disrupted if you rebalance the link load, but does not rebalance the link load.</p>
Automated load balancing configured for the first time	<p>The switch checks the NP_Port link load. If the load is not balanced across the links, the switch rebalances the link load. If the load is already balanced, nothing happens.</p>
NP_Port speed change	<p>If automated rebalancing is enabled, changing the port speed brings the port up and down (flaps the port) and causes the switch to rebalance the link loads. If the port speed change does not change the actual port speed (for example, changing the port speed from <i>auto</i> to 8 Gbps), the link loads are not rebalanced.</p> <p>If automated rebalancing is not enabled, port speed changes do not cause link load rebalancing.</p>

**NOTE:** When an NP\_Port link goes down, it does not trigger load rebalancing. The loads on the remaining active links are already balanced, and as the sessions logged out from the down link log in again, they are they assigned to links in a balanced manner determined by the configured load-balancing algorithm.

### Load-Balancing Timer

When you trigger load balancing from the CLI, the load-balancing action occurs immediately after you execute the command. However, when a load-balancing trigger occurs that is not a CLI command, the switch does not balance the link loads immediately. Instead, the switch follows an intelligent timer process:

1. The switch checks the current load balance on the NP\_Port links in the local gateway FC fabric. If the load is already balanced, the switch does nothing, and there is no session disruption.
2. If the check shows that the link load is not balanced, the switch starts a 10-second timer. If no other load-balancing triggers occur during the 10-second interval, the switch rebalances the load.

If another load-balancing trigger occurs during the 10-second interval, the timer resets to 10 seconds. The 10-second timer prevents the switch from performing multiple disruptive load-rebalancing actions in a short period of time.

**NOTE:** The switch processes new sessions that log in after the timer starts in the normal manner. The new sessions are considered in the load-balancing evaluation and operation.

3. At a maximum of 30 seconds after the first load-balancing trigger occurs, the switch checks the link load balance again. If the links are already balanced, the switch cancels the load-rebalancing operation. If the links are not balanced, the switch rebalances the link loads.

**NOTE:** If the trigger event that started the load-rebalancing timer is no longer valid when the timer elapses, the switch cancels the rebalancing operation. For example, if a new NP\_Port link comes up and triggers the timer, then goes down before the timer expires, the original link up event is no longer valid, and the switch cancels the rebalancing operation (unless another valid rebalancing trigger occurs in that time frame).

When a link load rebalancing operation is in progress, the switch defers any load-rebalancing triggers that occur until the load-rebalancing operation is complete. The new rebalancing operation begins after the current rebalancing operation finishes if a check shows that rebalancing is required.

If you explicitly request load rebalancing from the CLI using the **request fibre-channel proxy load-rebalance** operational command, the switch rejects the command and displays an error message stating that rebalancing is already in progress.

### Load Rebalancing Behavior When a Link Goes Down

---

If an NP\_Port link goes down, the ENode and VN\_Port sessions on that link are logged out. The ENodes and VN\_Port sessions log in again and are assigned to NP\_Port links based on the link load and the load-balancing algorithm. If a link goes down, the switch does not rebalance the remaining load on the remaining links to avoid disrupting the existing ENode and VN\_Port sessions. (Also, it is not necessary to rebalance the links in that manner because after a link goes down, the sessions on the remaining links are already balanced. As the logged out sessions log back in, the switch places them on the remaining active links in a balanced manner, according to the configured load-balancing algorithm.)

**NOTE:** When you use the simple load-balancing algorithm, an ENode and its associated VN\_Port sessions might be on different links. In that case, if the NP\_Port with the ENode goes down, only the VN\_Ports on the same link are logged out. VN\_Ports on other links remain up and running.

### Interface Load Calculation Algorithm

A weighted round-robin (WRR) algorithm determines the interface load based on:

- The current number of sessions on the interface

**NOTE:** The configured load-balancing algorithm determines how the switch counts the number of sessions. For simple and ENode-based load balancing, the number of sessions is the sum of the FLOGI and FDISC sessions on each link. For FLOGI-based load balancing, the number of sessions is the sum of the FLOGI sessions on each link.

- The interface weight, which is the speed of the Fibre Channel link (2 Gbps, 4 Gbps, or 8 Gbps)

The interface load algorithm is:

$$(\text{number-of-sessions} * \text{max-weight}) / \text{weight}$$

where *max-weight* is an internal constant.

If the load on the FC interfaces is equal, the session is assigned to the interface with the highest link speed (the greatest weight).

For example, if the three FC interfaces have the characteristics shown in [Table 377 on page 5333](#), the loads of the interfaces are not equal:

**Table 377: FC Interface Session-Based Load-Balancing Characteristics for Unequal Loads**

Interface	Number of Sessions	Weight (Speed)
fc-0/0/0	4	4 Gbps
fc-0/0/1	1	2 Gbps
fc-0/0/2	8	8 Gbps

In this example, interfaces fc-0/0/0 and fc-0/0/2 have a greater load than fc-0/0/1. For simple load balancing, the gateway assigns the next new FLOGI or FDISC to fc-0/0/1 because it is the least-loaded interface. For both ENode-based and FLOGI-based load balancing, the gateway assigns the next new FLOGI to fc-0/0/1 because it is the least-loaded interface. Then all VN\_Port FDISCs from that ENode follow the ENode FLOGI and are also assigned to fc-0/0/1 regardless of the link load.

For another example, if the three FC interfaces have the characteristics shown in [Table 378 on page 5334](#), the loads of the interfaces are equal:

**Table 378: FC Interface Session-Based Load-Balancing Characteristics for Equal Loads**

Interface	Number of Sessions	Weight (Speed)
fc-0/0/0	4	4 Gbps
fc-0/0/1	2	2 Gbps
fc-0/0/2	8	8 Gbps

In this case, all interfaces have the same relative load. For simple load balancing, the gateway assigns the next new FLOGI or FDISC to fc-0/0/2 because although the loads of the three interfaces are equal, fc-0/0/2 has the greatest weight. For both ENode-based and FLOGI-based load balancing, the gateway assigns the next new FLOGI to fc-0/0/2, and all VN\_Port FDISCs from that ENode follow the ENode FLOGI and are also assigned to fc-0/0/2 regardless of the link load.

After the gateway establishes a session between an ENode or a VN\_Port and an FC switch on an NP\_Port, the session remains on that NP\_Port until the ENode or VN\_Port performs a LOGO.

If the physical FC interface link goes down, the FLOGI and FDISC sessions on the down link are logged out. The ENodes and VN\_Ports log in again to start new sessions on other NP\_Ports in the local gateway FC fabric in accordance with the configured load-balancing algorithm (assuming there is more than one NP\_Port connected to the FC fabric).

### Load-Balancing Scenarios

The configured load-balancing algorithm, the sequence in which ENodes log in to the FC network, the current session count (number of sessions per interface) and the interface speed determine the way the session load is balanced across the native FC interfaces (NP\_Ports) in a gateway FC fabric. Whether you are balancing the link load for the first time or rebalancing an existing link load, the way the load is distributed across the active links is the same.

**NOTE:** The way the switch counts the number of sessions on a port depends on the load-balancing algorithm. For simple and ENode-based load balancing, the sum of the FLOGI and FDISC sessions equals the session count. For FLOGI-based load balancing, only the FLOGI sessions are counted in the total session count.

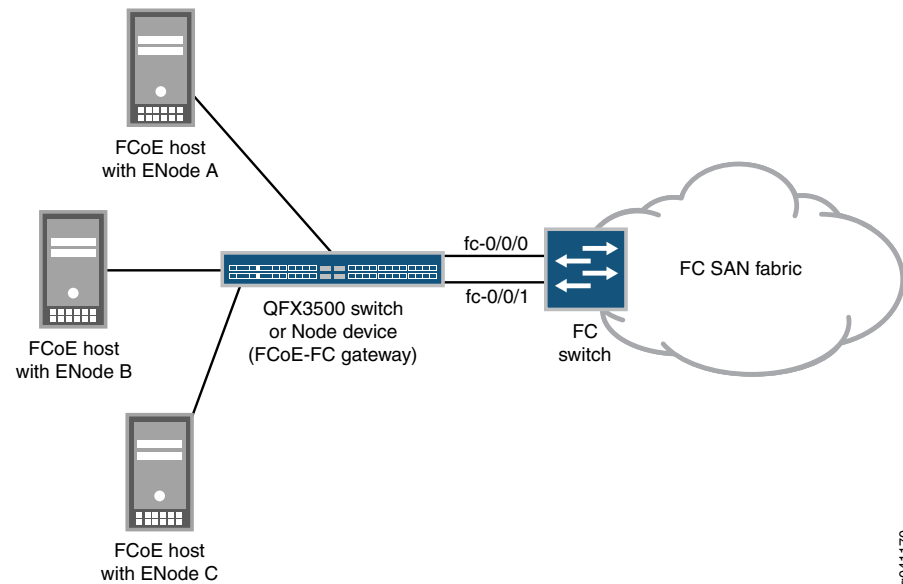

The following scenarios demonstrate how sessions are assigned to links for each load-balancing algorithm:

- [Simple Load-Balancing Algorithm Scenario on page 5335](#)
- [ENode-Based Load-Balancing Algorithm Scenarios on page 5336](#)
- [FLOGI-Based Load-Balancing Algorithm Scenarios on page 5337](#)

All of the scenarios use the topology shown in [Figure 208 on page 5335](#).

**Figure 208: Sample Load-Balancing Topology**

### **Simple Load-Balancing Algorithm Scenario**

Simple load balancing results in the most equal load distribution among the NP\_Ports connected to an FC SAN fabric because VN\_Port FDISC sessions do not need to “follow” the parent ENode FLOGI session on the same link between the gateway and the FC fabric. When a new FLOGI or FDISC session is initiated, it is assigned to the least-loaded link.

The simple load-balancing algorithm example uses the topology shown in [Figure 208 on page 5335](#) and has the following characteristics:

- QFX3500 switch configured as an FCoE-FC gateway
- Two gateway NP\_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes, ENode\_A, ENode\_B, and ENode\_C connected to the gateway
- NP\_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode\_A, ENode\_B, and ENode\_C, belong to the same local FC fabric on the gateway

When the NP\_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP\_Ports is equal. Now the ENodes and VN\_Ports start to log in to the fabric:

1. ENode\_A sends a FLOGI to log in to the fabric. Because the loads on the two NP\_Ports are equal, the session for ENode\_A is randomly placed on one of the links. In this example, the ENode\_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode\_B logs in. Because the load is less on port **fc-0/0/1**, the ENode\_B FLOGI session is placed on port **fc-0/0/1**.

3. ENode\_C logs in. Because the link loads are equal, the ENode\_C login session is randomly placed on one of the links. In this example, the ENode\_C login session is placed on port **fc-0/0/0**.
4. A VN\_Port on ENode\_A sends an FDISC to log in to the fabric. Because port **fc-0/0/1** currently is the least-loaded link, the VN\_Port session is placed on port **fc-0/0/1**, even though its parent ENode session is on port **fc-0/0/0**.
5. As each new VN\_Port session comes up, it is placed on the least-loaded link, regardless of the link on which its parent ENode session is placed.

### ***ENode-Based Load-Balancing Algorithm Scenarios***

ENode-based load balancing ensures that VN\_Port FDISC sessions are placed on the same link as their parent ENode FLOGI sessions, regardless of the link load. ENode-based load balancing can result in a less-balanced load among the NP\_Port links, but it provides the control and predictability of keeping ENodes and their VN\_Port sessions on the same link.

The examples in this section use the topology shown in [Figure 208 on page 5335](#).

- QFX3500 switch configured as an FCoE-FC gateway
- Two gateway NP\_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes connected to the gateway:
  - ENode\_A, which has 2 VN\_Port FDISC sessions
  - ENode\_B, which has 20 VN\_Port FDISC sessions
  - ENode\_C, which has 100 VN\_Port FDISC sessions
- NP\_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode\_A, ENode\_B, and ENode\_C, belong to the same local FC fabric on the gateway

When the NP\_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP\_Ports is equal. Now the ENodes and VN\_Ports start to log in to the fabric. As the following two scenarios show, how these sessions are placed on the links depends on the sequence in which they log in to the fabric.

#### **Scenario 1:**

1. ENode\_A sends a FLOGI to log in to the fabric. Because the loads on the two NP\_Ports are equal, the session for ENode\_A is randomly placed on one of the links. In this example, the ENode\_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode\_B logs in. Because the load is less on port **fc-0/0/1**, the ENode\_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN\_Ports on ENode\_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode\_A on the link. Now port **fc-0/0/0** has a greater load (one FLOGI session plus two FDISC sessions) than port **fc-0/0/1** (one FLOGI session).

4. The 20 VN\_Ports on ENode\_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode\_B on the link. Now port **fc-0/0/0** has a lesser load (one FLOGI, two FDISC) than port **fc-0/0/1**.
5. ENode\_C logs in. Because the load is less on port **fc-0/0/0**, the ENode\_C FLOGI session is placed on port **fc-0/0/0**.
6. The 100 VN\_Ports on ENode\_C log in to the fabric. Their sessions follow the ENode\_C session onto port **fc-0/0/0**.
7. If more VN\_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

#### Scenario 2:

1. ENode\_A sends a FLOGI to log in to the fabric. Because the loads on the two NP\_Ports are equal, the session for ENode\_A is randomly placed on one of the links. In this example, the ENode\_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode\_B logs in. Because the load is less on port **fc-0/0/1**, the ENode\_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN\_Ports on ENode\_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode\_A on the link. Now port **fc-0/0/0** has a greater load (one FLOGI session plus two FDISC sessions) than port **fc-0/0/1** (one FLOGI session).
4. In this step, the login sequence in Scenario 2 differs from the login sequence in Scenario 1, resulting in a different placement of sessions on the links, and therefore a different load on the links. ENode\_C logs in before the ENode\_B VN\_Ports log in, which changes the session count on the links compared to the first scenario. Because the load in this scenario is less on port **fc-0/0/1**, the ENode\_C FLOGI session is placed on port **fc-0/0/1** (instead of port **fc-0/0/0** as in the first scenario).
5. The 20 VN\_Ports on ENode\_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode\_B on the link. Now port **fc-0/0/0** carries one FLOGI and two FDISC sessions, and port **fc-0/0/1** carries two FLOGI and 20 FDISC sessions.
6. The 100 VN\_Ports on ENode\_C log in to the fabric. Their sessions follow the ENode\_C session onto port **fc-0/0/1**. Now port **fc-0/0/1** carries 2 FLOGI and 120 FDISC sessions, whereas port **fc-0/0/0** carries one FLOGI and two FDISC sessions.
7. If more VN\_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

Because of the sequence of ENode logins in Scenario 2, port **fc-0/0/1** carries a greater load than port **fc-0/0/0**. If the simple load-balancing algorithm had been used, the FLOGI and FDISC sessions would be allocated to the two links evenly. However, because the FDISC sessions are placed on the same link as their parent FLOGI sessions, this example demonstrates how using the ENode-based load-balancing algorithm can lead to scenarios in which the link loads are not equal.

#### *FLOGI-Based Load-Balancing Algorithm Scenarios*

FLOGI-based load balancing is similar in many ways to ENode-based load balancing. An important difference that affects how the switch places sessions on links is that for

FLOGI-based load balancing, only the FLOGI sessions are counted when the link load is calculated. FDISC sessions are not counted to determine the link load. Because ENode-based load balancing uses the sum of the FLOGI and FDISC sessions to determine the link load, an interface with exactly the same combination of FLOGI and FDISC sessions can have a different session count depending on the algorithm used. A different session count can change the interface to which the switch assigns the next session.

As with ENode-based load balancing, FLOGI-based load balancing ensures that VN\_Port FDISC sessions are placed on the same link as their parent ENode FLOGI sessions, regardless of the link load. FLOGI-based load balancing can result in a less-balanced load among the NP\_Port links, but it provides the control and predictability of keeping ENodes and their VN\_Port sessions on the same link.

The examples in this section use the topology shown in [Figure 208 on page 5335](#).

- QFX3500 switch configured as an FCoE-FC gateway
- Two gateway NP\_Ports, **fc-0/0/0** and **fc-0/0/1**, connected to an FC SAN fabric switch at a speed of 8 Gbps
- Three ENodes connected to the gateway:
  - ENode\_A, which has 2 VN\_Port FDISC sessions
  - ENode\_B, which has 20 VN\_Port FDISC sessions
  - ENode\_C, which has 100 VN\_Port FDISC sessions
- NP\_Ports **fc-0/0/0** and **fc-0/0/1**, and ENode\_A, ENode\_B, and ENode\_C, belong to the same local FC fabric on the gateway

When the NP\_Ports initialize, they send FLOGI messages to the FC switch and log in to the FC SAN fabric. The gateway then advertises the fabric to the ENodes on the Ethernet side of the network. At this point, the load on both of the NP\_Ports is equal. Now the ENodes and VN\_Ports start to log in to the fabric.

Because FLOGI-based load balancing does not count FDISC sessions when calculating the link load, how the sessions are placed on the link depends only on the number of FLOGI sessions per interface, not on the number of FLOGI sessions plus FDISC sessions. This means that an ENode with a FLOGI session and many FDISC sessions is counted as having the same load as an ENode with a FLOGI session and no FDISC sessions.

#### Scenario 1:

1. ENode\_A sends a FLOGI to log in to the fabric. Because the loads on the two NP\_Ports are equal, the session for ENode\_A is randomly placed on one of the links. In this example, the ENode\_A FLOGI session is placed on port **fc-0/0/0**.
2. ENode\_B logs in. Because the load is less on port **fc-0/0/1**, the ENode\_B FLOGI session is placed on port **fc-0/0/1**.
3. The two VN\_Ports on ENode\_A log in to the fabric. Their sessions are placed on port **fc-0/0/0**, following ENode\_A on the link. However, unlike simple load balancing or ENode-based load balancing, the session count of the two ports is still equal (one session each) because the FDISC sessions are not used in the session count.

4. The 20 VN\_Ports on ENode\_B log in to the fabric. Their sessions are placed on port **fc-0/0/1**, following ENode\_B on the link. Again, unlike simple load balancing or ENode-based load balancing, the session count of the two ports is still equal (one session each) because the FDISC sessions are not used in the session count.
5. ENode\_C logs in. Because the link loads are counted as equal, the ENode\_C login session is randomly placed on one of the links. In this example, the ENode\_C login session is placed on port **fc-0/0/0**.
6. The 100 VN\_Ports on ENode\_C log in to the fabric. Their sessions follow the ENode\_C session onto port **fc-0/0/0**.
7. If more VN\_Ports come up, their FDISC sessions are placed on the same link as the corresponding parent ENode session.

If a fourth ENode, ENode\_D, sends a FLOGI to log in to the fabric, it is placed on port **fc-0/0/1** because port **fc-0/0/0** has a session count of two (two FLOGIs from ENode\_A and ENode\_C, FDISCs not counted) and port **fc-0/0/1** has a session count of one (one FLOGI from ENode\_B, FDISCs not counted), so port **fc-0/0/1** is the least-loaded port.

With FLOGI-based load balancing, it is possible for ENodes with many FDISC sessions to be placed on the same link, whereas ENodes with few FDISC sessions are placed on different links because only FLOGIs are used in the session count.

## Understanding OxID Hash Control for FCoE Traffic Load Balancing on Standalone Switches

The originator exchange identifier (OxID) field is one of several fields that the switch can use in its hash function computation for FCoE traffic load balancing over multiple outgoing links in an Ethernet link aggregation group (LAG) on ports that face an FCoE forwarder (FCF). The originator of an exchange between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) uses the OxID field as an identifier for that exchange. The originator also uses the OxID field to track the progress of the series of sequences that comprise the exchange.

When FCoE traffic traverses a LAG that faces an FCF, it can take multiple different links between the source and destination endpoints. The idea is to distribute the FCoE traffic

across the FCF-facing LAG links, thus balancing the link load. The switch creates a hash value from some of the packet header fields, and uses the hash value to assign each packet to one of the LAG links. The switch always uses five packet header fields to compute the hash value:

- Source ID (SID)
- Destination ID (DID)
- Fabric ID (FID)
- Source Port ID (SPID)
- Source Module ID (SMID)

In addition, the OxID field is included by default in the FCoE load-balancing hash computation. However, if you do not want to use the OxID field in the FCoE load-balancing hash computation, you can remove it from the computation by using the **set forwarding-options hash-key family fcoe oxid disable** command.

Including the OxID field in the load-balancing hash computation allows different exchanges between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) to take different paths across the network, thus improving the aggregate network throughput.

However, if the paths between different sets of FC endpoints have common links, congestion on one set of FC endpoints can affect the other set of endpoints. Such congestion can happen if the FCoE traffic on the two sets of endpoints uses the same priority (IEEE 802.1p code point). It is common for networks to use priority 3 (IEEE 802.1p code point 011) for FCoE traffic. However, you can assign different IEEE priorities to different lossless FCoE flows as described in [“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5883](#) to further separate the traffic flows.

## Understanding VN\_Port to VF\_Port FIP Snooping on an FCoE Transit Switch

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping is a security mechanism that is designed to prevent unauthorized access and data transmission to a Fibre Channel (FC) network. It works by filtering traffic to permit only servers that have logged in to an FC network to access that network.

You explicitly enable VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping (FC-BB-5) on FCoE VLANs when the switch is an FCoE transit switch at the access edge that connects FCoE devices on the Ethernet network to FC switches or gateways at the FC storage area network (SAN) edge. The transit switch applies FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VF\_Port FIP snooping. An FCoE transit switch is a data center bridging (DCB) switch with FIP snooping capability.

An FCoE device that has a converged network adapter (CNA) uses the FIP process to log in to the FC network as an FCoE Node (ENode). The login process establishes a dedicated virtual link between a virtual N\_Port (VN\_Port) on the ENode and a virtual F\_Port (VF\_Port) on the FC switch. This dedicated virtual link emulates a point-to-point connection. The emulated connection is called a virtual link.

Virtual links pass transparently through the transit switch. The ENode VN\_Port and the FC switch VF\_Port do not detect the transit switch, and virtual links appear to be direct point-to-point links.

The switch applies VN2VF\_Port FIP snooping firewall filters at the FCoE-network facing ports associated with the FCoE VLANs on which you enable VN2VF\_Port FIP snooping. FIP snooping provides security for virtual links by creating firewall filters based on information gathered (snooped) about FC devices during FIP transactions.

The switch also supports VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping (FC-BB-6) to allow FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch, as described in [“Understanding VN\\_Port to VN\\_Port FIP Snooping on an FCoE Transit Switch” on page 5348](#).

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping (FC-BB-5) or VN2VN\_Port FIP snooping (FC-BB-6), but not both. The same switch can have multiple FCoE VLANs configured, some for VN2VF\_Port FIP snooping traffic and others for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port snooping VLANs, VN2VF\_Port FIP snooping traffic is dropped.

When you enable VN2VF\_Port FIP snooping on an FCoE VLAN, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN2VF\_Port virtual links.

When you enable VN2VN\_Port FIP snooping on an FCoE VLAN, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN2VN\_Port virtual links.

## FC Network Security

In traditional FC networks, the FC switch is usually a trusted entity, and server ENodes connect directly to its VF\_Ports. After an ENode gains access to the network through the fabric login (FLOGI) process, the FC switch enforces zoning configurations, ensures that the ENode uses valid addresses, monitors the connection, and performs other security functions to prevent unauthorized access.

However, FCoE exposes FC frames to Ethernet networks, which do not have the same level of security as native FC networks. VN2VF\_Port FIP snooping firewall filters emulate the native FC network security functions by preventing unauthorized access to the FC switch through the transit switch and by ensuring the security of the virtual link between each ENode and the FC switch, as shown in [Figure 209 on page 5342](#). VN2VF\_Port FIP snooping also prevents man-in-the-middle attacks.

**Figure 209: FCoE Transit Switch Performs VN2VF\_Port FIP Snooping**

The transit switch performs VN2VF\_Port FIP snooping at the ports connected to the FCoE devices. At the SAN edge, the FC switch must be able to convert the FCoE traffic to native FC traffic.

---

### VN2VF\_Port FIP Snooping Functions

---

When VN2VF\_Port FIP snooping is enabled, the transit switch sets and applies filters to block all FCoE traffic by default. The transit switch monitors FIP logins, solicitations, and advertisements that pass through it and gathers information about the ENode address and the address of the port on the FC switch. The transit switch uses the information to construct firewall filters that permit access only to logged-in ENodes. All other traffic on the VLAN is denied.

For example, when an ENode on an FCoE VLAN performs a successful login to an FC switch port, the transit switch snoops the FIP information and constructs a firewall filter that provides access for the ENode to that port on the FC switch.

The firewall filters enable FCoE frames to pass through the transit switch only on a virtual link established between an FCoE device ENode VN\_Port and the FC switch VF\_Port to which it has logged in. The firewall filters ensure that ENodes can only connect to the FC switches they have successfully logged in to and that only valid FCoE traffic along valid paths is transmitted. VN2VF\_Port FIP snooping maintains the filters by tracking FCoE sessions (ENode to FCF sessions).

---

### FIP Snooping Firewall Filters

---

The effect of the firewall filters is to protect the FCoE ports. VN2VF\_Port FIP snooping performs the following actions and checks to ensure that FCoE traffic is valid:

- Denies ENodes that use the FC switch media access control (MAC) address as the source address.
- Enables ENodes to transmit FIP and FCoE frames to the FC switch address.
- Ensures that the FCoE source address the FC switch assigns or accepts is only used for FCoE traffic.
- Ensures that FCoE frames are only addressed to the accepting FC switch.

---

### FIP Snooping Session Scalability

---

Enhanced FIP snooping session scaling, which supports up to 2,500 sessions, is enabled by default. On QFabric systems, if you want to disable enhanced FIP snooping scaling (which reduces the number of supported sessions to 376 sessions), you can do so as described in [“Disabling Enhanced FIP Snooping Scaling” on page 5553](#).

By default, up to 2500 total FIP snooping sessions are supported on an interface, an FCoE-FC gateway fabric (only supported on QFX3500 switches configured as standalone switches or as QFabric system Node devices), a switch, a QFabric Node device, or a QFabric Node group. For example, you can:

- Place all 2500 sessions on one FCoE interface.
- Split the 2500 sessions among multiple FCoE interfaces on one FCoE VLAN.
- Split the 2500 sessions among multiple FCoE interfaces on multiple FCoE VLANs.

- Split the 2500 sessions among the FCoE interfaces on multiple gateway FC fabrics on a switch.
- Split the 2500 sessions among the FCoE interfaces on multiple gateway FC fabrics on multiple Node devices in a QFabric Node group.

Regardless of how you allocate the sessions among interfaces and local FC fabrics on a switch or on a QFabric system Node device or Node group, the combined FIP session limit is a maximum of 2500 sessions.

**NOTE:** The total number of sessions the system can support is the combined number of VN2VF\_Port sessions and VN2VN\_Port sessions. If VN2VN\_Port sessions are active, the total number of available VN2VF\_Port sessions is reduced.

---

### VN2VF\_Port FIP Snooping Implementation

You enable VN2VF\_Port FIP snooping on a per-VLAN basis on VLANs that carry FCoE traffic. The switch snoops FIP frames at the ports associated with FCoE VLANs enabled for VN2VF\_Port FIP snooping. The switch then installs the resulting firewall filters on the ports to ensure that all VN2VF\_Port FIP snooping occurs on the switch network edge.

VN2VF\_Port FIP snooping FCoE VLANs must meet the following criteria:

- An FCoE VLAN should be dedicated to FCoE traffic only.
- An FCoE VLAN cannot support both VN2VF\_Port FIP snooping and VN2VN\_Port FIP snooping simultaneously. You must configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic.

**NOTE:** Changing an FCoE VLAN from VN2VF\_Port FIP snooping mode to VN2VN\_Port snooping mode terminates the existing virtual links on the VLAN. The transit switch removes the existing FIP snooping filters, creates the new FIP snooping filters, and applies them to the FIP snooping ports. If you downgrade the software to Junos OS Release 12.1 or earlier, VLANs configured for VN2VN\_Port FIP snooping revert to VN2VF\_Port FIP snooping VLANs.

- 
- For systems that use software that does not support Enhanced Layer 2 Software (ELS) CLI, configure all access ports that belong to an FCoE VLAN (ports connected to a converged network adapter [CNA] in an FCoE device) in **tagged-access** port mode. Access ports associated with an FCoE VLAN should not be configured as access ports or trunk ports on these platforms, although trunk port configuration is supported.

However, on switches that use the ELS CLI, configure access ports that belong to an FCoE VLAN in **trunk** interface mode.

- All ports connected to an FC switch (or FCoE forwarder) must be configured in **trunk** port mode. Ports connected to an FC switch must be configured as trusted ports.

- FIP traffic uses the native VLAN (FIP VLAN discovery and notification frames are exchanged as untagged packets).
- All FCoE VLAN traffic must be tagged and cannot belong to the native VLAN.
- FCoE VLAN traffic cannot be untagged or priority-tagged.

When you enable VN2VF\_Port FIP snooping, the switch inspects FIP frames.

The VN2VF\_Port FIP snooping implementation includes these considerations:

- [ENode-Facing Interfaces on page 5345](#)
- [Network-Facing Interfaces on page 5346](#)
- [FC-MAP on page 5346](#)

### ***ENode-Facing Interfaces***

When the interfaces that belong to an FCoE VLAN connect directly to FCoE devices (there is no other transit switch between the FCoE devices and the switch), we recommend that you enable VN2VF\_Port FIP snooping on all FCoE VLANs that connect VN\_Ports to VF\_Ports. Enabling FIP snooping ensures secure connections between server ENodes and FC switches. (Enabling VN2VN\_Port FIP snooping ensures secure connections on FCoE VLANs that connect VN\_Ports to other VN\_Ports). FIP snooping should always be enabled at the access edge.

Systems that run Enhanced Layer 2 Software (ELS) support a slightly different configuration on ENode-facing interfaces than systems that do not run ELS. This section describes:

- [Non-ELS Port Mode for FCoE Interfaces on page 5345](#)
- [ELS Interface Mode for FCoE Interfaces on page 5346](#)
- [Trusted and Untrusted FCoE Interfaces on page 5346](#)

### ***Non-ELS Port Mode for FCoE Interfaces***

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that do not support ELS should be configured in **tagged-access** port mode. After you enable VN2VF\_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and prior releases. In Release 11.3 and earlier, **trunk** port mode was used for Ethernet interfaces that connected to FCoE access devices. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** to **tagged-access** as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

### ***ELS Interface Mode for FCoE Interfaces***

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that support ELS should be configured in **trunk** interface mode. After you enable VN2VF\_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

### ***Trusted and Untrusted FCoE Interfaces***

Do not configure ENode-facing interfaces as FCoE trusted interfaces when VN2VF\_Port FIP snooping is enabled on those interfaces. If you enable VN2VF\_Port FIP snooping on an FCoE VLAN and you configure ENode-facing interfaces that are members of the FIP snooping VLAN as **fcoe-trusted**, then FCoE devices might not be able to log in to the FC network.

Changing ports from untrusted to trusted removes any existing VN2VF\_Port FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN\_Ports log in again, the switch can build the appropriate VN2VF\_Port FIP snooping filters.

### ***Network-Facing Interfaces***

When the switch acts as an FCoE transit switch, you must configure any interface that is connected to a switch as an FCoE trusted interface in **trunk** port mode and as a 10-Gigabit Ethernet interface.

Switch-facing Ethernet interfaces have the following requirements and behaviors:

- You must explicitly configure switch-facing trunk ports on an FCoE transit switch as FCoE trusted interfaces.
- After you configure an FC switch-facing trunk port as a trusted interface, the FCoE transit switch always processes FC switch frames because they come from a source on a trusted interface.
- All ports in an FCoE VLAN must be configured as tagged access or trunk ports.

### ***FC-MAP***

When the switch acts as an FCoE transit switch and you enable VN2VF\_Port FIP snooping on an FCoE VLAN, you can optionally specify a 24-bit FCoE mapped address prefix (FC-MAP) value. On a given VLAN, the transit switch learns only those FC switches that have a matching FC-MAP value. If the transit switch FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, the transit switch does not discover the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. An FCoE VLAN can have one and only one FC-MAP value.

The FC-MAP value is a MAC address prefix unique to an FC switch in the FC SAN fabric that the FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN). The FC switch combines the FC-MAP value with a unique 24-bit FCID value for the ENode VN\_Port during the login process. This creates a 48-bit identifier that is unique to the fabric. The FC switch assigns this 48-bit value to the ENode VN\_Port as its

MAC address and unique identifier for the session. Each VN\_Port session the ENode establishes with the FC switch receives a unique FCID from the FC switch, so an FCoE device can host multiple virtual links (one for each VN\_Port) to an FC switch, each with a 48-bit MAC address that is unique to the fabric.

The VN2VF\_Port FIP snooping filter compares the configured FC-MAP value with the FC-MAP value in the header of frames coming from the ENode VN\_Port. If the values do not match, the transit switch denies access.

**NOTE:** Changing the FC-MAP value causes all logins to be dropped and forces ENodes to log in again.

**NOTE:** Do not configure static MAC addresses with the FC-MAP value as a prefix (the first 24 bits of the MAC address). If you configure a static MAC address that uses the FC-MAP value as a prefix, the system deletes the static MAC address automatically after you enable FIP snooping. The static MAC address configuration is not restored even if you disable FIP snooping later. (The system considers a static MAC address with the FC-MAP value as the prefix to be a misconfiguration.) Do not use a MAC address with the FC-MAP value as the prefix for any traffic other than the FIP snooping traffic when the switch is acting as a transit switch.

### T11 VN2VF\_Port FIP Snooping Specification

For more details about VN2VF\_Port FIP snooping, see <http://www.t11.org/ftp/t11/pub/fc/bb-5/08-264v3.pdf> for the Technical Committee T11 organization document *Increasing FCoE Robustness using FIP Snooping*.

## Understanding VN\_Port to VN\_Port FIP Snooping on an FCoE Transit Switch

VN\_Port to VN\_Port (VN2VN\_Port) Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping (FC-BB-6) on an FCoE transit switch is conceptually similar to VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping (FC-BB-5) on an FCoE transit switch. An FCoE transit switch is a data center bridging (DCB) switch with FIP snooping capability. VN2VN\_Port FIP snooping provides security in the form of filters. The filters help prevent unauthorized access and data transmission on a bridge that connects ENodes on the Ethernet network.

The main difference between VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping is that you use VN2VN\_Port FIP snooping when the FCoE devices reside on the Ethernet network, so there is no need to forward traffic between FCoE devices to the Fibre Channel (FC) network, and you use VN2VF\_Port FIP snooping when FCoE devices on the Ethernet network need to access targets on the FC network, so FCoE traffic must be forwarded to the FC network. See [“Understanding VN\\_Port to VF\\_Port FIP Snooping on an FCoE Transit Switch” on page 5341](#) for information about VN2VF\_Port FIP snooping.

You enable VN2VN\_Port FIP snooping on the FCoE VLAN that transports the VN2VN traffic. The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

A key benefit of VN2VN\_Port FIP snooping is that it enables FCoE initiators and targets to communicate directly through the switch without going through an FCoE forwarder (FCF) or an FC switch. The transit switch does not differentiate between initiators and targets because the transit switch sees both VN\_Ports as FIP virtual link end points. Direct VN2VN\_Port communication requires secure access (FIP snooping filters) because ENodes are not trusted entities.

This topic describes:

### VN2VN\_Port FIP Snooping and FIP Snooping Virtual Links

FIP snooping under the T11 FC-BB-5 specification requires that an FC switch or an FCF be in the path between two VN\_Ports when they communicate. Introduced in the T11 FC-BB-6 specification (see <http://www.t11.org/ftp/t11/pub/fc/bb-6/10-019v3.pdf>), VN2VN\_Port FIP snooping allows the FCoE transit switch to connect two VN\_Ports to each other directly, without going through an FC switch or an FCF, provided that the ENodes have logged in to the FC network.

In VN2VF\_Port FIP snooping, when an ENode logs in to the FC network, the FCoE transit switch snoops the FIP communication between the ENode and the FC switch. In VN2VN\_Port FIP snooping mode, the transit switch creates filters on the switch access ports to control VN\_Port access to other VN\_Ports on the Ethernet network. The VN2VN\_Port FIP snooping filters allow the switch to establish a dedicated virtual link that emulates a point-to-point connection between two VN\_Ports, through the switch.

Virtual links pass transparently through the transit switch. The VN\_Ports do not detect the transit switch, and virtual links appear to be direct point-to-point links.

You explicitly enable VN2VN\_Port FIP snooping on FCoE VLANs when the switch or QFabric system Node device is an FCoE transit switch connecting FCoE devices on the Ethernet network to each other and to FC switches or gateways at the FC storage area network (SAN) edge.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN\_Port to VF\_Port traffic is dropped.

When you enable FIP snooping, the system snoops VN2VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port FIP packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN\_Port FIP snooping. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

### VN2VN\_Port Communication Modes

The transit switch supports two VN2VN\_Port communication modes:

- Point-to-point mode
- Multipoint mode

In point-to-point mode, two ENodes are connected to the network and form a single VN\_Port to VN\_Port virtual link. This is analogous to the point-to-point FC link between an FC initiator and an FC target.

In multipoint mode, multiple ENodes are connected to the network and form multiple virtual links. Each virtual link is created between one pair of VN\_Ports. This is analogous to loop mode in traditional FC networks.

The VN2VN\_Port communication mode is not configured; it is determined by the number of ENodes connected to the network.

---

### Network Security

In traditional FC networks, the FC switch is usually a trusted entity and the server ENodes are untrusted entities. The ENodes connect directly to the FC switch VF\_Ports. After an ENode gains access to the network through the fabric login (FLOGI) process, the FC switch enforces zoning configurations, ensures that the ENode uses valid addresses, monitors the connection, and performs other security functions to prevent unauthorized access.

However, FCoE exposes FC frames to Ethernet networks, which do not have the same level of security as native FC networks. VN2VN\_Port FIP snooping filters emulate the native FC network security functions by preventing unauthorized access and by ensuring the security of the virtual link between ENode VN\_Ports. The transit switch performs VN2VN\_Port FIP snooping at the ports connected to the FCoE VN\_Port devices.

---

### VN2VN\_Port FIP Snooping Functions

When you enable VN2VN\_Port FIP snooping, the transit switch sets and applies filters to block all FCoE traffic on the VLAN by default. The transit switch monitors FIP logins, solicitations, and advertisements that pass through it and gathers information about the ENode address. The transit switch uses the information to construct filters that permit access only to logged-in ENodes. All other traffic on the VLAN is denied.

The filters enable FCoE frames to pass through the transit switch only on a virtual link established between two VN\_Ports. The filters ensure that ENodes can only connect to other ENodes if they have successfully logged in to each other, and that only valid FCoE traffic along valid paths is transmitted. VN2VN\_Port FIP snooping maintains the filters by tracking VN\_Port to VN\_Port sessions.

---

### Scalability

Because ENodes are untrusted and the system needs to apply filters to untrusted FIP snooping interfaces, the total number of combined VN2VN\_Port FIP snooping sessions per switch is 376 sessions (ENode to ENode sessions) on untrusted interfaces. On interfaces that are configured as trusted interfaces, no FIP snooping filters are applied.

**NOTE:** The total number of sessions the system can support is the combined number of VN2VF\_Port sessions and VN2VN\_Port sessions. If VN2VF\_Port sessions are active, the total number of available VN2VN\_Port sessions is reduced.

---

### VN2VN\_Port FIP Snooping Implementation

You enable VN2VN\_Port FIP snooping on a per-VLAN basis on VLANs that carry FCoE traffic. The switch snoops FIP frames at the ports associated with FCoE VLANs enabled for VN2VN\_Port FIP snooping. The switch then installs the resulting filters on the ENode-facing ports to ensure that all FIP snooping occurs on the switch network edge.

VN2VN\_Port FIP snooping FCoE VLANs must meet the following criteria:

- An FCoE VLAN should be dedicated to FCoE traffic only.
- An FCoE VLAN cannot support both VN2VF\_Port FIP snooping (FC-BB-5) and VN2VN\_Port FIP snooping (FC-BB-6) simultaneously. You must configure separate FCoE VLANs for FIP snooping traffic and for VN2VN\_Port FIP snooping traffic.

**NOTE:** Changing an FCoE VLAN from VN2VF\_Port FIP snooping mode to VN2VN\_Port FIP snooping mode terminates the existing virtual links on the VLAN. The transit switch removes the existing FIP snooping filters, creates the new FIP snooping filters, and applies them to the FIP snooping ports. If you downgrade the software to Junos OS Release 12.1 or earlier, VLANs configured for VN2VN\_Port FIP snooping revert to VN2VF\_Port FIP snooping VLANs.

- For switches that do not run Enhanced Layer 2 Software (ELS), as a best practice, you should configure all access ports that belong to an FCoE VLAN (ports connected to a converged network adapter [CNA] in an FCoE device) in **tagged-access** port mode. However, access and trunk port modes are also supported. For switches that use ELS, configure access ports that belong to an FCoE VLAN in **trunk** interface mode.
- Access ports should be configured as untrusted ports.
- All ports connected to another transit switch must be configured in **trunk** port mode.
- FIP traffic uses the native VLAN.
- You can enable VN2VN\_Port FIP snooping on a native VLAN.

### ENode-Facing Interfaces

When the interfaces that belong to an FCoE VLAN connect directly to FCoE devices (there is no other transit switch between the FCoE devices and the switch), we recommend that you either enable VN2VN\_Port FIP snooping on all FCoE VLANs to ensure secure connections between VN\_Ports, or enable VN2VF\_Port FIP snooping on FCoE VLANs that connect ENodes to an FC switch. FIP snooping should always be enabled at the access edge.

Systems that run Enhanced Layer 2 Software (ELS) support a slightly different configuration on ENode-facing interfaces than systems that do not run ELS. This section describes:

- [Non-ELS Port Mode for FCoE Interfaces on page 5352](#)
- [ELS Interface Mode for FCoE Interfaces on page 5352](#)
- [Trusted and Untrusted FCoE Interfaces on page 5352](#)

#### ***Non-ELS Port Mode for FCoE Interfaces***

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) should be configured in **tagged-access** port mode, unless your CNA does not support tagged VN2VN traffic. After you enable VN2VN\_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login (FIP FLOGI) with another ENode.

The **tagged-access** port mode was not available in Junos OS Release 11.3 and prior releases. In Release 11.3 and earlier, **trunk** port mode was used for Ethernet interfaces that connected to FCoE access devices. Because **tagged-access** mode is now available, using **trunk** mode for interfaces connected to FCoE CNAs is not recommended.

If an existing configuration uses **trunk** mode for ports connected to FCoE CNAs, you can change the port mode to **tagged-access** without disrupting traffic. Although we recommend changing the port mode of these ports from **trunk** to **tagged-access** as a best practice, it is not mandatory. New configurations should use **tagged-access** mode for interfaces that connect to FCoE devices.

#### ***ELS Interface Mode for FCoE Interfaces***

The interfaces that belong to FCoE VLANs (interfaces that connect to CNAs in FCoE devices) on systems that support ELS should be configured in **trunk** interface mode. After you enable VN2VF\_Port FIP snooping on an FCoE VLAN, the transit switch denies FCoE traffic from any ENode on that VLAN until the ENode performs a valid fabric login with an FC switch.

#### ***Trusted and Untrusted FCoE Interfaces***

Do not configure ENode-facing interfaces as FCoE trusted interfaces when VN2VF\_Port FIP snooping is enabled on those interfaces. If you enable VN2VF\_Port FIP snooping on an FCoE VLAN and you configure ENode-facing interfaces that are members of the FIP snooping VLAN as **fcoe-trusted**, then FCoE devices might not be able to log in to the FC network.

Changing ports from untrusted to trusted removes any existing VN2VF\_Port FIP snooping filters from the ports and terminates the existing sessions. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN\_Ports log in again, the switch can build the appropriate VN2VF\_Port FIP snooping filters.

#### ***Network-Facing Interfaces (Connecting to Another Transit Switch)***

---

Configure any interface that is connected to another transit switch (not to an ENode) as an FCoE trusted interface, in **trunk** port mode, and as a 10-Gigabit Ethernet interface.

Network-facing Ethernet interfaces have the following requirements and behaviors:

- You must explicitly configure network-facing trunk ports on an FCoE transit switch as FCoE trusted interfaces.
- After you configure a network-facing trunk port as a trusted interface, the FCoE transit switch always processes frames from the connected switch because they come from a source on a trusted interface.
- As a best practice, configure ports in an FCoE VLAN as tagged access ports, but access and trunk port modes are also supported to accommodate whatever types of VN2VN traffic your CNA supports.

### Beacon Period (VN2VN\_Port FIP Snooping Link Maintenance)

The transit switch needs to maintain the virtual links between VN\_Ports, and needs to know when sessions begin and end, and when to install and remove the FIP snooping filters. FIP snooping uses a FIP keepalive advertisement to accomplish this task. VN2VN\_Port FIP snooping does not exchange FIP keepalive timer information. Instead, you configure a *beacon period*, which performs the same function as a keepalive timer.

The beacon period is the time interval between messages which verify that the connection is still valid and that the device at the other end of the virtual link is still reachable. You set the beacon period value for each FCoE VLAN that you configure to do VN2VN\_Port FIP snooping.

**NOTE:** Explicitly set the beacon period when you configure VN2VN\_Port FIP snooping. VN\_Ports do not automatically send beacons.

ENodes transmit periodic multicast N\_Port\_ID beacons to the ALL-VN2VN-ENode-MACs address. The transmission period varies by a random delay of between 0 ms and 100 ms to avoid synchronized bursts of multicast traffic on the network.

If the transit switch does not receive a beacon message from an ENode within 2.5 times the configured beacon period, the transit switch considers the virtual link to be down and terminates the virtual link to that ENode.

### QFabric System Differences in VN2VN\_Port FIP Snooping Traffic Handling

Configuring VN2VN\_Port FIP snooping on a QFabric system is the same as configuring VN2VN\_Port FIP snooping on a standalone switch. However, there are internal differences in the way a QFabric system handles VN2VN\_Port FIP snooping traffic compared to the way a standalone switch handles VN2VN\_Port FIP snooping traffic. The internal differences are transparent. Whether you configure VN2VN\_Port FIP snooping on a QFabric system or on a standalone switch, the proper FIP snooping filters and forwarding information are installed on each device.

On standalone switches, the VN2VN\_Port FIP snooping traffic does not cross a fabric (Interconnect device). VN2VN\_Port traffic enters and exits ports on a single switch, so the ingress port and the egress port have access to the same *local* forwarding and FIP snooping databases.

However, on a QFabric system, VN2VN\_Port FIP snooping traffic might enter on the ingress port of one Node device, traverse the Interconnect device fabric, and exit on the egress port of a different Node device. In this case, the QFabric system must ensure that the FIP snooping database and forwarding information for the VN2VN\_Port traffic is installed correctly on both of the Node devices so that traffic is correctly filtered and forwarded.

For example, [Figure 210 on page 5354](#) shows that VN2VN\_Port traffic from FCoE host ENode E1 enters the QFabric system at Node device ND1, traverses the Interconnect device fabric, and then exits from Node device ND2 before arriving at FCoE host ENode E2. Similarly, VN2VN\_Port traffic from FCoE host ENode E2 enters the QFabric system at Node device ND2, traverses the Interconnect device fabric, and then exits from Node device ND1 before arriving at FCoE host ENode E1.

**Figure 210: VN2VN\_Port Traffic Across a QFabric Interconnect Device**

When the QFabric system receives a FLOGI ACC from either ENode E1 or ENode E2, the QFabric system creates and installs the correct VN2VN\_Port FIP snooping filters on both Node devices, and updates the forwarding tables accordingly.

In addition, the QFabric system must also ensure that the VN2VN\_Port FIP snooping session statistics are correctly counted. Even though a session is running on each of the two Node devices, the QFabric system counts the complete VN2VN\_Port connection as one session because the two Node devices belong to the same session. This ensures that VN2VN\_Port sessions that traverse the Interconnect device fabric are counted as one unique session, not as two separate sessions.

## Understanding FIP Snooping, FBF, and MVR Filter Scalability

The VLAN filter processor (VFP) ternary content addressable memory (TCAM) stores the VLAN filter configuration for three filter types:

- Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping—FIP snooping filters prevent an FCoE device from gaining unauthorized access to a Fibre Channel (FC) storage device or to another FCoE device. VN2VF\_Port FIP snooping filters prevent an FCoE device from gaining unauthorized access to devices on an FC network. VN2VN\_Port FIP snooping filters prevent an FCoE device from gaining unauthorized access to another FCoE device directly through the standalone switch or QFabric system, without traversing the FC network.

The VFP TCAM stores the VN2VF\_Port and VN2VN\_Port FIP snooping filters that the switch automatically creates when you enable FIP snooping on a VLAN that carries FCoE traffic. See [“Understanding VN\\_Port to VF\\_Port FIP Snooping on an FCoE Transit Switch” on page 5341](#) and [“Understanding VN\\_Port to VN\\_Port FIP Snooping on an FCoE Transit Switch” on page 5348](#) for more information.

- Filter-based forwarding (FBF)—FBF enables you to use firewall filters to direct packets to virtual routing instances. The switch then forwards the matching packets based on the configuration of the routing instances. The VFP TCAM stores the terms you configure for FBF filters. See *Understanding Filter-Based Forwarding* for more information.
- Multicast VLAN registration (MVR)—MVR enables you to configure a multicast source VLAN (MVLAN) that is shared across a Layer 2 network. An MVLAN distributes IPTV multicast streams across different VLANs without having to create a separate multicast stream for each VLAN, and without compromising the security and separation of traffic in the different VLANs. The VFP TCAM stores the MVR rules you configure for MVLANs. See [“Understanding Multicast VLAN Registration” on page 4532](#) for more information.

FIP snooping filters, FBF filters, and MVR rules share the VFP TCAM memory space. In most use cases, the VFP TCAM memory is sufficient to store filter terms and information for all three applications.

- [VFP TCAM Architecture and Allocation on page 5356](#)
- [VFP TCAM Entry Consumption on page 5356](#)
- [Rejected Filter Configurations \(No Available VFP TCAM Space\) on page 5359](#)
- [VFP TCAM Allocation and Consumption \(Scaling\) Examples on page 5360](#)
- [Filter Configuration Recommendations on page 5362](#)

## VFP TCAM Architecture and Allocation

---

When packets arrive at an ingress interface, the VFP TCAM is the first TCAM in the packet pipeline. The VFP TCAM stores a total of 1024 entries. The 1024 entries are partitioned into four equal *slices* of 256 entries.

The VFP TCAM allocates entries to three filter types (FIP snooping filters, FBF filter terms, and MVR rules) in 256-entry slices. The VFP TCAM dynamically allocates the minimum number of memory slices required to store the filters for a particular filter type, as needed.

The TCAM does not allocate partial slices to a filter type, and slices cannot be shared among filter types. At any given time, each slice contains entries for one and only one filter type.

For example, if you configure one MVR rule, the system allocates a whole slice to MVR rules, even if the MVR rule consumes only one TCAM entry. The remaining 256 entries in the slice allocated to MVR rules can store subsequently configured MVR rules, but not FIP snooping or FBF filters. Similarly, if FIP snooping filters consume 50 entries of a 256-entry slice, the remaining 206 entries in the FIP snooping slice are available only to store more FIP snooping filters, not to store FBF filter terms or MVR rules.

The VFP TCAM allocates slices to a filter type only if there is at least one configured filter or rule for that filter type. If no filters exist for a filter type, then the VFP TCAM does not allocate a slice to that filter type.

**NOTE:** The VFP TCAM rejects partial filters. For example, if an FBF filter contains six terms, but there is only space in the TCAM for four of those terms, the whole filter is not committed.

---

Each filter type can use from zero slices to all four slices of VFP TCAM space. However, if one filter type uses three slices, then only one slice remains, so only one other filter type can use the remaining slice. In that situation, if you configure filters for all three filter types, the last filter type that you configure receives no TCAM space for its filter entries. Filters that receive no TCAM entry space are not implemented.

## VFP TCAM Entry Consumption

---

FIP snooping filters, FBF filters, and MVR rules consume VFP TCAM entry space in different ways:

- [FIP Snooping Filter VFP TCAM Consumption on page 5357](#)
- [FBF Filter VFP TCAM Consumption on page 5357](#)
- [MVR Filter VFP TCAM Consumption on page 5358](#)
- [VFP TCAM Consumption Summary Table on page 5359](#)

**FIP Snooping Filter VFP TCAM Consumption**

VN2VF\_Port FIP snooping filters consume VFP TCAM entry space differently than VN2VN\_Port FIP snooping filters:

- [VN2VF\\_Port FIP Snooping Filter VFP TCAM Consumption on page 5357](#)
- [VN2VN\\_Port FIP Snooping Filter VFP TCAM Consumption on page 5357](#)

**NOTE:** One FCoE VLAN cannot support both VN2VF\_Port traffic and VN2VN\_Port traffic. Configure separate FCoE VLANs for VN2VF\_Port traffic and for VN2VN\_Port traffic.

**VN2VF\_Port FIP Snooping Filter VFP TCAM Consumption**

The switch uses an algorithm that allows one 256-entry slice of the VFP TCAM to store the maximum possible number of VN2VF\_Port FIP snooping filters (2500 filters). VN2VF\_Port FIP snooping filters never consume more than one slice of the VFP TCAM.

Regardless of whether there is one VN2VF\_Port FIP snooping session or there are 2500 VN2VF\_Port FIP snooping sessions, VN2VF\_Port FIP snooping filters consume one slice of the VFP TCAM. (If there are no VN2VF\_Port or VN2VN\_Port FIP snooping sessions, the TCAM does not allocate a slice for FIP snooping filters.)

**VN2VN\_Port FIP Snooping Filter VFP TCAM Consumption**

VN2VN\_Port FIP snooping filters consume one VFP TCAM entry for each VN2VN\_Port session. The maximum number of VN2VN\_Port FIP snooping sessions is 376 sessions per switch. (If you configure an interface that carries VN2VN\_Port FIP snooping traffic as a trusted interface, the switch does not apply filters on the trusted interface.)

Because the switch can have up to 376 VN2VN\_Port sessions running simultaneously, with each session consuming one entry, VN2VN\_Port FIP snooping filters consume VFP TCAM space as follows:

- 1–256 filters consume one slice
- 257–376 filters consume two slices

**FBF Filter VFP TCAM Consumption**

Each FBF filter term is double-wide, so each FBF filter term consumes two entries in the VFP TCAM. One 256-entry slice can contain up to 128 FBF filter terms. FBF filters consume VFP TCAM space as follows:

- 1–128 entries consume one slice
- 129–256 entries consume two slices
- 257–384 entries consume three slices
- 385–512 entries consume four slices

**NOTE:** In practice, FBF filters can consume only three slices of the VFP TCAM because FBF filters are also stored simultaneously in the ingress filter processor (IFP) TCAM, and the IFP TCAM can store only 384 FBF filter terms (768 entries, or 3 TCAM slices).

For example, if you configure FBF filters that contain 200 terms, then the FBF filters require 400 VFP TCAM entries and consume 2 slices.

FBF filter entries are simultaneously stored in the VFP TCAM and the IFP TCAM. The IFP TCAM can only contain up to 768 entries—256 fewer entries (1 slice) than the VFP TCAM. As with the VFP TCAM, FBF filters consume two IFP TCAM entries per filter term. In addition to FBF filter terms, the IFP TCAM stores filter entries for firewall filters.

**CAUTION:** There must be enough space in the VFP TCAM *and* the IFP TCAM for the FBF filter entries. If both TCAMs do not have enough space for the FBF filters, the switch rejects the portion of the configuration that it cannot store and sends a syslog message to notify you.

For example, if you configure FBF filters that have 400 terms, even though the VFP TCAM has enough space to store the resulting 800 entries, the switch rejects a portion of the configuration because the IFP TCAM can store a maximum of only 768 entries. If the IFP TCAM stores no other filter entries, the switch rejects 32 FBF filter entries.

In another example, if you configure firewall filters that have a total of 200 terms, which consume 200 entries in the IFP TCAM, and you then configure FBF filters that have a total of 300 terms, the switch rejects a portion of the configuration because the FBF filters require 600 entries. Combined with the 200 entries required for the firewall filters, the total number of 800 entries exceeds the maximum of 768 entries that the IFP TCAM can store. In this case, the switch accepts the first 768 entries and rejects the rest of the filter entries. The switch installs the filter entries in the order that they are committed; the rejected entries are the last entries the switch attempts to commit after the TCAM space is exhausted.

The IFP TCAM limit of 768 entries means that the true maximum number of FBF filter terms is 384 terms, even though the VFP TCAM can store up to 512 FBF terms.

#### ***MVR Filter VFP TCAM Consumption***

Each MVR rule consumes one entry in the VFP TCAM, so MVR rules consume VFP TCAM space as follows:

- 1–256 rules consume one slice
- 257–512 rules consume two slices
- 513–758 rules consume three slices
- 759–1024 rules consume four slices

### VFP TCAM Consumption Summary Table

Table 379 on page 5359 summarizes VFP TCAM consumption.

**NOTE:** FBF filters are simultaneously stored in the VFP TCAM and in the IFP TCAM. Due to the IFP TCAM limit of 768 entries (384 FBF filters), which is 256 entries fewer than the VFP TCAM, the effective VFP TCAM consumption limit for FBF filters is lower than the total amount of VFP TCAM entry space, even when no other filters consume VFP TCAM space.

**Table 379: VFP TCAM Entry Consumption Summary**

Filter Type	VFP TCAM Entry Consumption	Maximum VFP TCAM Slices Consumed	Other Limitations
VN2VF_Port FIP snooping filters	Never consumes more than one slice	One slice (regardless of number of sessions)	2500 session maximum
VN2VN_Port FIP snooping filters	One entry per session	Two	376 session maximum
FBF filters	Two entries per filter	Three (due to IFP TCAM limitation)	384 filters (due to IFP TCAM limitation)
MVR rules	One entry per rule	Four	1024 rule maximum

### Rejected Filter Configurations (No Available VFP TCAM Space)

If there is not enough space available in the VFP TCAM to store the FIP snooping filters, the configured FBF filters, and the MVR rules, the switch rejects only the portion of the configuration that it cannot store. Any portion of the filter configuration that the TCAM can store, is stored. In most cases, even if the switch rejects part of the configuration, part of the configuration is also stored.

If the switch rejects any portion of a configuration, the switch sends a syslog message to notify you of the failure. The switch does not generate a commit error, and the rejected portion of the configuration remains on the switch, even though the rejected configuration does not function. (The accepted portions of the configuration function as expected.) The syslog message shows you the filter configuration that the switch rejected.

We strongly recommend that you always delete rejected filter configurations from the switch. It is important to delete rejected filter configurations because:

- Even though the rejected configuration remains on the switch, it does not function.
- After a reboot, there is no guarantee that the same filters will be rejected. The previously rejected filters might be accepted, and other filters that had previously been accepted might be rejected. Therefore, the functioning filter configuration could be changed inadvertently and unexpectedly.

- Even if a VFP TCAM slice becomes available, the switch does not automatically allocate the available slice to the rejected configuration. To use the available slice, you must delete and reconfigure the rejected configuration.

For example, you configure FBF filters and MVR rules on a switch, and that switch also transports FCoE traffic with VN2VF\_Port FIP snooping (never consumes more than one slice) enabled on FCoE access interfaces. After you commit the configuration, you check the syslog. You find that the VN2VF\_Port FIP snooping and FBF filters consume all four slices of the VFP TCAM, and the MVR configuration was rejected. Instead of deleting the MVR configuration, you leave it on the switch. Subsequently, all VN2VF\_Port FIP snooping sessions end, the FIP snooping filters time out and are removed from the VFP TCAM, so the slice that was allocated to VN2VF\_Port FIP snooping filters becomes free. However, the MVR rules do *not* automatically receive the free slice.

To force the switch to allocate the free slice to the MVR rules, you should delete the MVR rules from the configuration and then reconfigure the MVR rules. When you commit the new configuration, check the syslog messages to ensure that the MVR rule configuration was accepted.

In this example, you could also choose to free a VFP TCAM slice for MVR rule storage by deleting some of the FBF filters. To do this, you delete both the unneeded FBF filters and the MVR rule configuration. Then you reconfigure the MVR rules, and check the syslog to ensure that the configuration was successful.

---

### VFP TCAM Allocation and Consumption (Scaling) Examples

---

The following examples illustrate how FIP snooping entries, FBF filter entries, and MVR rule entries consume VFP TCAM slices:

- [Example 1: Three Filter Types Consume Three Slices on page 5360](#)
- [Example 2: Three Filter Types Consume Four Slices on page 5361](#)
- [Example 3: Two Filter Types Consume Four Slices on page 5361](#)
- [Example 4: Three Filter Types Oversubscribe the VFP TCAM on page 5361](#)

#### ***Example 1: Three Filter Types Consume Three Slices***

Filters and rules are configured in the following sequence:

- 100 VN2VN\_Port FIP snooping filters (1 slice)
- 2 MVR rules (1 slice, 2 entries)
- 60 FBF filter terms (1 slice, 120 entries)

One slice remains free. The slice allocated to VN2VN\_Port FIP snooping filters can store 156 more filters before another slice is required. The slice allocated to MVR rules can store 254 more rules before another slice is required. The slice allocated to FBF filters can store 68 more filter terms (136 entries) before another slice is required. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

**Example 2: Three Filter Types Consume Four Slices**

Filters and rules are configured in the following sequence:

- 2000 VN2VF\_Port FIP snooping filters (always 1 slice)
- 18 MVR rules (1 slice, 18 entries)
- 150 FBF filter terms (2 slices, 300 entries)

All four slices are allocated to filter types. The slice allocated to MVR rules can store 238 more rules before it is full. The slice allocated to FBF filters can store 106 more filter terms (212 entries) before it is full. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

**NOTE:** If you configure more MVR rules or FBF filters than entry space remaining in the slices, the switch rejects those rules and filters because no slice is available. The switch installs filters in the order that they were configured, so if filters are rejected, the filters configured last are rejected.

**Example 3: Two Filter Types Consume Four Slices**

Filters and rules are configured in the following sequence:

- 50 VN2VF\_Port FIP snooping filters (always 1 slice)
- 300 FBF filter terms (3 slices, 600 entries)

All four slices are allocated to filter types. No slices are available for MVR rules. The third slice allocated to FBF filters can store 84 more filter terms (168 entries) before it consumes all of its entry space. Providing that the IFP TCAM has space for the FBF filter terms, the switch accepts this configuration and rejects no filters.

**NOTE:** If you configure MVR rules or if you configure more than 84 more FBF filters, the switch rejects those rules and filters because no slice is available for the MVR rules, and the FBF filter slice has entry space for only 84 more filter terms.

**Example 4: Three Filter Types Oversubscribe the VFP TCAM**

Filters and rules are configured in the following sequence:

- 1750 VN2VF\_Port FIP snooping filters (always 1 slice)
- 10 MVR rules (1 slice, 10 entries)
- 275 FBF filter terms (2 slices, 512 accepted entries, 38 rejected entries)

All four slices are allocated to filter types. The slice allocated to MVR rules can store 246 more rules before it is full, but the number of FBF filter terms exceeds the amount of available VFP TCAM storage space. (The 275 FBF filter terms consume 550 VFP TCAM

entries. However, there are only two available slices, for a total of 512 available entry spaces, so only 256 FBF filter terms can be stored, leaving 19 rejected FBF filter terms.)

The switch accepts the VN2VF\_Port FIP snooping filters, the MVR rules, and 256 FBF filter terms. The switch retains the excess FBF filters in the configuration, but does not install those filters in the VFP TCAM. In this case, you delete the rejected FBF filter terms from the configuration. Alternatively, you could delete the MVR rules from the configuration to free a slice of the TCAM, and then delete and reconfigure the rejected FBF filters so that the system allocates the freed slice to the FBF filters.

**NOTE:** The sequence of configuration makes a difference; if there is not enough VFP TCAM space for a given filter type, the switch installs the filters that fit in the order they are configured. For example, if you configure the FBF filters before you configure the MVR rules, the VFP TCAM allocates one slice to FIP snooping filters, three slices to FBF filters (assuming the IFP TCAM has available space), and no slices to MVR rules, because all four slices are allocated before the switch attempts to install the MVR rules in the VFP TCAM.

---

### Filter Configuration Recommendations

---

To utilize the VFP TCAM space most efficiently:

- [Configure and Maintain the Fewest Number of Filters Needed on page 5362](#)
- [Always Delete Rejected Filter Configurations on page 5363](#)

#### ***Configure and Maintain the Fewest Number of Filters Needed***

To conserve VFP TCAM entry space, and because FBF filter storage also depends on the availability of IFP TCAM space, we recommend that you configure as few FBF filters and MVR rules as is practical to serve your network needs. The more filters you configure, the greater the possibility of exceeding TCAM storage capacity.

Several factors determine VFP TCAM consumption:

- **Type of filters configured**—Different filter types consume different amounts of VFP TCAM space. VN2VF\_Port FIP snooping filters never consume more than one slice. MVR rules and VN2VN\_Port FIP snooping filters consume entries in a slice at a rate of one entry per MVR rule or VN2VN\_Port session. FBF filter terms consume entries in a slice at a rate of two entries per FBF filter term.
- **Number of filters configured**—Although the number of filters does not affect the number of slices allocated to the VN2VF\_Port FIP snooping filter type (it is always one slice for one or more VN2VF\_Port FIP snooping filters and no slice for no FIP snooping filters), the number of VN2VN\_Port FIP snooping filters, MVR rules, and FBF filter terms that you configure determine how many VFP TCAM slices are required for each filter type.

For example, if you configure 257 MVR rules, the MVR rule entries consume 2 slices. One slice stores 256 MVR rules (entries), and one slice stores 1 MVR rule (entry). In this case, if you can eliminate one MVR rule, you can free a slice to allocate to other filter types.

- Sequence of filter configuration—If you configure too many filters for the VFP TCAM to store, the last filters you configure are not stored in the TCAM.

Always check the syslog after you configure FBF filters or MVR rules to ensure that the configuration was not rejected. If you enable FIP snooping on access ports, check the syslog to ensure that the configuration was not rejected due to lack of VFP TCAM space.

If you check the syslog and a filter configuration has been rejected, delete the filters that were rejected from the configuration.

**TIP:** If you no longer need an FBF filter or an MVR rule, delete it from the configuration to conserve VFP TCAM space. Enable VN2VF\_Port or VN2VN\_Port FIP snooping on access ports only if the switch port is directly connected to FCoE devices. (FIP snooping should be performed at the access edge. FIP snooping should not be performed on traffic that has already been snooped and filtered at the access edge. If another switch that is physically between the transit switch (or QFabric system) and the FCoE devices already performs FIP snooping, you do not have to enable FIP snooping on the transit switch or QFabric system, but you can.)

### ***Always Delete Rejected Filter Configurations***

The switch does not return a commit error if it rejects any portion of a configuration. Instead, the switch sends a syslog message to report the rejected portion of the configuration. The rejected portion of the configuration remains on the switch, but does not function.

After you configure FBF filters or MVR rules, or enable FIP snooping, check the syslog messages to ensure that the switch accepted the configuration. If the switch rejected any portion of the configuration, delete that portion of the configuration. (You do not need to delete the portion of the configuration that was accepted, unless you want to reconfigure those filters or rules.)

**CAUTION:** If you do not delete rejected filter configurations, and if you reboot the system, you cannot predict which filters the system installs after the reboot. For example, a switch with the following configuration has more configured filters than the VFP TCAM can support:

- VN2VF\_Port FIP snooping sessions (always consumes one slice)
- 20 MVR rules (consume one slice)
- 300 FBF filters (attempt to consume three slices, but because only two slices are available, 256 filters consume two slices, and the remaining 44 filters are rejected)

If you do not delete the 44 rejected FBF filters, then if the switch reboots, the 44 FBF filters that were rejected might be accepted, and 44 different FBF filters might be rejected. This unpredictable behavior is the reason that you

should check the syslog messages after you configure filters, and if any filters were rejected, you should always delete the rejected filters from the configuration.

## Understanding MC-LAGs on an FCoE Transit Switch

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

You can use an MC-LAG to provide a redundant aggregation layer for Fibre Channel over Ethernet (FCoE) traffic. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because MC-LAGs do not carry forwarding class and IEEE 802.1p priority information.

Ports that are part of an FCoE-FC gateway configuration (a virtual FCoE-FC gateway fabric) do not support MC-LAGs. Ports that are members of an MC-LAG act as passthrough transit switch ports.

Standalone switches support MC-LAGs. QFabric system Node devices do not support MC-LAGs. Virtual Chassis (VC) and mixed-mode Virtual Chassis Fabric (VCF) configurations do not support FCoE. Only pure QFX5100 VCFs (consisting of only QFX5100 switches) support FCoE.

This topic describes:

- [Supported Topology on page 5365](#)
- [FIP Snooping and FCoE Trusted Ports on page 5367](#)
- [CoS and Data Center Bridging \(DCB\) on page 5368](#)

---

### Supported Topology

Switches that are not directly connected to FCoE hosts and that act as passthrough transit switches support MC-LAGs for FCoE traffic in an *inverted-U* network topology. [Figure 211 on page 5366](#) shows an inverted-U topology using QFX3500 switches.

Figure 211: Supported Topology for an MC-LAG on an FCoE Transit Switch

9041307

The following rules and guidelines apply to MC-LAGs when used for FCoE traffic. The rules and guidelines help ensure the proper handling and lossless transport characteristics required for FCoE traffic:

- The two switches that form the MC-LAG (Switches S1 and S2) cannot use ports that are part of an FCoE-FC gateway fabric. The MC-LAG switch ports must be passthrough transit switch ports (used as part of an intermediate transit switch that is not directly connected to FCoE hosts).
- MC-LAG Switches S1 and S2 cannot be directly connected to the FCoE hosts.
- The two switches that serve as access devices for FCoE hosts (FCoE Transit Switches TS1 and TS2) use standard LAGs to connect to MC-LAG Switches S1 and S2. FCoE Transit Switches TS1 and TS2 can be standalone switches or they can be Node devices in a QFabric system.
- Transit Switches TS1 and TS2 must use transit switch ports for the FCoE hosts and for the standard LAGs to MC-LAG Switches S1 and S2.
- Enable FIP snooping on the FCoE VLAN on Transit Switches TS1 and TS2. You can configure either VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping or VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping, depending on whether the FCoE hosts need to access targets in the FC SAN (VN2VF\_Port FIP snooping) or targets in the Ethernet network (VN2VN\_Port FIP snooping).

FIP snooping should be performed at the access edge and is not supported on MC-LAG switches. Do not enable FIP snooping on MC-LAG Switches S1 and S2. (Do not enable FIP snooping on the MC-LAG ports that connect Switches S1 and S2 to Switches TS1 and TS2 or on the LAG ports that connect Switch S1 to S2.)

- The CoS configuration must be consistent on the MC-LAG switches. Because MC-LAGs carry no forwarding class or priority information, each MC-LAG switch needs to have

the same CoS configuration to support lossless transport. (On each MC-LAG switch, the name, egress queue, and CoS provisioning of each forwarding class must be the same, and the priority-based flow control (PFC) configuration must be the same.)

### ***Transit Switches (Server Access)***

The role of FCoE Transit Switches TS1 and TS2 is to connect FCoE hosts in a multihomed fashion to the MC-LAG switches. In essence, Transit Switches TS1 and TS2 act as access switches for the FCoE hosts. (FCoE hosts are directly connected to Transit Switches TS1 and TS2.)

The transit switch configuration depends on whether you want to do VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, and whether the transit switches also have ports configured as part of an FCoE-FC gateway virtual fabric. Ports that a QFX3500 switch uses in an FCoE-FC gateway virtual fabric cannot be included in the transit switch LAG connection to the MC-LAG switches. (Ports cannot belong to both a transit switch and an FCoE-FC gateway; you must use different ports for each mode of operation.)

### ***MC-LAG Switches (FCoE Aggregation)***

The role of MC-LAG Switches S1 and S2 is to provide redundant, load-balanced connections between FCoE transit switches. In essence, MC-LAG Switches S1 and S2 act as aggregation switches. FCoE hosts are not directly connected to the MC-LAG switches.

The MC-LAG switch configuration is the same regardless of which type of FIP snooping that FCoE Transit Switches TS1 and TS2 perform.

## **FIP Snooping and FCoE Trusted Ports**

To maintain secure access, enable VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping at the transit switch access ports connected directly to the FCoE hosts. FIP snooping should be performed at the access edge of the network to prevent unauthorized access. For example, in [Figure 211 on page 5366](#), you enable FIP snooping on the FCoE VLANs on Transit Switches TS1 and TS2 that include the access ports connected to the FCoE hosts.

Do not enable FIP snooping on the switches used to create the MC-LAG. For example, in [Figure 211 on page 5366](#), you would not enable FIP snooping on the FCoE VLANs on Switches S1 and S2.

Configure links between switches as FCoE trusted ports to reduce FIP snooping overhead and ensure that the system performs FIP snooping only at the access edge. In the sample topology, configure the Transit Switch TS1 and TS2 LAG ports connected to the MC-LAG switches as FCoE trusted ports, configure the Switch S1 and S2 MC-LAG ports connected to Switches TS1 and TS2 as FCoE trusted ports, and configure the ports in the LAG that connects Switches S1 to S2 as FCoE trusted ports.

## CoS and Data Center Bridging (DCB)

---

The MC-LAG links do not carry forwarding class or priority information. The following CoS properties must have the same configuration on each MC-LAG switch or on each MC-LAG interface to support lossless transport:

- FCoE forwarding class name—For example, the forwarding class for FCoE traffic could use the default **fcoe** forwarding class on both MC-LAG switches.
- FCoE output queue—For example, the **fcoe** forwarding class could be mapped to queue 3 on both MC-LAG switches (queue 3 is the default mapping for the **fcoe** forwarding class).
- Classifier—The forwarding class for FCoE traffic must be mapped to the same IEEE 802.1p code point on each member interface of the MC-LAG on both MC-LAG switches. For example, the FCoE forwarding class **fcoe** could be mapped to IEEE 802.1p code point **011** (code point **011** is the default mapping for the **fcoe** forwarding class).
- Priority-based flow control (PFC)—PFC must be enabled on the FCoE code point on each MC-LAG switch and applied to each MC-LAG interface using a congestion notification profile.

You must also configure enhanced transmission selection (ETS) on the MC-LAG interfaces to provide sufficient scheduling resources (bandwidth, priority) for lossless transport. The ETS configuration can be different on each MC-LAG switch, as long as enough resources are scheduled to support lossless transport for the expected FCoE traffic.

LLDP and DCBX must be enabled on each MC-LAG member interface (LLDP and DCBX are enabled by default on all interfaces).

**NOTE:** As with all other FCoE configurations, FCoE traffic requires a dedicated VLAN that carries only FCoE traffic, and IGMP snooping must be disabled on the FCoE VLAN.

## Understanding DCBX

Data Center Bridging Capability Exchange protocol (DCBX) is an extension of Link Layer Data Protocol (LLDP). If you disable LLDP on an interface, that interface cannot run DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit operation fails. Data center bridging (DCB) devices use DCBX to exchange configuration information with directly connected peers.

Video: [What is DCBX Protocol?](#)

This topic describes:

- [DCBX Basics on page 5369](#)
- [DCBX Modes and Support on page 5370](#)
- [DCBX Attribute Types on page 5373](#)
- [DCBX Application Protocol TLV Exchange on page 5374](#)
- [DCBX and PFC on page 5375](#)
- [DCBX and ETS on page 5375](#)

### DCBX Basics

DCBX can:

- Discover the DCB capabilities of peers.
- Detect DCB feature misconfiguration or mismatches between peers.
- Configure DCB features on peers.

You can configure DCBX operation for priority-based flow control (PFC), Layer 2 and Layer 4 applications such as FCoE and iSCSI, and ETS. DCBX is enabled or disabled on a per-interface basis.

By default, for PFC and ETS, DCBX automatically negotiates administrative state and configuration with each interface's connected peer. To enable DCBX negotiation for applications, you must configure the applications, map them to IEEE 802.1p code points in an application map, and apply the application map to interfaces.

The FCoE application only needs to be included in an application map when you want an interface to exchange type, length, and values (TLVs) for other applications in addition to FCoE. If FCoE is the only application you want an interface to advertise, then you do not need to use an application map. For ETS, DCBX pushes the switch configuration to peers if they are set to learn the configuration from the switch (unless you disable sending the ETS recommendation TLV on interfaces in IEEE DCBX mode).

You can override the default behavior for PFC, for ETS, or for all applications mapped to an interface by turning off autonegotiation to force an interface to enable or disable that feature. You can also disable DCBX autonegotiation for applications on an interface by

excluding those applications from the application map you apply to that interface or by deleting the application map from the interface.

The default autonegotiation behavior for applications that are mapped to an interface is:

- DCBX is enabled on the interface if the connected peer device also supports DCBX.
- DCBX is disabled on the interface if the connected peer device does not support DCBX.

During negotiation of capabilities, the switch can push the PFC configuration to an attached peer if the peer is configured as “willing” to learn the PFC configuration from other peers. The Juniper Networks switch does not support self autoprovisioning and does not change its configuration during autonegotiation to match the peer configuration. (The Juniper switch is not “willing” to learn the PFC configuration from peers.)

**NOTE:** When a port with DCBX enabled begins to exchange type, length, and value (TLV) entries, optional LLDP TLVs on that port are not advertised to neighbors, so that the switch can interoperate with a wider variety of converged network adapters (CNAs) and Layer 2 switches that support DCBX.

---

## DCBX Modes and Support

This section describes DCBX support:

- [DCBX Modes \(Versions\) on page 5370](#)
- [Autonegotiation on page 5372](#)
- [CNA Support for DCBX Modes on page 5373](#)
- [Interface Support for DCBX on page 5373](#)

### ***DCBX Modes (Versions)***

The two most common DCBX modes are supported:

- IEEE DCBX—The newest DCBX version. Different TLVs have different subtypes (for example, the subtype for the ETS configuration TLV is 9); the IEEE DCBX Organizationally Unique Identifier (OUI) is 0x0080c2.
- DCBX version 1.01—The Converged Enhanced Ethernet (CEE) version of DCBX. It has a subtype of 2 and an OUI of 0x001b21.

IEEE DCBX and DCBX version 1.01 differ mainly in frame format. DCBX version 1.01 uses one TLV that includes all DCBX attribute information, which is sent as sub-TLVs. IEEE DCBX uses a unique TLV for each DCB attribute.

**NOTE:** The switch does not support pre-CEE (pre-DCB) DCBX versions. Unsupported older versions of DCBX have a subtype of 1 and an OUI of 0x001b21. The switch drops LLDP frames that contain pre-CEE DCBX TLVs.

Table 380 on page 5371 summarizes the differences between IEEE DCBX and DCBX version 1.01, including show command output:

**Table 380: Summary of Differences Between IEEE DCBX and DCBX Version 1.01**

Characteristic	IEEE DCBX	DCBX Version 1.01
OUI	0x0080c2	0x001b21
Frame Format	Sends a separate, unique TLV for each DCBX attribute. For example, IEEE DCBX uses separate TLVs for ETS, PFC, and each application. Configuration and Recommendation information is sent in different TLVs	Sends one TLV that includes all DCBX attribute information organized in sub-TLVs. The “willing” bit determines whether or not an interface can change its configuration to match the connected peer.
Symmetric/asymmetric configuration with peer	Asymmetric or symmetric	Symmetric only
Differences in the <b>show dcbx interface interface-name</b> operational command	<ul style="list-style-type: none"> <li>• Synchronization information is not shown because symmetric configuration is not required.</li> <li>• Operational state information is not shown because the operational states do not have to be symmetric.</li> <li>• TLV type is shown because unique TLVs are sent for each DCBX attribute.</li> <li>• ETS peer Configuration TLV and Recommendation TLV information is shown separately because they are different TLVs.</li> </ul>	<ul style="list-style-type: none"> <li>• Synchronization information is shown because symmetric configuration is required.</li> <li>• Operational state information is shown because the operational states do have to be symmetric.</li> <li>• TLV type is not shown because one TLV is used for all attribute information.</li> <li>• Recommendation TLV is not sent (DCBX Version 1.01 uses the “willing” bit to determine whether or not an interface uses the peer interface configuration).</li> </ul>

For more information about how each DCBX mode exchanges TLVs, see the following specifications:

- For DCBX version 1.01—<http://www.ieee802.org/1/files/public/docs2008/az-wedekar-dcbx-capability-exchange-discovery-protocol-1108-v1.01.pdf>
- For IEEE DCBX—<http://www.ieee802.org/1/files/private/az-drafts/d2/802-1az-d2-4.pdf>

**NOTE:** As of Junos OS Release 12.2, this document is located in a private area of the IEEE website, and access requires a password from the IEEE organization. If you are not an IEEE member, you might not be able to access this document until it moves to the public area of the IEEE website.

You can configure interfaces to use the following DCBX modes:

- IEEE DCBX—The interface uses IEEE DCBX regardless of the configuration on the connected peer.
- DCBX version 1.01—The interface uses DCBX version 1.01 regardless of the configuration on the connected peer.
- Autonegotiation—The interface automatically negotiates with the connected peer to determine the DCBX version the peers use. Autonegotiation is the default DCBX mode.

If you configure a DCBX mode on an interface, the interface ignores DCBX protocol data units (PDUs) it receives from the connected peer if the PDUs do not match the DCBX version configured on the interface. For example, if you configure an interface to use IEEE DCBX and the connected peer sends DCBX version 1.01 LLDP PDUs, the interface ignores the version 1.01 PDUs. If you configure an interface to use DCBX version 1.01 and the peer sends IEEE DCBX LLDP PDUs, the interface ignores the IEEE DCBX PDUs.

**NOTE:** On interfaces that use the IEEE DCBX mode, the `show dcbx neighbors interface interface-name` operational command does not include application, PFC, or ETS operational state in the output.

---

### ***Autonegotiation***

Autonegotiation is the default DCBX mode. Each interface automatically negotiates with its connected peer to determine the DCBX version that both interfaces use to exchange DCBX information.

When an interface connects to its peer interface, the interface advertises IEEE DCBX TLVs to the peer. If the interface receives one IEEE DCBX PDU from the peer, the interface sets the DCBX mode as IEEE DCBX. If the interface receives three DCBX version 1.01 TLVs from the peer, the interface sets DCBX version 1.01 as the DCBX mode.

Autonegotiation works slightly differently on standalone switches compared to QFabric systems:

- Standalone switches—When an interface connects to its peer interface, the interface advertises IEEE DCBX TLVs to the peer. If the interface receives an IEEE DCBX TLV from the peer, the interface sets IEEE DCBX as the DCBX mode. If the interface receives three consecutive DCBX version 1.01 TLVs from the peer, the interface sets DCBX version 1.01 as the DCBX mode.
- QFabric system—When an interface connects to its peer interface, the interface advertises DCBX version 1.01 TLVs to the peer. If the interface receives an IEEE DCBX TLVs from the peer, the interface sets IEEE DCBX as the DCBX mode. If the interface receives three consecutive DCBX version 1.01 TLVs from the peer, the interface retains DCBX version 1.01 as the DCBX mode.

**NOTE:** If the link flaps or the LLDP process restarts, the interface starts the autonegotiation process again. The interface does not use the last received DCBX communication mode.

---

### ***CNA Support for DCBX Modes***

Different CNA vendors support different versions and capabilities of DCBX. The DCBX configuration you use on switch interfaces depends on the DCBX features that the CNAs in your network support.

### ***Interface Support for DCBX***

You can configure DCBX on 10-Gigabit Ethernet interfaces and on link aggregation group (LAG) interfaces whose member interfaces are all 10-Gigabit Ethernet interfaces.

### **DCBX Attribute Types**

DCBX has three attribute types:

- **Informational**—These attributes are exchanged using LLDP, but do not affect DCBX state or operation; they only communicate information to the peer. For example, application priority TLVs are informational TLVs.
- **Asymmetric**—The values for these types of attributes do not have to be the same on the connected peer interfaces. Peers exchange asymmetric attributes when the attribute values can differ on each peer interface. The peer interface configurations might match or they might differ. For example, ETS Configuration and Recommendation TLVs are asymmetric TLVs.
- **Symmetric**—The intention is that the values for these types of attributes should be the same on both of the connected peer interfaces. Peer interfaces exchange symmetric attributes to ensure symmetric DCBX configuration for those attributes. For example, PFC Configuration TLVs are symmetric TLVs.

The following sections describe asymmetric and symmetric DCBX attributes:

- [Asymmetric Attributes on page 5373](#)
- [Symmetric Attributes on page 5374](#)

### ***Asymmetric Attributes***

DCBX passes asymmetric attributes between connected peer interfaces to communicate parameter information about those attributes (features). The resulting configuration for an attribute might be different on each peer, so the parameters configured on one interface might not match the parameters on the connected peer interface.

There are two types of asymmetric attribute TLVs:

- **Configuration TLV**—Configuration TLVs communicate the current operational state and the state of the “willing” bit. The “willing” bit communicates whether or not the interface is willing to accept and use the configuration from the peer interface. If an interface is “willing,” the interface uses the configuration it receives from the peer interface. (The peer interface configuration can override the configuration on the “willing” interface.) If an interface is “not willing,” the configuration on the interface cannot be overridden by the peer interface configuration.
- **Recommendation TLV**—Recommendation TLVs communicate the parameters the interface recommends that the connected peer interface should use. When an interface

sends a Recommendation TLV, if the connected peer is “willing,” the connected peer changes its configuration to match the parameters in the Recommendation TLV.

### ***Symmetric Attributes***

DCBX passes symmetric attributes between connected peer interfaces to communicate parameter information about those attributes (features), with the objective that both interfaces should use the same configuration. The intent is that the parameters configured on one interface should match the parameters on the connected peer interface.

There is one type of symmetric attribute TLV, the Configuration TLV. As with asymmetric attributes, symmetric attribute Configuration TLVs communicate the current operational state and the state of the “willing” bit. “Willing” interfaces use the peer interface parameter values for the attribute. (The attribute configuration of the peer overrides the configuration on the “willing” interface.)

### **DCBX Application Protocol TLV Exchange**

---

DCBX advertises the switch’s capabilities for Layer 2 applications such as FCoE and Layer 4 applications such as iSCSI:

- [Application Protocol TLV Exchange on page 5374](#)
- [FCoE Application Protocol TLV Exchange on page 5374](#)
- [Disabling Application Protocol TLV Exchange on page 5375](#)

### ***Application Protocol TLV Exchange***

For all applications, DCBX advertises the application’s state and IEEE 802.1p code points on the interfaces to which the application is mapped. If an application is not mapped to an interface, that interface does not advertise the application’s TLVs. There is an exception for FCoE application protocol TLV exchange when FCoE is the only application you want DCBX to advertise on an interface.

### ***FCoE Application Protocol TLV Exchange***

Protocol TLV exchange for the FCoE application depends on whether FCoE is the only application you want the interface to advertise or whether you want the interface to exchange other application TLVs in addition to FCoE TLVs.

If FCoE is the only application you want DCBX to advertise on an interface, DCBX exchanges FCoE application protocol TLVs by default if the interface:

- Carries FCoE traffic (traffic mapped by CoS configuration to the FCoE forwarding class)
- Has a congestion notification profile with PFC enabled on the FCoE priority (IEEE 802.1p code point)
- Does *not* have an application map

**NOTE:** If no CoS configuration for FCoE is mapped to an interface, that interface does not exchange FCoE application protocol TLVs.

---

If you want DCBX to advertise FCoE and other applications on an interface, you must specify all of the applications, including FCoE, in an application map, and apply the application map to the desired interfaces.

**NOTE:** If an application map is applied to an interface, the FCoE application must be explicitly configured in the application map, or the interface does not exchange FCoE TLVs.

When DCBX advertises the FCoE application, it advertises the FCoE state and IEEE 802.1p code points. If a peer device connected to a switch interface does not support FCoE, DCBX uses autonegotiation to mark the interface as “FCoE down,” and FCoE is disabled on that interface.

### ***Disabling Application Protocol TLV Exchange***

To disable DCBX application protocol exchange for all applications on an interface, issue the **set protocols dcbx interface *interface-name* applications no-auto-negotiation** command.

You can also disable DCBX application protocol exchange for applications on an interface by deleting the application map from the interface, or by deleting a particular application from the application map. However, when you delete an application from an application map, the application protocol is no longer exchanged on any interface which uses that application map.

## **DCBX and PFC**

After you enable PFC on a switch interface, DCBX uses autonegotiation to control the operational state of the PFC functionality.

If the peer device connected to the interface supports PFC and is provisioned compatibly with the switch, DCBX sets the PFC operational state to enabled. If the peer device connected to the interface does not support PFC or is not provisioned compatibly with the switch, DCBX sets the operational state to disabled. (PFC must be symmetrical.)

If the peer advertises that it is “willing” to learn its PFC configuration from the switch, DCBX pushes the switch’s PFC configuration to the peer and does not check the peer’s administrative state.

You can manually override DCBX control of the PFC operational state on a per-interface basis by disabling autonegotiation. If you disable autonegotiation on an interface on which you have configured PFC, then PFC is enabled on that interface regardless of the peer configuration. To disable PFC on an interface, do not configure PFC on that interface.

## **DCBX and ETS**

This section describes:

- [Default DCBX ETS Advertisement on page 5376](#)
- [ETS Advertisement and Peer Configuration on page 5376](#)
- [ETS Recommendation TLV on page 5376](#)

### ***Default DCBX ETS Advertisement***

If you do not configure ETS on an interface, the switch automatically creates a default priority group that contains all of the priorities (forwarding classes, which represent output queues) and assigns 100 percent of the port output bandwidth to that priority group. The default priority group is transparent. It does not appear in the configuration and is used for DCBX advertisement. DCBX advertises the default priority group, its priorities, and the assigned bandwidth.

If you configure ETS on an interface, DCBX advertises:

- Each priority group on the interface
- The priorities in each priority group
- The bandwidth properties of each priority group and priority

Any priority on that interface that is not part of an explicitly configured priority group (forwarding class set) is assigned to the automatically generated default priority group and receives no bandwidth. If you configure ETS on an interface, every forwarding class (priority) on that interface for which you want to forward traffic must belong to a forwarding class set (priority group).

### ***ETS Advertisement and Peer Configuration***

DCBX does not control the switch's ETS (hierarchical scheduling) operational state. If the connected peer is configured as "willing," DCBX pushes the switch's ETS configuration to the switch's peers if the ETS Recommendation TLV is enabled (it is enabled by default). If the peer does not support ETS or is not consistently provisioned with the switch, DCBX does not change the ETS operational state on the switch. The ETS operational state remains enabled or disabled based only on the switch hierarchical scheduling configuration and is enabled by default.

When ETS is configured, DCBX advertises the priority groups, the priorities in the priority groups, and the bandwidth configuration for the priority groups and priorities. Any priority (essentially a forwarding class or queue) that is not part of a priority group has no scheduling properties and receives no bandwidth.

You can manually override whether DCBX advertises the ETS state to the peer on a per-interface basis by disabling autonegotiation. This does not affect the ETS state on the switch or on the peer, but it does prevent the switch from sending the Recommendation TLV or the Configuration TLV to the connected peer. To disable ETS on an interface, do not configure priority groups (forwarding class sets) on the interface.

### ***ETS Recommendation TLV***

The ETS Recommendation TLV communicates the ETS settings that the switch wants the connected peer interface to use. If the peer interface is "willing," it changes its configuration to match the configuration in the ETS Recommendation TLV. By default, the switch interfaces send the ETS Recommendation TLV to the peer. The settings communicated are the egress ETS settings defined by configuring hierarchical scheduling on the interface.

We recommend that you use the same ETS settings on the connected peer that you use on the switch interface and that you leave the ETS Recommendation TLV enabled. However, on interfaces that use IEEE DCBX as the DCBX mode, if you want an asymmetric configuration between the switch interface and the connected peer, you can disable the ETS Recommendation TLV by including the **no-recommendation-tlv** statement at the **[edit protocols dcbx interface *interface-name* enhanced-transmission-selection]** hierarchy level.

**NOTE:** You can disable the ETS Recommendation TLV only when the DCBX mode on the interface is IEEE DCBX. Disabling the ETS Recommendation TLV has no effect if the DCBX mode on the interface is DCBX version 1.01. (IEEE DCBX uses separate application attribute TLVs, but DCBX version 1.01 sends all application attributes in the same TLV and uses sub-TLVs to separate the information.)

If you disable the ETS Recommendation TLV, the switch still sends the ETS Configuration TLV to the connected peer. The result is that the connected peer is informed about the switch DCBX ETS configuration, but even if the peer is “willing,” the peer does not change its configuration to match the switch configuration. This is asymmetric configuration—the two interfaces can have different parameter values for the ETS attribute.

For example, if you want a CNA connected to a switch interface to have different bandwidth allocations than the switch ETS configuration, you can disable the ETS Recommendation TLV and configure the CNA for the desired bandwidth. The switch interface and the CNA exchange configuration parameters, but the CNA does not change its configuration to match the switch interface configuration.

## Understanding DCBX Application Protocol TLV Exchange

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of connected peers. DCBX also advertises the capabilities of applications on interfaces by exchanging application protocol information through application type, length, and value (TLV) elements. DCBX is an extension of Link Layer Discovery Protocol (LLDP). LLDP must remain enabled on every interface on which you want to use DCBX.

**NOTE:** LLDP and DCBX are enabled by default on all interfaces.

---

Setting up application protocol exchange consists of:

- Defining applications
- Mapping the applications to IEEE 802.1p code points in an *application map*
- Configuring classifiers to prioritize incoming traffic and map the incoming traffic to the application by the traffic code points
- Applying the application maps and classifiers to interfaces

You need to explicitly define the applications that you want an interface to advertise. The FCoE application is a special case (see [“Applications” on page 5378](#)) and only needs to be defined on an interface if you want DCBX to exchange application protocol TLVs for other applications in addition to FCoE on that interface.

You also need to explicitly map all defined applications that you want an interface to advertise to IEEE 802.1p code points in an application map. The FCoE application is a special case (see [“Application Maps” on page 5379](#)) and only requires inclusion in an application map when you want an interface to use DCBX for other applications in addition to FCoE, as described later in this topic.

This topic describes:

- [Applications on page 5378](#)
- [Application Maps on page 5379](#)
- [Classifying and Prioritizing Application Traffic on page 5380](#)
- [Enabling Interfaces to Exchange Application Protocol Information on page 5381](#)
- [Disabling DCBX Application Protocol Exchange on page 5381](#)

---

### Applications

Before an interface can exchange application protocol information, you need to define the applications that you want to advertise, except FCoE if FCoE is the only application that you want the interface to advertise.

**NOTE:** If FCoE is the only application that you want DCBX to advertise on an interface, DCBX exchanges FCoE application protocol TLVs by default if the interface:

- Carries FCoE traffic (traffic mapped by CoS configuration to the FCoE forwarding class and applied to the interface)
- Has a congestion notification profile with PFC enabled on the FCoE priority (IEEE 802.1p code point)
- Does *not* have an application map

If you apply an application map to an interface, then all applications that you want DCBX to advertise must be defined and configured in the application map, including the FCoE application.

If no CoS configuration for FCoE is mapped to an interface, that interface does not exchange FCoE application protocol TLVs.

You can define:

- Layer 2 applications by EtherType
- Layer 4 applications by a combination of protocol (TCP or UDP) and destination port number

The EtherType is a two-octet field in the Ethernet frame that denotes the protocol encapsulated in the frame. For a list of common EtherTypes, see <http://standards.ieee.org/develop/regauth/ethertype/eth.txt> on the IEEE standards organization website. For a list of port numbers and protocols, see the *Service Name and Transport Protocol Port Number Registry* at <http://www.iana.org/assignments/service-names-port-numbers/service-names-port-numbers.xml> on the Internet Assigned Numbers Authority (IANA) website.

You must explicitly define each application that you want to advertise, except FCoE. The FCoE application is defined by default (EtherType 0x8906).

### Application Maps

An application map maps defined applications to one or more IEEE 802.1p code points. Each application map contains one or more applications. DCBX includes the configured application code points in the protocol TLVs exchanged with the connected peer.

To exchange protocol TLVs for an application, you must include the application in an application map. The FCoE application is a special case:

- If you want DCBX to exchange application protocol TLVs for more than one application on a particular interface, you must configure the applications, define an application map to map the applications to code points, and apply the application map to the interface. In this case, you must also define the FCoE application and add it to the application map.

This is the same process and treatment required for all other applications. In addition, for DCBX to exchange FCoE application TLVs, you must enable priority-based flow control (PFC) on the FCoE priority (the FCoE IEEE 802.1p code point) on the interface.

- If FCoE is the only application that you want DCBX to advertise on an interface, then you do not need to configure an application map and apply it to the interface. By default, when an interface has no application map, and the interface carries traffic mapped to the FCoE forwarding class, and PFC is enabled on the FCoE priority, the interface advertises FCoE TLVs (autonegotiation mode). DCBX exchanges FCoE application protocol TLVs by default until you apply an application map to the interface, remove the FCoE traffic from the interface (you can do this by removing the or editing the classifier for FCoE traffic), or disable PFC on the FCoE priority.

If you apply an application map to an interface that did not have an application map and was exchanging FCoE application TLVs, and you do not include the FCoE application in the application map, the interface stops exchanging FCoE TLVs. Every interface that has an application map must have FCoE included in the application map (and PFC enabled on the FCoE priority) in order for DCBX to exchange FCoE TLVs.

Mapping an application to code points does two things:

- Maps incoming traffic with the same code points to that application
- Allows you to configure classifiers that map incoming application traffic, by code point, to a forwarding class and a loss priority, in order to apply class of service (CoS) to application traffic and prioritize application traffic

You apply an application map to an interface to enable DCBX application protocol exchange on that interface for each application specified in the application map. All of the applications that you want an interface to advertise must be configured in the application map that you apply to the interface, with the previously noted exception for the FCoE application when FCoE is the only application for which you want DCBX to exchange protocol TLVs on an interface.

---

### Classifying and Prioritizing Application Traffic

---

When traffic arrives at an interface, the interface classifies the incoming traffic based on its code points. Classifiers map code points to loss priorities and forwarding classes. The loss priority prioritizes the traffic. The forwarding class determines the traffic output queue and CoS service level.

When you map an application to an IEEE 802.1p code point in an application map and apply the application map to an interface, incoming traffic on the interface that matches the application code points is mapped to the appropriate application. The application receives the loss priority and the CoS associated with the forwarding class for those code points, and is placed in the output queue associated with the forwarding class.

You can use the default classifier or you can configure a classifier to map the application code points defined in the application map to forwarding classes and loss priorities.

### Enabling Interfaces to Exchange Application Protocol Information

Each interface with the **fcoe** forwarding class and PFC enabled on the FCoE code point is enabled for FCoE application protocol exchange by default until you apply an application map to the interface. If you apply an application map to an interface and you want that interface to exchange FCoE application protocol TLVs, you must include the FCoE application in the application map. (In all cases, to achieve lossless transport, you must also enable PFC on the FCoE code point or code points.)

Except when FCoE is the only protocol you want DCBX to advertise on an interface, interfaces on which you want to exchange application protocol TLVs must include the following two items:

- The application map that contains the application(s)
- A classifier

**NOTE:** You must also enable PFC on the code point of any traffic for which you want to achieve lossless transport.

### Disabling DCBX Application Protocol Exchange

To disable DCBX application protocol exchange for all applications on an interface, issue the **set protocols dcbx interface *interface-name* applications no-auto-negotiation** command.

You can also disable DCBX application protocol exchange for applications on an interface by deleting the application map from the interface, or by deleting a particular application from the application map. However, when you delete an application from an application map, the application protocol is no longer exchanged on any interface which uses that application map.

On interfaces that use IEEE DCBX mode to exchange DCBX parameters, you can disable sending the enhanced transmission selection (ETS) Recommendation TLV to the peer if you want an asymmetric ETS configuration between the peers.

## Understanding CoS Flow Control (Ethernet PAUSE and PFC)

Flow control supports lossless transmission by regulating traffic flows to avoid dropping frames during periods of congestion. Flow control stops and resumes the transmission of network traffic between two connected peer nodes on a full-duplex Ethernet physical link. Controlling the flow by pausing and restarting it prevents buffers on the nodes from overflowing and dropping frames. You configure flow control on a per-interface basis.

Two methods of peer-to-peer flow control are supported:

- IEEE 802.3X Ethernet PAUSE
- IEEE 802.1Qbb priority-based flow control (PFC)

Ethernet PAUSE and PFC are link-level flow control mechanisms.

**NOTE:** For end-to-end congestion control, see *Understanding CoS Explicit Congestion Notification*.

Ethernet PAUSE pauses transmission of all traffic on a physical Ethernet link.

PFC decouples the pause function from the physical Ethernet link and enables you to divide traffic on one link into eight priorities. You can think of the eight priorities as eight “lanes” of traffic that are mapped to forwarding classes and output queues. Each priority is mapped to a 3-bit IEEE 802.1p CoS code point flag in the VLAN header. You can enable PFC on one or more priorities (IEEE 802.1p code points) on a link. When PFC-enabled traffic is paused on a link, traffic that is not PFC-enabled continues to flow (or is dropped if congestion is severe enough).

**Video:** [Why Use PFC in a Data Center Network?](#)

Use Ethernet PAUSE when you want to prevent packet loss on all of the traffic on a link. Use PFC to prevent traffic loss only on specified types of traffic (for example, Fibre Channel over Ethernet traffic).

**NOTE:** Depending on the amount of traffic on a link or assigned to a priority, pausing traffic can cause ingress port congestion and spread congestion through the network.

Attempting to configure both Ethernet PAUSE and PFC on a link causes a commit error. Ethernet PAUSE and PFC are mutually exclusive configurations on an interface.

By default, all forms of flow control are disabled. You must explicitly enable flow control on interfaces to pause traffic.

- [Ethernet PAUSE on page 5384](#)

- [PFC on page 5388](#)
- [Lossless Transport Support Summary on page 5391](#)

## Ethernet PAUSE

---

Ethernet PAUSE is a congestion relief feature that works by providing link-level flow control for all traffic on a full-duplex Ethernet link. Ethernet PAUSE works in both directions on the link. In one direction, an interface generates and sends Ethernet PAUSE messages to stop the connected peer from sending more traffic. In the other direction, the interface responds to Ethernet PAUSE messages it receives from the connected peer to stop sending traffic. Ethernet PAUSE also works on aggregated Ethernet interfaces. For example, if the connected peer interfaces are called Node A and Node B:

- When the receive buffers on interface Node A reach a certain level of fullness, the interface generates and sends an Ethernet PAUSE message to the connected peer (interface Node B) to tell the peer to stop sending frames. The Node B buffers store frames until the time period specified in the Ethernet PAUSE frame elapses; then Node B resumes sending frames to Node A.
- When interface Node A receives an Ethernet PAUSE message from interface Node B, interface Node A stops transmitting frames until the time period specified in the Ethernet PAUSE frame elapses; then Node A resumes transmission. (The Node A transmit buffers store frames until Node A resumes sending frames to Node B.)

In this scenario, if Node B sends an Ethernet PAUSE frame with a time value of 0 to Node A, the 0 time value indicates to Node A that it can resume transmission. This happens when the Node B buffer empties to below a certain threshold and the buffer can once again accept traffic.

*Symmetric flow control* means an interface has the same Ethernet PAUSE configuration in both directions. The Ethernet PAUSE generation and Ethernet PAUSE response functions are both configured as enabled, or they are both disabled. You configure symmetric flow control by including the **flow-control** statement at the **[edit interfaces interface-name ether-options]** hierarchy level.

*Asymmetric flow control* allows you to configure the Ethernet PAUSE functionality in each direction independently on an interface. The configuration for generating Ethernet PAUSE messages and for responding to Ethernet PAUSE messages does not have to be the same. It can be enabled in both directions, disabled in both directions, or enabled in one direction and disabled in the other direction. You configure asymmetric flow control by including the **configured-flow-control** statement at the **[edit interfaces interface-name ether-options]** hierarchy level.

On any particular interface, symmetric and asymmetric flow control are mutually exclusive. Asymmetric flow control overrides and disables symmetric flow control. (If PFC is configured on an interface, the PFC configuration overrides Ethernet PAUSE flow control.) Both symmetric and asymmetric flow control are supported.

- [Symmetric Flow Control on page 5385](#)
- [Asymmetric Flow Control on page 5385](#)

### ***Symmetric Flow Control***

Symmetric flow control configures both the receive and transmit buffers in the same state. The interface can both send Ethernet PAUSE messages and respond to them (flow control is enabled), or the interface cannot send Ethernet PAUSE messages or respond to them (flow control is disabled).

When you enable symmetric flow control on an interface, the Ethernet PAUSE behavior depends on the configuration of the connected peer. With symmetric flow control enabled, the interface can perform any Ethernet PAUSE functions that the connected peer can perform. (When symmetric flow control is disabled, the interface does not send or respond to Ethernet PAUSE messages.)

### ***Asymmetric Flow Control***

Asymmetric flow control enables you to specify independently whether or not the interface receive buffer generates and sends Ethernet PAUSE messages to stop the connected peer from transmitting traffic, and whether or not the interface transmit buffer responds to Ethernet PAUSE messages it receives from the connected peer and stops transmitting traffic. The receive buffer configuration determines if the interface transmits Ethernet PAUSE messages, and the transmit buffer configuration determines if the interface receives and responds to Ethernet PAUSE messages:

- Receive buffers on—Enable Ethernet PAUSE transmission (generate and send Ethernet PAUSE frames)
- Transmit buffers on—Enable Ethernet PAUSE reception (respond to received Ethernet PAUSE frames)

You must explicitly set the flow control for both the receive buffer and the transmit buffer (**on** or **off**) to configure asymmetric Ethernet PAUSE. [Table 381 on page 5385](#) describes the configured flow control state when you set the receive (Rx) and transmit (Tx) buffers on an interface:

**Table 381: Asymmetric Ethernet PAUSE Flow Control Configuration**

Receive (Rx) Buffer	Transmit (Tx) Buffer	Configured Flow Control State
On	Off	Interface generates and sends Ethernet PAUSE messages. Interface does not respond to Ethernet PAUSE messages (interface continues to transmit even if peer requests that the interface stop sending traffic).
Off	On	Interface responds to Ethernet PAUSE messages received from the connected peer, but does not generate or send Ethernet PAUSE messages. (The interface does not request that the connected peer stop sending traffic.)
On	On	Same functionality as symmetric Ethernet PAUSE. Interface generates and sends Ethernet PAUSE messages and responds to received Ethernet PAUSE messages.
Off	Off	Ethernet PAUSE flow control is disabled.

The configured flow control is the Ethernet PAUSE state configured on the interface.

On 1-Gigabit Ethernet interfaces, autonegotiation of Ethernet PAUSE with the connected peer is supported. (Autonegotiation on 10-Gigabit Ethernet interfaces is not supported.) Autonegotiation enables the interface to exchange state advertisements with the connected peer so that the two devices can agree on the Ethernet PAUSE configuration. Each interface advertises its flow control state to the connected peer using a combination of the Ethernet PAUSE and ASM\_DIR bits, as described in [Table 382 on page 5386](#):

**Table 382: Flow Control State Advertised to the Connected Peer (Autonegotiation)**

Rx Buffer State	Tx Buffer State	PAUSE Bit	ASM_DIR Bit	Description
Off	Off	0	0	The interface advertises no Ethernet PAUSE capability. This is equivalent to disabling flow control on an interface.
On	On	1	0	The interface advertises symmetric flow control (both the transmission of Ethernet PAUSE messages and the ability to receive and respond to Ethernet PAUSE messages).
On	Off	0	1	The interface advertises asymmetric flow control (the transmission of Ethernet PAUSE messages, but not the ability to receive and respond to Ethernet PAUSE messages).
Off	On	1	1	The interface advertises both symmetric and asymmetric flow control. Although the interface does not generate and send Ethernet PAUSE requests to the peer, the interface supports both symmetric and asymmetric Ethernet PAUSE configuration on the peer because the peer is not affected if the peer does not receive Ethernet PAUSE requests. (If the interface responds to the peer's Ethernet PAUSE requests, that is sufficient to support either symmetric or asymmetric flow control on the peer.)

The flow control configuration on each switch interface interacts with the flow control configuration of the connected peer. Each peer advertises its state to the other peer. The interaction of the flow control configuration of the peers determines the flow control behavior (resolution) between them, as shown in [Table 383 on page 5387](#). The first four columns show the Ethernet PAUSE configuration on the local QFX Series or EX4600 switch and on the connected peer (also known as the link partner). The last two columns show the Ethernet PAUSE resolution that results from the local and peer configurations

on each interface. This illustrates how the Ethernet PAUSE configuration of each interface affects the Ethernet PAUSE behavior on the other interface.

**NOTE:** In the Resolution columns of the table, disabling Ethernet PAUSE transmit means that the interface receive buffers do not generate and send Ethernet PAUSE messages to the peer. Disabling Ethernet PAUSE receive means that the interface transmit buffers do not respond to Ethernet PAUSE messages received from the peer.

**Table 383: Asymmetric Ethernet PAUSE Behavior on Local and Peer Interfaces**

Local Interface (QFX Series or EX4600 Switch)		Peer Interface		Local Resolution	Peer Resolution
PAUSE Bit	ASM_DIR Bit	PAUSE Bit	ASM_DIR Bit		
0	0	Don't care	Don't care	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
0	1	0	Don't care	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
0	1	1	0	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
0	1	1	1	Enable Ethernet PAUSE transmit and disable Ethernet PAUSE receive	Disable Ethernet PAUSE transmit and enable Ethernet PAUSE receive
1	0	0	Don't care	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
1	0	1	Don't care	Enable Ethernet PAUSE transmit and receive	Enable Ethernet PAUSE transmit and receive
1	1	0	0	Disable Ethernet PAUSE transmit and receive	Disable Ethernet PAUSE transmit and receive
1	1	0	1	Enable Ethernet PAUSE receive and disable Ethernet PAUSE transmit	Enable Ethernet PAUSE transmit and disable Ethernet PAUSE receive
1	1	Don't care	Don't care	Enable Ethernet PAUSE transmit and receive	Enable Ethernet PAUSE transmit and receive

**NOTE:** For your convenience, [Table 383 on page 5387](#) replicates Table 28B-3 of Section 2 of the IEEE 802.X specification.

## PFC

---

PFC is a lossless transport and congestion relief feature that works by providing granular link-level flow control for each IEEE 802.1p code point (priority) on a full-duplex Ethernet link. When the receive buffer on a switch interface fills to a threshold, the switch transmits a pause frame to the sender (the connected peer) to temporarily stop the sender from transmitting more frames. The buffer threshold must be low enough so that the sender has time to stop transmitting frames and the receiver can accept the frames already on the wire before the buffer overflows. The switch automatically sets queue buffer thresholds to prevent frame loss.

When congestion forces one priority on a link to pause, all of the other priorities on the link continue to send frames. Only frames of the paused priority are not transmitted. When the receive buffer empties below another threshold, the switch sends a message that starts the flow again.

You configure PFC using a congestion notification profile (CNP). A CNP has two parts:

- Input—Specify the code point (or code points) on which to enable PFC, and optionally specify the maximum receive unit (MRU) and the cable length between the interface and the connected peer interface.
- Output—Specify the output queue or output queues that respond to pause messages from the connected peer.

You apply a PFC configuration by configuring a CNP on one or more interfaces. Each interface that uses a particular CNP is enabled to pause traffic with the priorities (code points) specified in that CNP. You can configure one CNP on an interface, and you can configure different CNPs on different interfaces. When you configure a CNP on an interface, ingress traffic that is mapped to a priority that the CNP enables for PFC is paused whenever the queue buffer fills to the pause threshold. (The pause threshold is not user-configurable.)

Configure PFC for a priority end to end along the entire data path to create a lossless lane of traffic on the network. You can selectively pause the traffic in any queue without pausing the traffic for other queues on the same link. You can create lossless lanes for traffic such as Fibre Channel over Ethernet (FCoE), LAN backup, or management, while using standard frame-drop congestion management for IP traffic on the same link.

Potential consequences of link-level flow control are:

- Ingress port congestion (configuring too many lossless flows can cause ingress port congestion)
- A paused priority that causes upstream devices to pause the same priority, thus spreading congestion back through the network

By definition, PFC supports symmetric pause only (as opposed to Ethernet PAUSE, which supports symmetric and asymmetric pause). With symmetric pause, a device can:

- Transmit pause frames to pause incoming traffic. (You configure this using the input stanza of a congestion notification profile.)

- Receive pause frames and stop sending traffic to a device whose buffer is too full to accept more frames. (You configure this using the output stanza of a congestion notification profile.)

Receiving a PFC frame from a connected peer pauses traffic on egress queues based on the IEEE 802.1p priorities that the PFC pause frame identifies. The priorities are 0 through 7. By default, the priorities map to queue numbers 0 through 7, respectively, and to specific forwarding classes, as shown in [Table 384 on page 5389](#):

**Table 384: Default PFC Priority to Queue and Forwarding Class Mapping**

IEEE 802.1p Priority (Code Point)	Queue	Forwarding Class
0 (000)	0	best-effort
1 (001)	1	best-effort
2 (010)	2	best-effort
3 (011)	3	fcoe
4 (100)	4	no-loss
5 (101)	5	best-effort
6 (110)	6	network-control
7 (111)	7	network-control

For example, a received PFC pause frame that pauses priority 3 pauses output queue 3. If you do not want to use the default configuration, you can configure customized mapping of priorities to queues and forwarding classes.

**NOTE:** By convention, deployments with converged server access typically use IEEE 802.1p priority 3 for FCoE traffic. The default forwarding class configuration sets the fcoe forwarding class as a lossless forwarding class that is mapped to queue 3. The default classifier maps incoming priority 3 traffic to the fcoe forwarding class. *However, you must apply PFC to the entire FCoE data path to configure the end-to-end lossless behavior that FCoE traffic requires.*

If your network uses priority 3 for FCoE traffic, we recommend that you use the default configuration. If your network uses a priority other than 3 for FCoE traffic, you can configure lossless FCoE transport on any IEEE 802.1p priority as described in [“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5883](#) and [“Understanding CoS IEEE 802.1p Priority Remapping on an FCoE-FC Gateway” on page 5902](#).

You enable PFC on a priority by:

1. Specifying the IEEE 802.1p code point to pause in the input stanza of a CNP
2. Applying the CNP to the ingress interfaces on which you want to pause the traffic

**CAUTION:** Any change to the PFC configuration on a port temporarily blocks the entire port (not just the priorities affected by the PFC change) so that the port can implement the change, then unblocks the port. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

A change to the PFC configuration means any change to a CNP, including changing the input portion of the CNP (enabling or disabling PFC on a priority, or changing the MRU or cable-length values) or changing the output portion the CNP that enables or disables output flow control on a queue. A PFC configuration change only affects ports that use the changed CNP.

The following actions change the PFC configuration:

- Deleting or disabling a PFC configuration (input or output) in a CNP that is in use on one or more interfaces. For example:
  1. An existing CNP with an input stanza that enables PFC on priorities 3, 5, and 6 is configured on interfaces xe-0/0/20 and xe-0/0/21.
  2. We disable the PFC configuration for priority 6 in the input CNP, and then commit the configuration.
  3. The PFC configuration change causes all traffic on interfaces xe-0/0/20 and xe-0/0/21 to stop until the PFC change has been implemented. When the PFC change has been implemented, traffic resumes.
- Configuring a CNP on an interface. (This changes the PFC state by enabling PFC on one or more priorities.)
- Deleting a CNP from an interface. (This changes the PFC state by disabling PFC on one or more priorities.)

When you associate the CNP with an interface, the interface uses PFC to send pause requests when the output queue buffer for the lossless traffic fills to the pause threshold.

Although unicast traffic and multideestination (multicast, broadcast, and destination lookup fail) traffic must use different classifiers, you can map a unicast queue (queue 0 through 7) and a multideestination queue (queue 8, 9, 10, or 11) to the same PFC priority so that both unicast and multicast traffic use that priority. Do not map multideestination traffic to lossless priorities. Starting with Junos OS Release 12.3, you can map one priority to multiple output queues.

**NOTE:** You can attach a maximum of one CNP to an interface, but you can create an unlimited number of CNPs that explicitly configure only the input stanza and use the default output stanza.

The output stanza of the CNP maps to a profile that interfaces use to respond to pause messages received from the connected peer. On standalone switches, you can create two CNPs with an explicitly configured output stanza.

When a switch is a Node device in a QFabric system, you can create one CNP with an explicitly configured output stanza. (One fewer profile is available on QFabric systems because the system needs a default profile for fabric interfaces, which are not used as fabric interfaces when the switches are not part of a QFabric system. “[Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows](#)” on page 5883 describes configuring output flow control.

### Lossless Transport Support Summary

The switch supports up to six lossless forwarding classes. For lossless transport, you must enable PFC on the IEEE 802.1p priorities (code points) mapped to lossless forwarding classes.

**CAUTION:** Any change to the PFC configuration on a port temporarily blocks the entire port (not just the priorities affected by the PFC change) so that the port can implement the change, then unblocks the port. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

The following limitation applies to support lossless transport on QFabric systems only:

- The internal fiber cable length from the QFabric system Node device to the QFabric system Interconnect device cannot exceed 150 meters.

The default CoS configuration provides two lossless forwarding classes, *fcoe* and *no-loss*. If you explicitly configure lossless forwarding classes, you must include the **no-loss** packet drop attribute to enable lossless behavior, or the traffic is not lossless. For both default and explicit lossless forwarding class configuration, you must configure CNP input stanzas to enable PFC on the priority of the lossless traffic and apply the CNPs to ingress interfaces.

**NOTE:** Junos OS Release 12.2 introduced changes to the way the switch handles lossless forwarding classes (including the default fcoe and no-loss forwarding classes).

In Junos OS Release 12.1, either explicitly configuring the fcoe and no-loss forwarding classes or using the default configuration for these forwarding classes resulted in the same lossless behavior for traffic mapped to those forwarding classes.

However, in Junos OS Release 12.2, if you explicitly configure the fcoe or the no-loss forwarding class, that forwarding class is no longer treated as a lossless forwarding class. Traffic mapped to these forwarding classes is treated as lossy (best-effort) traffic. This is true even if the explicit configuration is exactly the same as the default configuration.

If your CoS configuration from Junos OS Release 12.1 or earlier includes the explicit configuration of the fcoe or the no-loss forwarding class, then when you upgrade to Junos OS Release 12.2, those forwarding classes are not lossless. To preserve the lossless treatment of these forwarding classes, delete the the explicit fcoe and no-loss forwarding class configuration before you upgrade to Junos OS Release 12.2.

See [“Overview of CoS Changes Introduced in Junos OS Release 12.2” on page 5795](#) for detailed information about this change and how to delete an existing lossless configuration.

In Junos OS Release 12.3, the default behavior of the fcoe and no-loss forwarding classes is the same as in Junos OS Release 12.2. However, in Junos OS Release 12.3, you can configure up to six lossless forwarding classes. All explicitly configured lossless forwarding classes must include the new no-loss packet drop attribute or the forwarding class is lossy.

[“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5883](#) provides detailed information about the explicit configuration of lossless priorities and about the default configuration of lossless priorities, including the input and output stanzas of the CNP.

**NOTE:** PFC and Ethernet PAUSE are used only on Ethernet interfaces. Fabric (fte) ports on QFabric systems (Node device fabric ports and Interconnect device fabric ports) use link-layer flow control (LLFC) to ensure the appropriate treatment of lossless traffic.

## Understanding Fibre Channel Terminology

To understand the Fibre Channel (FC) and Fibre Channel over Ethernet (FCoE) capabilities of the switches, you should become familiar with the terms defined in [Table 385 on page 5393](#).

**Table 385: Fibre Channel Terms**

Term	Definition
addressing mode	<p>Format for the locally unique MAC address the FC switch assigns to FCoE devices for FCoE transactions after FIP establishes a connection between an FCoE device and the FC switch. The two addressing modes are <i>fabric-provided MAC address (FPMA)</i> and <i>server-provided MAC address (SPMA)</i>. Only FPMA is supported.</p> <p>During FLOGI or FDISC, the ENode advertises the addressing modes it supports. If the FC switch supports an addressing mode that the ENode uses, the virtual link can be established, and the devices can communicate.</p> <p>See also <i>fabric-provided MAC address (FPMA)</i> and <i>server-provided MAC address (SPMA)</i>.</p>
ALL-ENode-MACs	<p>Well-known multicast MAC address to which all FCoE ENodes listen. FCFs send multicast <i>FIP discovery advertisement</i> messages and <i>FIP keepalive</i> messages to the ALL-ENode-MACs address so that ENodes can discover and maintain connections to FCFs. The hexadecimal format of the address is <b>01:10:18:01:00:01</b>.</p> <p>See also <i>well-known address (WKA)</i>.</p>
ALL-FCF-MACs	<p>Well-known multicast MAC address to which all FCFs listen. ENodes send multicast <i>FIP discovery solicitation</i> messages to the ALL-FCF-MACs address to find out which FCFs can accept a login. The hexadecimal format of the address is <b>01:10:18:01:00:02</b>.</p> <p>See also <i>well-known address (WKA)</i>.</p>
congestion notification	See <i>quantized congestion notification (QCN)</i> .

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
converged network adapter (CNA)	<p>Physical adapter that combines the functions of a Fibre Channel <i>host bus adapter (HBA)</i> to process FCoE frames and a <i>lossless Ethernet network interface card (NIC)</i> to process non-FCoE Ethernet frames. CNAs have one or more Ethernet ports. CNAs encapsulate Fibre Channel frames in Ethernet for FCoE transport and de-encapsulate Fibre Channel frames from FCoE to native Fibre Channel.</p> <p>See also <i>host bus adapter (HBA)</i>.</p>
data center bridging (DCB)	<p>Set of IEEE specifications that enhance Ethernet to allow it to support converged Ethernet (LAN) and Fibre Channel (SAN) traffic on one Ethernet network. DCB features include <i>priority-based flow control (PFC)</i>, <i>enhanced transmission selection (ETS)</i>, <i>Data Center Bridging Capability Exchange protocol (DCBX)</i>, <i>quantized congestion notification (QCN)</i>, and full-duplex 10-Gigabit Ethernet ports.</p> <p>See also <i>priority-based flow control (PFC)</i>, <i>Ethernet PAUSE</i>, <i>enhanced transmission selection (ETS)</i>, <i>Data Center Bridging Capability Exchange protocol (DCBX)</i>, and <i>quantized congestion notification (QCN)</i>.</p>
expansion port (E_Port)	<p>An expansion port in an FC switch/FCF that connects the FC switch/FCF to the E_Port of another FC switch/FCF to form an <i>Interswitch Link (ISL)</i> in a common FC fabric.</p>
Data Center Bridging Capability Exchange protocol (DCBX)	<p>Discovery and exchange protocol for conveying configuration and capabilities among neighbors to ensure consistent configuration across the network. It is an extension of the Link Layer Data Protocol (LLDP, described in IEEE 802.1AB)</p> <p>See also <i>data center bridging (DCB)</i>.</p>
enhanced transmission selection (ETS)	<p>Mechanism that provides finer granularity of bandwidth management within a link.</p> <p>See also <i>data center bridging (DCB)</i>.</p>
ENode	<p>See <i>FCoE Node (ENode)</i></p>
ENode MAC	<p><i>Lossless Ethernet MAC</i> paired with an <i>FCoE controller</i> in an ENode.</p> <p>See also <i>FCoE node (ENode)</i>.</p>
ENode MAC address	<p>Globally unique address assigned to the CNA by the manufacturer and used to identify the node for FIP transactions.</p>

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
Ethernet PAUSE	<p>As defined in IEEE 802.3X, a flow control mechanism that temporarily stops the transmission of Ethernet frames on a link for a specified period. A receiving element sends an Ethernet PAUSE frame when a sender transmits data faster than the receiver can accept it. Ethernet PAUSE affects the entire link, not just an individual flow. An Ethernet PAUSE frame temporarily stops all traffic transmission on the link and allows the receiver's input buffer to empty sufficiently to restart traffic on the link. Ethernet PAUSE messages are sent to the previous hop and do not automatically propagate to the source of the congestion.</p> <p>See also <i>priority-based flow control (PFC)</i>.</p>
fabric	Interconnection of network nodes using one or more network switches that function as a network single logical entity.
fabric discovery (FDISC)	<p>Subsequent logins from the same ENode for different users, applications, or virtual machines after an ENode performs an initial FLOGI to log in to a switch.</p> <p>FC and FIP FDISC messages serve the same function in FC and FCoE networks, respectively. N_Ports send FC FDISC messages to the FC switch and VN_Ports send FIP FDISC messages to the FCF.</p> <p>After an N_Port acquires its initial N_Port ID through the FC FLOGI process, it can acquire additional N_Port IDs by sending an FC FDISC with a new worldwide port name and a source ID of 0x000000. The new port name and blank source ID tell the FC switch to assign a new N_Port ID to the N_Port. The different N_Port IDs allow multiple virtual machines or users on the N_Port to have separate, secure virtual links on the same physical N_Port. These additional ports are also referred to as VN_Ports.</p> <p>FIP FDISC works the same way, except the VN_Port logs in using a FIP FLOGI message.</p> <p>See also <i>fabric login (FLOGI)</i> and <i>N_Port ID</i>.</p>
fabric login (FLOGI)	<p>Creation of a logical connection to the FC switch and establishment of a node's operating environment.</p> <p>For FC devices, an N_Port logs in to the FC network by sending an FC FLOGI message to the F_Port of an FC switch.</p> <p>For FCoE devices, a VN_Port logs in to the FC network by sending a FIP FLOGI message to the VF_Port of an FC switch.</p>
fabric port (F_Port)	<p>FC port on an FC switch or an FCF that connects point-to-point to an FC node port (N_Port) on an FC host (server or storage device). An F_Port provides access to fabric services for FC devices.</p> <p>F_Ports are intermediate ports in a connection between FC device end-point N_Ports. For example, a connection between an FC host server and an FC storage device through an FC switch looks like this: FC server N_Port to FC switch ingress F_Port to FC switch egress F_Port to FC storage device N_Port.</p> <p>See also <i>node port (N_Port)</i>.</p>

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
fabric-provided MAC address (FPMA)	<p>MAC address that an FCF assigns to a single ENode MAC through the FLOGI or FDISC process that is unique to the local fabric. The FPMA uniquely identifies a single VN_Port at that ENode MAC in FCoE transactions with the FCF.</p> <p>Because an ENode can have more than one ENode MAC, an FCF can assign multiple FPMAs to an ENode, one FPMA per ENode MAC.</p> <p>An FPMA is a 48-bit value that consists of two 24-bit values, the N_Port ID and the FC-MAP value. The N_Port ID uniquely identifies the VN_Port and the FC-MAP value identifies the FCF.</p> <p>See also <i>FCoE node (ENode)</i>, <i>N_Port ID</i>, and <i>FCoE mapped address prefix (FC-MAP)</i>.</p>
FCF-MAC	Lossless Ethernet MAC paired with an FCoE controller in an FCF. The FCF-MAC enables the FCF to handle FCoE traffic.
FCoE controller	<p>Instantiates and terminates VN_Port and VF_Port instances on an ENode. An ENode can have more than one FCoE controller. Each FCoE controller is paired with a lossless Ethernet MAC on the ENode.</p> <p>See also <i>lossless Ethernet MAC</i>.</p>
FC forwarder (FCF)	Alternative term and acronym to refer to an FC switch that has all physical Fibre Channel ports and the necessary set of services as defined in the T11 Organization <i>Fibre Channel Switched Fabric</i> (FC-SW) standards.
FCoE forwarder (FCF)	Defined by the <i>Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00</i> specification available at <a href="http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf">http://www.t11.org/ftp/t11/pub/fc/bb-5/09-056v5.pdf</a> as a device that has the necessary set of services as defined in FC-SW and the FCoE capabilities to act as an FCoE-based FC switch.
FCoE Initialization Protocol (FIP)	<p>Layer 2 protocol for endpoint discovery, fabric login, and fabric association. FIP enables FCoE devices and FC switches to discover one another. Through FIP, FCoE nodes can log in to an FC switch, access the SAN FC fabric, and communicate with target FC devices. FIP messages also maintain the connection between the FCoE initiator and the FCF.</p> <p>FIP has its own EtherType (0x8914) to distinguish its traffic from payload-carrying FCoE traffic and other Ethernet traffic.</p>
FCoE link endpoint (LEP)	Virtual FC interface mapped onto a physical Ethernet interface to handle FC frame encapsulation and de-encapsulation and transmission and reception of FC frames encapsulated in Ethernet through a single virtual link.
FCoE mapped address prefix (FC-MAP)	<p>24-bit value that identifies the FC switch and is half of the 48-bit FPMA MAC address. The FC-MAP value can be configured on the FC switch and has a default value of 0EFC00h. The FC-MAP value was originally called the Fibre Channel Organizationally Unique Identifier (FC-OUI).</p> <p>See also <i>fabric-provided MAC address (FPMA)</i>.</p>

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
FCoE node (ENode)	<p>Fibre Channel node that has one or more lossless Ethernet MACs, each paired with an <i>FCoE Controller</i> in order to transmit FCoE frames. An ENode combines FCoE termination functions and the FC stack on a CNA. ENodes present virtual FC interfaces to FC switches or FCFs in the form of VN_Ports, which can establish FCoE virtual links with FC switch/FCF VF_Ports. ENodes perform FCoE related functions in a <i>converged network adapter (CNA)</i>.</p> <p>See also <i>converged network adapter (CNA)</i>.</p>
FCoE-FC gateway	A form of N_Port virtualizer in which the node-facing ports are FCoE ports and the FC switch-facing ports are FC ports.
FCoE-FCoE gateway	A form of N_Port virtualizer in which the node-facing ports are FCoE ports and the FC switch-facing ports are FCoE ports.
FC-FC gateway	A form of N_Port virtualizer in which the node-facing ports are FC ports and the FC switch-facing ports are FC ports.
FCoE transit switch (also known as a FIP snooping bridge)	<p>Switch with a minimum set of features designed to support FCoE Layer 2 forwarding and FCoE security. The switch can also have optional additional features.</p> <p>Minimum feature support is:</p> <ul style="list-style-type: none"> <li>• Priority-based flow control (PFC)</li> <li>• Enhanced transmission selection (ETS)</li> <li>• Data Center Bridging Capability Exchange Protocol (DCBX), including the FCoE application TLV</li> <li>• FIP snooping (minimum support is FIP automated filter programming at the ENode edge)</li> </ul> <p>Additional FIP snooping capabilities can include learning the virtual FC connection paths (VN2VF, VN2VN, or VE2VE) and monitoring the FIP keepalive mechanisms. Other optional capabilities can also enhance FCoE within the standards. FIP snooping is typically configurable on a per-VLAN basis.</p> <p>A transit switch has an FC stack even though it is not an FC switch or an FCF.</p>
FCoE VLAN	VLAN dedicated to carrying only FCoE traffic. FCoE traffic must travel in a VLAN. Only FCoE interfaces should be members of an FCoE VLAN. Ethernet traffic that is not FCoE traffic must travel in a different VLAN.
Fibre Channel	High-speed network technology used for storage area networks (SANs).
Fibre Channel fabric	<p>Network of Fibre Channel devices that allows communication among devices, device name lookup, security, and redundancy.</p> <p>Also a local fabric on a QFX3500 switch with FCoE interfaces connected to FCoE devices on the Ethernet network and native FC interfaces connected to an FC switch in a SAN.</p>

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
Fibre Channel ID (FCID)	<p>24-bit value the FC switch assigns to the N_Port or VN_Port as a unique identifier within the local FC network. The FCID consists of an 8-bit domain value, an 8-bit area value, and an 8-bit port value. The FCID is sometimes called an N_Port ID.</p> <p>See also <i>N_Port ID</i>.</p>
Fibre Channel over Ethernet (FCoE)	<p>Standard for transporting FC frames over Ethernet networks. FCoE encapsulates Fibre Channel frames in Ethernet so that the same high-speed Ethernet physical infrastructure can transport both data and storage traffic while preserving the lossless CoS that FC requires. FCoE has its own EtherType (0x8906) to differentiate it from other Ethernet traffic.</p> <p>FCoE runs on a DCB network. FCoE servers connect to a switch that supports both FCoE and native FC protocols. This allows FCoE servers on the Ethernet network to access FC storage devices in the SAN fabric on one converged network.</p> <p>See also <i>data center bridging (DCB)</i>.</p>
Fibre Channel services	Functions required for establishing FC network connectivity among devices and for managing devices on the FC network, such as login servers, domain managers, name servers, and zone servers.
FC stack	<p>FC or FCoE protocol capability implemented on a device to support the FC or FCoE functionality. Having an FC stack does not imply consuming a domain ID.</p> <p>Each FC or FCoE enabled server or storage device has an FC stack. Similarly, an FC or FCoE switch, an FCF, an FCoE-FC gateway, and an FCoE transit switch have FC stacks.</p>
Fibre Channel switch	Network switch that implements the Fibre Channel protocol.
FIP discovery advertisement	<p>Multicast or unicast message that the FC switch (or FCF) transmits to ENodes to advertise the switch's presence on the network so that ENodes can discover the switch and request to log in to the FC fabric.</p> <p>The FC switch periodically sends multicast FIP discovery advertisements to the ALL-ENode-MACs address, a well-known address to which all ENodes listen. The multicast messages advertise the FC switch to all ENodes on the VLAN and serve as keepalive messages to maintain connectivity between the FC switch and ENodes.</p> <p>When an ENode sends a FIP discovery solicitation message to the FC switch, the FC switch responds with a unicast FIP discovery advertisement to that ENode.</p>

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
FIP discovery solicitation	<p>Multicast or unicast message that an ENode transmits to FC switches (or FCFs) to find compatible switches in the network.</p> <p>When an ENode initializes, it sends a multicast FIP discovery solicitation to the ALL-FCF-MACs address, a well-known address to which all FC switches and FCFs listen. Compatible switches reply with a unicast FIP discovery advertisement.</p> <p>The ENode compiles a list of compatible switches, selects a switch, and logs in to that switch.</p>
FIP keepalive	Periodic multicast FIP discovery advertisement sent from the FC switch or FCF to all ENodes to maintain connectivity.
FIP snooping	<p>For VN_Port to VF_Port (VN2VF) paths (Technical Committee T11 BB-FC-5 specification), FIP snooping is a security feature enabled for FCoE VLANs on an Ethernet switch that connects ENodes to FC switches or FCFs. FIP snooping inspects data in FIP frames and uses that data to create firewall filters. The filters permit only traffic from sources that perform a successful FLOGI to the FC switch. All other traffic on the VLAN is denied. FIP snooping filters are installed on the ports in the FCoE VLAN.</p> <p>For VN_Port to VN_Port (VN2VN) paths (Technical Committee T11 BB-FC-6 specification), the FIP snooping security feature filters access between VN_Ports in a similar manner to VN2VF_Port FIP snooping.</p> <p>FIP snooping can also apply similarly to VE_Port to VE_Port (VE2VE) paths.</p> <p>FIP snooping can also snoop to provide additional visibility of FCoE Layer 2 operation.</p> <p>See also <i>FCoE node (ENode)</i>.</p>
FIP snooping bridge	See <i>FCoE transit switch</i> and <i>FIP snooping</i> .
host bus adapter (HBA)	Physical mechanism that connects a host system to other FC network and storage devices. HBAs have a unique worldwide node name (WWNN) for the HBA node, which all of the ports on the HBA share, and each port on an HBA has a unique worldwide port name (WWPN).
initiator	System component that originates an I/O command over an I/O bus or network. An FCoE server sending a request to an FC storage device is an example of an initiator.

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
iSCSI transit switch	<p>Layer 2 Ethernet switch with a minimum set of best-practice Ethernet features to support iSCSI, along with optional enhancements. Minimum feature support is:</p> <ul style="list-style-type: none"> <li>• IEEE 802.3X asymmetric and symmetric flow control on ports not running in DCB mode</li> <li>• Priority-based flow control (PFC)</li> <li>• Enhanced transmission selection (ETS)</li> <li>• Data Center Bridging Capability Exchange Protocol (DCBX), including the iSCSI application TLV</li> </ul> <p>Other capabilities such as Internet storage name service (iSNS) are optional.</p>
interswitch link (ISL)	<p>Link between the <i>E_Ports</i> of two FC switches in a common FC fabric. When two FCoE-based FC switches are connected together, there is a virtual ISL through Layer 2.</p>
logout (LOGO)	<p>For FC devices, an N_Port logs out from the FC network by sending an FC LOGO message to the F_Port of an FC switch. The switch can also send a LOGO message to an N_Port to terminate its connection.</p> <p>For FCoE devices, a VN_Port logs out from the FC network by sending a FIP LOGO message to the VF_Port of an FC switch. The switch can also send a LOGO message to a VN_Port to terminate its connection.</p>
lossless Ethernet MAC	<p>Full-duplex Ethernet MAC that implements Ethernet extensions to avoid Ethernet frame loss due to congestion and supports at least 2.5-KB jumbo frames. Each lossless Ethernet MAC combines with an FCoE Controller to perform FCoE termination functions on an ENode.</p> <p>See also <i>priority-based flow control (PFC)</i>, <i>quantized congestion notification (QCN)</i>, <i>FCoE controller</i>, and <i>FCoE node (ENode)</i>.</p>
lossless Ethernet network	<p>Ethernet network composed of only full-duplex links and lossless Ethernet MACs and with CoS and flow control to prevent dropping of frames.</p>
lossless transport	<p>In DCB networks, the ability to switch FCoE frames over an Ethernet network without dropping any frames. Lossless transport uses mechanisms such as priority-based flow control and quantized congestion notification to control traffic flows and avoid congestion.</p>
N_Port ID	<p>See <i>Fibre Channel ID (FCID)</i>.</p>

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
N_Port ID virtualizer	<p>Presents itself as an FC or FCoE switch to external devices, but connects to an actual FC or FCoE switch in the other direction to provide the FC-SW services.</p> <p>An N_Port ID virtualizer logs in to the actual FC or FCoE switch in the same way as a normal node device and uses the NPIV mechanism to proxy incoming FLOGIs to FDISCs on the actual FC or FCoE switch.</p> <p>An N_Port ID virtualizer has an FC stack even though it is not an FC switch or an FCF.</p> <p>The acronym <i>NPV</i> is commonly used for N_Port ID virtualizer even though the acronym is not defined in the standards.</p>
N_Port ID Virtualization (NPIV)	<p>NPIV enables a physical N_Port to acquire multiple N_Port IDs. Each N_Port ID maps to a different application (such as a virtual machine) or to a different user. This allows you to associate one F_Port with many N_Port IDs and create multiple discrete, secure virtual links over one physical point-to-point connection.</p> <p>NPIV increases resource and bandwidth utilization and allows the implementation of access control, zoning, and port security on a per-application or per-user basis.</p> <p>After an N_Port performs a FLOGI and receives its first N_Port ID, it can request more N_Port IDs by sending FDISC messages.</p> <p>See also <i>fabric login (FLOGI)</i>, <i>fabric discovery (FDISC)</i>, and <i>virtual link</i>.</p>
node port (N_Port)	<p>N_Ports can be in two modes:</p> <ul style="list-style-type: none"> <li>• Fabric N_Port—Node port that is an FC host or storage device end port in a point-to-point link between the device and the F_Port of an FC switch. The point-to-point link can be virtual or physical.</li> <li>• Point-to-point N_Port—Node port that connects to another N_Port. The switch does not support this configuration.</li> </ul> <p>N_Ports handle creation, detection, and flow of messages to and from the connected devices.</p>
node worldwide name (NWWN)	<p>WWN that is unique worldwide and is assigned to an FC node. An NWWN is valid for multiple ports that are on that node (this identifies the ports as network interfaces of a particular node).</p>
port mode	<p>Role that the port plays in the FC fabric (endpoint device, FC switch connection to endpoint devices, interswitch link).</p> <p>See also <i>node port (N_Port)</i>, <i>virtual node port (VN_Port)</i>, <i>proxy node port (NP_Port)</i>, <i>fabric port (F_Port)</i>, and <i>virtual fabric port (VF_Port)</i>.</p>
port worldwide name (PWWN)	<p>WWN that is unique worldwide and is assigned to an FC port.</p>

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
priority-based flow control (PFC)	<p>Link-level flow control mechanism defined by IEEE 802.1Qbb that allows independent flow control for each class of service (as defined in the 3-bit CoS field of the Ethernet header by IEEE 802.1Q tags) to ensure that no frame loss from congestion occurs in DCB networks.</p> <p>PFC is an enhancement of the Ethernet PAUSE mechanism, but PFC controls classes of flows, whereas Ethernet PAUSE indiscriminately pauses all of the traffic on a link. With PFC, a receiving device can signal a transmitting device to pause transmission based on traffic class.</p> <p>PFC provides application-specific bandwidth reservations so you can ensure that time-critical protocols and applications such as FCoE receive the priority necessary to prevent frame loss. PFC allows the same physical link to carry FCoE traffic and provide lossless service while also carrying loss-tolerant Ethernet traffic.</p> <p>See also <i>Ethernet PAUSE</i>.</p>
proxy gateway mode	Connects FCoE initiators to FC switches in a converged Ethernet and Fibre Channel network and acts as an intermediary for these devices. The FCoE-FC gateway represents and acts for the FCoE initiators in transactions from the FCoE initiators destined for an FC switch, including converting FIP and FCoE frames to FC frames. The gateway represents and acts for an FC switch in transactions from the FC switch destined for an FCoE initiator, including converting FC frames to FIP frames and encapsulating FC frames in Ethernet.
proxy node port (NP_Port)	N_Port on the QFX3500 switch that performs proxy functions when it is configured as an FCoE-FC gateway. The NP_Port acts as a proxy for the FCoE device VN_Ports in transactions with the FC switch.
quantized congestion notification (QCN)	Mechanism defined by IEEE 802.1Qau that manages network congestion within a Layer 2 domain. When a queue reaches a configured threshold, QCN throttles traffic at the source of the congestion by transmitting messages that propagate back to the source and temporarily stop the source from transmitting. When the queue crosses the threshold that indicates the congestion has dissipated, QCN sends a message to allow the source to resume transmitting frames.
session	Fabric login (FLOGI) or fabric discovery (FDISC) login to the FC SAN fabric. Session does not refer to end-to-end server-to-storage sessions.
server-provided MAC address (SPMA)	<p>MAC address that an ENode assigns to one of its ENode MACs and is not assigned to any other ENode MAC in the same FCoE VLAN. An SPMA can be associated with more than one VN_Port at that ENode MAC.</p> <p>The switch does not support SPMA.</p> <p>See also <i>ENode MAC</i> and <i>fabric-provided MAC address (FPMA)</i>.</p>
storage area network (SAN)	Network whose primary purpose is the transfer of data between computer systems and storage devices. This term is most commonly used in the context of any network that supports block storage, usually iSCSI, FC, and FCoE networks.

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
target	System component that receives an I/O command. An FC storage device that receives a request from a server is an example of a target.
VE_Port	Virtual ports created to form a connection (an <i>interswitch link</i> ) between two FCoE-based FC switches as part of a common FC fabric.
VE2VE (VE_Port to VE_Port)	The <i>Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00</i> specification capability of FCFs to connect to each other as a single FCoE FC SAN.
VN2VF (VN_Port to VF_Port)	The <i>Fibre Channel Backbone - 5 (FC-BB-5) Rev 2.00</i> specification capability of an ENode to connect to an FCF or to an FCoE-enabled FC SAN.
VN2VN (VN_Port to VN_Port)	The <i>Fibre Channel Backbone - 6 (FC-BB-6)</i> specification capability of an ENode to connect directly over Layer 2 to another ENode without the need of any FC-related services. This capability is most often used in small-scale FCoE SANs.
virtual fabric port (VF_Port)	<p>Data-forwarding component that emulates an F_Port. A VF_Port is dynamically instantiated on successful completion of a FIP FLOGI exchange and connects to one or more VN_Ports. The term <i>virtual</i> indicates the use of a non-FC link such as an FCoE link.</p> <p>See also <i>fabric port (F_Port)</i>.</p>
virtual link	<p>Logical link connecting two FCoE Link End Points (LEPs) over a lossless Ethernet network, for example, the link between a VF_Port and a VN_Port. The MAC addresses of the two LEPs identifies a virtual link.</p> <p>See also <i>FCoE link end point (LEP)</i> and <i>lossless Ethernet network</i>.</p>
virtual node port (VN_Port)	<p>Data-forwarding component that emulates an N_Port. With FCoE, a VN_Port is dynamically instantiated on successful completion of a FIP FLOGI exchange and connects to one or more VF_Ports. The term <i>virtual</i> indicates the use of a non-FC link such as an FCoE link.</p> <p>VN_Port is also used for the virtual N_Ports created in both FC and FCoE when additional NPIV-based logins occur over a previously created N_Port-to-VN_Port or N_Port-to-VF_Port connection.</p> <p>See also <i>node port (N_Port)</i>.</p>
well-known address (WKA)	Address identifier used to access a service provided by an FC fabric. The service can be distributed in many elements throughout a fabric, or it can be centralized in one element. A WKA is always accessible, regardless of zoning. An example of a WKA is the <i>ALL-FCF-MACs</i> address to which all FCFs listen.
worldwide name (WWN)	64-bit identifier that is similar to a MAC address except that it is not used for forwarding. It uniquely identifies an FC device. The WWN is derived from the IEEE organizationally unique identifier (OUI) and vendor-supplied information. A WWN is unique worldwide.
worldwide node name (WWNN)	See <i>node worldwide name (NWWN)</i> .

Table 385: Fibre Channel Terms (*continued*)

Term	Definition
worldwide port name (WWPN)	See <i>port worldwide name (PWWN)</i> .

## Understanding Fibre Channel Fabrics on the QFabric System

A Fibre Channel (FC) fabric on a QFabric system is a construct that you configure on a QFX3500 Node device when the Node device is in FCoE-FC gateway mode. The FC fabric on a QFabric Node device is not the same as an FC fabric on a storage area network (SAN). The FC fabric on a QFabric Node device is local to that particular node device. We call the FC fabric on a QFabric Node device a *local FC fabric* to differentiate it from an FC fabric on the SAN.

**NOTE:** The QFX3600 Node device does not support FC or FCoE features.

A local FC fabric does not span Node devices and does not span the fabric Interconnect device. Local FC fabrics are entirely contained on a single Node device. A local FC fabric creates associations that connect FCoE devices that have converged network adapters (CNAs) on the Ethernet network to an FC switch or FCoE forwarder (FCF) on the FC network. A local FC fabric consists of:

- A unique fabric name.
- A unique fabric ID.
- One or more FCoE VLAN interfaces that include one or more 10-Gigabit Ethernet interfaces connected to FCoE devices. The FCoE VLANs transport traffic between the FCoE servers and the FCoE-FC gateway. Each FCoE VLAN must carry only FCoE traffic. You cannot mix FCoE traffic and standard Ethernet traffic on the same VLAN.

The 10-Gigabit Ethernet interfaces that connect to FCoE devices must include a native VLAN to transport FIP traffic because FIP VLAN discovery and notification frames are exchanged as untagged packets.

Each FCoE VLAN interface can present multiple VF\_Port interfaces to the FCoE network.

- One or more native FC interfaces. The native FC interfaces transport traffic between the gateway and the FC switch or FCF.

**TIP:** If the network does not use a dual-rail architecture for redundancy, configure more than one native FC interface for each local FC fabric to create redundant connections between the FCoE devices and the FC network. If one physical link goes down, any sessions it carried can log in again and connect to the FC network on a different interface.

All of the FC and FCoE traffic that belongs to a local FC fabric on a Node device must enter and exit that Node device. This means that the FC switch or FCF and the FCoE devices in the Ethernet network must be connected to the same Node device. The interfaces that connect to the FC switch and the interfaces that connect to the FCoE devices must be included in the local FC fabric. You cannot configure a local FC fabric that spans more than one Node device.

Traffic flows from FC and FCoE devices that are not in the same local FC fabric remain separate and cannot communicate with each other through the FCoE-FC gateway.

**NOTE:** The QFabric system enforces commit checks to ensure that local FC fabrics and FCoE VLANs on FCoE-FC gateways do not span more than one Node device.

## Understanding CoS Fabric Forwarding Class Sets

Fabric forwarding class sets (fabric fc-sets) are similar to the fc-sets (priority groups) you configure on Node devices. The major differences are:

1. Fabric fc-sets group traffic for transport across the QFX3008-I or QFX3600-I Interconnect device (the fabric). Node device fc-sets group traffic on a Node device for transport across that Node device.
2. Fabric fc-sets are global. They apply to the entire fabric. Node device fc-sets apply only to the Node device on which they are configured.
3. Fabric fc-sets are mapped directly to Interconnect device output queues; in this way, they behave similarly to forwarding classes on a Node device.

Fabric fc-sets map to Interconnect device fabric output queues statically—you cannot configure the mapping of fabric fc-sets to fabric output queues. All traffic in a fabric fc-set maps to the same output queue.

Node device fc-sets include forwarding classes that map to Node device output queues, and you can configure the mapping of forwarding classes to output queues (or you can use the default mapping). Because output queues are mapped to forwarding classes, different classes of traffic in a Node device fc-set can be mapped to different output queues.

Node device fc-sets consist of forwarding classes containing traffic that requires similar CoS treatment. (Forwarding classes are default forwarding classes or user-defined forwarding classes.) You can configure CoS for each fc-set to determine how the traffic of its forwarding classes is scheduled on a Node device.

When traffic exits a Node device interface and enters an Interconnect device fabric interface, the Interconnect device uses the same forwarding classes to group traffic. The forwarding classes are mapped to global fabric fc-sets for transport across the fabric. Like fc-sets on a Node device, fabric fc-sets also contain traffic that requires similar CoS treatment. Also like fc-sets on a Node device, you can configure CoS on fabric fc-sets.

Fabric fc-sets reside on the Interconnect device and are global to the QFabric system. Fabric fc-sets apply to all traffic that traverses the fabric. The mapping of forwarding classes to fabric fc-sets is global and applies to all forwarding classes with traffic that traverses the fabric from all connected Node devices. You can change the mapping of forwarding classes to fabric fc-sets. All mapping changes you make are global. For example, if you change the fabric fc-set to forwarding class mapping of the default best-effort forwarding class, then every Node device's best-effort forwarding class traffic that traverses the fabric is mapped to that fabric fc-set. The CoS you configure on a fabric fc-set applies to all the traffic that belongs to that fabric fc-set, from all connected Node devices.

This topic describes:

### Default Fabric Forwarding Class Sets

Interconnect devices have 12 default fabric fc-sets, including five visible default fabric fc-sets, four for unicast traffic and one for multidestination (multicast, broadcast, and destination lookup failure) traffic.

There are also seven hidden default fabric fc-sets. There are three hidden default fabric fc-sets for multidestination traffic that you can use if you want to map different multidestination forwarding classes to different multidestination fabric fc-sets. There are four hidden default fabric fc-sets for lossless traffic that you can use to map different lossless forwarding classes (priorities) to different lossless fabric fc-sets.

[Table 82 on page 1374](#) shows the default fabric fc-sets:

**Table 386: Default Fabric Forwarding Class Sets**

Fabric Forwarding Class Set Name	Characteristics
<code>fabric_fcset_be</code>	Transports best-effort unicast traffic across the fabric.
<code>fabric_fcset_strict_high</code>	Transports unicast traffic that has been configured with <b>strict-high</b> priority and in the <b>network-control</b> forwarding class across the fabric. This fabric fc-set receives as much bandwidth across the fabric as it needs to service the traffic in the group up to the entire fabric interface bandwidth. For this reason, exercise caution when mapping traffic to this fabric fc-set to avoid starving other traffic.
<code>fabric_fcset_noloss1</code>	Transports unicast traffic in the default <b>fcoe</b> forwarding class across the fabric.
<code>fabric_fcset_noloss2</code>	Transports unicast traffic in the default <b>no-loss</b> forwarding class across the fabric.
<code>fabric_fcset_noloss3</code>	(Hidden) No traffic is assigned by default to this fabric fc-set. Unless traffic is mapped to this fabric fc-set, this fabric fc-set remains hidden. This fabric fc-set is valid only for lossless forwarding classes.
<code>fabric_fcset_noloss4</code>	(Hidden) No traffic is assigned by default to this fabric fc-set. Unless traffic is mapped to this fabric fc-set, this fabric fc-set remains hidden. This fabric fc-set is valid only for lossless forwarding classes.
<code>fabric_fcset_noloss5</code>	(Hidden) No traffic is assigned by default to this fabric fc-set. Unless traffic is mapped to this fabric fc-set, this fabric fc-set remains hidden. This fabric fc-set is valid only for lossless forwarding classes.

Table 386: Default Fabric Forwarding Class Sets (*continued*)

Fabric Forwarding Class Set Name	Characteristics
<b>fabric_fcset_noloss6</b>	(Hidden) No traffic is assigned by default to this fabric fc-set. Unless traffic is mapped to this fabric fc-set, this fabric fc-set remains hidden. This fabric fc-set is valid only for lossless forwarding classes.
<b>fabric_fcset_multicast1</b>	Transports multdestination traffic in the <b>mcast</b> forwarding class across the fabric. This fabric fc-set is valid only for multdestination forwarding classes.
<b>fabric_fcset_multicast2</b>	(Hidden) No traffic is assigned by default to this fabric fc-set. Unless traffic is mapped to this fabric fc-set, this fabric fc-set remains hidden. This fabric fc-set is valid only for multdestination forwarding classes.
<b>fabric_fcset_multicast3</b>	(Hidden) No traffic is assigned by default to this fabric fc-set. Unless traffic is mapped to this fabric fc-set, this fabric fc-set remains hidden. This fabric fc-set is valid only for multdestination forwarding classes.
<b>fabric_fcset_multicast4</b>	(Hidden) No traffic is assigned by default to this fabric fc-set. Unless traffic is mapped to this fabric fc-set, this fabric fc-set remains hidden. This fabric fc-set is valid only for multdestination forwarding classes.

The five default forwarding classes (**best-effort**, **fcoe**, **no-loss**, **network-control**, and **mcast**) are mapped to the fabric fc-sets by default as shown in [Table 83 on page 1375](#).

Table 387: Default Forwarding Class to Fabric Forwarding Class Set Mapping

Forwarding Class	Fabric Forwarding Class Set	Fabric Output Queue	Maximum MTU Supported for Lossless Operation
<b>best-effort</b>	fabric_fcset_be	0	NA
<b>network-control</b>	fabric_fcset_strict_high	7	NA
<b>fcoe</b>	fabric_fcset_noloss1	1	9K
<b>no-loss</b>	fabric_fcset_noloss2	2	9K
<b>mcast</b>	fabric_fcset_multicast1	8	NA
No forwarding classes are mapped by default to this hidden fabric fc-set.	fabric_fcset_noloss3	3	9k

**Table 387: Default Forwarding Class to Fabric Forwarding Class Set Mapping (*continued*)**

Forwarding Class	Fabric Forwarding Class Set	Fabric Output Queue	Maximum MTU Supported for Lossless Operation
No forwarding classes are mapped by default to this hidden fabric fc-set.	fabric_fcset_noloss4	4	9k
No forwarding classes are mapped by default to this hidden fabric fc-set.	fabric_fcset_noloss5	5	9k
No forwarding classes are mapped by default to this hidden fabric fc-set.	fabric_fcset_noloss6	6	9k
No forwarding classes are mapped by default to this hidden fabric fc-set.	fabric_fcset_multicast2	9	NA
No forwarding classes are mapped by default to this hidden fabric fc-set.	fabric_fcset_multicast3	10	NA
No forwarding classes are mapped by default to this hidden fabric fc-set.	fabric_fcset_multicast4	11	NA

The maximum fiber cable length between the QFabric system Node device and the QFabric system Interconnect device is 150 meters.

**TIP:** If you explicitly configure lossless forwarding classes, we recommend that you map each user-configured lossless forwarding class to an unused fabric fc-set (fabric\_fcset\_noloss3 through fabric\_fcset\_noloss6) on a one-to-one basis: one lossless forwarding class mapped to one lossless fabric fc-set.

The reason for one-to-one mapping is to avoid fate sharing of lossless flows. Because each fabric fc-set is mapped statically to an output queue, when you map more than one forwarding class to a fabric fc-set, all of the traffic in all of the forwarding classes that belong to the fabric fc-set uses the same output queue. If that output queue becomes congested due to congestion caused by one of the flows, the other flows are also affected. (They share fate because the flow that congests the output queue affects flows that are not experiencing congestion.)

If you want to map different multdestination forwarding classes to different multdestination fabric fc-sets, use one or more of the hidden multdestination fabric fc-sets.

**NOTE:** The global mapping of forwarding classes to fabric fc-sets is independent of the mapping of forwarding classes to Node device fc-sets. Global mapping of forwarding classes to fabric fc-sets occurs only on the Interconnect device. The Node device mapping of forwarding classes to fc-sets does not affect the global mapping of forwarding classes to fabric fc-sets on the Interconnect device, and vice versa.

When you define new forwarding classes on a Node device, you explicitly map those forwarding classes to Node device fc-sets. However, new (user-created) forwarding classes are mapped by default to fabric fc-sets. (You can override the default mapping if you want to configure the forwarding class to fabric fc-set mapping explicitly, as described in the next section.)

By default:

- All best-effort traffic forwarding classes that you create are mapped to the **fabric\_fcset\_be** fabric fc-set.
- All lossless traffic forwarding classes that you create are mapped to the **fabric\_fcset\_noloss1** or **fabric\_fcset\_noloss2** fabric fc-set.

**NOTE:** To avoid fate sharing, we recommend that you configure one-to-one mapping of user-configured lossless forwarding classes to lossless fabric fc-sets instead of using the default mapping. You can also use firewall filters to mitigate fate sharing by separating flows that belong to the same forwarding class as the traffic traverses the Interconnect device (see [“Understanding How to Mitigate Fate Sharing on a QFabric System Interconnect Device by Remapping Traffic Flows \(Forwarding Classes\)”](#) on page 6006 for more information.)

- All multidestination traffic forwarding classes that you create are mapped to the **fabric\_fcset\_multicast1** fabric fc-set.
- All **strict-high** priority traffic and **network-control** forwarding classes that you create are mapped to the **fabric\_fcset\_strict\_high** fabric fc-set.

---

## Fabric Forwarding Class Set Configuration and Implementation

You can map forwarding classes to fabric fc-sets and configure CoS scheduling for fabric fc-sets. This section describes:

- [Mapping Forwarding Classes to Fabric Forwarding Class Sets on page 5410](#)
- [Fabric Forwarding Class Set Implementation on page 5411](#)

### **Mapping Forwarding Classes to Fabric Forwarding Class Sets**

If you do not want to use the default mapping of forwarding classes to fabric fc-sets, you can map forwarding classes to fabric fc-sets in the same way as you map forwarding classes to Node device fc-sets. To do this, use exactly the same statement that you use

to map forwarding classes to fc-sets, but instead of specifying a Node device fc-set name, specify a fabric fc-set name.

**NOTE:** The global mapping of forwarding classes to fabric fc-sets does not affect the mapping of forwarding classes to Node device fc-sets. The global forwarding class mapping to fabric fc-sets pertains to the traffic only when it enters, traverses, and exits the fabric. The forwarding class mapping to fc-sets on a Node device is valid within that Node device.

Mapping forwarding classes to fabric fc-sets does not affect the scheduling configuration of the forwarding classes or fc-sets on Node devices. Fabric fc-set scheduling pertains to traffic only when it enters, traverses, and exits the Interconnect device fabric.

If you change the mapping of a forwarding class to a fabric fc-set, the new mapping is global and applies to all traffic in that forwarding class, regardless of which Node device forwards the traffic to the Interconnect device.

- To assign one or more forwarding classes to a fabric fc-set:

```
[edit class-of-service]
```

```
user@switch# set forwarding-class-sets fabric-forwarding-class-set-name class
forwarding-class-name
```

For example, to map a user-defined forwarding class named **best-effort-2** to the fabric fc-set **fabric\_fcset\_be**:

```
[edit class-of-service]
```

```
user@switch# set forwarding-class-sets fabric_fcset_be class best-effort-2
```

**NOTE:** Because fabric fc-set configuration is global, in this example all forwarding classes with the name **best-effort-2** on all of the Node devices connected to the fabric use the **fabric\_fcset\_be** fabric fc-set to transport traffic across the fabric.

### ***Fabric Forwarding Class Set Implementation***

The following rules apply to fabric fc-sets:

- You cannot create new fabric fc-sets. Only the twelve default fabric fc-sets are available.
- You cannot delete a default fabric fc-set.
- You cannot attach a fabric fc-set to a Node device interface. Fabric fc-sets are used only on the Interconnect device fabric, not on Node devices.
- You can map only multidestination forwarding classes to multidestination fabric fc-sets.
- You cannot map multidestination forwarding classes to unicast fabric fc-sets.
- You cannot map unicast forwarding classes to multidestination fabric fc-sets.

## QFabric System CoS

---

When traffic enters and exits the same QFabric system Node device, CoS works the same as it works on a standalone switch.

However, when traffic enters a QFabric system Node device, crosses the Interconnect device, and then exits a different Node device, CoS is applied differently:

1. Traffic entering the ingress Node device receives the CoS configured at the Node ingress (packet classification and congestion notification profile for PFC).
2. When traffic goes from the ingress Node device to the Interconnect device, the fabric fc-set CoS is applied to the traffic.
3. When traffic goes from the Interconnect device to the egress Node device, the egress Node device applies CoS at the egress port (egress queue scheduling, WRED, and IEEE 802.1p or DSCP code-point rewrite).

Traffic that traverses the Interconnect device can use the default CoS fabric scheduling or you can configure two-tier hierarchical CoS scheduling explicitly on fabric fc-sets as described in [“Understanding CoS Scheduling Across the QFabric System” on page 5984](#).

## Support for Flow Control and Lossless Transport Across the Fabric

---

The Interconnect device incorporates flow control mechanisms to support lossless transport during periods of congestion on the fabric. To support the priority-based flow control (PFC) feature on the Node devices, the fabric interfaces use LLFC to support lossless transport for up to six IEEE 802.1p priorities when the following two configuration constraints are met:

1. The IEEE 802.1p priority used for the traffic that requires lossless transport is mapped to a lossless forwarding class on the Node devices.
2. The lossless forwarding class must be mapped to a lossless fabric fc-set on the Interconnect device (**fabric\_fcset\_noloss1**, **fabric\_fcset\_noloss2**, **fabric\_fcset\_noloss3**, **fabric\_fcset\_noloss4**, **fabric\_fcset\_noloss5**, or **fabric\_fcset\_noloss6**).

When traffic meets the two configuration constraints, the fabric propagates the back pressure from the egress Node device across the fabric to the ingress Node device during periods of congestion. However, to achieve end-to-end lossless transport across the switch, you must also configure a congestion notification profile to enable PFC on the Node device ingress ports.

For all other combinations of IEEE 802.1p priority to forwarding class mapping and all other combinations of forwarding class to fabric fc-set mapping, the congestion control mechanism is normal packet drop. For example:

- **Case 1**—If the IEEE 802.1p priority 5 is mapped to the lossless **fcoe** forwarding class, and the **fcoe** forwarding class is mapped to the **fabric\_fcset\_noloss1** fabric fc-set, then the congestion control mechanism is PFC.
- **Case 2**—If the IEEE 802.1p priority 5 is mapped to the lossless **fcoe** forwarding class, and the **fcoe** forwarding class is mapped to the **fabric\_fcset\_be** fabric fc-set, then the congestion control mechanism is packet drop.
- **Case 3**—If the IEEE 802.1p priority 5 is mapped to the lossless **no-loss** forwarding class, and the **no-loss** forwarding class is mapped to the **fabric\_fcset\_noloss2** fabric fc-set, then the congestion control mechanism is PFC.
- **Case 4**—If the IEEE 802.1p priority 5 is mapped to the lossless **no-loss** forwarding class, and the **no-loss** forwarding class is mapped to the **fabric\_fcset\_be** fabric fc-set, then the congestion control mechanism is packet drop.
- **Case 5**—If the IEEE 802.1p priority 5 is mapped to the **best-effort** forwarding class, and the **best-effort** forwarding class is mapped to the **fabric\_fcset\_be** fabric fc-set, then the congestion control mechanism is packet drop.
- **Case 6**—If the IEEE 802.1p priority 5 is mapped to the **best-effort** forwarding class, and the **best-effort** forwarding class is mapped to the **fabric\_fcset\_noloss1** fabric fc-set, then the congestion control mechanism is packet drop.

**NOTE:** Lossless transport across the fabric also must meet the following two conditions:

1. The maximum cable length between the Node device and the Interconnect device is a 150 meters of fiber cable.
2. The maximum frame size is 9216 bytes.

If the MTU is 9216 KB, in some cases the QFabric system supports only five lossless forwarding classes instead of six lossless forwarding classes because of headroom buffer limitations.

The number of IEEE 802.1p priorities (forwarding classes) the QFabric system can support for lossless transport across the Interconnect device fabric depends on several factors:

- **Approximate fiber cable length**—The longer the fiber cable that connects Node device fabric (FTE) ports to the Interconnect device fabric ports, the more data the connected ports need to buffer when a pause is asserted. (The longer the fiber cable, the more frames are traversing the cable when a pause is asserted. Each port must be able to store all of the “in transit” frames in the buffer to preserve lossless behavior and avoid dropping frames.)
- **MTU size**—The larger the maximum frame sizes the buffer must hold, the fewer frames the buffer can hold. The larger the MTU size, the more buffer space each frame consumes.
- **Total number of Node device fabric ports connected to the Interconnect device**—The higher the number of connected fabric ports, the more headroom buffer space the

Node device needs on those fabric ports to support the lossless flows that traverse the Interconnect device. Because more buffer space is used on the Node device fabric ports, less buffer space is available for the Node device access ports, and a lower total number of lossless flows are supported.

The QFabric system supports six lossless priorities (forwarding classes) under most conditions. The priority group headroom that remains after allocating headroom to lossless flows is sufficient to support best-effort and multdestination traffic.

Table 84 on page 1381 shows how many lossless priorities the QFabric system supports under different conditions (fiber cable lengths and MTUs) in cases when the QFabric system supports fewer than six lossless priorities. The number of lossless priorities is the same regardless of how many Node device FTE ports are connected to the Interconnect device. However, the higher the number of FTE ports connected to the Interconnect device, the lower the number of total lossless flows supported. In all cases that are not shown in Table 84 on page 1381, the QFabric system supports six lossless priorities.

**NOTE:** The system does not perform a configuration commit check that compares available system resources with the number of lossless forwarding classes configured. If you commit a configuration with more lossless forwarding classes than the system resources can support, frames in lossless forwarding classes might be dropped.

**Table 388: Lossless Priority (Forwarding Class) Support for Node Devices When Fewer than Six Lossless Priorities Are Supported**

MTU in Bytes	Fiber Cable Length in Meters (Approximate)	Maximum Number of Lossless Priorities (Forwarding Classes) on the Node Device
9216 (9K)	100	5
9216 (9K)	150	5

**NOTE:** The total number of lossless flows decreases as resource consumption increases. For a Node device, the higher the number of FTE ports connected to the Interconnect device, the larger the MTU, and the longer the fiber cable length, the fewer total lossless flows the QFabric system can support.

### Viewing Fabric Forwarding Class Set Information

You can display information about fabric fc-sets using the same CLI command you use to display information about Node device fc-sets:

```
user@switch> show class-of-service forwarding-class-set
Forwarding class set: fabric_fcset_be, Type: fabric-type, Forwarding class set
index: 1
  Forwarding class      Index
  best-effort           0
```

Forwarding class set: fabric\_fcset\_mcast1, Type: fabric-type, Forwarding class set index: 5

Forwarding class	Index
mcast	8

Forwarding class set: fabric\_fcset\_mcast2, Type: fabric-type, Forwarding class set index: 6

Forwarding class set: fabric\_fcset\_mcast3, Type: fabric-type, Forwarding class set index: 7

Forwarding class set: fabric\_fcset\_mcast4, Type: fabric-type, Forwarding class set index: 8

Forwarding class set: fabric\_fcset\_noloss1, Type: fabric-type, Forwarding class set index: 2

Forwarding class	Index
fcoe	1

Forwarding class set: fabric\_fcset\_noloss2, Type: fabric-type, Forwarding class set index: 3

no-loss	2

Forwarding class set: fabric\_fcset\_noloss3, Type: fabric-type, Forwarding class set index: 9

Forwarding class set: fabric\_fcset\_noloss4, Type: fabric-type, Forwarding class set index: 10

Forwarding class set: fabric\_fcset\_noloss5, Type: fabric-type, Forwarding class set index: 11

Forwarding class set: fabric\_fcset\_noloss6, Type: fabric-type, Forwarding class set index: 12

Forwarding class set: fabric\_fcset\_strict\_high, Type: fabric-type, Forwarding class set index: 4

Forwarding class	Index
network-control	3

[Table 85 on page 1382](#) describes the meaning of the **show class-of-service forwarding-class-set** output fields when you display fabric fc-set information.

**Table 389: show class-of-service forwarding-class-set Command Output Fields**

Field Name	Field Description
Forwarding class set	Name of the fabric forwarding class set.
Type	Type of forwarding class set: <ul style="list-style-type: none"> <li>Fabric-type—Fabric fc-set</li> <li>Normal-type—Node device fc-set</li> </ul>
Forwarding class set index	Index of this forwarding class set.

**Table 389: show class-of-service forwarding-class-set Command Output Fields (continued)**

Field Name	Field Description
<b>Forwarding class</b>	Name of a forwarding class.
<b>Index</b>	Index of the forwarding class.

### Summary of Fabric Forwarding Class Set and Node Device Forwarding Class Set Differences

Table 86 on page 1383 summarizes the differences between fabric fc-sets and fc-sets:

**Table 390: Summary of Differences Between Fabric fc-sets and Local fc-sets**

Characteristic	Fabric fc-set	Local fc-set
Location	QFX3008-I or QFX3600-I Interconnect device (the fabric).	QFabric Node device.
Global or local	Global, valid for the entire fabric.	Local to the Node device on which the fc-set is configured.
Ability to create (define) a new fc-set	No. Use the 12 default fabric fc-sets provided.	Yes.
Ability to configure CoS	User-configurable using fabric fc-set scheduler maps.	User-configurable using traffic control profiles.
Ability to map forwarding classes to an fc-set	Yes. Mapping is global and applies to all forwarding classes across the Interconnect device fabric (traffic from all connected Node devices).	Yes. Mapping is local to a Node device and applies only to the forwarding classes on the Node device.

## Understanding FCoE LAGs

A Fibre Channel over Ethernet (FCoE) link aggregation group (LAG) is a special LAG that enables you to transport FCoE traffic and regular Ethernet traffic across the same link aggregation bundle. Fibre Channel (FC) storage area network (SAN) switches require a point-to-point connection (or a virtual point-to-point connection) to FCoE devices. This requirement means that communication between an FCoE device and a QFabric system Node device must use the same physical link in a LAG to maintain the virtual point-to-point connection.

However, a standard LAG can use any member link for any particular transmission, so a standard LAG cannot guarantee that the same link is used for requests and responses between an FCoE device and a QFabric system Node device. Using different LAG member links for communication breaks the virtual point-to-point connection, which results in dropped FCoE traffic.

Unlike a standard LAG, an FCoE LAG always uses the same member link to transmit FCoE traffic between an FCoE device and a QFabric system Node device. However, regular Ethernet traffic (traffic that is not FCoE traffic) on the LAG is distributed across member interfaces in the same way as on a standard LAG. The special treatment of FCoE traffic does not affect the way regular Ethernet traffic behaves on the LAG. FCoE traffic is treated properly in terms of maintaining a virtual point-to-point link, and regular Ethernet traffic enjoys the usual LAG benefits of load balancing and link redundancy.

**NOTE:** Configuring a LAG as an FCoE LAG does not provide link redundancy for FCoE traffic, and does not load balance FCoE traffic.

A LAG interface can be a member of both an FCoE VLAN and a regular Ethernet VLAN. An FCoE LAG allows FCoE and standard Ethernet traffic to coexist on the same LAG, and treats both types of traffic properly.

On QFabric systems, all of the member links of an FCoE LAG must belong to one Node group. The member links of an FCoE LAG cannot belong to different Node groups.

Like a standard LAG, an FCoE LAG can have up to 32 member interfaces. FCoE devices are usually servers with CNAs connected to a switch that performs FIP snooping, such as an FCoE transit switch or an FCoE-FC gateway switch that performs FIP snooping.

- [Limitations on page 5422](#)

### Why a Standard LAG Does Not Work for FCoE Traffic

---

Each physical link that carries FCoE traffic connects to a CNA port on an FCoE device. The connection that the FIP process creates between the CNA and the FC SAN switch emulates a point-to-point connection between that CNA and the SAN switch through the QFabric system Node device. If a connection to an FCoE device is not on a point-to-point link, communication from the FC SAN switch to the FCoE device CNA might not reach the CNA.

In a LAG, two (or more) physical links connect to the same device. Standard LAGs use a hashing algorithm to determine which physical LAG link to use for each transmission. Because the hashing algorithm might choose any LAG link for a given transmission, there is no way a standard LAG can guarantee that a response from the FC SAN will use the same LAG link on a Node device as the request from the CNA.

To ensure that communication between the CNA and the FC SAN is successful, communication from the SAN to the CNA must use the same physical link. If the FCoE CNA sends a request to the FC SAN, the response from the FC SAN must come on the same link the FCoE device CNA used to send the request. For example, if a request from the CNA goes out on Node device LAG member interface RSNG1:xe-0/0/20, then the response from the FC SAN must be received on interface RSNG1:xe-0/0/20.

If the FC SAN switch response to the FCoE CNA uses a different physical link on the Node device LAG, the response arrives at a different CNA port than the CNA port on which the request was sent. This breaks the virtual point-to-point link and the SAN switch response does not reach the correct requestor, so the response is lost. This is why a standard LAG does not work for FCoE traffic.

### How an FCoE LAG Works

---

For FIP and FCoE transactions with the FC SAN to work properly, a LAG for FIP and FCoE traffic must allow the FC SAN switch to respond to the FCoE CNA device on the same link that the CNA used to communicate with the FC SAN switch.

To accomplish this, an FCoE LAG selects the member interface that the CNA used to communicate with the FC SAN switch as the link for the SAN switch response to the CNA. This preserves the virtual point-to-point link across the LAG and ensures that traffic from the FC SAN reaches the correct CNA port.

In a standard LAG, other devices learn the MAC address of the LAG interface, not the MAC address of the physical member interface that actually carries the traffic. However, for FCoE communication, other devices need to learn and use the VN\_Port MAC address that the SAN switch assigns to the virtual node port (VN\_Port) on the FCoE device's CNA. The VN\_Port MAC address uniquely identifies the CNA port used for FCoE transmission. (The VN\_Port MAC address is based on the Fibre Channel ID and the FC-MAP value, which the FC SAN switch provides to the FCoE CNA as a unique port identifier.)

In an FCoE LAG, the Node device performs FIP snooping to learn the VN\_Port MAC address of the CNA (in addition to other information). The Node device assigns the VN\_Port MAC address to the particular interface that was used to connect to the CNA. For FCoE traffic, this replaces the normal LAG hashing logic, so instead of using an arbitrary LAG interface

on the Node device for FCoE communication between the SAN switch and the CNA, an FCoE LAG uses the same physical LAG link for all FCoE transactions based on the VN\_Port MAC address.

VLAN discovery traffic is untagged, so it must use a native VLAN. When you configure an FCoE LAG, VLAN discovery traffic on a native VLAN in the LAG also automatically uses the same physical link, preserving the virtual point-to-point link.

For multicast packets such as multicast discovery advertisements (MDAs), the advertisement is forwarded on all member links of the FCoE LAG. This ensures that multicast advertisements reach all of the FCoE devices attached to FCoE LAG member interfaces.

### Behavior on FCoE LAG Link Failure

If an FCoE LAG link goes down, FCoE traffic and regular Ethernet traffic are treated differently.

If an FCoE LAG link goes down, the FCoE sessions on that link also go down. The Node device cannot simply move a session to another LAG link because that breaks the virtual point-to-point link. FCoE LAGs do not provide link redundancy for FCoE traffic.

As on a normal LAG, an FCoE LAG provides link redundancy for regular Ethernet traffic. Regular Ethernet sessions on the down FCoE LAG link are moved to other member links of the FCoE LAG (assuming that other member links are up).

### FIP Snooping Session Scaling on QFabric System Node Devices

When the switch is on the FCoE access edge, you must enable FIP snooping on the FCoE VLAN to provide secure access when connecting to the FC SAN. (You can also enable FIP snooping on FCoE VLANs on switches that are not at the access edge if you want to collect FIP snooping statistics on the switch or if you are not confident that the edge switch is properly snooping traffic.)

FIP snooping VLANs support scaling up to 2,500 sessions by default, which is called enhanced FIP snooping scaling mode. Software releases before Junos OS Release 12.3 limited VN2VF\_Port FIP snooping session scaling to 376 sessions on untrusted interfaces and untrusted FC fabrics, but scaled to 2,500 sessions on trusted interfaces and trusted FC fabrics. Starting with Junos OS Release 12.3, by default, all VN2VF\_Port FIP snooping VLANs used enhanced FIP snooping scaling (2,500 sessions) for both trusted and untrusted interfaces and FC fabrics. The old limit of 376 sessions for untrusted interfaces and untrusted FC fabrics was deprecated and could not be configured.

The FCoE LAG feature introduces the ability to disable FIP snooping session scaling so that only 376 sessions are supported instead of the default 2,500 sessions. The reason for reintroducing FIP snooping session scaling limits is that when a Node device is configured as an FCoE-FC gateway that has one or more untrusted gateway Fibre Channel fabric (fc-fabric), placing FCoE traffic in a LAG forces the TCAM to store additional session data to ensure that the virtual point-to-point link between the FCoE device and the FC SAN is maintained. This case is described later in this document.

### FCoE LAG Configuration on an FCoE Transit Switch

---

To create an FCoE LAG on an FCoE transit switch, you include the **fcoe-lag** option in the **[edit interfaces *interface-name* aggregated-ether-options]** hierarchy.

In addition to creating the FCoE LAG, you also need to:

- Add interfaces to the FCoE LAG.
- Configure at least one dedicated VLAN for FCoE traffic (an FCoE VLAN).
- Configure a native VLAN to carry untagged FIP traffic.
- Configure the FCoE LAG interfaces as a member of both the FCoE VLAN and the native VLAN.
- Enable FIP snooping on the FCoE VLAN.

### FCoE LAG Configuration and FIP Snooping Scaling on an FCoE-FC Gateway

---

There are differences in the way you configure an FCoE LAG on an FCoE-FC gateway compared to configuring an FCoE LAG on an FCoE transit switch.

- [Configuring an FCoE LAG on an FCoE-FC Gateway on page 5420](#)
- [FIP Snooping Session Scaling on an FCoE-FC Gateway on page 5421](#)
- [Summary of FCoE LAG and FIP Snooping Scaling on an FCoE-FC Gateway on page 5421](#)

#### **Configuring an FCoE LAG on an FCoE-FC Gateway**

To create an FCoE LAG on an FCoE-FC gateway, you include the **fcoe-lag** option in the **[edit interfaces *interface-name* aggregated-ether-options]** hierarchy.

In addition to creating the FCoE LAG, you also need to:

- Add interfaces to the FCoE LAG.
- Configure at least one dedicated VLAN for FCoE traffic (an FCoE VLAN).
- Configure a native VLAN to carry untagged FIP traffic.
- Configure the FCoE LAG interfaces as a member of both the FCoE VLAN and the native VLAN.
- Configure an FCoE VLAN interface (a Layer 3 routed VLAN interface that is configured as a virtual F\_Port) for the FCoE traffic. This enables the FCoE VLAN (and the member FCoE LAG interfaces) to interface with the native Fibre Channel ports in the FCoE-FC gateway switch Fibre Channel fabric (fc-fabric).
- Add the FCoE VLAN interface to the fc-fabric.
- Enable FIP snooping on the FCoE VLAN.
- Configure FIP snooping session scaling as described in the next section. The FIP snooping scaling mode depends on whether the fc-fabric is trusted or untrusted.

### FIP Snooping Session Scaling on an FCoE-FC Gateway

FIP snooping session scaling on an FCoE-FC gateway depends on whether or not the gateway has an untrusted fc-fabric:

- If the FCoE-FC gateway fc-fabric is FCoE trusted, then you can use enhanced FIP snooping scaling (2,500 sessions), and you do not have to do any additional configuration even if two or more FCFs in an FCoE VLAN have the same FC-MAP value.
- If the FCoE-FC gateway fc-fabric is FCoE untrusted, then you must disable enhanced FIP snooping scaling (reduce the number of supported sessions to 376 sessions) by including the **no-fip-snooping-scaling** statement in the **[edit fc-options]** hierarchy.

**NOTE:** On an FCoE-FC gateway, disabling enhanced FIP snooping scaling is global.

Gateway fc-fabrics are untrusted by default. FCoE-FC gateways do not support FCoE LAGs on untrusted fc-fabrics when enhanced FIP snooping scaling is enabled.

### Summary of FCoE LAG and FIP Snooping Scaling on an FCoE-FC Gateway

Table 391 on page 5421 summarizes FCoE LAG and FIP snooping scaling on an FCoE-FC gateway.

**Table 391: Summary of FCoE LAG and FIP Snooping Scaling (FCoE-FC Gateway)**

FCoE Fabric Trusted or Untrusted	FCoE LAG Configured	FIP Snooping Session Scaling	Configuration Notes
Trusted	Yes ( <b>fcoe-lag</b> option included in the <b>[edit interfaces interface-name aggregated-ether-options]</b> hierarchy)	2,500 sessions (enhanced FIP snooping scaling)	Configure the fc-fabric as an FCoE trusted fabric by including the <b>fcoe-trusted</b> option in the <b>[edit fc-fabrics fc-fabric-name protocols fip fcoe-trusted]</b> hierarchy.
Untrusted	Yes ( <b>fcoe-lag</b> option included in the <b>[edit interfaces interface-name aggregated-ether-options]</b> hierarchy)	376 sessions (no FIP snooping scaling)	Disable FIP snooping scaling by including the <b>no-fip-snooping-scaling</b> option in the <b>[edit fc-options]</b> hierarchy. This disables FIP snooping scaling globally on the gateway.
Untrusted	No ( <b>fcoe-lag</b> option not included in LAG configuration)	2,500 sessions (enhanced FIP snooping scaling)	FCoE LAGs with enhanced FIP snooping scaling enabled are not supported on untrusted FCoE-FC gateway fc-fabrics.  To configure an FCoE LAG on an untrusted fc-fabric, FIP snooping scaling must be disabled.

## FCoE Blade Switches

---

If you are using an FCoE blade switch, you need to configure an FCoE LAG only if the blade switch uses a passthrough module instead of an integrated switch.

## Limitations

---

There are several limitations to configuring FCoE LAGs:

1. All FCoE LAG member links must belong to the same QFabric system Node group.
2. On an FCoE-FC gateway, you must disable FIP snooping scaling on untrusted fc-fabrics. Disabling FIP snooping scaling is global to the gateway Node device. If all of the fc-fabrics on an FCoE-FC gateway are trusted fabrics, you do not need to disable FIP snooping scaling.
3. FCoE LAGs with enhanced FIP snooping scaling enabled are not supported on untrusted FCoE-FC gateway fc-fabrics.

## Understanding OxID Hash Control for FCoE Traffic Load Balancing on QFabric Systems

The originator exchange identifier (OxID) field is one of several fields used in the hash function computation for FCoE traffic load balancing over multiple outgoing links in an Ethernet link aggregation group (LAG) on ports that face an FCoE forwarder (FCF). The QFabric system Node device ports can be 10-Gigabit Ethernet ports or 40-Gigabit fabric ports. (The 40-Gigabit fabric ports that connect a QFabric system Node device to QFabric system Interconnect devices function as a LAG even though they are not explicitly configured as a LAG.)

The OxID field is a unique identifier used to identify an exchange between a target and an initiator. The OxID value can be different for different exchanges between the same target and initiator.

- [OxID Hash Control on page 5423](#)
- [Advantages and Disadvantages of OxID Hash Control on page 5423](#)
- [Disabling OxID Hash Control on page 5424](#)

---

## Oxid Hash Control

---

When FCoE traffic has multiple paths to an FCF (crosses a LAG that faces an FCF), packets can take different links between the source and destination endpoints. For each packet, the network bases the LAG link selection on the cost of the path (for example, link bandwidth or the number of hops). Using multiple paths distributes the FCoE traffic across the FCF-facing links, thus balancing the link load. The switch creates a hash value from some of the packet header fields, and uses the hash value to assign each packet to one of the LAG links. The switch always uses the following five packet header fields to compute the hash value:

- Source ID (SID)
- Destination ID (DID)
- Fabric ID (FID)
- Source Port ID (SPID)
- Source Module ID (SMID)

In addition, the QFabric system includes the OxID field by default in the FCoE load-balancing hash computation. However, if you do not want to use the OxID field in the FCoE load-balancing hash computation, you can remove it from the computation.

---

## Advantages and Disadvantages of OxID Hash Control

---

The advantage of including the OxID field in the load-balancing hash computation is that OxID hash control allows different exchanges between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) to take different paths across the network, thus improving the aggregate network throughput and balancing the link load.

However, if communication between two FC endpoints uses different links, frames might not be delivered in the order that they are sent because of variance in the time each path takes to process and transmit frames. If your network is not experiencing out-of-order delivery of FCoE frames, then you can leave OxID hash control enabled and enjoy the benefits of load balancing. However, if your network experiences out-of-order delivery of FCoE frames, you can disable OxID hash control to force FCoE traffic to use the same path to the FCF and ensure in-order delivery of FCoE frames.

For example, when OxID hash control is enabled on a QFabric system, a Node device that is connected by 40-Gigabit fabric ports to four QFabric system Interconnect devices can send FCoE traffic across any of the four Interconnect devices to the FCF. (The connections to the four Interconnect devices function as a fabric LAG, even though they are not explicitly configured as a LAG.) Different Interconnect devices might not forward the FCoE frames at the same rate, so the frames might not be delivered in the order they were sent.

If FCoE frames are delivered out-of-order, you can disable OxID hash control to prevent the FCoE traffic from using different fabric links that connect to different Interconnect devices. Because disabling OxID hash control forces the frames to be delivered over the same link, the frames traverse the same Interconnect device and are delivered in order.

The same scenario is true when FCoE traffic traverses an FCF-facing LAG composed of 10-Gigabit interfaces. When OxID hash control is enabled, FCoE traffic can use any LAG link, which could result in out-of-order frame delivery. If your network experiences out-of-order FCoE frame delivery, disabling OxID hash control ensures that the FCoE traffic uses the same LAG link for every transaction, so the FCoE frames are delivered in order.

### [Disabling OxID Hash Control](#)

---

You can disable OxID hash control on the 40-Gigabit fabric interfaces and on the 10-Gigabit Ethernet interfaces of a QFabric system Node group. Disabling OxID hash control affects all of the fabric or Ethernet interfaces of a Node group. For example, you cannot disable OxID hash control on some fabric interfaces in a Node group and leave OxID hash control enabled on other fabric interfaces of the same Node group.

### Example: Setting Up Fibre Channel and FCoE VLAN Interfaces in an FCoE-FC Gateway Fabric

To transmit Fibre Channel (FC) traffic between FCoE devices and a storage area network (SAN) FC switch, you configure a local FC fabric on the gateway. The gateway FC fabric includes FCoE and native FC interfaces, and a VLAN to carry FCoE traffic from FCoE-capable devices. The gateway FC fabric creates the path between the FCoE devices and the SAN.

This example describes how to configure the interfaces, VLAN, and FC fabric to connect FCoE devices to the FC switch and route traffic between the VLAN and FC interfaces:

- [Requirements on page 5428](#)
- [Overview on page 5428](#)

- [Configuration on page 5432](#)
- [Verification on page 5438](#)

## Requirements

---

This example uses the following hardware and software components:

- A configured and provisioned Juniper Networks QFX3500 Switch to act as an FCoE-FC gateway
- FCoE-capable devices in an Ethernet network equipped with converged network adapters (CNAs)
- An FC switch to transmit and receive native FC traffic
- FC storage devices in the SAN
- Junos OS Release 11.1 or later for the QFX Series

## Overview

---

No interfaces are configured for FC network connectivity by default. You need to configure the FC fabric and its interfaces explicitly. Each FC fabric consists of a combination of at least one FCoE VLAN interface between the FCoE-FC gateway and the FCoE devices, and one or more native FC interfaces between the FCoE-FC gateway and the FC switch.

An FCoE VLAN interface connects the FCoE-FC gateway to FCoE devices. FCoE traffic between the devices and the FCoE-FC gateway requires a dedicated VLAN used only for FCoE traffic. You cannot mix standard Ethernet traffic and FCoE traffic on the FCoE VLAN.

.....

**NOTE:** IGMP snooping is not supported on FCoE VLANs. IGMP snooping is enabled by default on all VLANs in all software versions before Junos OS Release 13.2. Disable IGMP snooping on FCoE VLANs if you are using software that is older than 13.2.

Storm control is not supported on Ethernet interfaces that belong to the FCoE VLAN. Ensure that storm control is disabled on all Ethernet interfaces that belong to the FCoE VLAN to prevent FCoE traffic from being dropped.

.....

When FCoE frames enter the FCoE-FC gateway, the gateway:

1. Strips the Ethernet encapsulation from the FCoE frames.
2. Sends the resulting native FC frames to the FC switch through the gateway's native FC interfaces.

Each FC interface and FCoE VLAN interface can belong to only one FC fabric. Different FC fabrics must use different native FC interfaces and different FCoE VLAN interfaces. Multiple FC fabrics on the FCoE-FC gateway can connect to the same FC switch, but they must use different FC interfaces and different FCoE VLAN interfaces.

The Ethernet interfaces that belong to the FCoE VLAN should be configured in tagged-access port mode and must include the native VLAN because FIP VLAN discovery and notification frames are exchanged as untagged packets. These Ethernet interfaces require a maximum transmission unit (MTU) size of at least 2180 bytes to accommodate the FC payload and FCoE encapsulation. (Sometimes the MTU is rounded up to 2500 bytes. If larger frames are expected on the interface, set the MTU size accordingly.)

This example shows a simple configuration to illustrate the basic steps for creating:

- The FCoE-device-facing VLAN and its 10-Gigabit Ethernet interfaces
- The VLAN interface
- The FC-switch-facing native FC interfaces
- One FC fabric on the FCoE-FC gateway

Configuring these elements results in traffic being routed between the VLAN and FC interfaces, thus connecting the FCoE devices to the FC switch through the FCoE-FC gateway.

A VLAN called **blue** transports FCoE traffic between FCoE devices and the FCoE-FC gateway using an FCoE VLAN interface called **vlan.100**. The FCoE-FC gateway's **vlan.100** interface presents an F\_Port interface to the FCoE devices on the VLAN. For each FCoE device ENode that logs in to the FCoE-FC gateway, the gateway instantiates a virtual F\_Port (VF\_Port) interface. This creates a virtual link between the ENode VN\_Port and the FCoE-FC gateway. The FCoE-FC gateway's native FC interfaces transport FC traffic between the gateway and the FC switch.

Configuring both the FCoE VLAN interface and the native FC interfaces as part of a gateway fabric associates them in the switch and makes the connection between the FCoE servers and the FC switch.

### Topology

The topology for this example consists of one QFX3500 switch with FC-capable ports to connect to the FC switch and with Ethernet ports in tagged-access mode to connect to the FCoE devices. [Table 392 on page 5429](#) and [Figure 212 on page 5431](#) show the configuration components of this example.

**Table 392: Components of the Fibre Channel Interface Configuration Topology**

Property	Settings
Switch hardware	QFX3500 switch in gateway mode
FCoE VLAN name and tag ID	<b>blue</b> , tag <b>100</b>  IGMP snooping disabled on the FCoE VLAN.

Table 392: Components of the Fibre Channel Interface Configuration Topology (*continued*)

Property	Settings
Interfaces in VLAN <b>blue</b>	<p>Interfaces: <b>xe-0/0/6</b>, <b>xe-0/0/7</b>, <b>xe-0/0/8</b>, <b>xe-0/0/9</b>, <b>xe-0/0/10</b>, <b>xe-0/0/11</b>  Port mode: <b>tagged-access</b>  MTU: <b>2180</b>  Native VLAN: <b>1</b></p> <p><b>NOTE:</b> FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.</p> <p>FCoE traffic cannot use a standard LAG because traffic might be hashed to different physical LAG links on different transmissions. This breaks the (virtual) point-to-point link that Fibre Channel traffic requires. If you configure a standard LAG interface for FCoE traffic, FCoE traffic might be rejected by the FC SAN.</p> <p>QFabric systems support a special LAG called an FCoE LAG, which enables you to transport FCoE traffic and regular Ethernet traffic across the same link aggregation bundle. An FCoE LAG ensures that FCoE traffic uses the same physical link in the LAG for requests and replies in order to preserve the virtual point-to-point link between the FCoE device converged network adapter (CNA) and the FC SAN switch across the QFabric system Node device. An FCoE LAG does not provide load balancing or link redundancy for FCoE traffic. However, regular Ethernet traffic receives the usual LAG benefits of load balancing and link redundancy in an FCoE LAG.</p>
FCoE VLAN interface	<p><b>vlan.100</b>  Port mode: <b>f-port</b></p>
Native Fibre Channel interfaces	<p>Interfaces: <b>fc-0/0/0</b>, <b>fc-0/0/1</b>, <b>fc-0/0/2</b>, <b>fc-0/0/3</b>, <b>fc-0/0/4</b>, <b>fc-0/0/5</b>  Port mode: <b>np-port</b>  Speed: <b>4 Gbps</b></p>
Fibre Channel fabric <b>fcproxy1</b>	<p>Fabric type: <b>proxy</b>  Fabric ID: <b>1</b>  FC interfaces: <b>fc-0/0/0</b>, <b>fc-0/0/1</b>, <b>fc-0/0/2</b>, <b>fc-0/0/3</b>, <b>fc-0/0/4</b>, <b>fc-0/0/5</b></p>

Figure 212: Fibre Channel Interface Configuration Topology

This configuration example creates a VLAN for FCoE traffic and routes its traffic to an FCoE VLAN interface that is part of the FC fabric. It also creates the FC interfaces needed to connect to the FC switch.

To set up FC interfaces and FCoE VLAN interfaces:

- Configure a VLAN to use as a dedicated FCoE VLAN:
  - Configure the interfaces the FCoE VLAN uses as Ethernet switching interfaces in tagged-access port mode.
  - If storm control is enabled, disable it on the interfaces.
  - Configure the interfaces the FCoE VLAN uses with the native VLAN.
  - Configure the FCoE VLAN to use the desired Ethernet interfaces.
  - Disable IGMP snooping on the FCoE VLAN. (Before Junos OS Release 13.2, IGMP snooping was enabled by default on all VLANs, but is not supported on FCoE VLANs. Starting with Junos OS Release 13.2, IGMP snooping is enabled by default only on the default VLAN.)
- Configure the FCoE VLAN interface.
- Define the interface for the FCoE VLAN (associate the VLAN with the FCoE VLAN interface).
- Configure the physical FC interfaces (either one or two 6-port blocks) that connect to the FC switch.
- Configure the logical FC interfaces that connect to the FC switch.
- Configure the FCoE-FC gateway fabric:
  - Configure the fabric ID.
  - Configure the fabric as a proxy fabric.

- Add the FCoE VLAN interface and the native FC interfaces to the fabric.

To keep the example simple, the configuration steps show six Ethernet interfaces in the FCoE VLAN and six native FC interfaces in the FC fabric. Use the same configuration procedure to add more interfaces to the FCoE VLAN or to the FC fabric.

### Configuration

---

#### CLI Quick Configuration

To quickly configure FCoE and native FC interfaces on an FCoE-FC gateway and route traffic between the FCoE VLAN and FC interfaces, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans blue vlan-id 100
set vlans native vlan-id 1
set interfaces xe-0/0/6 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/7 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/8 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/9 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode tagged-access vlan members blue
set interfaces xe-0/0/6 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/7 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/8 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/9 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/11 unit 0 family ethernet-switching native-vlan-id 1
set interfaces xe-0/0/6 mtu 2180
set interfaces xe-0/0/7 mtu 2180
set interfaces xe-0/0/8 mtu 2180
set interfaces xe-0/0/9 mtu 2180
set interfaces xe-0/0/10 mtu 2180
set interfaces xe-0/0/11 mtu 2180
set vlans blue interface xe-0/0/6.0
set vlans blue interface xe-0/0/7.0
set vlans blue interface xe-0/0/8.0
set vlans blue interface xe-0/0/9.0
set vlans blue interface xe-0/0/10.0
set vlans blue interface xe-0/0/11.0
set protocols igmp-snooping vlan blue disable
set interfaces vlan unit 100 family fibre-channel port-mode f-port
set vlans blue l3-interface vlan.100
set chassis fpc 0 pic 0 fibre-channel port-range 0 5
set interfaces fc-0/0/0 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/1 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/2 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/3 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/4 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/5 unit 0 family fibre-channel port-mode np-port
set interfaces fc-0/0/0 fibrechannel-options speed 4g
set interfaces fc-0/0/1 fibrechannel-options speed 4g
set interfaces fc-0/0/2 fibrechannel-options speed 4g
```

```

set interfaces fc-0/0/3 fibrechannel-options speed 4g
set interfaces fc-0/0/4 fibrechannel-options speed 4g
set interfaces fc-0/0/5 fibrechannel-options speed 4g
set fc-fabrics fcproxy1 fabric-id 1
set fc-fabrics fcproxy1 fabric-type proxy
set fc-fabrics fcproxy1 interface vlan.100
set fc-fabrics fcproxy1 interface fc-0/0/0.0
set fc-fabrics fcproxy1 interface fc-0/0/1.0
set fc-fabrics fcproxy1 interface fc-0/0/2.0
set fc-fabrics fcproxy1 interface fc-0/0/3.0
set fc-fabrics fcproxy1 interface fc-0/0/4.0
set fc-fabrics fcproxy1 interface fc-0/0/5.0

```

**Step-by-Step Procedure** Configure FCoE and FC interfaces in an FCoE-FC gateway FC fabric and set up traffic routing between the FCoE VLAN and FC interfaces:

1. Configure the VLAN for FCoE traffic:
 

```

[edit vlans]
user@switch# set blue vlan-id 100

```
2. Configure the native VLAN:
 

```

[edit vlans]
user@switch# set native vlan-id 1

```
3. Configure the Ethernet interfaces for the FCoE VLAN in tagged-access mode and as members of the FCoE VLAN (VLAN blue):
 

```

[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/7 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/8 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/9 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue
user@switch# set xe-0/0/11 unit 0 family ethernet-switching port-mode tagged-access
vlan members blue

```
4. Configure the native VLAN on the Ethernet interfaces in the FCoE VLAN:
 

```

[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/7 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/8 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/9 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
user@switch# set xe-0/0/11 unit 0 family ethernet-switching native-vlan-id 1

```
5. Set the MTU to 2180 for each Ethernet interface:
 

```

[edit interfaces]
user@switch# set xe-0/0/6 mtu 2180
user@switch# set xe-0/0/7 mtu 2180
user@switch# set xe-0/0/8 mtu 2180
user@switch# set xe-0/0/9 mtu 2180
user@switch# set xe-0/0/10 mtu 2180
user@switch# set xe-0/0/11 mtu 2180

```

6. Assign the Ethernet interfaces to the FCoE VLAN:

```
[edit vlans blue interface]
user@switch# set xe-0/0/6.0
user@switch# set xe-0/0/7.0
user@switch# set xe-0/0/8.0
user@switch# set xe-0/0/9.0
user@switch# set xe-0/0/10.0
user@switch# set xe-0/0/11.0
```

7. Disable IGMP snooping on the FCoE VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan blue disable
```

8. Configure the FCoE VLAN interface and port mode for the FCoE traffic:

```
[edit interfaces]
user@switch# set vlan unit 100 family fibre-channel port-mode f-port
```

9. Define the FCoE VLAN interface as the interface for the FCoE VLAN:

```
[edit vlans]
user@switch# set blue l3-interface vlan.100
```

10. Configure the physical FC interfaces the fabric uses to connect to the FC switch:

```
[edit chassis fpc 0 pic 0]
user@switch# set fibre-channel port-range 0 5
```

**NOTE:** When you configure ports as FC ports, the port designation changes from `xe-n/n/n.n` format to `fc-n/n/n.n` format to indicate that the interface is an FC interface. FC interfaces do not support 10-Gbps interface speed but instead conform to FC interface speeds of 2 Gbps, 4 Gbps, or 8 Gbps.

11. Configure the native FC interfaces and port mode:

```
[edit interfaces]
user@switch# set fc-0/0/0 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/1 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/2 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/3 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/4 unit 0 family fibre-channel port-mode np-port
user@switch# set fc-0/0/5 unit 0 family fibre-channel port-mode np-port
```

12. Configure the native FC interface port speed:

```
[edit interfaces]
user@switch# set fc-0/0/0 fibrechannel-options speed 4g
user@switch# set fc-0/0/1 fibrechannel-options speed 4g
user@switch# set fc-0/0/2 fibrechannel-options speed 4g
user@switch# set fc-0/0/3 fibrechannel-options speed 4g
user@switch# set fc-0/0/4 fibrechannel-options speed 4g
user@switch# set fc-0/0/5 fibrechannel-options speed 4g
```

13. Configure the FC fabric name and unique ID:

```
[edit fc-fabrics]
user@switch# set fcproxy1 fabric-id 1
```

14. Define the FC fabric as an FCoE-FC gateway:

```
[edit fc-fabrics]
user@switch# set fcproxy1 fabric-type proxy
```

15. Assign the FCoE VLAN interface to the fabric:

```
[edit fc-fabrics]
user@switch# set fcproxy1 interface vlan.100
```

16. Assign the native FC interfaces to the fabric:

```
[edit fc-fabrics]
user@switch# set fcproxy1 interface fc-0/0/0.0
user@switch# set fcproxy1 interface fc-0/0/1.0
user@switch# set fcproxy1 interface fc-0/0/2.0
user@switch# set fcproxy1 interface fc-0/0/3.0
user@switch# set fcproxy1 interface fc-0/0/4.0
user@switch# set fcproxy1 interface fc-0/0/5.0
```

**Results** Display the results of the configuration:

```
user@switch> show configuration
```

```
fc-0/0/0 {
  fibrechannel-options {
    speed 4g;
  }

        }
        l3-interface vlan.100
    }
    native {
        vlan-id 1;
    }
}
```

**TIP:** To quickly configure the interfaces, issue the `load merge terminal` command and then copy the hierarchy and paste it into the switch terminal window.

---

## Verification

To verify that the native FC interfaces and FCoE VLAN interface have been created, added to the FC fabric, and are operating properly, perform these tasks:

- [Verifying That the Native FC Interfaces and the FCoE VLAN Interface Have Been Created on page 5439](#)
- [Verifying That the FCoE VLAN Includes the Correct Ethernet Interfaces on page 5439](#)
- [Verifying That the FC Fabric Includes the Correct Interfaces on page 5440](#)
- [Verifying Native FC Interface Operation on page 5440](#)
- [Verifying That IGMP Snooping Has Been Disabled on the FCoE VLAN on page 5441](#)

**Verifying That the Native FC Interfaces and the FCoE VLAN Interface Have Been Created**

**Purpose** Verify that the six native FC interfaces and the FCoE VLAN interface have been created on the switch and are configured in the correct mode.

**Action** List all of the FC interfaces configured on the switch using the **show fibre-channel interfaces** command:

```
user@switch> show fibre-channel interfaces
```

Interface	Idx	Type	Native Fabric-id	NPIV	Config Mode	Oper Mode	State
fc-0/0/0.0	70	FC	1	YES	NP	NP	up
fc-0/0/1.0	71	FC	1	YES	NP	NP	up
fc-0/0/2.0	72	FC	1	YES	NP	NP	up
fc-0/0/3.0	73	FC	1	YES	NP	NP	up
fc-0/0/4.0	74	FC	1	YES	NP	NP	up
fc-0/0/5.0	75	FC	1	YES	NP	NP	up
vlan.100	67	FCOE	1	YES	F	F	up

**Meaning** The **show fibre-channel interfaces** command lists all native FC interfaces and FCoE VLAN interfaces configured on the switch. The command output shows that the FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, **fc-0/0/2.0**, **fc-0/0/3.0**, **fc-0/0/4.0**, and **fc-0/0/5.0** have been created and that those six interfaces:

- Are native Fibre Channel interfaces (type **FC**).
- Belong to the FC fabric with a configured fabric ID of 1.
- Are capable of N\_Port ID virtualization (NPIV).
- Have a configured mode and an operational mode of proxy N\_Port (**NP**), which means that they should be connected to an FCF or an FC switch, not to an FCoE device, and that they carry native FC traffic.
- Show an operational state of **up**.

The command output also shows that the FCoE VLAN interface **vlan.100** has been created and that interface:

- Is an FCoE VLAN interface (type **FCOE**).
- Belongs to the FC fabric with a configured fabric ID of 1.
- Is capable of N\_Port ID virtualization (NPIV).
- Has a configured mode and an operational mode of F\_Port (**F**), which means that its interfaces connect to FCoE devices and carry FCoE traffic.
- Shows an operational state of **up**.

**Verifying That the FCoE VLAN Includes the Correct Ethernet Interfaces**

**Purpose** Verify that the FCoE VLAN **blue** has been created with the correct VLAN tag (**100**) and with the correct Ethernet interfaces.

**Action** List all of the interfaces configured on the switch in VLAN **blue** using the **show vlans** command:

```
user@switch> show vlans blue
Name      Tag      Interfaces
blue      100
          xe-0/0/6.0, xe-0/0/7.0, xe-0/0/8.0, xe-0/0/9.0, xe-0/0/10.0
          xe-0/0/11.0
```

**Meaning** The **show vlans blue** command lists the interfaces that are members of the FCoE VLAN **blue**. The command output shows that the **blue** VLAN has a tag ID of 100 and includes the interfaces **xe-0/0/6.0**, **xe-0/0/7.0**, **xe-0/0/8.0**, **xe-0/0/9.0**, **xe-0/0/10.0**, and **xe-0/0/11.0**.

#### *Verifying That the FC Fabric Includes the Correct Interfaces*

**Purpose** Verify that the FC fabric configuration is configured on the switch with the correct native FC and FCoE VLAN interfaces.

**Action** List all of the interfaces configured on FC fabrics on the switch using the **show fibre-channel fabric** command:

```
user@switch> show fibre-channel fabric
Name      Fabric-id  Type      Interfaces
fcproxy1  1          PROXY
          fc-0/0/0.0
          fc-0/0/1.0
          fc-0/0/2.0
          fc-0/0/3.0
          fc-0/0/4.0
          fc-0/0/5.0
          vlan.100
```

**Meaning** The **show fibre-channel fabric** command lists the interfaces that are members of each FC fabric. The command output shows that the only fabric configured on the switch is named **fcproxy1**, has a fabric-id of 1, and is a **proxy** fabric in an FCoE-FC gateway. The command output also shows that the native FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, **fc-0/0/2.0**, **fc-0/0/3.0**, **fc-0/0/4.0**, and **fc-0/0/5.0**, and the FCoE VLAN interface **vlan.100** belong to **fcproxy1**.

#### *Verifying Native FC Interface Operation*

**Purpose** Verify that the native FC interfaces are online and display the number of FC sessions on each interface.

**Action** List all of the native FC NP\_Port interface states and sessions by FC fabric using the **show fibre-channel proxy np-port** command:

```
user@switch> show fibre-channel proxy np-port
Fabric: fcproxy1, Fabric-id: 1
NP-Port   State      Sessions   LB state   LB weight
fc-0/0/0.0 online     3          ON         4
fc-0/0/1.0 online     3          ON         4
fc-0/0/2.0 online     2          ON         4
```

fc-0/0/3.0	online	2	ON	4
fc-0/0/4.0	online	2	ON	4
fc-0/0/5.0	online	2	ON	4

**Meaning** The **show fibre-channel proxy np-port** command lists the interfaces that are configured as native FC proxy N\_Port interfaces. The command output shows:

- The fabric name is **fcproxy1** and its fabric ID is 1.
- The interfaces are **online**.
- The number of FC sessions (virtual links) running on each interface.
- The load-balancing (LB) state is **ON** for all of the interfaces.
- The LB weight reflects the port speed of each interface, which is 4 Gbps.

#### *Verifying That IGMP Snooping Has Been Disabled on the FCoE VLAN*

**Purpose** Verify that IGMP snooping is disabled on the FCoE VLAN.

**Action** List the IGMP snooping protocol information for the FCoE VLAN using the **show configuration protocols igmp-snooping vlan blue** command:

```
user@switch> show configuration protocols igmp-snooping vlan blue
disable;
```

**Meaning** The **show configuration protocols igmp-snooping vlan blue** command lists the IGMP snooping configuration for the FCoE VLAN. The command output shows that IGMP snooping is disabled on the FCoE VLAN.

### Example: Configuring CoS PFC for FCoE Traffic

Priority-based flow control (PFC, described in IEEE 802.1Qbb) is a link-level flow control mechanism that you apply at ingress interfaces. PFC enables you to divide traffic on one physical link into eight priorities. You can think of the eight priorities as eight “lanes” of

traffic that correspond to queues (forwarding classes). Each priority is mapped to a 3-bit IEEE 802.1p CoS flag in the VLAN header.

You can selectively apply PFC to the traffic in any queue without pausing the traffic in other queues on the same link. You must apply PFC to FCoE traffic to ensure lossless transport.

To configure PFC on FCoE traffic, use the default FCoE forwarding-class-to-queue mapping and:

- Configure a classifier that associates the FCoE forwarding class with FCoE traffic.
- Configure a congestion notification profile to apply PFC to the FCoE traffic.
- Apply the classifier and the PFC configuration to ingress interfaces.
- Configure the bandwidth scheduling for the FCoE forwarding class output queue.
- Create a forwarding class set (priority group) that includes the FCoE forwarding class; this is required to configure enhanced transmission selection (ETS) and support data center bridging (DCB).
- Configure the bandwidth scheduling for the FCoE priority group.
- Apply the scheduling to the egress interfaces.

**NOTE:** If you are using Junos OS Release 12.2 or later, use the default forwarding classes for the lossless fcoe forwarding class. If you explicitly configure default lossless forwarding classes, the traffic mapped to those forwarding classes is treated as lossy (best-effort) traffic and does *not* receive lossless treatment.

In Junos OS Release 12.3 and later, you can include the *no-loss* packet drop attribute in explicit forwarding class configurations to configure a lossless forwarding class.

---

This example describes how to configure PFC for FCoE traffic:

- [Requirements on page 5442](#)
- [Overview on page 5443](#)
- [Configuration on page 5444](#)
- [Verification on page 5448](#)

### Requirements

---

This example uses the following hardware and software components:

- A Juniper Networks QFX3500 Switch
- Junos OS Release 11.1 or later for the QFX Series

## Overview

FCoE traffic requires PFC to ensure lossless packet transport. This example shows you how to:

- Assign FCoE traffic to the FCoE priority at the ingress.
- Create and apply CoS for the FCoE traffic using ETS (hierarchical port scheduling).
- Apply PFC to the FCoE traffic.
- Apply the configuration to ingress and egress interfaces.

**NOTE:** Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

Each interface in this example is configured as both an ingress interface and an egress interface, so the classifier, congestion notification profile, and port scheduling are applied to all of the interfaces.

## Topology

Table 393 on page 5443 shows the configuration components for this example.

**Table 393: Components of the PFC for FCoE Traffic Configuration Topology**

Figure 213 on page 5444 shows a block diagram of the configuration components and the configuration flow of the CLI statements used in the example.

Figure 213: PFC for FCoE Traffic Configuration Components Block Diagram

### Configuration

#### CLI Quick Configuration

To quickly configure PFC for FCoE traffic, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```

[edit class-of-service]
set classifiers ieee-802.1 fcoe-classifier forwarding-class fcoe loss-priority low code-points 011
set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set interfaces xe-0/0/31 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/32 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/33 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/34 unit 0 classifiers ieee-802.1 fcoe-classifier
set interfaces xe-0/0/31 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/32 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/33 congestion-notification-profile fcoe-cnp
set interfaces xe-0/0/34 congestion-notification-profile fcoe-cnp
set schedulers fcoe-sched priority low transmit-rate 3g
set schedulers fcoe-sched shaping-rate percent 100
set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
set forwarding-class-sets fcoe-pg class fcoe
set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map guaranteed-rate 3g
set traffic-control-profiles fcoe-tcp shaping-rate percent 100
set interfaces xe-0/0/31 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/32 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/33 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set interfaces xe-0/0/34 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp

```

- Step-by-Step Procedure** To configure the FCoE forwarding class (priority), ingress classifier, output queue scheduling, forwarding class set (priority group) and its output port scheduling, PFC application, and interfaces to set up PFC for FCoE traffic:
1. Configure a classifier to set the loss priority and IEEE 802.1 code point assigned to the FCoE forwarding class at the ingress:
 

```
[edit class-of-service]
user@switch# set classifiers ieee-802.1 fcoe-classifier forwarding-class fcoe loss-priority
low code-points 011
```
  2. Configure PFC on the FCoE queue by applying FCoE to the IEEE 802.1 code point 011:
 

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```
  3. Apply the PFC configuration to the ingress interfaces:
 

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/32 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/33 congestion-notification-profile fcoe-cnp
user@switch# set interfaces xe-0/0/34 congestion-notification-profile fcoe-cnp
```
  4. Assign the classifier to the ingress interfaces:
 

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/32 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/33 unit 0 classifiers ieee-802.1 fcoe-classifier
user@switch# set interfaces xe-0/0/34 unit 0 classifiers ieee-802.1 fcoe-classifier
```
  5. Configure output scheduling for the FCoE queue:
 

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```
  6. Map the FCoE forwarding class to the FCoE scheduler:
 

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```
  7. Configure the forwarding class set for the FCoE traffic:
 

```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```
  8. Define the traffic control profile for the FCoE forwarding class set:
 

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```
  9. Apply the FCoE forwarding class set and traffic control profile to the egress ports:
 

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/31 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/32 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```

```
user@switch# set interfaces xe-0/0/33 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set interfaces xe-0/0/34 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```

### Results

Display the results of the configuration (the system shows only the explicitly configured parameters; it does not show default parameters such as the **fcoe** lossless forwarding class):

```
user@switch> show configuration class-of-service
classifiers {
  ieee-802.1 fcoe-classifier {
    forwarding-class fcoe {
      loss-priority low code-points 011;
    }
  }
}
traffic-control-profiles {
  fcoe-tcp {
    scheduler-map fcoe-map;
    shaping-rate percent 100;
    guaranteed-rate 3000000000;
  }
}
forwarding-class-sets {
  fcoe-pg {
    class fcoe;
  }
}
congestion-notification-profile {
  fcoe-cnp {
    input {
      ieee-802.1 {
        code-point 011 {
          pfc;
        }
      }
    }
  }
}
}
interfaces {
  xe-0/0/31 {
    congestion-notification-profile fcoe-cnp;
    forwarding-class-set {
      fcoe-pg {
        output-traffic-control-profile fcoe-tcp;
      }
    }
    unit 0 {
      classifiers {
        ieee-802.1 fcoe-classifier;
      }
    }
  }
}
```

```

xe-0/0/32 {
  congestion-notification-profile fcoe-cnp;
  forwarding-class-set {
    fcoe-pg {
      output-traffic-control-profile fcoe-tcp;
    }
  }
  unit 0 {
    classifiers {
      ieee-802.1 fcoe-classifier;
    }
  }
}
xe-0/0/33 {
  congestion-notification-profile fcoe-cnp;
  forwarding-class-set {
    fcoe-pg {
      output-traffic-control-profile fcoe-tcp;
    }
  }
  unit 0 {
    classifiers {
      ieee-802.1 fcoe-classifier;
    }
  }
}
xe-0/0/34 {
  congestion-notification-profile fcoe-cnp;
  forwarding-class-set {
    fcoe-pg {
      output-traffic-control-profile fcoe-tcp;
    }
  }
  unit 0 {
    classifiers {
      ieee-802.1 fcoe-classifier;
    }
  }
}
}
scheduler-maps {
  fcoe-map {
    forwarding-class fcoe scheduler fcoe-sched;
  }
}
schedulers {
  fcoe-sched {
    transmit-rate 3000000000;
    shaping-rate percent 100;
    priority low;
  }
}
}

```

**TIP:** To quickly configure the interfaces, issue the `load merge` terminal command and then copy the hierarchy and paste it into the switch terminal window.

---

## Verification

To verify that the PFC configuration for FCoE traffic components has been created and is operating properly, perform these tasks:

- [Verifying That Priority-Based Flow Control Has Been Enabled on page 5448](#)
- [Verifying the Ingress Interface PFC Configuration on page 5449](#)

### *Verifying That Priority-Based Flow Control Has Been Enabled*

**Purpose** Verify that PFC is enabled on the FCoE queue to enable lossless transport.

**Action** List the congestion notification profiles using the operational mode command `show class-of-service congestion-notification`:

```
user@switch> show class-of-service congestion-notification
```

```
Type: Input, Name: fcoe-cnp, Index: 51697
```

```
Cable Length: 100 m
```

Priority	PFC	MRU
000	Disabled	
001	Disabled	
010	Disabled	
011	Enabled	2500
100	Disabled	
101	Disabled	
110	Disabled	
111	Disabled	

```
Type: Output
```

Priority	Flow-Control-Queues
000	0
001	
	1
010	2
011	3
100	4
101	5
110	6
111	7

**Meaning** The `show class-of-service congestion-notification` operational command lists all of the congestion notification profiles and which IEEE 802.1p code points have PFC enabled.

The command output shows that PFC is enabled on code point 011 for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

### *Verifying the Ingress Interface PFC Configuration*

**Purpose** Verify that the classifier **fcoe-classifier** and the congestion notification profile **fcoe-cnp** are configured on ingress interfaces **xe-0/0/31**, **xe-0/0/32**, **xe-0/0/33**, and **xe-0/0/34**.

**Action** List the ingress interfaces using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces xe-0/0/31
congestion-notification-profile fcoe-cnp;
unit 0 {
  classifiers {
    ieee-802.1 fcoe-classifier;
  }
}
```

```
user@switch> show configuration class-of-service interfaces xe-0/0/32
congestion-notification-profile fcoe-cnp;
unit 0 {
  classifiers {
    ieee-802.1 fcoe-classifier;
  }
}
```

```
user@switch> show configuration class-of-service interfaces xe-0/0/33
congestion-notification-profile fcoe-cnp;
unit 0 {
  classifiers {
    ieee-802.1 fcoe-classifier;
  }
}
```

```
user@switch> show configuration class-of-service interfaces xe-0/0/34
congestion-notification-profile fcoe-cnp;
unit 0 {
  classifiers {
    ieee-802.1 fcoe-classifier;
  }
}
```

**Meaning** The **show configuration class-of-service interfaces** commands list the congestion notification profile that is mapped to the interface (**fcoe-cnp**) and the IEEE 802.1p classifier associated with the interface (**fcoe-classifier**).

## Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG

Multichassis link aggregation groups (MC-LAGs) provide redundancy and load balancing between two switches, multihoming support for client devices such as servers, and a loop-free Layer 2 network without running Spanning Tree Protocol (STP).

**NOTE:** This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Example: Configuring CoS for FCoE Transit Switch Traffic Across an MC-LAG*.

You can use an MC-LAG to provide a redundant aggregation layer for Fibre Channel over Ethernet (FCoE) traffic in an *inverted-U* topology. To support lossless transport of FCoE traffic across an MC-LAG, you must configure the appropriate class of service (CoS) on both of the switches with MC-LAG port members. The CoS configuration must be the same on both of the MC-LAG switches because an MC-LAG does not carry forwarding class and IEEE 802.1p priority information.

**NOTE:** This example describes how to configure CoS to provide lossless transport for FCoE traffic across an MC-LAG that connects two switches. It also describes how to configure CoS on the FCoE transit switches that connect FCoE hosts to the two switches that form the MC-LAG.

This example does *not* describe how to configure the MC-LAG itself. For a detailed example of MC-LAG configuration, see [“Example: Configuring Multichassis Link Aggregation” on page 2665](#). However, this example includes a subset of MC-LAG configuration that only shows how to configure interface membership in the MC-LAG.

Ports that are part of an FCoE-FC gateway configuration (a virtual FCoE-FC gateway fabric) do not support MC-LAGs. Ports that are members of an MC-LAG act as FCoE passthrough transit switch ports.

QFX Series switches and EX4600 switches support MC-LAGs. QFabric system Node devices do not support MC-LAGs.

This topic describes:

- [Requirements on page 5451](#)
- [Overview on page 5451](#)
- [Configuration on page 5456](#)
- [Verification on page 5464](#)

## Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX3500 Switches that form an MC-LAG for FCoE traffic.
- Two Juniper Networks QFX3500 Switches that provide FCoE server access in transit switch mode and that connect to the MC-LAG switches. These switches can be standalone QFX3500 switches or they can be Node devices in a QFabric system.
- FCoE servers (or other FCoE hosts) connected to the transit switches.
- Junos OS Release 12.2 or later for the QFX Series.

## Overview

FCoE traffic requires lossless transport. This example shows you how to:

- Configure CoS for FCoE traffic on the two QFX3500 switches that form the MC-LAG, including priority-based flow control (PFC) and enhanced transmission selection (ETS; hierarchical scheduling of resources for the FCoE forwarding class priority and for the forwarding class set priority group).

**NOTE:** Configuring or changing PFC on an interface blocks the entire port until the PFC change is completed. After a PFC change is completed, the port is unblocked and traffic resumes. Blocking the port stops ingress and egress traffic, and causes packet loss on all queues on the port until the port is unblocked.

- Configure CoS for FCoE on the two FCoE transit switches that connect FCoE hosts to the MC-LAG switches and enable FIP snooping on the FCoE VLAN at the FCoE transit switch access ports.
- Disable IGMP snooping on the FCoE VLAN.

**NOTE:** This is only necessary if IGMP snooping is enabled on the VLAN. Before Junos OS Release 13.2, IGMP snooping was enabled by default on VLANs. Beginning with Junos OS Release 13.2, IGMP snooping is enabled by default only on the default VLAN.

- Configure the appropriate port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

## Topology

Switches that act as transit switches support MC-LAGs for FCoE traffic in an inverted-U network topology, as shown in [Figure 214 on page 5452](#).

Figure 214: Supported Topology for an MC-LAG on an FCoE Transit Switch

Table 394 on page 5452 shows the configuration components for this example.

Table 394: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology

Component	Settings
Hardware	Four QFX3500 switches (two to form the MC-LAG as passthrough transit switches and two transit switches for FCoE access).
Forwarding class (all switches)	Default <b>fcoe</b> forwarding class.
Classifier (forwarding class mapping of incoming traffic to IEEE priority)	Default IEEE 802.1p trusted classifier on all FCoE interfaces.

Table 394: Components of the CoS for FCoE Traffic Across an MC-LAG Configuration Topology (*continued*)

Component	Settings
PFC congestion notification profile (all switches)	<p><b>fcoe-cnp:</b> Code point 011</p> <p>Ingress interfaces:</p> <ul style="list-style-type: none"> <li>• S1—LAG ae0 and MC-LAG ae1</li> <li>• S2—LAG ae0 and MC-LAG ae1</li> <li>• TS1—LAG ae1, interfaces xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33</li> <li>• TS2—LAG ae1, interfaces xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33</li> </ul>
FCoE VLAN name and tag ID	<p>Name—<b>fcoe_vlan</b> ID—100</p> <p>Include the FCoE VLAN on the interfaces that carry FCoE traffic on all four switches.</p> <p>Disable IGMP snooping on the interfaces that belong to the FCoE VLAN on all four switches.</p>
FIP snooping	<p>Enable FIP snooping on Transit Switches TS1 and TS2 on the FCoE VLAN. Configure the LAG interfaces that connect to the MC-LAG switches as FCoE trusted interfaces so that they do not perform FIP snooping.</p> <p>This example enables VN2VN_Port FIP snooping on the FCoE transit switch interfaces connected to the FCoE servers. The example is equally valid with VN2VF_Port FIP snooping enabled on the transit switch access ports. The method of FIP snooping you enable depends on your network configuration.</p>

**NOTE:** This example uses the default IEEE 802.1p trusted BA classifier, which is automatically applied to trunk mode and tagged access mode ports if you do not apply an explicitly configured classifier.

To configure CoS for FCoE traffic across an MC-LAG:

- Use the default FCoE forwarding class and forwarding-class-to-queue mapping (do not explicitly configure the FCoE forwarding class or output queue). The default FCoE forwarding class is **fcoe**, and the default output queue is queue 3.

**NOTE:** In Junos OS Release 12.2, traffic mapped to explicitly configured forwarding classes, even lossless forwarding classes such as **fcoe**, is treated as lossy (**best-effort**) traffic and does *not* receive lossless treatment. To receive lossless treatment in Release 12.2, traffic must use one of the default lossless forwarding classes (**fcoe** or **no-loss**).

In Junos OS Release 12.3 and later, you can include the *no-loss* packet drop attribute in the explicit forwarding class configuration to configure a lossless forwarding class.

- Use the default trusted BA classifier, which maps incoming packets to forwarding classes by the IEEE 802.1p code point (CoS priority) of the packet. The trusted classifier is the default classifier for interfaces in trunk and tagged-access port modes. The default trusted classifier maps incoming packets with the IEEE 802.1p code point 3 (011) to the FCoE forwarding class. If you choose to configure the BA classifier instead of using the default classifier, you must ensure that FCoE traffic is classified into forwarding classes in exactly the same way on both MC-LAG switches. Using the default classifier ensures consistent classifier configuration on the MC-LAG ports.
- Configure a congestion notification profile that enables PFC on the FCoE code point (code point 011 in this example). The congestion notification profile configuration must be the same on both MC-LAG switches.
- Apply the congestion notification profile to the interfaces.
- Configure enhanced transmission selection (ETS, also known as hierarchical scheduling) on the interfaces to provide the bandwidth required for lossless FCoE transport. Configuring ETS includes configuring bandwidth scheduling for the FCoE forwarding class, a forwarding class set (priority group) that includes the FCoE forwarding class, and a traffic control profile to assign bandwidth to the forwarding class set that includes FCoE traffic.
- Apply the ETS scheduling to the interfaces.
- Configure the port mode, MTU, and FCoE trusted or untrusted state for each interface to support lossless FCoE transport.

In addition, this example describes how to enable FIP snooping on the Transit Switch TS1 and TS2 ports that are connected to the FCoE servers and how to disable IGMP snooping on the FCoE VLAN. To provide secure access, FIP snooping must be enabled on the FCoE access ports.

This example focuses on the CoS configuration to support lossless FCoE transport across an MC-LAG. This example does not describe how to configure the properties of MC-LAGs and LAGs, although it does show you how to configure the port characteristics required

to support lossless transport and how to assign interfaces to the MC-LAG and to the LAGs.

Before you configure CoS, configure:

- The MC-LAGs that connect Switches S1 and S2 to Switches TS1 and TS2. ([“Example: Configuring Multichassis Link Aggregation” on page 2665](#) describes how to configure MC-LAGs.)
- The LAGs that connect the Transit Switches TS1 and TS2 to MC-LAG Switches S1 and S2. ([“Configuring Link Aggregation” on page 2777](#) describes how to configure LAGs.)
- The LAG that connects Switch S1 to Switch S2.

### Configuration

---

To configure CoS for lossless FCoE transport across an MC-LAG, perform these tasks:

- [Configuring MC-LAG Switches S1 and S2 on page 5458](#)
- [Configuring FCoE Transit Switches TS1 and TS2 on page 5459](#)
- [Results on page 5461](#)

#### CLI Quick Configuration

To quickly configure CoS for lossless FCoE transport across an MC-LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI for MC-LAG Switch S1 and MC-LAG Switch S2 at the **[edit]** hierarchy level. The configurations on Switches S1 and S2 are identical because the CoS configuration must be identical, and because this example uses the same ports on both switches.

#### Switch S1 and Switch S2

```
set class-of-service schedulers fcoe-sched priority low transmit-rate 3g
set class-of-service schedulers fcoe-sched shaping-rate percent 100
set class-of-service scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
set class-of-service forwarding-class-sets fcoe-pg class fcoe
set class-of-service traffic-control-profiles fcoe-tcp scheduler-map fcoe-map guaranteed-rate 3g
set class-of-service traffic-control-profiles fcoe-tcp shaping-rate percent 100
set class-of-service interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set class-of-service interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile fcoe-tcp
set class-of-service congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set class-of-service interfaces ae0 congestion-notification-profile fcoe-cnp
set class-of-service interfaces ae1 congestion-notification-profile fcoe-cnp
set vlans fcoe_vlan vlan-id 100
set protocols igmp-snooping vlan fcoe_vlan disable
set interfaces xe-0/0/10 ether-options 802.3ad ae0
set interfaces xe-0/0/11 ether-options 802.3ad ae0
set interfaces xe-0/0/20 ether-options 802.3ad ae1
set interfaces xe-0/0/21 ether-options 802.3ad ae1
set interfaces ae0 unit 0 family ethernet-switching port-mode trunk vlan members fcoe_vlan
set interfaces ae1 unit 0 family ethernet-switching port-mode trunk vlan members fcoe_vlan
set interfaces ae0 mtu 2180
set interfaces ae1 mtu 2180
```

```
set ethernet-switching-options secure-access-port interface ae0 fcoe-trusted
set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted
```

To quickly configure CoS for lossless FCoE transport across an MC-LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI for Transit Switch TS1 and Transit Switch TS2 at the **[edit]** hierarchy level. The configurations on Switches TS1 and TS2 are identical because the CoS configuration must be identical, and because this example uses the same ports on both switches.

## Switch TS1 and Switch TS2

```
set class-of-service schedulers fcoe-sched priority low transmit-rate 3g
set class-of-service schedulers fcoe-sched shaping-rate percent 100

set interfaces xe-0/0/31 mtu 2180
set interfaces xe-0/0/32 mtu 2180
set interfaces xe-0/0/33 mtu 2180
set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted
set ethernet-switching-options secure-access-port vlan fcoe_vlan examine-fip examine-vn2v2
beacon-period 90000
```

### *Configuring MC-LAG Switches S1 and S2*

**Step-by-Step Procedure** To configure CoS resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG and MC-LAG interface membership and characteristics to support lossless FCoE transport across an MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:  

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```
2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):  

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```
3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:  

```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```
4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:  

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```
5. Apply the FCoE forwarding class set and traffic control profile to the LAG and MC-LAG interfaces:  

```
[edit class-of-service]
user@switch# set interfaces ae0 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
```
6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point **011**:  

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```
7. Apply the PFC configuration to the LAG and MC-LAG interfaces:  

```
[edit class-of-service]
user@switch# set interfaces ae0 congestion-notification-profile fcoe-cnp
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
```
8. Configure the VLAN for FCoE traffic (**fcoe\_vlan**):  

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```
9. Disable IGMP snooping on the FCoE VLAN:  

```
[edit protocols]
user@switch# set igmp-snooping vlan fcoe_vlan disable
```

10. Add the member interfaces to the LAG between the two MC-LAG switches:

```
[edit interfaces]
user@switch# set xe-0/0/10 ether-options 802.3ad ae0
user@switch# set xe-0/0/11 ether-options 802.3ad ae0
```

11. Add the member interfaces to the MC-LAG:

```
[edit interfaces]
user@switch# set xe-0/0/20 ether-options 802.3ad ae1
user@switch# set xe-0/0/21 ether-options 802.3ad ae1
```

12. Configure the port mode as **trunk** and membership in the FCoE VLAN (**fcoe\_vlan**) for the LAG (**ae0**) and for the MC-LAG (**ae1**):

```
[edit interfaces]
user@switch# set interfaces ae0 unit 0 family ethernet-switching port-mode trunk vlan
members fcoe_vlan
user@switch# set interfaces ae1 unit 0 family ethernet-switching port-mode trunk vlan
members fcoe_vlan
```

13. Set the MTU to **2180** for the LAG and MC-LAG interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```
[edit interfaces]
user@switch# set ae0 mtu 2180
user@switch# set ae1 mtu 2180
```

14. Set the LAG and MC-LAG interfaces as FCoE trusted ports. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```
[edit]
user@switch# set ethernet-switching-options secure-access-port interface ae0 fcoe-trusted
user@switch# set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted
```

### *Configuring FCoE Transit Switches TS1 and TS2*

#### **Step-by-Step Procedure**

The CoS configuration on FCoE Transit Switches TS1 and TS2 is similar to the CoS configuration on MC-LAG Switches S1 and S2. However, the port configurations differ, and you must enable FIP snooping on the Switch TS1 and Switch TS2 FCoE access ports.

To configure resource scheduling (ETS), PFC, the FCoE VLAN, and the LAG interface membership and characteristics to support lossless FCoE transport across the MC-LAG (this example uses the default **fcoe** forwarding class and the default classifier to map incoming FCoE traffic to the FCoE IEEE 802.1p code point **011**, so you do not configure them):

1. Configure output scheduling for the FCoE queue:

```
[edit class-of-service]
user@switch# set schedulers fcoe-sched priority low transmit-rate 3g
user@switch# set schedulers fcoe-sched shaping-rate percent 100
```

2. Map the FCoE forwarding class to the FCoE scheduler (**fcoe-sched**):

```
[edit class-of-service]
user@switch# set scheduler-maps fcoe-map forwarding-class fcoe scheduler fcoe-sched
```

3. Configure the forwarding class set (**fcoe-pg**) for the FCoE traffic:

- ```
[edit class-of-service]
user@switch# set forwarding-class-sets fcoe-pg class fcoe
```
4. Define the traffic control profile (**fcoe-tcp**) to use on the FCoE forwarding class set:

```
[edit class-of-service]
user@switch# set traffic-control-profiles fcoe-tcp scheduler-map fcoe-map
guaranteed-rate 3g
user@switch# set traffic-control-profiles fcoe-tcp shaping-rate percent 100
```
  5. Apply the FCoE forwarding class set and traffic control profile to the LAG interface and to the FCoE access interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae1 forwarding-class-set fcoe-pg output-traffic-control-profile
fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/30 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/31 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/32 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
user@switch# set class-of-service interfaces xe-0/0/33 forwarding-class-set fcoe-pg
output-traffic-control-profile fcoe-tcp
```
  6. Enable PFC on the FCoE priority by creating a congestion notification profile (**fcoe-cnp**) that applies FCoE to the IEEE 802.1 code point 011:

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point
011 pfc
```
  7. Apply the PFC configuration to the LAG interface and to the FCoE access interfaces:

```
[edit class-of-service]
user@switch# set interfaces ae1 congestion-notification-profile fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/30 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/31 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/32 congestion-notification-profile
fcoe-cnp
user@switch# set class-of-service interfaces xe-0/0/33 congestion-notification-profile
fcoe-cnp
```
  8. Configure the VLAN for FCoE traffic (**fcoe\_vlan**):

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```
  9. Disable IGMP snooping on the FCoE VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan fcoe_vlan disable
```
  10. Add the member interfaces to the LAG:

```
[edit interfaces]
user@switch# set xe-0/0/25 ether-options 802.3ad ae1
user@switch# set xe-0/0/26 ether-options 802.3ad ae1
```
  11. On the LAG (**ae1**), configure the port mode as **trunk** and membership in the FCoE VLAN (**fcoe\_vlan**):

```
[edit interfaces]
user@switch# set interfaces ae1 unit 0 family ethernet-switching port-mode trunk vlan
members fcoe_vlan
```

12. On the FCoE access interfaces (xe-0/0/30, xe-0/0/31, xe-0/0/32, xe-0/0/33), configure the port mode as **tagged-access** and membership in the FCoE VLAN (**fcoe\_vlan**):

```
[edit interfaces]
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/32 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
user@switch# set interfaces xe-0/0/33 unit 0 family ethernet-switching port-mode
tagged-access vlan members fcoe_vlan
```

13. Set the MTU to **2180** for the LAG and FCoE access interfaces. 2180 bytes is the minimum size required to handle FCoE packets because of the payload and header sizes; you can configure the MTU to a higher number of bytes if desired, but not less than 2180 bytes:

```
[edit interfaces]
user@switch# set ae1 mtu 2180
user@switch# set xe-0/0/30 mtu 2180
user@switch# set xe-0/0/31 mtu 2180
user@switch# set xe-0/0/32 mtu 2180
user@switch# set xe-0/0/33 mtu 2180
```

14. Set the LAG interface as an FCoE trusted port. Ports that connect to other switches should be trusted and should not perform FIP snooping:

```
[edit]
user@switch# set ethernet-switching-options secure-access-port interface ae1 fcoe-trusted
```

**NOTE:** Access ports xe-0/0/30, xe-0/0/31, xe-0/0/32, and xe-0/0/33 are not configured as FCoE trusted ports. The access ports remain in the default state as untrusted ports because they connect directly to FCoE devices and must perform FIP snooping to ensure network security.

15. Enable FIP snooping on the FCoE VLAN to prevent unauthorized FCoE network access (this example uses VN2VN\_Port FIP snooping; the example is equally valid if you use VN2VF\_Port FIP snooping):

```
[edit]
user@switch# set ethernet-switching-options secure-access-port vlan fcoe_vlan
examine-fip examine-vn2vn beacon-period 90000
```

## Results

Display the results of the CoS configuration on MC-LAG Switch S1 and on MC-LAG Switch S2 (the results on both switches are the same):

```
user@switch> show configuration class-of-service
traffic-control-profiles {
```

```
fcoe-tcp {
  scheduler-map fcoe-map;
  shaping-rate percent 100;
  guaranteed-rate 3000000000;
}
}
forwarding-class-sets {
  fcoe-pg {
    class fcoe;
  }
}
congestion-notification-profile {
  fcoe-cnp {
    input {
      ieee-802.1 {
        code-point 011 {
          pfc;
        }
      }
    }
  }
}
}
interfaces {
  ae0 {
    forwarding-class-set {

    shaping-rate percent 100;
    priority low;
  }
}
```

**NOTE:** The forwarding class and classifier configurations are not shown because the `show` command does not display default portions of the configuration.

---

## Verification

---

To verify that the CoS components and FIP snooping have been configured and are operating properly, perform these tasks. Because this example uses the default **fcoe** forwarding class and the default IEEE 802.1p trusted classifier, the verification of those configurations is not shown:

- [Verifying That the Output Queue Schedulers Have Been Created on page 5465](#)
- [Verifying That the Priority Group Output Scheduler \(Traffic Control Profile\) Has Been Created on page 5466](#)

- [Verifying That the Forwarding Class Set \(Priority Group\) Has Been Created on page 5466](#)
- [Verifying That Priority-Based Flow Control Has Been Enabled on page 5466](#)
- [Verifying That the Interface Class of Service Configuration Has Been Created on page 5467](#)
- [Verifying That the Interfaces Are Correctly Configured on page 5469](#)
- [Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces on page 5471](#)
- [Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2 on page 5472](#)
- [Verifying That IGMP Snooping Is Disabled on the FCoE VLAN on page 5473](#)

### ***Verifying That the Output Queue Schedulers Have Been Created***

**Purpose** Verify that the output queue scheduler for FCoE traffic has the correct bandwidth parameters and priorities, and is mapped to the correct forwarding class (output queue). Queue scheduler verification is the same on each of the four switches.

**Action** List the scheduler map using the operational mode command **show class-of-service scheduler-map fcoe-map**:

```
user@switch> show class-of-service scheduler-map fcoe-map
Scheduler map: fcoe-map, Index: 9023
```

```
Scheduler: fcoe-sched, Forwarding class: fcoe, Index: 37289
  Transmit rate: 3000000000 bps, Rate Limit: none, Buffer size: remainder,
  Buffer Limit: none, Priority: low
  Excess Priority: unspecified
  Shaping rate: 100 percent,
  drop-profile-map-set-type: mark
  Drop profiles:
    Loss priority  Protocol  Index  Name
    Low           any       1      <default-drop-profile>
    Medium high   any       1      <default-drop-profile>
    High          any       1      <default-drop-profile>
```

**Meaning** The **show class-of-service scheduler-map fcoe-map** command lists the properties of the scheduler map **fcoe-map**. The command output includes:

- The name of the scheduler map (**fcoe-map**)
- The name of the scheduler (**fcoe-sched**)
- The forwarding classes mapped to the scheduler (**fcoe**)
- The minimum guaranteed queue bandwidth (transmit rate **3000000000 bps**)
- The scheduling priority (**low**)
- The maximum bandwidth in the priority group the queue can consume (shaping rate **100 percent**)
- The drop profile loss priority for each drop profile name. This example does not include drop profiles because you do not apply drop profiles to FCoE traffic.

***Verifying That the Priority Group Output Scheduler (Traffic Control Profile) Has Been Created***

**Purpose** Verify that the traffic control profile **fcoe-tcp** has been created with the correct bandwidth parameters and scheduler mapping. Priority group scheduler verification is the same on each of the four switches.

**Action** List the FCoE traffic control profile properties using the operational mode command **show class-of-service traffic-control-profile fcoe-tcp**:

```
user@switch> show class-of-service traffic-control-profile fcoe-tcp
Traffic control profile: fcoe-tcp, Index: 18303
  Shaping rate: 100 percent
  Scheduler map: fcoe-map
  Guaranteed rate: 3000000000
```

**Meaning** The **show class-of-service traffic-control-profile fcoe-tcp** command lists all of the configured traffic control profiles. For each traffic control profile, the command output includes:

- The name of the traffic control profile (**fcoe-tcp**)
- The maximum port bandwidth the priority group can consume (shaping rate **100 percent**)
- The scheduler map associated with the traffic control profile (**fcoe-map**)
- The minimum guaranteed priority group port bandwidth (guaranteed rate **3000000000** in bps)

***Verifying That the Forwarding Class Set (Priority Group) Has Been Created***

**Purpose** Verify that the FCoE priority group has been created and that the **fcoe** priority (forwarding class) belongs to the FCoE priority group. Forwarding class set verification is the same on each of the four switches.

**Action** List the forwarding class sets using the operational mode command **show class-of-service forwarding-class-set fcoe-pg**:

```
user@switch> show class-of-service forwarding-class-set fcoe-pg
Forwarding class set: fcoe-pg, Type: normal-type, Forwarding class set index:
31420
  Forwarding class          Index
  fcoe                      1
```

**Meaning** The **show class-of-service forwarding-class-set fcoe-pg** command lists all of the forwarding classes (priorities) that belong to the **fcoe-pg** priority group, and the internal index number of the priority group. The command output shows that the forwarding class set **fcoe-pg** includes the forwarding class **fcoe**.

***Verifying That Priority-Based Flow Control Has Been Enabled***

**Purpose** Verify that PFC is enabled on the FCoE code point. PFC verification is the same on each of the four switches.

**Action** List the FCoE congestion notification profile using the operational mode command **show class-of-service congestion-notification fcoe-cnp**:

```
user@switch> show class-of-service congestion-notification fcoe-cnp
Type: Input, Name: fcoe-cnp, Index: 6879
Cable Length: 100 m
  Priority  PFC      MRU
  000      Disabled
  001      Disabled
  010      Disabled
  011      Enabled   2500
  100      Disabled
  101      Disabled
  110      Disabled
  111      Disabled
Type: Output
  Priority  Flow-Control-Queues
  000      0
  001      1
  010      2
  011      3
  100      4
  101      5
  110      6
  111      7
```

**Meaning** The **show class-of-service congestion-notification fcoe-cnp** command lists all of the IEEE 802.1p code points in the congestion notification profile that have PFC enabled. The command output shows that PFC is enabled on code point **011** (**fcoe** queue) for the **fcoe-cnp** congestion notification profile.

The command also shows the default cable length (100 meters), the default maximum receive unit (2500 bytes), and the default mapping of priorities to output queues because this example does not include configuring these options.

#### *Verifying That the Interface Class of Service Configuration Has Been Created*

**Purpose** Verify that the CoS properties of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches TS1 and TS2.

**Action** List the interface CoS configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces
ae0 {
    forwarding-class-set {
        fcoe-pg {
            output-traffic-control-profile fcoe-tcp;
```

```
    }  
  }  
  congestion-notification-profile fcoe-cnp;  
}  
  
ae1 {  
  forwarding-class-set {  
    fcoe-pg {  
      output-traffic-control-profile fcoe-tcp;  
    }  
  }  
  congestion-notification-profile fcoe-cnp;  
}
```

List the interface CoS configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration class-of-service interfaces**:

```
user@switch> show configuration class-of-service interfaces  
xe-0/0/30 {  
  forwarding-class-set {  
    fcoe-pg {  
      output-traffic-control-profile fcoe-tcp;  
    }  
  }  
  congestion-notification-profile fcoe-cnp;  
}  
xe-0/0/31 {  
  forwarding-class-set {  
    fcoe-pg {  
      output-traffic-control-profile fcoe-tcp;  
    }  
  }  
  congestion-notification-profile fcoe-cnp;  
}  
xe-0/0/32 {  
  forwarding-class-set {  
    fcoe-pg {  
      output-traffic-control-profile fcoe-tcp;  
    }  
  }  
  congestion-notification-profile fcoe-cnp;  
}  
xe-0/0/33 {  
  forwarding-class-set {  
    fcoe-pg {  
      output-traffic-control-profile fcoe-tcp;  
    }  
  }  
  congestion-notification-profile fcoe-cnp;  
}  
ae1 {  
  forwarding-class-set {  
    fcoe-pg {  
      output-traffic-control-profile fcoe-tcp;  
    }  
  }  
  congestion-notification-profile fcoe-cnp;  
}
```

**Meaning** The **show configuration class-of-service interfaces** command lists the class of service configuration for all interfaces. For each interface, the command output includes:

- The name of the interface (for example, **ae0** or **xe-0/0/30**)
- The name of the forwarding class set associated with the interface (**fcoe-pg**)
- The name of the traffic control profile associated with the interface (output traffic control profile, **fcoe-tcp**)
- The name of the congestion notification profile associated with the interface (**fcoe-cnp**)

**NOTE:** Interfaces that are members of a LAG are not shown individually. The LAG or MC-LAG CoS configuration is applied to all interfaces that are members of the LAG or MC-LAG. For example, the interface CoS configuration output on MC-LAG Switches S1 and S2 shows the LAG CoS configuration but does not show the CoS configuration of the member interfaces separately. The interface CoS configuration output on FCoE Transit Switches TS1 and TS2 shows the LAG CoS configuration but also shows the configuration for interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33**, which are not members of a LAG.

### *Verifying That the Interfaces Are Correctly Configured*

**Purpose** Verify that the LAG membership, MTU, VLAN membership, and port mode of the interfaces are correct. The verification output on MC-LAG Switches S1 and S2 differs from the output on FCoE Transit Switches T1 and T2.

**Action** List the interface configuration on MC-LAG Switches S1 and S2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
xe-0/0/10 {
    ether-options {
        802.3ad ae0;
    }
}
xe-0/0/11 {
    ether-options {
        802.3ad ae0;
    }
}
xe-0/0/20 {
    ether-options {
        802.3ad ae1;
    }
}
xe-0/0/21 {
    ether-options {
        802.3ad ae1;
    }
}
```

```
ae0 {
  mtu 2180;
  unit 0 {
    family ethernet-switching {
      port-mode trunk;
      vlan {
        members fcoe_vlan;
      }
    }
  }
}
ae1 {
  mtu 2180;
  unit 0 {
    family ethernet-switching {
      port-mode trunk;
      vlan {
        members fcoe_vlan;
      }
    }
  }
}
```

List the interface configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration interfaces**:

```
user@switch> show configuration interfaces
xe-0/0/25 {
  ether-options {
    802.3ad ae1;
  }
}
xe-0/0/26 {
  ether-options {
    802.3ad ae1;
  }
}
xe-0/0/30 {
  mtu 2180;
  unit 0 {
    family ethernet-switching {
      port-mode tagged-access;
      vlan {
        members fcoe_vlan;
      }
    }
  }
}
xe-0/0/31 {
  mtu 2180;
  unit 0 {
    family ethernet-switching {
      port-mode tagged-access;
      vlan {
        members fcoe_vlan;
      }
    }
  }
}
xe-0/0/32 {
```

```

mtu 2180;
unit 0 {
    family ethernet-switching {
        port-mode tagged-access;
        vlan {
            members fcoe_vlan;
        }
    }
}
xe-0/0/33 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            port-mode tagged-access;
            vlan {
                members fcoe_vlan;
            }
        }
    }
}
ae1 {
    mtu 2180;
    unit 0 {
        family ethernet-switching {
            port-mode trunk;
            vlan {
                members fcoe_vlan;
            }
        }
    }
}

```

**Meaning** The `show configuration interfaces` command lists the configuration of each interface by interface name.

For each interface that is a member of a LAG, the command lists only the name of the LAG to which the interface belongs.

For each LAG interface and for each interface that is not a member of a LAG, the command output includes:

- The MTU (**2180**)
- The unit number of the interface (**0**)
- The port mode (**trunk** mode for interfaces that connect two switches, **tagged-access** mode for interfaces that connect to FCoE hosts)
- The name of the VLAN in which the interface is a member (**fcoe\_vlan**)

*Verifying That FIP Snooping Is Enabled on the FCoE VLAN on FCoE Transit Switches TS1 and TS2 Access Interfaces*

**Purpose** Verify that FIP snooping is enabled on the FCoE VLAN access interfaces. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches

TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

**Action** List the port security configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show configuration ethernet-switching-options secure-access-port**:

```
user@switch> show configuration ethernet-switching-options secure-access-port
interface ae1.0 {
    fcoe-trusted;
}
vlan fcoe_vlan {
    examine-fip {
        examine-vn2vn {
            beacon-period 90000;
        }
    }
}
```

**Meaning** The **show configuration ethernet-switching-options secure-access-port** command lists port security information, including whether a port is trusted. The command output shows that:

- LAG port **ae1.0**, which connects the FCoE transit switch to the MC-LAG switches, is configured as an FCoE trusted interface. FIP snooping is not performed on the member interfaces of the LAG (**xe-0/0/25** and **xe-0/0/26**).
- FIP snooping is enabled (**examine-fip**) on the FCoE VLAN (**fcoe\_vlan**), the type of FIP snooping is VN2VN\_Port FIP snooping (**examine-vn2vn**) and the beacon period is set to 90000 milliseconds. On Transit Switches TS1 and TS2, all interface members of the FCoE VLAN perform FIP snooping unless the interface is configured as FCoE trusted. On Transit Switches TS1 and TS2, interfaces **xe-0/0/30**, **xe-0/0/31**, **xe-0/0/32**, and **xe-0/0/33** perform FIP snooping because they are not configured as FCoE trusted. The interface members of LAG **ae1** (**xe-0/0/25** and **xe-0/0/26**) do not perform FIP snooping because the LAG is configured as FCoE trusted.

#### ***Verifying That the FIP Snooping Mode Is Correct on FCoE Transit Switches TS1 and TS2***

**Purpose** Verify that the FIP snooping mode is correct on the FCoE VLAN. FIP snooping is enabled only on the FCoE access interfaces, so it is enabled only on FCoE Transit Switches TS1 and TS2. FIP snooping is not enabled on MC-LAG Switches S1 and S2 because FIP snooping is done at the Transit Switch TS1 and TS2 FCoE access ports.

**Action** List the FIP snooping configuration on FCoE Transit Switches TS1 and TS2 using the operational mode command **show fip snooping brief**:

```
user@switch> show fip snooping brief
VLAN: fcoe_vlan,      Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
...
```

**NOTE:** The output has been truncated to show only the relevant information.

**Meaning** The **show fip snooping brief** command lists FIP snooping information, including the FIP snooping VLAN and the FIP snooping mode. The command output shows that:

- The VLAN on which FIP snooping is enabled is **fcoe\_vlan**
- The FIP snooping mode is VN2VN\_Port FIP snooping (**VN2VN Snooping**)

#### *Verifying That IGMP Snooping Is Disabled on the FCoE VLAN*

**Purpose** Verify that IGMP snooping is disabled on the FCoE VLAN on all four switches.

**Action** List the IGMP snooping protocol information on each of the four switches using the **show configuration protocols igmp-snooping** command:

```
user@switch> show configuration protocols igmp-snooping
vlan fcoe_vlan {
    disable;
}
```

**Meaning** The **show configuration protocols igmp-snooping** command lists the IGMP snooping configuration for the VLANs configured on the switch. The command output shows that IGMP snooping is disabled on the FCoE VLAN (**fcoe\_vlan**).

## Example: Configuring DCBX Application Protocol TLV Exchange

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of connected peers by exchanging application configuration information. DCBX detects feature misconfiguration and mismatches and can configure DCB on peers. DCBX is an extension of the Link Layer Discovery Protocol (LLDP). LLDP must remain enabled on every interface on which you want to use DCBX.

**NOTE:** LLDP and DCBX are enabled by default on all interfaces.

The switch supports DCBX application protocol exchange for Layer 2 and Layer 4 applications such as the Internet Small Computer System Interface (iSCSI). You specify

applications by EtherType (for Layer 2 applications) or by the destination port and protocol (for Layer 4 applications; the protocol can be either TCP or UDP).

The switch handles Fibre Channel over Ethernet (FCoE) application protocol exchange differently than other protocols in some cases:

- If FCoE is the only application for which you want to enable DCBX application protocol TLV exchange on an interface, you do not have to explicitly configure the FCoE application or an application map. By default, the switch exchanges FCoE application protocol TLVs on all interfaces that carry FCoE traffic (traffic mapped to the **fcoe** forwarding class) and have priority-based flow control (PFC) enabled on the FCoE priority (the FCoE IEEE 802.1p code point). The default priority mapping for the FCoE application is IEEE 802.1p code point 011 (the default **fcoe** forwarding class code point).
- If you want an interface to use DCBX to exchange application protocol TLVs for any other applications in addition to FCoE, you must configure the applications (including FCoE), define an application map (including FCoE), and apply the application map to the interface. If you apply an application map to an interface, you must explicitly configure the FCoE application, or the interface does not exchange FCoE application protocol TLVs.

This example shows how to configure interfaces to exchange both Layer 2 and Layer 4 applications by configuring one interface to exchange iSCSI and FCoE application protocol information and configuring another interface to exchange iSCSI and Precision Time Protocol (PTP) application protocol information.

- [Verification on page 5480](#)

---

## Requirements

This example uses the following hardware and software components:

- Juniper Networks QFX Series device
- Junos OS Release 12.1 or later for the QFX Series

---

## Overview

The switch supports DCBX application protocol exchange for:

- Layer 2 applications, defined by EtherType
- Layer 4 applications, defined by destination port and protocol

**NOTE:** DCBX also advertises PFC and enhanced transmission selection (ETS) information. See [“Configuring DCBX Autonegotiation” on page 5561](#) for how DCBX negotiates and advertises configuration information for these features and for the applications.

---

DCBX is configured on a per-interface basis for each supported feature or application. For applications that you want to enable for DCBX application protocol exchange, you must:

- Define the application name and configure the EtherType or the destination port and protocol (TCP or UDP) of the application. Use the EtherType for Layer 2 applications, and use the destination port and protocol for Layer 4 protocols.
- Map the application to an IEEE 802.1p code point in an application map.
- Add the application map to DCBX interface.

In addition, for all applications (including FCoE, even when you do not use an application map), you either must create an IEEE 802.1p classifier and apply it to the appropriate ingress interfaces or use the default classifier. A classifier maps the code points of incoming traffic to a forwarding class and a loss priority so that ingress traffic is assigned to the correct class of service (CoS). The forwarding class determines the output queue on the egress interface.

If you do not create classifiers, trunk and tagged-access ports use the unicast IEEE 802.1 default trusted classifier. [Table 395 on page 5475](#) shows the default mapping of IEEE 802.1 code-point values to unicast forwarding classes and loss priorities for ports in trunk mode or tagged-access mode. [Table 396 on page 5476](#) shows the default untrusted classifier IEEE 802.1 code-point values to unicast forwarding class mapping for ports in access mode.

**Table 395: Default IEEE 802.1 Classifiers for Trunk Ports and Tagged-Access Ports (Default Trusted Classifier)**

| Code Point | Forwarding Class | Loss Priority |
|------------|------------------|---------------|
| be (000)   | best-effort      | low           |
| be1 (001)  | best-effort      | low           |
| ef (010)   | best-effort      | low           |
| ef1 (011)  | fcoe             | low           |
| af11 (100) | no-loss          | low           |
| af12 (101) | best-effort      | low           |
| nc1 (110)  | network-control  | low           |
| nc2 (111)  | network-control  | low           |

**Table 396: Default IEEE 802.1 Unicast Classifiers for Access Ports (Default Untrusted Classifier)**

| Code Point | Forwarding Class | Loss Priority |
|------------|------------------|---------------|
| 000        | best-effort      | low           |
| 001        | best-effort      | low           |
| 010        | best-effort      | low           |
| 011        | best-effort      | low           |
| 100        | best-effort      | low           |
| 101        | best-effort      | low           |
| 110        | best-effort      | low           |
| 111        | best-effort      | low           |

**Topology**

This example shows how to configure DCBX application protocol exchange for three protocols (iSCSI, PTP, and FCoE) on two interfaces. One interface exchanges iSCSI and FCoE application protocol information, and the other interface exchanges iSCSI and PTP application protocol information.

**NOTE:** You must map FCoE traffic to the interfaces on which you want to forward FCoE traffic. You must also enable PFC on the FCoE interfaces and create an ingress classifier for FCoE traffic, or else use the default classifier.

Table 397 on page 5476 shows the configuration components for this example.

**Table 397: Components of DCBX Application Protocol Exchange Configuration Topology**

| Component | Settings                                  |
|-----------|-------------------------------------------|
| Hardware  | QFX Series device                         |
| LLDP      | Enabled by default on Ethernet interfaces |
| DCBX      | Enabled by default on Ethernet interfaces |

**Table 397: Components of DCBX Application Protocol Exchange Configuration Topology (*continued*)**

| Component                                                         | Settings                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| iSCSI application (Layer 4)                                       | Application name— <b>iscsi</b><br>protocol— <b>TCP</b><br>destination-port— <b>3260</b><br>code-points— <b>111</b>                                                                                                                                                                                                                                           |

| Behavior aggregate classifiers (map forwarding classes to incoming packets by the packet's IEEE 802.1 code point) | <p><b>fcoe-iscsi-cl1:</b></p> <ul style="list-style-type: none"> <li>Maps the <b>fcoe</b> forwarding class to the IEEE 802.1p code point used for the FCoE application (011) and a loss priority of <b>high</b></li> <li>Maps the <b>network-control</b> forwarding class to the IEEE 802.1p code point used for the iSCSI application (111) and a loss priority of <b>high</b></li> <li>Applied to interface <b>xe-0/0/10</b></li> </ul> <p><b>iscsi-ntp-cl2:</b></p> <ul style="list-style-type: none"> <li>Maps the <b>network-control</b> forwarding class to the IEEE 802.1p code point used for the iSCSI application (111) and a loss priority of <b>low</b></li> <li>Maps the <b>best-effort</b> forwarding class to the IEEE 802.1p code points used for the PTP application (001 and 101) and a loss priority of <b>low</b></li> <li>Applied to interface <b>xe-0/0/11</b></li> </ul> |

**NOTE:** This example does not include scheduling (bandwidth allocation) configuration or lossless configuration for the iSCSI forwarding class.

### Configuration

#### CLI Quick Configuration

To quickly configure DCBX application protocol exchange, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

set applications application iSCSI protocol tcp destination-port 3260
set applications application FCoE ether-type 0x8906
set applications application PTP ether-type 0x88F7
set policy-options application-maps dcbx-iscsi-fcoe-app-map application iSCSI code-points 111
set policy-options application-maps dcbx-iscsi-fcoe-app-map application FCoE code-points 011
set policy-options application-maps dcbx-iscsi-ntp-app-map application iSCSI code-points 111
set policy-options application-maps dcbx-iscsi-ntp-app-map application PTP code-points [001 101]
set protocols dcbx interface xe-0/0/10 application-map dcbx-iscsi-fcoe-app-map
set protocols dcbx interface xe-0/0/11 application-map dcbx-iscsi-ntp-app-map
set class-of-service congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
set class-of-service interfaces xe-0/0/10 congestion-notification-profile fcoe-cnp
set class-of-service classifiers ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class fcoe
loss-priority high code-points 011
set class-of-service classifiers ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class
network-control loss-priority high code-points 111
set class-of-service classifiers ieee-802.1 iscsi-ntp-cl2 import default forwarding-class
network-control loss-priority low code-points 111
set class-of-service classifiers ieee-802.1 iscsi-ntp-cl2 import default forwarding-class best-effort
loss-priority low code-points [001 101]
set class-of-service interfaces xe-0/0/10 unit 0 classifiers ieee-802.1 fcoe-iscsi-cl1

```

```
set class-of-service interfaces xe-0/0/11 unit 0 classifiers ieee-802.1 iscsi-ptp-cl2
```

### *Configuring DCBX Application Protocol TLV Exchange*

**Step-by-Step Procedure** To define the applications, map the applications to IEEE 802.1p code points, apply the applications to interfaces, and create classifiers for DCBX application protocol exchange:

1. Define the iSCSI application by specifying its protocol and destination port, and define the FCoE and PTP applications by specifying their EtherTypes.  

```
[edit applications]
user@switch# set application iSCSI protocol tcp destination-port 3260
user@switch# set application FCoE ether-type 0x8906
user@switch# set application PTP ether-type 0x88F7
```
2. Define an application map that maps the iSCSI and FCoE applications to IEEE 802.1p code points.  

```
[edit policy-options]
user@switch# set application-maps dcbx-iscsi-fcoe-app-map application iSCSI code-points 111
user@switch# set application-maps dcbx-iscsi-fcoe-app-map application FCoE code-points 011
```
3. Define the application map that maps the iSCSI and PTP applications to IEEE 802.1p code points.  

```
[edit policy-options]
user@switch# set application-maps dcbx-iscsi-ptp-app-map application iSCSI code-points 111
user@switch# set application-maps dcbx-iscsi-ptp-app-map application PTP code-points [001 101]
```
4. Apply the iSCSI and FCoE application map to interface xe-0/0/10, and apply the iSCSI and PTP application map to interface xe-0/0/11.  

```
[edit protocols dcbx]
user@switch# set interface xe-0/0/10 application-map dcbx-iscsi-fcoe-app-map
user@switch# set interface xe-0/0/11 application-map dcbx-iscsi-ptp-app-map
```
5. Create the congestion notification profile to enable PFC on the FCoE code point (011), and apply the congestion notification profile to interface xe-0/0/10.  

```
[edit class-of-service]
user@switch# set congestion-notification-profile fcoe-cnp input ieee-802.1 code-point 011 pfc
user@switch# set interfaces xe-0/0/10 congestion-notification-profile fcoe-cnp
```
6. Configure the classifier to apply to the interface that exchanges iSCSI and FCoE application information.  

```
[edit class-of-service classifiers]
user@switch# set ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class fcoe loss-priority high code-points 011
user@switch# set ieee-802.1 fcoe-iscsi-cl1 import default forwarding-class network-control loss-priority high code-points 111
```
7. Configure the classifier to apply to the interface that exchanges iSCSI and PTP application information.  

```
[edit class-of-service classifiers]
```

```
user@switch# set ieee-802.1 iscsi-ptp-cl2 import default forwarding-class network-control
loss-priority low code-points 111
user@switch# set ieee-802.1 iscsi-ptp-cl2 import default forwarding-class best-effort
loss-priority low code-points [001 101]
```

8. Apply the classifiers to the appropriate interfaces.

```
[edit class-of-service]
user@switch# set interfaces xe-0/0/10 unit 0 classifiers ieee-802.1 fcoe-iscsi-cl1
user@switch# set interfaces xe-0/0/11 unit 0 classifiers ieee-802.1 iscsi-ptp-cl2
```

---

### Verification

To verify that DCBX application protocol exchange configuration has been created and is operating properly, perform these tasks:

- [Verifying the Application Configuration on page 5480](#)
- [Verifying the Application Map Configuration on page 5480](#)
- [Verifying DCBX Application Protocol Exchange Interface Configuration on page 5481](#)
- [Verifying the PFC Configuration on page 5481](#)
- [Verifying the Classifier Configuration on page 5482](#)

#### *Verifying the Application Configuration*

**Purpose** Verify that DCBX applications have been configured.

**Action** List the applications by using the configuration mode command **show applications**:

```
user@switch# show applications
application iSCSI {
    protocol tcp;
    destination-port 3260;
}

application fcoe {
    ether-type 0x8906;
}

application ptp {
    ether-type 0x88F7;
}
```

**Meaning** The **show applications** configuration mode command lists all of the configured applications and either their protocol and destination port (Layer 4 applications) or their EtherType (Layer 2 applications). The command output shows that the iSCSI application is configured with the **tcp** protocol and destination port **3260**, the FCoE application is configured with the EtherType **0x8906**, and that the PTP application is configured with the EtherType **0x88F7**.

#### *Verifying the Application Map Configuration*

**Purpose** Verify that the application maps have been configured.

**Action** List the application maps by using the configuration mode command **show policy-options application-maps**:

```
user@switch# show policy-options application-maps
dcbx-iscsi-fcoe-app-map {
    application iSCSI code-points 111;
    application FCoE code-points 011;
}

dcbx-iscsi-ptp-app-map {
    application iSCSI code-points 111;
    application PTP code-points [001 101];
}
```

**Meaning** The **show policy-options application-maps** configuration mode command lists all of the configured application maps and the applications that belong to each application map. The command output shows that there are two application maps, **dcbx-iscsi-fcoe-app-map** and **dcbx-iscsi-ptp-app-map**.

The application map **dcbx-iscsi-fcoe-app-map** consists of the iSCSI application, which is mapped to IEEE 802.1p code point 111, and the FCoE application, which is mapped to IEEE 802.1p code point 011.

The application map **dcbx-iscsi-ptp-app-map** consists of the iSCSI application, which is mapped to IEEE 802.1p code point 111, and the PTP application, which is mapped to IEEE 802.1p code points 001 and 101.

#### *Verifying DCBX Application Protocol Exchange Interface Configuration*

**Purpose** Verify that the application maps have been applied to the correct interfaces.

**Action** List the application maps by using the configuration mode command **show protocols dcbx**:

```
user@switch# show protocols dcbx
interface xe-0/0/10.0 {
    application-map dcbx-iscsi-fcoe-app-map;
}

interface xe-0/0/11.0 {
    application-map dcbx-iscsi-ptp-app-map;
}
```

**Meaning** The **show protocols dcbx** configuration mode command lists whether the interfaces are enabled for DCBX and lists the application map applied to each interface. The command output shows that interfaces **xe-0/0/10.0** and **xe-0/0/11.0** are enabled for DCBX, and that interface **xe-0/0/10.0** uses application map **dcbx-iscsi-fcoe-app-map**, and interface **xe-0/0/11.0** uses application map **dcbx-iscsi-ptp-app-map**.

#### *Verifying the PFC Configuration*

**Purpose** Verify that PFC has been enabled on the FCoE code point and applied to the correct interface.

**Action** Display the PFC configuration to verify that PFC is enabled on the FCoE code point (011) in the congestion notification profile **fcoe-cnp** by using the configuration mode command **show class-of-service congestion-notification-profile**:

```
user@switch# show class-of-service congestion-notification-profile
fcoe-cnp {
  input {
    ieee-802.1 {
      code-point 011 {
        pfc;
      }
    }
  }
}
```

Display the class-of-service (CoS) interface information to verify that the correct interface has PFC enabled for the FCoE application by using the configuration mode command **show class-of-service interfaces**:

```
user@switch# show class-of-service interfaces
xe-0/0/10 {
  congestion-notification-profile fcoe-cnp;
}
```

**NOTE:** The sample output does not include all of the information this command can show. The output is abbreviated to focus on verifying the PFC configuration.

**Meaning** The **show class-of-service congestion-notification-profile** configuration mode command lists the configured congestion notification profiles. The command output shows that the congestion notification profile **fcoe-cnp** has been configured and has enabled PFC on the IEEE 802.1p code point **011** (the default FCoE code point).

The **show class-of-service interfaces** configuration mode command shows the interface CoS configuration. The command output shows that the congestion notification profile **fcoe-cnp**, which enables PFC on the FCoE code point, is applied to interface **xe-0/0/10**.

### *Verifying the Classifier Configuration*

**Purpose** Verify that the classifiers have been configured and applied to the correct interfaces.

**Action** Display the classifier configuration by using the configuration mode command **show class-of-service**:

```
user@switch# show class-of-service
classifiers {
  ieee-802.1 fcoe-iscsi-cl1 {
    import default;
    forwarding-class network-control {
      loss-priority high code-points 111;
    }
  }
  forwarding-class fcoe {
    loss-priority high code-points 011;
  }
}
```

```

    }
  }
  ieee-802.1 iscsi-ptp-cl2 {
    import default;
    forwarding-class network-control {
      loss-priority low code-points 111;
    }
    forwarding-class best-effort {
      loss-priority low code-points [ 001 101 ];
    }
  }
}
interfaces {
  xe-0/0/10 {
    congestion-notification-profile fcoe-cnp;
    unit 0 {
      classifiers {
        ieee-802.1 fcoe-iscsi-cl1;
      }
    }
  }
  xe-0/0/11 {
    unit 0 {
      classifiers {
        ieee-802.1 iscsi-ptp-cl2;
      }
    }
  }
}
}

```

**NOTE:** The sample output does not include all of the information this command can show. The output is abbreviated to focus on verifying the classifier configuration.

**Meaning** The **show class-of-service** configuration mode command lists the classifier and CoS interface configuration, as well as other information not shown in this example. The command output shows that there are two classifiers configured, **fcoe-iscsi-cl1** and **iscsi-ptp-cl2**.

Classifier **fcoe-iscsi-cl1** uses the **default** classifier as a template and edits the template as follows:

- The forwarding class **network-control** is set to a loss priority of **high** and is mapped to code point **111** (the code point mapped to the iSCSI application).
- The forwarding class **fcoe** is set to a loss priority of **high** and is mapped to code point **011** (the code point mapped by default to the FCoE application).

Classifier **iscsi-ptp-cl2** uses the **default** classifier as a template and edits the template as follows:

- The forwarding class **network-control** is set to a loss priority of **low** and is mapped to IEEE 802.1p code point **111** (the code point mapped to the iSCSI application).

- The forwarding class **best-effort** is set to a loss priority of **low** and is mapped to IEEE 802.1p code points **001** and **101** (the code points mapped by default to the PTP application).

The command output also shows that classifier **fcoe-iscsi-cl1** is mapped to interface **xe-0/0/10.0** and that classifier **iscsi-ptp-cl2** is mapped to interface **xe-0/0/11.0**.

### Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are directly connected to the same FCoE transit switch.

**NOTE:** This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)*.

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VN\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are directly connected to the same FCoE transit switch, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN\_Port to VF\_Port (FIP snooping) traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF\_Port FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are directly connected to the same transit switch:

- [Requirements on page 5485](#)
- [Overview on page 5486](#)
- [Configuration on page 5486](#)
- [Verification on page 5487](#)

### Requirements

This example uses the following hardware and software components:

- One Juniper Networks QFX3500 Switch used as a transit switch
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

## Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

## Topology

Table 398 on page 5486 shows the configuration components for this example.

**Table 398: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)**

| Component                           | Settings                                                                                                                                                                                                                                                                               |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| FIP snooping mode and beacon period | Set <b>examine-vn2vn</b> (VN2VN_Port FIP snooping)<br>Beacon period—90000 ms                                                                                                                                                                                                           |

Figure 215 on page 5486 shows the network topology for this example.

**Figure 215: VN2VN\_Port FIP Snooping (FCoE Hosts Connected to Same Transit Switch) Topology**

## Configuration

### CLI Quick Configuration

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to the same transit switch, copy the following commands, paste them in a text file, remove line

breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to the Same FCoE Transit Switch)*

**Step-by-Step Procedure** To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host ENodes:  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode tagged-access
```
2. Configure the interface VLAN membership so that the interfaces connected to the ENodes are members of the dedicated VN2VN\_Port VLAN (vlan200):  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```
3. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:  

```
user@switch# set vlans vlan200 vlan-id 200
```
4. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:  

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000
```

### **Verification**

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping is Enabled on the FCoE VLAN on page 5487](#)
- [Verifying the Interface Port Mode on page 5488](#)

### *Verifying That VN2VN\_Port FIP Snooping is Enabled on the FCoE VLAN*

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (vlan200), the beacon period is set to 90000 milliseconds, and the correct interfaces (xe-0/0/20 and xe-0/0/21) are members of the VLAN.

**Action** List the FIP snooping information using the operational mode command **show fip snooping detail**.

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
  Enode Information
    Enode-MAC: 10:10:94:01:00:02,      Interface: xe-0/0/20
    Active VN_Ports : 1
    VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
      Active Sessions : 1
      Session Information
        Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
    Enode-MAC: 10:10:94:01:00:02,      Interface: xe-0/0/21
    Active VN_Ports : 1
    VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
      Active Sessions : 1
      Session Information
        Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces for the ENodes are **xe-0/0/20** and **xe-0/0/21**.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

#### *Verifying the Interface Port Mode*

**Purpose** Verify that the interface port modes are **tagged-access**.

**Action** List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command.

Use the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail** to list the Ethernet switching interface information. The output is truncated to show only the relevant portions:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.
```

```

user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Tagged-Access
.
.
.

```

**Meaning** The `show ethernet-switching interfaces detail` command lists the port mode as `tagged-access` for both interfaces.

### Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other.

**NOTE:** This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Directly Connected to Different FCoE Transit Switches)*.

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VF\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are directly connected to different FCoE transit switches, and the transit switches are directly connected to each other, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN2VF\_Port traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.
- ENode-facing ports must be untrusted ports.
- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable VN2VF\_Port FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are directly connected to different transit switches, and the transit switches are directly connected to each other:

- [Requirements on page 5490](#)
- [Overview on page 5491](#)
- [Configuration on page 5492](#)
- [Verification on page 5493](#)

---

## Requirements

This example uses the following hardware and software components:

- Two Juniper Networks QFX3500 Switches used as transit switches
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

Topology

Table 399 on page 5491 shows the configuration components for this example.

Table 399: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Directly Connected to Different FCoE Transit Switches)

| Component                           | Settings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Interface VLAN membership           | The interfaces on both transit switches use VLAN <b>vlan200</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| VN2VN_Port FIP snooping VLAN        | VLAN name (both transit switches)— <b>vlan200</b><br>VLAN ID—200                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FIP snooping mode and beacon period | Set <b>examine-vn2vn</b> (VN2VN_Port FIP snooping)<br>Beacon period—90000 ms                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Figure 216 on page 5491 shows the network topology for this example.

Figure 216: VN2VN\_Port FIP Snooping (FCoE Hosts Connected to Different Transit Switches) Topology

## Configuration

To configure VN2VN\_Port FIP snooping for VN\_Ports that are directly connected to different transit switches (and the transit switches are directly connected to each other), perform these tasks:

- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS1 on page 5492](#)
- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS2 on page 5493](#)

### CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts connected directly to different transit switches, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

### Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS1

### Step-by-Step Procedure

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to FCoE transit switch TS2 (**xe-0/0/21**):  

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
user@switch# set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
```
2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members
vlan200
```

```
user@switch# set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members
vlan200
```

3. Configure the network-facing port (xe-0/0/21) as an FCoE trusted port:

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/21
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS2*

#### **Step-by-Step Procedure**

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode2 (xe-0/0/30) and to FCoE transit switch TS1 (xe-0/0/31):

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode
tagged-access
```

```
user@switch# set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (vlan200):

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members
vlan200
```

```
user@switch# set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members
vlan200
```

3. Configure the network-facing port (xe-0/0/31) as an FCoE trusted port:

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/31
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

### **Verification**

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly on both switches, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping is Enabled on the FCoE VLAN \(Transit Switches TS1 and TS2\) on page 5494](#)
- [Verifying the Interface Port Mode on page 5496](#)

***Verifying That VN2VN\_Port FIP Snooping is Enabled on the FCoE VLAN (Transit Switches TS1 and TS2)***

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (**vlan200**), the beacon period is set to **90000** milliseconds, and that the correct interfaces (**xe-0/0/20** and **xe-0/0/21** on TS1, and **xe-0/0/30** and **xe-0/0/31** on TS2) are members of the VLAN.

**Action** List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
  Enode Information
    Enode-MAC: 10:10:94:01:00:02,      Interface: xe-0/0/20
    Active VN_Ports : 1
    VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
      Active Sessions : 1
      Session Information
        Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
    Enode-MAC: 10:10:94:01:00:02,      Interface: xe-0/0/21
    Active VN_Ports : 1
    VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
      Active Sessions : 1
      Session Information
        Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
```

List the FIP snooping information on transit switch TS2 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
  Enode Information
    Enode-MAC: 10:10:94:01:00:02,      Interface: xe-0/0/30
    Active VN_Ports : 1
    VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0b:01
      Active Sessions : 1
      Session Information
        Vlink far-end VN-Port-MAC: 0e:fd:00:00:0a:01
    Enode-MAC: 10:10:94:01:00:02,      Interface: xe-0/0/31
    Active VN_Ports : 1
    VN_Port Information
      VN-Port MAC: 0e:fd:00:00:0a:01
      Active Sessions : 1
      Session Information
        Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01
```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)

- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, and **xe-0/0/30** and **xe-0/0/31** on transit switch TS2. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN\_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

### ***Verifying the Interface Port Mode***

**Purpose** Verify that the interface port modes are **tagged-access** for ENode-facing ports and **trunk** for network-facing ports on each transit switch.

**Action** List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command.

Use the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail** to list the Ethernet switching interface information on FCoE transit switch TS1. The output is truncated to show only the relevant portions:

```
user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on FCoE transit switch TS2 using the operational mode commands **show ethernet-switching interfaces xe-0/0/30.0 detail** and **show ethernet-switching interfaces xe-0/0/31.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/30.0 detail
Interface: xe-0/0/30.0, Index: 56, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/31.0 detail
Interface: xe-0/0/31.0, Index: 59, State: up, Port mode: Trunk
.
.
.
```

### Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)

This example shows how to configure VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping when the hosts are indirectly connected through an aggregation layer FCoE transit switch. Each FCoE host ENode is directly connected to an FCoE transit switch, but the FCoE transit switches are not directly connected to each other. The FCoE transit switches are both connected to a third FCoE transit switch that acts as an aggregation layer switch.

**NOTE:** This example uses Junos OS without support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Example: Configuring VN2VN\_Port FIP Snooping (FCoE Hosts Indirectly Connected Through an Aggregation Layer FCoE Transit Switch)*.

VN2VN\_Port FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VN\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through one or more transit switches on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

To configure VN2VN\_Port FIP snooping when the hosts are indirectly connected, you must follow these configuration rules:

- VN2VN\_Port traffic must use a dedicated FCoE VLAN, and all ENodes that communicate using VN2VN\_Port FIP snooping must use that FCoE VLAN. The FCoE VLAN must be configured on each transit switch. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN\_Port to VF\_Port traffic is dropped.

- ENode-facing ports must be set in **tagged-access** port mode.
- ENode-facing ports must be untrusted ports.

- Network-facing (switch-facing) ports must be set in **trunk** port mode.
- Network-facing ports must be FCoE trusted ports.
- Explicitly configure the beacon period. The beacon period is essentially a keepalive timer for virtual link maintenance.

When you enable FIP snooping, the system snoops VN\_Port to VF\_Port packets and enforces security only on VN\_Port to VF\_Port virtual links. When you enable VN2VN\_Port FIP snooping, the system snoops VN\_Port to VN\_Port packets and enforces security only on VN\_Port to VN\_Port virtual links.

The transit switch applies VN2VN\_Port FIP snooping filters at the ports associated with the FCoE VLANs on which you enable VN2VN FIP snooping.

This example describes how to configure VN2VN\_Port FIP snooping when the FCoE hosts are indirectly connected across an aggregation layer FCoE transit switch:

- [Requirements on page 5498](#)
- [Overview on page 5498](#)
- [Configuration on page 5500](#)
- [Verification on page 5502](#)

---

### Requirements

This example uses the following hardware and software components:

- Three Juniper Networks QFX3500 Switches used as transit switches
- Junos OS Release 12.2 or later for the QFX Series
- Two FCoE hosts that have ENodes

---

### Overview

This example shows you how to:

- Set the correct interface port modes on the transit switch.
- Configure the interfaces to use the dedicated FCoE VLAN for VN2VN\_Port FIP snooping.
- Configure the network-facing interfaces as FCoE trusted interfaces.
- Configure the dedicated FCoE VLAN for VN2VN\_Port FIP snooping traffic.
- Enable VN2VN\_Port FIP snooping on the FCoE VLAN and configure the beacon period.

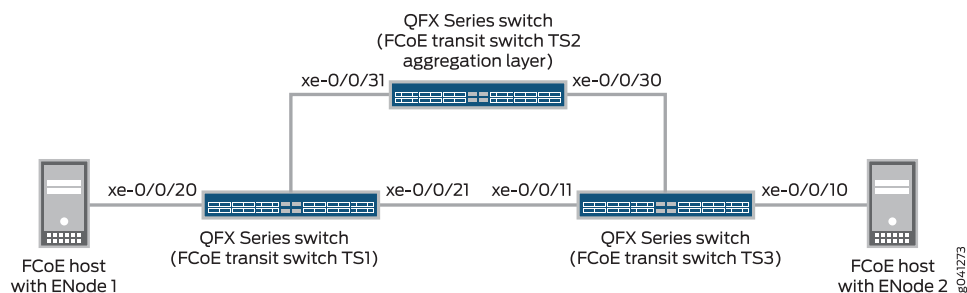

### Topology

[Table 400 on page 5499](#) shows the configuration components for this example.

**Table 400: Components of the VN2VN\_Port FIP Snooping Configuration Topology (FCoE Hosts Indirectly Connected Across an Aggregation Layer FCoE Transit Switch)**

| Component                           | Settings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hardware                            | <p>Three QFX3500 switches, two of which are FCoE transit switches that are directly attached to the FCoE hosts (transit switches TS1 and TS2) and one of which is an aggregation layer FCoE transit switch (TS3)</p> <p>Two FCoE hosts that have ENodes (ENode1 and ENode2, respectively)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Figure 217 on page 5499 shows the network topology for this example.

**Figure 217: VN2VN\_Port FIP Snooping (FCoE Hosts Indirectly Connected) Topology**

## Configuration

---

To configure VN2VN\_Port FIP snooping for VN\_Ports that are indirectly connected across an aggregation layer FCoE transit switch, perform these tasks:

- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS1 on page 5501](#)
- [Configuring VN2VN\\_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2 on page 5501](#)
- [Configuring VN2VN\\_Port FIP Snooping on FCoE Transit Switch TS3 on page 5502](#)

### CLI Quick Configuration

The configuration for each FCoE transit switch is shown separately.

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS1:

```
set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS2:

```
set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/30 fcoe-trusted
set ethernet-switching-options secure-access-port interface xe-0/0/31 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

To quickly configure VN2VN\_Port FIP snooping for FCoE hosts that are indirectly connected across an aggregation layer FCoE transit switch, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level. To configure FCoE transit switch TS3:

```
set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
set vlans vlan200 vlan-id 200
set ethernet-switching-options secure-access-port interface xe-0/0/11 fcoe-trusted
set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2
beacon-period 90000
```

**Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS1**

- Step-by-Step Procedure** To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:
1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode1 (**xe-0/0/20**) and to aggregation layer FCoE transit switch TS2 (**xe-0/0/21**):
 

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching port-mode tagged-access
set interfaces xe-0/0/21 unit 0 family ethernet-switching port-mode trunk
```
  2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):
 

```
user@switch# set interfaces xe-0/0/20 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/21 unit 0 family ethernet-switching vlan members vlan200
```
  3. Configure the network-facing port (**xe-0/0/21**) as an FCoE trusted port:
 

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/21 fcoe-trusted
```
  4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:
 

```
user@switch# set vlans vlan200 vlan-id 200
```
  5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:
 

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip examine-vn2v2 beacon-period 90000
```

**Configuring VN2VN\_Port FIP Snooping on Aggregation Layer FCoE Transit Switch TS2**

- Step-by-Step Procedure** To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing ports as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:
1. Configure the port modes of the interfaces that connect directly to FCoE transit switches TS1 (**xe-0/0/31**) and TS3 (**xe-0/0/30**). Both interfaces are network-facing and must be configured as trunk interfaces:
 

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/31 unit 0 family ethernet-switching port-mode trunk
```
  2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (**vlan200**):
 

```
user@switch# set interfaces xe-0/0/30 unit 0 family ethernet-switching vlan members vlan200
set interfaces xe-0/0/31 unit 0 family ethernet-switching vlan members vlan200
```
  3. Configure the network-facing ports (**xe-0/0/30** and **xe-0/0/31**) as FCoE trusted ports:
 

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/30 fcoe-trusted
```

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/31
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

### *Configuring VN2VN\_Port FIP Snooping on FCoE Transit Switch TS3*

#### **Step-by-Step Procedure**

To configure interface port modes, configure interface VLAN membership in the FCoE VLAN dedicated to VN2VN\_Port traffic, set the network-facing port as FCoE trusted, configure the VLAN, set the beacon period, and enable VN2VN\_Port FIP snooping:

1. Configure the port modes of the interfaces that connect directly to the FCoE host with ENode2 (xe-0/0/10) and to aggregation layer FCoE transit switch TS2 (xe-0/0/11):

```
user@switch# set interfaces xe-0/0/10 unit 0 family ethernet-switching port-mode
tagged-access
set interfaces xe-0/0/11 unit 0 family ethernet-switching port-mode trunk
```

2. Configure the interface VLAN membership so that the interfaces are members of the dedicated VN2VN\_Port VLAN (vlan200):

```
user@switch# set interfaces xe-0/0/10 unit 0 family ethernet-switching vlan members
vlan200
set interfaces xe-0/0/11 unit 0 family ethernet-switching vlan members vlan200
```

3. Configure the network-facing port (xe-0/0/11) as an FCoE trusted port:

```
user@switch# set ethernet-switching-options secure-access-port interface xe-0/0/11
fcoe-trusted
```

4. Configure the FCoE VLAN dedicated to VN2VN\_Port FIP snooping:

```
user@switch# set vlans vlan200 vlan-id 200
```

5. Enable VN2VN\_Port FIP snooping on the VLAN and configure the beacon period:

```
user@switch# set ethernet-switching-options secure-access-port vlan vlan200 examine-fip
examine-vn2v2 beacon-period 90000
```

---

### **Verification**

To verify that the VN2VN\_Port FIP snooping configuration has been created and is operating properly on all three switches, perform these tasks:

- [Verifying That VN2VN\\_Port FIP Snooping Is Enabled on the FCoE VLAN \(All Three Transit Switches\)](#) on page 5502
- [Verifying the Interface Port Mode](#) on page 5505

#### ***Verifying That VN2VN\_Port FIP Snooping Is Enabled on the FCoE VLAN (All Three Transit Switches)***

**Purpose** Verify that VN2VN\_Port FIP snooping is enabled on the correct VLAN (vlan200), the beacon period is set to 90000 milliseconds, and that the correct interfaces (xe-0/0/20

and **xe-0/0/21** on TS1, **xe-0/0/30** and **xe-0/0/31** aggregation layer TS2, and **xe-0/0/10** and **xe-0/0/11** on TS3) are members of the VLAN.

**Action** List the FIP snooping information on transit switch TS1 using the operational mode command **show fip snooping detail**

```
user@switch> show fip snooping detail
VLAN: vlan200, Mode: VN2VN Snooping
FC-MAP: 0e:fd:00
Beacon_Period: 90000
VN2VN Mode: Point-to-Point
  Enode Information
    Enode-MAC: 10:10:94:01:00:02,      Interface: xe-0/0/20
    Active VN_Ports : 1

VN-Port MAC: 0e:fd:00:00:0a:01
Active Sessions : 1
Session Information
Vlink far-end VN-Port-MAC: 0e:fd:00:00:0b:01

```

**Meaning** The **show fip snooping detail** command lists all of the transit switch information about VN2VN\_Port FIP snooping and VN2VF\_Port FIP snooping on each transit switch. The command shows that:

- The VLAN is **vlan200**.
- The mode is FIP snooping mode **VN2VN**, for VN2VN\_Port FIP snooping. (If the Mode field shows **VN2VF**, then the FIP snooping mode is VN2VF\_Port FIP snooping.)
- The beacon period is **90000**.
- The interfaces connected to the ENodes are **xe-0/0/20** and **xe-0/0/21** on transit switch TS1, **xe-0/0/30** and **xe-0/0/31** on aggregation layer transit switch TS2, and **xe-0/0/10** and **xe-0/0/11** on transit switch TS3. Because the transit switches are transparent passthrough switches, the network-facing trunk ports “see” the FCoE host ENodes at the far end of the VN2VN\_Port virtual link.

In addition, this useful command shows information about the ENodes and the VN2VN\_Port sessions.

#### *Verifying the Interface Port Mode*

**Purpose** Verify that the interface port modes are **tagged-access** for ENode-facing ports and **trunk** for network-facing ports on each transit switch.

**Action** List the Ethernet switching interfaces to confirm the port mode using the **show ethernet-switching interfaces detail** operational command for each interface. The output is truncated to show only the relevant portions.

List the Ethernet switching interface information on FCoE transit switch TS1 using the operational mode commands **show ethernet-switching interfaces xe-0/0/20.0 detail** and **show ethernet-switching interfaces xe-0/0/21.0 detail**:

```

user@switch> show ethernet-switching interfaces xe-0/0/20.0 detail
Interface: xe-0/0/20.0, Index: 75, State: up, Port mode: Tagged-Access
.
.
.
user@switch> show ethernet-switching interfaces xe-0/0/21.0 detail

```

```
Interface: xe-0/0/21.0, Index: 83, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on aggregation layer FCoE transit switch TS2 using the operational mode commands **show ethernet-switching interfaces xe-0/0/30.0 detail** and **show ethernet-switching interfaces xe-0/0/31.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/30.0 detail
Interface: xe-0/0/30.0, Index: 71, State: up, Port mode: Trunk
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/31.0 detail
Interface: xe-0/0/31.0, Index: 73, State: up, Port mode: Trunk
.
.
.
```

List the Ethernet switching interface information on FCoE transit switch TS3 using the operational mode commands **show ethernet-switching interfaces xe-0/0/10.0 detail** and **show ethernet-switching interfaces xe-0/0/11.0 detail**:

```
user@switch> show ethernet-switching interfaces xe-0/0/10.0 detail
Interface: xe-0/0/10.0, Index: 56, State: up, Port mode: Tagged-Access
.
.
.
```

```
user@switch> show ethernet-switching interfaces xe-0/0/11.0 detail
Interface: xe-0/0/11.0, Index: 59, State: up, Port mode: Trunk
.
.
.
```

## Example: Configuring Automated Fibre Channel Interface Load Rebalancing

Automated Fibre Channel (FC) interface (NP\_Port) load rebalancing configures the switch to rebalance the session loads on the native FC interfaces automatically on a load-rebalancing trigger event. (Alternatively, you can rebalance the link load on the FC interfaces on demand so that you control when the link load is rebalanced.) Rebalancing the FC link load is a disruptive action that causes some or all of the current sessions to log out, then log in again to be placed on the active FC links in a balanced manner.

This example shows you how to configure and verify automated FC link load rebalancing on an FCoE-FC gateway local FC fabric.

- [Requirements on page 5507](#)
- [Overview on page 5507](#)
- [Configuration on page 5508](#)
- [Verification on page 5509](#)

---

## Requirements

This example uses the following hardware and software components:

- Juniper Networks QFX3500 Switch
- Junos OS Release 12.3 or later for the QFX Series

---

## Overview

When a load rebalancing trigger occurs, the switch automatically rebalances the link loads by redistributing the sessions across the active NP\_Port links.

There are three possible load-rebalancing triggers:

1. When you enable automated load rebalancing, the switch checks the load balance on the existing NP\_Port links. If the links are already balanced, the switch does not rebalance the link load. If the links are not balanced, the switch rebalances the link loads using the configured load-balancing algorithm.
2. When a new NP\_Port link comes up on a local FCoE-FC gateway fabric, the switch rebalances the link load using the configured load-balancing algorithm if automated load balancing is enabled.
3. When the port speed is changed (unless the port speed change does not change the actual port speed, for example, changing the port speed from auto to 8 Gbps).

Automated load rebalancing logs out sessions in accordance with the configured load-balancing algorithm. Disabling automated load rebalancing is not disruptive because the link load is already balanced.

Use automated load rebalancing if you want link loads to be rebalanced automatically instead of at times of your choosing. Keep in mind that load rebalancing is a disruptive event (sessions are logged out).

## Topology

This example configures automated load rebalancing on a local FC fabric on an FCoE-FC gateway. This example does not show you how to configure the load-balancing algorithm or any other load-balancing characteristics. The load-balancing configuration for this example is:

- FC fabric name—`fc_fabric_100`
- FC fabric ID—100

- FC fabric type—Proxy
- FC fabric interfaces—fc-0/0/0, fc-0/0/1, fc-0/0/42, fc-0/0/43, vlan.100, vlan.20
- Load-balancing algorithm—Simple
- No fabric WWN verify—Configured
- Traceoptions—Configured to log in file fc\_fabric\_100\_proxy.log

---

## Configuration

To configure automated load balancing on a local FC fabric, perform this task:

- [\[xref target has no title\]](#)
- [Results on page 5508](#)

### CLI Quick Configuration

To quickly configure automated load balancing, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
[edit]
set fc-fabrics fc_fabric_100 proxy auto-load-rebalance
```

### Step-by-Step Procedure

- Configure automated load balancing on FC fabric fc\_fabric\_100:  
user@switch# set fc-fabrics fc\_fabric\_100 proxy auto-load-rebalance

## Results

Display the results of the configuration:

```
user@switch> show configuration fc-fabrics
fc_fabric_100 {
  fabric-id 100;
  fabric-type proxy;
  interface {
    fc-0/0/0.0;
    fc-0/0/1.0;
    vlan.100;
    vlan.20;
    fc-0/0/42.0;
    fc-0/0/43.0;
  }
  proxy {
    traceoptions {
      file fc_fabric_100_proxy.log size 20m;
      flag all;
    }
    load-balance-algorithm simple;
    auto-load-rebalance;
    no-fabric-wwn-verify;
  }
}
```

## Verification

### *Verifying That Automated Load Rebalancing Is Enabled*

**Purpose** Verify that automated load rebalancing is configured on local FC fabric `fc_fabric_100`.

**Action** Verify the results of the automated load-rebalancing configuration using the operational mode command `show fibre-channel proxy fabric-state fabric fc_fabric_100`:

```
user@switch> show fibre-channel proxy fabric-state fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
Proxy load balance algorithm: Simple, Fabric WWN verification: No
Auto load rebalance enabled : Yes
Last rebalance start-time   : Never
Last rebalance end-time     : Never
Last rebalance trigger      : None
Last rebalance trigger-time : Mon Sep 10 21:42:30 2012 usec: 814602
Last rebalance trigger-result: None
```

**Meaning** The `show fibre-channel proxy fabric-state fabric fc_fabric_100` operational command displays information about the specified local FC fabric. The output shows that the **Auto load rebalance enabled** field value is **Yes**, which indicates that automated load rebalancing is enabled on fabric `fc_fabric_100`.

## Example: Configuring an FCoE LAG on a Redundant Server Node Group

This example shows how to configure a Fibre Channel over Ethernet (FCoE) link aggregation group (LAG) on a redundant server Node group (RSNG) to transport FCoE traffic and regular Ethernet traffic across the same link aggregation bundle. The FCoE servers have converged network adapters (CNAs) and communicate with the Fibre Channel (FC) storage area network (SAN). FCoE servers are usually connected to a switch that performs FIP snooping, such as an FCoE transit switch or an FCoE-FC gateway switch that performs FIP snooping. This example provides a common FCoE LAG configuration for an FCoE transit switch and an FCoE-FC gateway, and shows how to disable FIP snooping scaling on an FCoE untrusted FCoE-FC gateway fabric (`fc-fabric`).

- [Verification on page 5516](#)

## Requirements

---

This example uses the following hardware and software components:

- Two Juniper Networks QFabric System Node devices configured as an RSNG. The Node devices can be configured as FCoE transit switches or as FCoE-FC gateways. (A configuration with one Node device as an FCoE transit switch and the other Node device as an FCoE-FC gateway is possible providing that the transit switch and the FCoE-FC gateway use different FCoE VLANs.)
- Junos OS Release 13.2X52-D10 or later for the QFX Series
- One FCoE server with two CNA ports

## Overview

---

Standard LAGs use a hashing algorithm to determine which physical link in the LAG is used for a transmission, so a series of communications between two devices might use different physical links in the LAG for different transmissions. However, FCoE traffic requires a point-to-point link (or a virtual point-to-point link) between the FCoE device and the Fibre Channel (FC) storage area network (SAN) switch.

An FCoE LAG solves this problem by ensuring that the same LAG link is used for communication between a given FCoE device and the QFabric system Node device, preserving point-to-point link emulation. At the same time, regular Ethernet traffic (traffic that is not FCoE traffic) on the LAG is distributed across member interfaces in the same way as on a standard LAG. FCoE traffic is treated properly in terms of maintaining a virtual point-to-point link with the FC SAN, and regular Ethernet traffic enjoys the usual LAG benefits of load balancing and link redundancy.

**NOTE:** Configuring a LAG as an FCoE LAG does not provide link redundancy for FCoE traffic, and does not load balance FCoE traffic.

---

On FCoE-FC gateway untrusted Fibre Channel fabrics (fc-fabrics), if you configure an FCoE LAG, you must also disable enhanced FIP snooping scaling (scaling up to 2,500 sessions), which reduces the number of supported FIP snooping sessions to 376 sessions. On an FCoE-FC gateway, disabling enhanced FIP snooping scaling is global to the Node device. Trusted fc-fabrics on an FCoE-FC gateway support enhanced FIP snooping scaling.

This example shows you how to:

- Configure the RSNG and its Node devices
- Configure the FCoE LAG on the RSNG
- Configure a dedicated VLAN for FCoE traffic (an FCoE VLAN) and a native VLAN for untagged FCoE initialization protocol (FIP) traffic
- Enable VN2VF\_Port FIP snooping on the FCoE VLAN
- Disable FIP snooping scaling on an untrusted FCoE-FC gateway fabric

**NOTE:** FCoE traffic requires lossless transport across the Ethernet network to comply with the requirements for transporting storage traffic. This example describes how to configure an FCoE LAG to provide redundancy for FCoE traffic. See [“Example: Configuring CoS PFC for FCoE Traffic” on page 5441](#) for how to configure lossless transport for FCoE traffic.

**NOTE:** On a Node device that is configured as an FCoE-FC gateway, you must create a Fibre Channel fabric, configure native FC interfaces, configure an FCoE VLAN interface (a Layer 3 RVI) for the FCoE VLAN (which includes the FCoE LAG as a member interface), and add the native FC interfaces and FCoE VLAN interface to the FC fabric. For an example of FCoE-FC gateway interface configuration, see [“Example: Setting Up Fibre Channel and FCoE VLAN Interfaces in an FCoE-FC Gateway Fabric” on page 5427](#).

Topology

[Table 401 on page 5511](#) shows the configuration components for this example.

Table 401: Components of the FCoE LAG Configuration Example

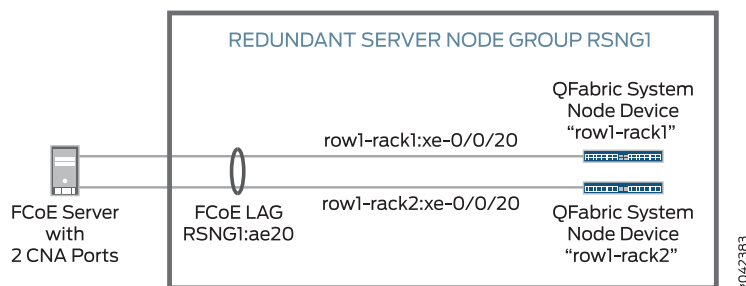

| Component         | Settings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Figure 218 on page 5512 shows the network topology for this example.

Figure 218: FCoE LAG Example Topology

### Configuration

To configure an FCoE LAG between an FCoE server with two CNA ports and the two Node device members of an RSNG, perform these tasks:

- [Configuring an FCoE LAG on an RSNG \(FCoE Transit Switch or FCoE-FC Gateway\) on page 5514](#)
- [Disabling Enhanced FIP Snooping Scaling on an FCoE-FC Gateway on page 5515](#)
- [Results on page 5515](#)

#### CLI Quick Configuration

In this example, the enhanced FIP snooping scaling is disabled (376 sessions) in the FCoE-FC gateway because the gateway fabric is an untrusted fc-fabric.

Most of the FCoE LAG configuration is common to both the FCoE transit switch and FCoE-FC gateway modes of operation. The CLI Quick Configuration shows the common configuration statements first, followed by the additional configuration statement that

disables FIP snooping scaling on the FCoE-FC gateway. Disabling FIP snooping scaling on an FCoE-FC gateway is a global configuration that affects all of the fc-fabrics on the gateway. (On an FCoE transit switch, you can disable FIP snooping scaling on an individual FCoE VLAN without affecting other FCoE VLANs.)

**NOTE:** This example does not include configuring the FC fabric, the native FC fabric ports, and the Layer 3 FCoE VLAN interface.

### Common Configuration

To quickly configure an FCoE LAG, copy the following commands, paste them in a text file, remove line breaks, change variables and details to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

```
set fabric aliases node-device ABCD1234 row1-rack1
set fabric aliases node-device ABCD1235 row1-rack2
set fabric resources node-group RSVG1 node-device row1-rack1
set fabric resources node-group RSVG1 node-device row1-rack2
set chassis node-group RSVG1 aggregated-devices ethernet device-count 48
set interfaces RSVG1:ae20 unit 0 family ethernet-switching port-mode trunk vlan members
fcoe-vlan1
set interfaces RSVG1:ae20 unit 0 family ethernet-switching native-vlan-id 1
set interfaces RSVG1:ae20 mtu 2180
set interfaces RSVG1:ae20 aggregated-ether-options fcoe-lag
set interfaces RSVG1:ae20 aggregated-ether-options lacp active
set interfaces row1-rack1:xe-0/0/20 ether-options 802.3ad RSVG1:ae20
set interfaces row1-rack2:xe-0/0/20 ether-options 802.3ad RSVG1:ae20
set vlans fcoe-vlan1 vlan-id 2000
set vlans native vlan-id 1
set vlans fcoe-vlan1 interface RSVG1:ae20
set ethernet-switching-options secure-access-port vlan fcoe-vlan1 examine-fip
```

**NOTE:** If you want to configure an FCoE-FC gateway fabric as a trusted fabric so that you can leave enhanced FIP snooping scaling enabled on the gateway, add the following statement to the configuration, replacing the variable *fc-fabric-name* with the name of the FC fabric (if you do this, do not disable FIP snooping scaling as shown in the FCoE-FC Gateway Additional Configuration):

```
set fc-fabrics fc-fabric-name protocols fip fcoe-trusted
```

### FCoE-FC Gateway Additional Configuration (Untrusted FC Fabric)

To disable enhanced FIP snooping scaling on an FCoE-FC gateway untrusted FC fabric, copy the following command, paste it in a text file, remove line breaks, and then copy and paste the command into the CLI at the [edit] hierarchy level.

```
set fc-options no-fip-snooping-scaling
```

**Configuring an FCoE LAG on an RSNG (FCoE Transit Switch or FCoE-FC Gateway)**

- Step-by-Step Procedure** To configure the RSNG member Node devices, the FCoE LAG, the FCoE VLAN, and VN2VF\_Port FIP snooping on an FCoE transit switch or an FCoE-FC gateway:
1. Define aliases for the two Node devices that will be in the RSNG (aliases are easier to remember and more descriptive than the Node device serial number). Name the Node device with serial number **ABCD1234** as **row1-rack1** and the Node device with the serial number **ABCD1235** as **row1-rack2**:  
  

```
admin@qfabric# set fabric aliases node-device ABCD1234 row1-rack1
admin@qfabric# set fabric aliases node-device ABCD1235 row1-rack2
```
  2. Configure the Node device membership for **row1-rack1** and **row1-rack2** in the RSNG **RSNG1**:  
  

```
admin@qfabric# set fabric resources node-group RSNG1 node-device row1-rack1
admin@qfabric# set fabric resources node-group RSNG1 node-device row1-rack2
```
  3. Configure the number of LAG interfaces that RSNG **RSNG1** can support. (Each Node device in the RSNG has 48 server-facing ports. If we used one port from each Node device to provide Node device redundancy for each LAG, we might need to support a maximum of 48 LAGs, so we set the device count to 48 LAGs.)  
  

```
admin@qfabric# set chassis node-group RSNG1 aggregated-devices ethernet device-count 48
```
  4. Configure the LAG interface (**ae20**) on RSNG1 and set the port mode to **trunk** mode. In the same statement, configure the LAG interface membership in the dedicated FCoE VLAN **fcoe-vlan1**:  
  

```
admin@qfabric# set interfaces RSNG1:ae20 unit 0 family ethernet-switching port-mode trunk
vlan members fcoe-vlan1
```
  5. Configure the LAG interface membership in the native VLAN:  
  

```
admin@qfabric# set interfaces RSNG1:ae20 unit 0 family ethernet-switching native-vlan-id 1
```
  6. Configure the LAG interface with an MTU of **2180** to accommodate the size of the FCoE frame and headers.  
  

```
admin@qfabric# set interfaces RSNG1:ae20 mtu 2180
```
  7. Configure the LAG **RSNG1:ae20** as an FCoE LAG:  
  

```
admin@qfabric# set interfaces RSNG1:ae20 aggregated-ether-options fcoe-lag
```
  8. Enable LACP on the FCoE LAG:  
  

```
admin@qfabric# set interfaces RSNG1:ae20 aggregated-ether-options lacp active
```
  9. Assign one Ethernet interface on each RSNG Node device to the FCoE LAG:  
  

```
admin@qfabric# set interfaces row1-rack1:xe-0/0/20 ether-options 802.3ad RSNG1:ae20
admin@qfabric# set interfaces row1-rack2:xe-0/0/20 ether-options 802.3ad RSNG1:ae20
```
  10. Configure a dedicated VLAN for FCoE traffic (an FCoE VLAN) named **fcoe-vlan1** with the VLAN ID **2000**:  
  

```
admin@qfabric# set vlans fcoe-vlan1 vlan-id 2000
```

11. Configure a native VLAN with the VLAN ID 1 to carry untagged FIP traffic:  

```
admin@qfabric# set vlans native vlan-id 1
```
12. Assign the FCoE LAG interface to the FCoE VLAN:  

```
admin@qfabric# set vlans fcoe-vlan1 interface RSNG:ae20
```
13. Assign the FCoE LAG interface to the native VLAN:  

```
admin@qfabric# set vlans native interface RSNG:ae20
```
14. Enable VN2VF\_Port FIP snooping on the FCoE VLAN:  

```
admin@qfabric# set ethernet-switching-options secure-access-port vlan fcoe-vlan1
examine-fip
```

### *Disabling Enhanced FIP Snooping Scaling on an FCoE-FC Gateway*

#### **Step-by-Step Procedure**

To disable enhanced FIP snooping scaling on an FCoE-FC gateway:

1. Disable FIP snooping scaling on the gateway fabrics. Disabling FIP snooping scaling on an FCoE-FC gateway is global to the gateway, so every FC fabric on the gateway reverts to supporting 376 sessions (instead of 2,500 sessions as with FIP snooping scaling enabled).  

```
admin@qfabric# set fc-options no-fip-snooping-scaling
```

### **Results**

Display the results of the configuration. The results below show the configuration on an FCoE transit switch and have been edited to include only the components configured in the example:

```
admin@qfabric> show configuration
root@qfabric> fabric {
  resources {
    node-group RSNG1 {
      node-device row1-rack1;
      node-device row1-rack2;
    }
  }
  aliases {
    node-device ABCD1234 {
      row1-rack1;
    }
    node-device ABCD1235 {
      row1-rack2;
    }
  }
}
chassis {
  node-group RSNG1 {
    aggregated-devices {
      ethernet {
        device-count 48;
      }
    }
  }
}
interfaces {
```

```
RSNG1:ae20 {
    aggregated-ether-options {
        fcoe-lag;
        lacp {
            active;
        }
    }
    unit 0 {
        family ethernet-switching {
            port-mode trunk;
            vlan {
                members fcoe-vlan1;
            }
            native-vlan-id 1;
        }
    }
}
row1-rack1:xe-0/0/20 {
    ether-options {
        802.3ad RSNG1:ae20;
    }
}
row1-rack2:xe-0/0/20 {
    ether-options {
        802.3ad RSNG1:ae20;
    }
}
}
ethernet-switching-options {
    secure-access-port {
        vlan fcoe-vlan1 {
            examine-fip;
        }
    }
}
}
vlans {
    fcoe-vlan1 {
        vlan-id 2000;
        interface {
            RSNG1:ae20.0;
        }
    }
    native {
        vlan-id 1;
        interface {
            RSNG1:ae20.0;
        }
    }
}
}
```

---

## Verification

To verify the configuration of the QFabric system Node device resources, FCoE LAG, FCoE VLAN, native VLAN, and FIP snooping, perform these tasks:

- [Verifying the Node Device Aliases \(Names\) on page 5517](#)
- [Verifying the Node device Assignment to the Node Group on page 5517](#)
- [Verifying the Number of Aggregated Ethernet Logical Devices \(LAG Interfaces\) That the Node Group Can Support on page 5517](#)

- [Verifying the FCoE LAG Interface Configuration on page 5518](#)
- [Verifying the FCoE VLAN and Native VLAN Configuration on page 5519](#)
- [Verifying the FIP Snooping Configuration on page 5519](#)

### ***Verifying the Node Device Aliases (Names)***

**Purpose** Verify that the Node device alias names are configured.

**Action** List the Node device inventory on the QFabric system using the **show fabric administration inventory node-devices** command:

```
admin@qfabric> show fabric administration inventory node-devices
root@qfabric> show fabric administration inventory node-devices
Item                Identifier          Connection      Model
Node device
  row1-rack1         ABCD1234           Connected       qfx3500
  row1-rack2         ABCD1235           Connected       qfx3500
```

**Meaning** The **show fabric administration inventory node-devices** command lists the Node device names in the *Node device* column and lists the Node device serial numbers in the *Identifier* column. The *Connection* column shows if the Director device has detected the Node device, and the *Model* column lists QFX switch model type.

The command output shows that Node device **ABCD1234** is configured with the name (alias) **row1-rack1**, and the Node device **ABCD1235** is configured with the name **row1-rack2**.

### ***Verifying the Node device Assignment to the Node Group***

**Purpose** Verify that the redundant server Node group includes the two Node devices.

**Action** Verify that the QFabric system Node group **RSNG1** is configured with the correct Node devices using the **show configuration fabric resources** command:

```
admin@qfabric> show configuration fabric resources
root@qfabric> show configuration fabric resources
node-group RSNG1 {
    node-device row1-rack1;
    node-device row1-rack2;
}
```

**Meaning** The **show configuration fabric resources** command lists the Node groups and the Node devices in the Node groups. The command output shows that Node group **RSNG1** consists of the Node devices **row1-rack1** and **row1-rack2**.

### ***Verifying the Number of Aggregated Ethernet Logical Devices (LAG Interfaces) That the Node Group Can Support***

**Purpose** Verify the number of LAG interfaces that the redundant server node group supports.

**Action** List the LAG interface device count using the **show configuration chassis** command:

```
admin@qfabric> show configuration chassis
node-group RSNG1 {
  aggregated-devices {
    ethernet {
      device-count 48;
    }
  }
}
```

**Meaning** The **show configuration chassis** command displays the Ethernet device count (the number of LAG interfaces supported) as **48** devices.

#### *Verifying the FCoE LAG Interface Configuration*

**Purpose** Verify that the FCoE LAG interface, port mode, interface VLAN membership, and Node device interface membership in the FCoE LAG are correctly configured.

**Action** List the FCoE LAG interface and Node device interface information using the **show configuration interfaces** command:

```
admin@qfabric> show configuration interfaces
RSNG1:ae20 {
  aggregated-ether-options {
    fcoe-lag;
    lacp {
      active;
    }
  }
  unit 0 {
    family ethernet-switching {
      port-mode trunk;
      vlan {
        members fcoe-vlan1;
      }
      native-vlan-id 1;
    }
  }
}
row1-rack1:xe-0/0/20 {
  ether-options {
    802.3ad RSNG1:ae20;
  }
}
row1-rack2:xe-0/0/20 {
  ether-options {
    802.3ad RSNG1:ae20;
  }
}
```

**Meaning** The **show configuration interfaces** command lists both the LAG interfaces and the individual Node device interfaces, and their configuration.

The command output shows a lot of information about the interfaces:

- The LAG interface name is **RSNG1:ae20**
- **fcoe-lag** confirms the LAG is an FCoE LAG
- **lACP** is configured in **active** mode
- Port mode is **trunk**
- The LAG has membership in the **fcoe-vlan1** VLAN and in the native VLAN with the VLAN ID 1.
- Interface **row1-rack1:xe-0/0/20** is a member of FCoE LAG **RSNG1:ae20**
- Interface **row1-rack2:xe-0/0/20** is a member of FCoE LAG **RSNG1:ae20**

### *Verifying the FCoE VLAN and Native VLAN Configuration*

**Purpose** Verify that the FCoE VLAN **fcoe-vlan1** and the native VLAN **native** are configured with the correct VLAN tags (**2000** and **1**, respectively) and that the FCoE LAG interface **RSNG1:ae20** is assigned to the VLANs.

**Action** List the VLAN information using the **show configuration vlans** command:

```
admin@qfabric> show configuration vlans
fcoe-vlan1 {
    vlan-id 2000;
    interface {
        RSNG1:ae20.0;
    }
}
native {
    vlan-id 1;
    interface {
        RSNG1:ae20.0;
    }
}
```

**Meaning** The **show configuration vlans** command lists the configured VLANs, their VLAN IDs, and the interfaces assigned to the VLANs.

The command output shows that the FCoE VLAN **fcoe-vlan1** is configured with the VLAN ID **2000** and is assigned to the FCoE LAG interface **RSNG1:ae20**.

The command output also shows that the native VLAN **native** is configured with the VLAN ID **1** and is assigned to the FCoE LAG interface **RSNG1:ae20**.

### *Verifying the FIP Snooping Configuration*

**Purpose** Verify that VN2VF\_Port FIP snooping is enabled on the FCoE VLAN (**fcoe-vlan1**).

**Action** List the FIP snooping information using the **show configuration ethernet-switching-options** command:

```
admin@qfabric> show configuration ethernet-switching-options
secure-access-port {
    vlan fcoe-vlan1 {
        examine-fip;
    }
}
```

**Meaning** The **show configuration ethernet-switching-options** command lists the security options configured on VLANs. The command output shows that on VLAN **fcoe-vlan1**, VN2VF\_Port FIP snooping is enabled (**examine-fip** output).

## Configuring an FCoE-FC Gateway Fibre Channel Fabric

Fibre Channel (FC) fabric configuration consists of creating a unique name and identifier for each FC fabric you want to create and configuring it as an FCoE-FC gateway.

You can create a maximum of 12 FC fabrics on a QFX3500 switch. After you create a fabric, you can create and assign interfaces to the fabric, configure FIP parameters for the fabric, and set proxy traceoptions.

To configure an FC fabric using the CLI, specify a unique name and identification number for the fabric:

1. Configure the fabric name and fabric ID:

```
[edit]
user@switch# set fc-fabrics fabric-name fabric-id fabric-id
```

**NOTE:** Changing the fabric name or the fabric ID causes all logins to drop and forces the ENodes to log in again.

For example, to configure an FC fabric with the name **fab\_ulous** and the fabric ID 10 (the range of **fabric-id** values is 1 through 4095):

```
[edit]
user@switch# set fc-fabrics fab_ulous fabric-id 10
```

2. Configure the fabric as a gateway fabric:

```
[edit fc-fabrics fabric-name]
user@switch# set fabric-type proxy
```

For example, to configure the FC fabric with the name **fab\_ulous** as a gateway fabric:

```
[edit fc-fabrics fab_u1ous]
user@switch# set fabric-type proxy
```

## Disabling the Fabric WWN Verification Check

When a QFX Series NP\_Port sends a fabric login (FLOGI) request to a Fibre Channel (FC) switch, the FLOGI accept (FLOGI-ACC) reply from the FC switch contains the SAN fabric worldwide name (WWN). The QFX Series uses the SAN fabric WWN in the multicast discovery advertisement (MDA) that the QFX Series sends to the ENodes in the FCoE network.

However, some FC switches substitute their own WWN (often the FC switch's virtual WWN) for the SAN fabric WWN in the FLOGI-ACC message. In this case, different NP\_Ports that log in to the same FC fabric might receive different fabric WWNs in the FLOGI-ACC messages if the NP\_Ports are connected to different FC switches in the SAN fabric.

If the QFX Series receives different fabric WWNs on NP\_Ports that are connected to the same SAN fabric, the QFX Series uses the first fabric WWN it receives in the MDA it sends to the ENodes. The QFX Series isolates the NP\_Ports that receive a different fabric WWN from other FC switches in that SAN fabric. No ENode sessions are assigned to the isolated NP\_Ports. FC traffic is assigned only to NP\_Ports that receive a fabric WWN in the FLOGI-ACC message that matches the fabric WWN received by the first NP\_Port to log in to the FC fabric. (If an NP\_Port receives a fabric WWN that does not match the fabric WWN received by the first NP\_Port to log in to the FC fabric, it does not carry traffic to the SAN fabric.)

To prevent ENodes from being isolated due to a mismatched fabric WWN, you can disable the gateway fabric WWN verification check. Disabling the fabric WWN verification check enables all NP\_Ports connected to a SAN fabric are used to carry traffic between the gateway and the FC switch, regardless of the fabric WWN the NP\_Port receives in the FLOGI-ACC message.

**NOTE:** Disabling or enabling the fabric WWN verification check logs out all FCoE sessions.

To disable the fabric WWN verification check:

- [edit fc-fabrics *fabric-name* proxy]  
user@switch# **set no-fabric-wwn-verify**

## Configuring a Physical Fibre Channel Interface

When you configure the switch as an FCoE-FC gateway, you must configure either 6 or 12 of the physical interfaces as native FC interfaces. Native FC interfaces connect to the storage area network (SAN) FC switch.

You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.

You can configure:

- Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.
- No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.
- To configure physical FC interfaces using the CLI, specify the physical port block you want to configure on the switch as native FC interfaces:

```
[edit chassis]
user@switch# set fpc fpc pic pic fibre-channel port-range port-range-low port-range-high
```

For example, to configure six native FC interfaces, you can configure ports 0 through 5 as physical FC interfaces:

```
[edit chassis]
user@switch# set fpc 0 pic 0 fibre-channel port-range 0 5
```

To configure 12 native FC interfaces requires two separate statements:

```
[edit chassis]
user@switch# set fpc 0 pic 0 fibre-channel port-range 0 5
user@switch# set fpc 0 pic 0 fibre-channel port-range 42 47
```

## Configuring a Fibre Channel Interface

When a QFX3500 acts as an FCoE-FC gateway, native Fibre Channel (FC) traffic flows between the switch and the storage area network (SAN) FC switch. When you configure a port as an FC interface, it transports only FC traffic. It does not transport Ethernet traffic.

You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces.

Each of these blocks of ports must be configured either as all Ethernet ports or as all native FC ports. Within each block of ports, you cannot mix FC and Ethernet interfaces. This means that you can configure 0, 6, or 12 ports as native FC ports. “[Configuring a Physical Fibre Channel Interface](#)” on page 5524 describes how to configure the port blocks as physical FC interfaces.

**NOTE:** Do not configure ports that you want to use for native FC traffic as part of an Ethernet VLAN or as Ethernet ports.

Configure a port as an FC interface when the port connects to the F\_Port of an FC switch.

FC interface configuration includes:

- Explicitly specifying one or more ports as an FC family interface in NP\_Port mode (mandatory).
- Configuring the FC interface options port speed and buffer-to-buffer credit state change number (BB\_SC\_N) (optional).
- Configuring the interface as a loopback interface (optional).

The buffer-to-buffer state change number feature prevents the loss of buffer-to-buffer credits between the two interfaces on either end of an FC link. The state change number determines the number of frames and receiver ready (R\_RDY) primitives the interfaces exchange between the state change send (BB\_SCs) and the state change receive (BB\_SCr) primitives used to track these transactions.

Enabling BB\_SC\_N by configuring BB\_SC\_N on both of the FC link interfaces:

- Requests that  $2^{BB\_SC\_N}$  number of frames be sent between two consecutive BB\_SCs primitives, and
- Requests that  $2^{BB\_SC\_N}$  number of R\_RDY primitives be sent between two consecutive BB\_SCr primitives.

When the number of R\_RDY primitives received equals  $2^{BB\_SC\_N}$ , the R\_RDY counter resets to zero. When the number of frames received equals  $2^{BB\_SC\_N}$ , the frame counter resets to zero. The interfaces calculate the number of buffer-to-buffer credits lost based on counter discrepancies and take corrective action to recover the lost credits.

If you enable BB\_SC\_N, the recommended BB\_SC\_N setting is eight. Setting the BB\_SC\_N number to zero (0) disables the feature. If either of the two connected FC interfaces is configured with zero as the BB\_SC\_N value, then both interfaces disable the feature. If the two connected FC interfaces have different nonzero BB\_SC\_N numbers configured, both interfaces use the higher number.

For the port to transport FC traffic, you must also set the physical port as an FC port using the **port-range** command.

To configure an FC interface using the CLI:

1. Specify the interface as family FC and set the port mode to NP\_Port (setting the port mode to NP\_Port is a mandatory configuration):

```
[edit]
user@switch# set interfaces interface-name unit unit family fibre-channel port-mode np-port
```

For example, to configure the interface **fc-0/0/3** as an FC interface and set the port mode to **np-port**:

```
[edit]
user@switch# set interfaces fc-0/0/3 unit 0 family fibre-channel port-mode np-port
```

2. Configure the FC interface speed option:

```
[edit]
user@switch: set interfaces interface-name fibrechannel-options speed (auto-negotiation
| 2g | 4g | 8g)
```

For example, to set the FC interface speed option to **8g** for the interface **fc-0/0/3**:

```
[edit]
user@switch: set interfaces fc-0/0/3 fibrechannel-options speed 8g
```

The default port mode is **auto-negotiation**, which sets the port speed to match the speed of the attached FC F\_Port interface (2 Gbps, 4 Gbps, or 8 Gbps).

3. Configure the optional buffer-to-buffer credit state change number:

```
[edit]
user@switch: set interfaces interface-name fibrechannel-options bb-sc-n 0..15
```

For example, to set the FC interface buffer-to-buffer credit state change number to **8** for the interface **fc-0/0/3**:

```
[edit]
user@switch: set interfaces fc-0/0/3 fibrechannel-options bb-sc-n 8
```

After you configure one or more FC interfaces, assign them and an FCoE VLAN to an FC fabric.

## Configuring an FCoE VLAN Interface on an FCoE-FC Gateway

When you configure the switch as an FCoE-FC gateway, a Layer 3 FCoE VLAN interface transmits and receives Fibre Channel over Ethernet (FCoE) traffic between the gateway and FCoE-capable servers on the Ethernet network. Configuring a Layer 3 FCoE VLAN interface on the switch creates virtual fabric port (VF\_Port) interfaces facing the FCoE server virtual node ports (VN\_Ports).

The FCoE VLAN interface is the interface for the dedicated VLAN the FCoE servers use for FCoE traffic. Each FC fabric requires at least one dedicated FCoE VLAN and at least one Layer 3 FCoE VLAN interface to transport FCoE traffic. On QFabric systems, the FCoE VLAN interface, the FCoE VLAN, and the interfaces that are members of the FCoE VLAN must be on the same Node device.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

FCoE traffic cannot use a standard LAG because traffic might be hashed to different physical LAG links on different transmissions. This breaks the (virtual) point-to-point link that Fibre Channel traffic requires. If you configure a standard LAG interface for FCoE traffic, FCoE traffic might be rejected by the FC SAN.

QFabric systems support a special LAG called an FCoE LAG, which enables you to transport FCoE traffic and regular Ethernet traffic (traffic that is not FCoE traffic) across the same link aggregation bundle. Standard LAGs use a hashing algorithm to determine which physical link in the LAG is used for a transmission, so communication between two devices might use different physical links in the LAG for different transmissions. An FCoE LAG ensures that FCoE traffic uses the same physical link in the LAG for requests and replies in order to preserve the virtual point-to-point link between the FCoE device converged network adapter (CNA) and the FC SAN switch across a QFabric system Node device. An FCoE LAG does not provide load balancing or link redundancy for FCoE traffic. However, regular Ethernet traffic uses the standard hashing algorithm and receives the usual LAG benefits of load balancing and link redundancy in an FCoE LAG.

If the member interfaces of an FCoE VLAN belong to an FCoE LAG and are part of an FCoE untrusted FC fabric on the gateway, you must disable FIP snooping scaling on the gateway. FCoE untrusted gateway fabrics that include FCoE LAGs do not support enhanced FIP snooping scaling.

**NOTE:** To configure an FCoE VLAN on a device that you are using as transit switch, you do not use an FCoE VLAN interface. Instead, use the procedure described in [“Configuring VLANs for FCoE Traffic on an FCoE Transit Switch” on page 5544](#).

Before you configure an FCoE VLAN interface, create the FCoE VLAN and assign 10-Gigabit Ethernet interfaces configured in tagged-access port mode to the VLAN. These 10-Gigabit Ethernet interfaces are the physical interfaces that transport the FCoE traffic to and from the FCoE devices in the Ethernet network.

Each Ethernet interface that connects to FCoE devices must also include the native VLAN to transport FIP traffic, because FIP VLAN discovery and notification frames are exchanged as untagged packets. The FCoE VLAN must carry only FCoE traffic. A VLAN cannot transport a mix of FCoE and standard Ethernet traffic.

FCoE VLAN interface configuration includes:

- Configuring a VLAN to use as a dedicated FCoE VLAN.
- Configuring a native VLAN for FIP traffic.
- Configuring member interfaces for the FCoE VLAN.
- Configuring the FCoE VLAN as a Fibre Channel (family) VLAN and setting the port mode value to **f-port**. Explicitly configuring the FCoE VLAN interface in F\_Port mode is mandatory. The switch interface with which the FCoE server VN\_Ports communicate must present a VF\_Port to the servers.
- Configuring the FCoE VLAN interface as the Layer 3 interface for FCoE traffic.

To configure an FCoE VLAN interface:

1. Configure a dedicated FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name vlan-id vlan-id
```

For example, to configure a VLAN named **fcoe\_vlan** with a VLAN ID of **100** as the FCoE VLAN:

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

2. Configure a native VLAN for FIP traffic:

```
[edit vlans]
user@switch# set native vlan-id vlan-id
```

For example, to configure the native VLAN with a VLAN ID of 1:

```
[edit vlans]
user@switch# set native vlan-id 1
```

3. Configure member interfaces for the FCoE VLAN (use **ethernet-switching** as the family and **tagged-access** as the port mode):

```
[edit interfaces]
user@switch# set interface-name unit unit family family port-mode mode vlan members vlan-name
```

For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe\_vlan**:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan members fcoe_vlan
```

4. Configure the native VLAN on the FCoE VLAN member interfaces:

```
[edit interfaces]
user@switch# set interface-name unit unit family family native-vlan-id vlan-id
```

For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID 1:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
```

5. Assign the Ethernet interfaces to the FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name interface interface-name
```

For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan interface xe-0/0/10.0
```

6. Define an interface as an FCoE VLAN interface in F\_Port mode (to present a VF\_Port to the FCoE servers):

```
[edit interfaces]
user@switch# set vlan unit unit family fibre-channel port-mode f-port
```

For example, to configure VLAN unit **100** as an FCoE VLAN interface and set the port mode to **f-port**:

```
[edit interfaces]
user@switch# set vlan unit 100 family fibre-channel port-mode f-port
```

7. Define the Layer 3 FCoE VLAN interface:

```
[edit vlans]
user@switch# set vlan-name l3-interface vlan-interface-name
```

For example, to configure VLAN interface unit **100** (the FCoE VLAN interface defined earlier in this example) as the Layer 3 FCoE VLAN interface for FCoE VLAN **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan l3-interface vlan.100
```

## Assigning Interfaces to a Fibre Channel Fabric

When you configure the switch as an FCoE-FC gateway, you assign one or more (up to 12) native Fibre Channel (FC) interfaces and at least one FCoE VLAN interface to each FC fabric. FC interfaces transport native FC traffic between the proxy gateway and the storage area network (SAN) FC switch. FCoE VLAN interfaces transport FCoE traffic between FCoE-capable servers and the gateway.

Each FC fabric needs both types of interfaces to transport traffic between FCoE servers on the Ethernet network and FC storage devices in the core FC network behind the FC switch. FCoE traffic between the FCoE servers and the gateway must travel in a dedicated FCoE VLAN. Native FC traffic passes between the gateway and the FC switch on the native FC interfaces.

You must configure the FC interfaces and the FCoE VLAN interfaces that you assign to a particular fabric on the same Juniper Networks QFX3500 Switch. Traffic between an FCoE device and the FC switch must ingress and egress the same gateway.

To assign core-facing native FC interfaces and a server-facing FCoE VLAN interface to an FC fabric, configure a fabric and then specify the interfaces:

1. Assign the native FC interfaces to the FC fabric:

```
[edit fc-fabrics fabric-name]
user@switch: set interface interface-name
user@switch: set interface interface-name
user@switch: set interface interface-name
...
```

2. Assign an FCoE VLAN interface to the FC fabric:

```
[edit fc-fabrics fabric-name]
user@switch: set interface vlan-name
```

For example, to assign the native FC interfaces **fc-0/0/0.0**, **fc-0/0/1.0**, and **fc-0/0/2.0** and the FCoE VLAN interface **vlan.100** to an FC fabric named **san\_tana**:

```
user@switch: set fc-fabrics san_tana interface fc-0/0/0.0
user@switch: set fc-fabrics san_tana interface fc-0/0/1.0
user@switch: set fc-fabrics san_tana interface fc-0/0/2.0
user@switch: set fc-fabrics san_tana interface vlan.100
```

## Deleting a Fibre Channel Interface

Before you delete a Fibre Channel (FC) interface, you must first delete the interface from the FC fabric configuration. This prevents configuration errors that would result if you deleted an FC interface from the **[edit interfaces]** hierarchy level but did not delete the interface from the FC fabric.

When you configure the switch as an FCoE-FC gateway, FC interfaces transmit and receive native FC traffic between the gateway and the FC switch. You can configure ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create one or two blocks of six native FC interfaces.

To delete an FC interface using the CLI:

1. Delete the FC interface from the FC fabric to which it belongs:

```
[edit]
user@switch# delete fc-fabrics fabric-name interface interface-name
```

For example, to delete the FC interface **fc-0/0/3.0** from an FC fabric named **sanfab1**:

```
[edit]
user@switch# delete fc-fabrics sanfab1 interface fc-0/0/3.0
```

2. Delete the FC interface from the switch **[edit interfaces]** hierarchy:

```
[edit]
user@switch: delete interfaces interface-name
```

For example, to delete the interface **fc-0/0/3.0** from the switch:

```
[edit]
user@switch: delete interfaces fc-0/0/3.0
```

The FC interface has been deleted from the FC fabric and from the switch.

## Disabling Storm Control on FCoE Interfaces on an FCoE-FC Gateway

Storm control is not supported on the FCoE interfaces of an FCoE-FC gateway VLAN. Enabling storm control on an FCoE-FC gateway VLAN interface may cause FCoE packet loss. Storm control is disabled by default on all interfaces. However, if you enabled storm control globally on all switch interfaces or on any interfaces that are part of the FCoE VLAN interface, you must disable storm control on the Ethernet interfaces of the FCoE VLAN.

If storm control is enabled on only a few interfaces of the FCoE VLAN, you can disable storm control on individual interfaces by including the **delete ethernet-switching-options storm-control interface *interface-name*** statement in the configuration, where *interface-name* is the name of the interface on which you want to disable storm control.

If storm control is enabled globally on the switch when the switch is acting as an FCoE-FC gateway, it is often easiest to disable storm control on all interfaces, then enable storm control only on Ethernet interfaces that are not part of the FCoE VLAN interface.

If storm control is enabled globally, you can disable storm control in either of two ways:

- Disable storm control on all interfaces, then enable storm control on the interfaces you want to use storm control. (From the default configuration, you cannot disable storm control on individual interfaces because the default configuration enables storm control on **all** interfaces, not on individual interfaces.)

For example, if you want interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22 to use storm control, disable storm control on all interfaces, then enable storm control on those three interfaces:

1. Disable storm control on all interfaces:

```
user@switch# delete ethernet-switching-options storm-control interface all
```

2. Enable storm control on interfaces xe-0/0/20, xe-0/0/21, and xe-0/0/22:

```
user@switch# set ethernet-switching-options storm-control interface xe-0/0/20
user@switch# set ethernet-switching-options storm-control interface xe-0/0/21
user@switch# set ethernet-switching-options storm-control interface xe-0/0/22
```

- Disable storm control for all unknown unicast traffic on all interfaces by including the following statement in your configuration:

```
user@switch# set ethernet-switching-options storm-control interface all no-unknown-unicast
```

## Defining the Proxy Load-Balancing Algorithm

When the QFX Series is configured as an FCoE-FC gateway, it balances the FCoE session load assigned to each NP\_Port link between the gateway and the FC switch in the FC

SAN to avoid overloading or underutilizing each link. The QFX Series supports three types of load-balancing mechanisms:

- **Simple load balancing**—Load balancing is based on the weighted utilization (session load) of the NP\_Ports connected to an FC fabric. The session load is the sum of the FLOGI and FDISC sessions on each link. Each new ENode fabric login (FLOGI) or VN\_Port fabric discovery (FDISC) session is assigned to the least-loaded link, so an FDISC session initiated by the VN\_Port on an ENode might not be assigned to the same link as the parent ENode's FLOGI session. Simple load balancing is the default algorithm. Simple load balancing is the default load-balancing algorithm. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).
- **ENode-based load balancing**—Load balancing is based on the weighted utilization (session load) of the NP\_Ports connected to an FC fabric. The session load is the sum of the FLOGI and FDISC sessions on each link. However, when an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. The switch calculates the link load based on the combined total of FLOGIs and FDISCs on each NP\_Port link. Rebalancing the link load disrupts all sessions (all sessions log out and then log in again).
- **FLOGI-based load balancing**—Load balancing is based on the weighted utilization (session load) of the NP\_Ports connected to an FC fabric. The session load is the sum of the FLOGI sessions on each link. FDISC sessions are not counted. When an ENode logs in to the fabric, the switch places all subsequent VN\_Port FDISC sessions associated with that ENode on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. Rebalancing the link load disrupts only selected sessions to minimize the impact (the switch uses an algorithm to log out only the sessions that need to be moved to other links to balance the load when those sessions log in again).

To define the proxy load-balancing algorithm for a proxy fabric on the FCoE-FC gateway, set the algorithm as **enode-based**, **simple**, or **flogi-based**:

- `[edit fc-fabrics fabric-name proxy]`  
`user@switch# set load-balance-algorithm (enode-based | simple | flogi-based)`

For example, to configure a gateway fabric named **san\_fab1** to use **enode-based** load balancing:

```
user@switch# set fc-fabrics san_fab1 proxy load-balance-algorithm enode-based
```

#### Related Documentation

## Simulating On-Demand Fibre Channel Link Load Rebalancing (Dry Run Test)

On-demand Fibre Channel (FC) link load rebalancing on an FCoE-FC gateway is a disruptive action that causes sessions to log out of the network, then log back in to be placed on FC links (NP\_Ports) in a balanced manner. The number of sessions logged out to rebalance the links depends on the load-balancing algorithm used (simple, ENode-based, or FLOGI-based) and whether or not the load is already balanced. (If the link load is already balanced, the switch does not rebalance the loads when you request on-demand load rebalancing.)

You can use the **dry-run** option to list the sessions that might be affected (logged out to be redistributed among the active FC interface links) by on-demand load rebalancing *before* you actually rebalance the link load. (Because new sessions might log in between the time you perform a dry run and the time you request on-demand load rebalancing, the affected sessions may change. Therefore, the sooner that you perform an on-demand load rebalance after you perform a dry run, the more accurate the dry run results are likely to be.)

To request a link load rebalancing dry run:

```
user@switch> request fibre-channel proxy load-rebalance dry-run fabric fabric-name
```

For example, to request a dry run on an FC fabric named *fc\_fabric\_100* to display a list of sessions that might be disrupted if you request an actual link load rebalance:

```
user@switch> request fibre-channel proxy load-rebalance dry-run fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
F-Port      FCID      Port-WWN      NP-Port
vlan.100    0x8a013a  02:01:00:64:00:00:2a  fc-0/0/1.0
vlan.100    0x8a013c  02:01:00:64:00:00:2b  fc-0/0/1.0
vlan.100    0x8a0146  02:01:00:64:00:00:2e  fc-0/0/1.0
vlan.100    0x8a014c  02:01:00:64:00:00:2f  fc-0/0/1.0
```

## Enabling and Disabling CoS OxID Hash Control on Standalone Switches

The originator exchange identifier (OxID) field is one of several fields that the switch can use in its hash function computation for FCoE traffic load balancing over multiple outgoing links in an Ethernet link aggregation group (LAG) on ports that face an FCoE forwarder (FCF). You can configure whether or not the switch uses the OxID in the hash computation.

Including the OxID field in the load-balancing hash computation allows different exchanges between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) to take different paths across the network, thus improving the aggregate network throughput.

However, if the paths between different sets of FC endpoints have common links, congestion on one set of FC endpoints can affect the other set of endpoints. Such congestion can happen if the FCoE traffic on the two sets of endpoints uses the same priority (IEEE 802.1p code point). It is common for networks to use priority 3 (IEEE 802.1p code point 011) for FCoE traffic. However, you can assign different IEEE priorities to different lossless FCoE flows as described in [“Understanding CoS IEEE 802.1p Priorities for Lossless Traffic Flows” on page 5883](#) to further separate the traffic flows.

OxID hash control is enabled by default.

- To enable OxID hash control field for FCoE traffic load balancing:

```
[edit forwarding-options hash-key]  
user@switch# set family fcoe oxid enable
```

- To disable OxID hash control field for FCoE traffic load balancing:

```
[edit forwarding-options hash-key]  
user@switch# set family fcoe oxid disable
```

### Related Documentation

## Enabling and Disabling CoS OxID Hash Control on QFabric Systems

The originator exchange identifier (OxID) field is one of several fields used in the hash function computation for FCoE traffic load balancing over multiple outgoing links in an Ethernet link aggregation group (LAG) on ports that face an FCoE forwarder (FCF). The QFabric system Node device ports can be 10-Gigabit Ethernet ports or 40-Gigabit fabric ports. (The 40-Gigabit fabric ports that connect a QFabric system Node device to QFabric system Interconnect devices function as a LAG even though they are not explicitly configured as a LAG.)

The originator of an exchange between a pair of Fibre Channel (FC) endpoints (such as an FCoE host and an FC storage device) uses the OxID field as an identifier for that exchange. The originator also uses the OxID field to track the progress of the series of sequences that comprise the exchange.

OxID hash control is enabled by default.

You can enable or disable OxID hash control on the 10-Gigabit Ethernet interfaces and on the 40-Gigabit fabric interfaces of a QFabric system Node group. OxID hash control is either enabled or disabled on all of the fabric or Ethernet interfaces of a Node group. For example, you cannot disable OxID hash control on some fabric interfaces in a Node group and leave OxID hash control enabled on other fabric interfaces of the same Node group.

1. To enable or disable OxID hash control on all of the 10-Gigabit Ethernet interfaces of a specified Node group or on all Node groups:

```
[edit forwarding-options hash-key]
admin@qfabric# set family fcoe ethernet-interfaces node-group [node-group-name | all]
oxid [enable | disable]
```

For example, to disable OxID hash control on all of the 10-Gigabit Ethernet interfaces of a Node group named **RSNG1**:

```
admin@qfabric# set family fcoe ethernet-interfaces node-group RSNG1 oxid disable
```

2. To enable or disable OxID hash control on all of the 40-Gigabit fabric interfaces of a specified Node group or on all Node groups:

```
[edit forwarding-options hash-key]
admin@qfabric# set family fcoe fabric-interfaces node-group [node-group-name | all] oxid
[enable | disable]
```

For example, to disable OxID hash control on the fabric interfaces of all Node groups:

```
admin@qfabric# set family fcoe fabric-interfaces node-group all oxid disable
```

## Configuring FIP on an FCoE-FC Gateway

Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) establishes and maintains Fibre Channel (FC) virtual links between pairs of FCoE devices. A virtual link emulates the physical point-to-point link that FC requires between two FC devices.

FIP is enabled by default and uses the default FIP settings on all FCoE interfaces that are part of the gateway FC fabric. You can use the default FIP parameter values, or you can configure FIP parameters globally or on a per-interface basis. Configuring FIP on an individual interface overrides the global FIP configuration.

You can configure the following parameters globally for the fabric and per interface:

- FIP keepalive message transmission interval—This interval is the time period between sending FIP keepalive messages.
- Priority—If an FCoE node (ENode) connects to more than one switch, the priority value determines the switch to which the ENode connects. The switch with the lowest priority number has the highest priority.

You can only configure the following parameters globally on an FC fabric:

- FC-MAP—The 24-bit FCoE mapped address prefix that identifies the attached FC switch in the SAN fabric. The FC-MAP value is used in the fabric provided MAC address (FPMA) created for each ENode that logs in. This value must be the same for the FC switch and the QFX Series.

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

---

- FCoE trusted—You can globally configure all of the Ethernet ports in a specified FC fabric to be FCoE trusted. You might want to configure interfaces as FCoE trusted if the interfaces are connected to a transit switch that is performing FIP snooping. For interfaces that are directly connected to FCoE hosts, FIP snooping should be enabled, and you should not configure the fabric as FCoE trusted.
- 

**NOTE:** Do not configure interfaces with FIP snooping enabled as FCoE trusted.

---

Configuring interfaces as FCoE trusted reduces system overhead by eliminating the need for filters. The total number of sessions the system can support is 2500 sessions. Sessions are defined as the combined number of VN\_Port to VF\_Port sessions and VN\_Port to VN\_Port sessions. (Although VN2VF and VN2VN sessions run in different FCoE VLANs, the session limit is a system limit, not a per-VLAN limit.)

**NOTE:** A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions. There is no limit to the number of end-to-end storage sessions.

**NOTE:** Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN\_Ports log in again, the switch can build the appropriate FIP snooping filters.

- Maximum number of FCoE sessions per ENode—You can globally configure the maximum number of FCoE sessions (FLOGI plus FDISC) permitted from an ENode. The maximum number of sessions per ENode is 2000 sessions. The total number of sessions (VN2VF\_Port sessions and VN2VN\_Port sessions combined) cannot exceed the gateway fabric's maximum limit of 2500 sessions.

To configure FIP options globally using the CLI:

1. Specify the fabric on which you want to configure FIP:

```
[edit]
user@switch# set fc-fabrics fabric-name protocols fip
```

2. Configure the FIP keepalive message transmission interval in milliseconds to specify the amount of time between periodic FIP discovery advertisements for the fabric interfaces (the default is 8000 ms; the range is 250 through 90000 ms):

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fka-adv-period milliseconds
```

3. Configure the priority value the switch advertises to ENodes in the range from 0 through 255; the default value is 128:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set priority priority
```

4. Configure the FC-MAP value to match the FC-MAP value of the attached FC switch in the FC SAN fabric; the range of possible values is 0EFC00 through 0EFCFF, and the default value is 0EFC00:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fc-map fc-map
```

5. Configure the interfaces in the FC fabric as FCoE trusted (in this example, we assume that the interfaces have not been enabled for FIP snooping):

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set fcoe-trusted
```

6. Configure the maximum number of FCoE sessions for each ENode in the fabric:

```
[edit fc-fabrics fabric-name protocols fip]
user@switch# set max-sessions-per-enode
```

For example, to configure all FCoE interfaces associated with an FC fabric called **movieco\_san** with a FIP keepalive interval value of **25000** milliseconds, a priority of **70**, an FC-MAP value of **0EFC01**, as FCoE trusted, and with a maximum number of FCoE sessions per ENode of 200 sessions:

```
[edit fc-fabrics movieco_san protocols fip]
user@switch# set fka-adv-period 25000
user@switch# set priority 70
user@switch# set fc-map 0EFC01
user@switch# set fcoe-trusted
user@switch# set max-sessions-per-enode 200
```

To override the global FC fabric FIP configuration for a specific FCoE interface using the CLI:

1. Specify the fabric and interface on which you want to configure FIP:

```
[edit fc-fabrics fabric-name protocols fip interface interface-name]
```

2. Configure the FIP keepalive message transmission interval and priority:

```
[edit fc-fabrics fabric-name protocols fip interface interface-name]
user@switch# set fka-adv-period milliseconds
user@switch# set priority priority
```

## Setting the Maximum Number of FIP Login Sessions per ENode

When the switch acts as an FCoE-FC gateway, FCoE node (ENode) devices in the Ethernet network use the gateway to connect to the Fibre Channel (FC) storage area network (SAN). You can limit the maximum number of FIP login sessions permitted on each ENode. Limiting the number of login sessions can prevent login session rejections caused when the connected FC switch port configuration limits the number of FIP login sessions.

The maximum number of FIP sessions per ENode is 2000 sessions (FLOGI plus FDISC sessions). The limit you set applies to every ENode in the specified gateway fabric. Each ENode in the fabric can have up to the maximum number of sessions, but the total number of active sessions cannot exceed the session limits you apply to the fabric or the Node device.

There are also configurable FIP login session limits that you can apply to the gateway FC fabric, to the QFX3500 switch or QFabric system Node device, and to the interfaces in each FC fabric.

- To set a maximum number of FIP login sessions per ENode using the CLI:

```
[edit fc-fabrics fc-fabric-name protocols fip]
user@switch# set max-sessions-per-enode max-login-sessions
```

For example, to configure the ENodes on an FC fabric named **sanfab1** with a maximum FIP login session limit of **250** sessions:

```
[edit fc-fabrics sanfab1]
user@switch# set protocols fip max-sessions-per-enode 250
```

#### Related Documentation

## Setting the Maximum Number of FIP Login Sessions per FC Interface

When the switch acts as an FCoE-FC gateway, NP\_Ports are the native FC interfaces the gateway uses to connect to the FC switch. You can limit the maximum number of FIP login sessions permitted on an NP\_Port interface. Limiting the number of login sessions on an interface can prevent login session rejections caused when the connected FC switch port configuration limits the number of FIP login sessions.

**TIP:** A good practice is to configure a maximum number of login sessions on each NP\_Port that is less than or equal to the maximum number of login sessions permitted on the connected FC switch port.

The maximum number of FIP sessions is 2500 sessions. (This is the combined total of all VN2VF\_Port and VN2VN\_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the gateway FC fabric, to the QFX3500 switch or QFabric system Node device, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections, the sum of the maximum FIP login sessions on all of the NP\_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.

- To set a maximum number of FIP login sessions on an NP\_Port using the CLI:

```
[edit fc-fabrics fc-fabric-name interface interface-name]
user@switch# set max-login-sessions max-login-sessions
```

For example, to configure NP\_Port interface **fc-0/0/5** with a maximum FIP login session limit of **500** sessions on an FC fabric named **sanfab1**:

```
[edit fc-fabrics sanfab1]
user@switch# set interface fc-0/0/5 max-login-sessions 500
```

#### Related Documentation

## Setting the Maximum Number of FIP Login Sessions per FC Fabric

When the QFX Series acts as an FCoE-FC gateway, you configure at least one local FC fabric on the gateway. A gateway FC fabric creates associations that connect FCoE devices on an Ethernet network to an FC switch on a Fibre Channel network. Each FC fabric on a gateway includes native FC interfaces (NP\_Ports) that connect the gateway to the FC switch. When FCoE devices want to log in to the FC switch, the gateway sends the FIP login requests to the FC switch on the NP\_Port links.

You can limit the maximum number of FIP login sessions permitted on a gateway FC fabric. If a QFX3500 switch or QFabric system Node device has more than one FC fabric, limiting the number of login sessions on an FC fabric can prevent one FC fabric from using all of the login sessions available on the device.

The maximum number of FIP sessions is 2500 sessions. (This is the combined total of all VN2VF\_Port and VN2VN\_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the FC fabric NP\_Port interfaces, to the QFX3500 switch or QFabric system Node device, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections:

- The sum of the maximum FIP login sessions on all of the NP\_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.
- The sum of the maximum FIP login sessions on all of the FC fabrics on a device should not exceed the maximum number of sessions per device.
- To set a maximum number of FIP login sessions on an FC fabric using the CLI:

```
[edit fc-fabrics fc-fabric-name]  
user@switch# set max-login-sessions max-login-sessions
```

For example, to configure an FC fabric named **sanfab1** with a maximum FIP login session limit of **2000** sessions:

```
[edit fc-fabrics sanfab1]  
user@switch# set fc-fabrics sanfab1 max-login-sessions 2000
```

### Related Documentation

- [Setting the Maximum Number of FIP Login Sessions per Node Device on page 5543](#)
- [Understanding Interfaces on an FCoE-FC Gateway on page 5311](#)

## Setting the Maximum Number of FIP Login Sessions per Node Device

When a QFX3500 switch or QFabric system Node device acts as an FCoE-FC gateway, it connects FCoE devices on an Ethernet network to an FC switch in a Fibre Channel network. You can limit the maximum number of FIP login sessions for the FCoE devices on each Node device.

For QFX3500 switches, the maximum limit means that the sum of the FIP login sessions on all of the local FC fabrics on that QFX3500 switch cannot exceed the device maximum.

For the QFabric system, the limit applies to each Node device in the QFabric system. For example, if you configure a maximum FIP login session value of 2000 sessions, each Node device in the QFabric system can have a total of up to 2000 FIP login sessions running on its FC fabrics.

The maximum number of FIP sessions a device can support is 2500 sessions. (This is the combined total of all VN2VF\_Port and VN2VN\_Port sessions on the system.)

There are also configurable FIP login session limits that you can apply to the FC fabrics on the devices, to the NP\_Port interfaces in each FC fabric, and to the ENodes in each FC fabric. To prevent unexpected FIP login rejections:

- The sum of the maximum FIP login sessions for all of the FC fabrics on a device should not exceed the maximum number of sessions per device.
- The sum of the maximum FIP login sessions on all of the NP\_Port interfaces that belong to an FC fabric should not exceed the maximum number of sessions the FC fabric supports or the device supports.
- To set a maximum number of FIP login sessions for Node devices using the CLI:

[edit **fc-options**]

```
user@switch# set max-login-sessions-per-node max-login-sessions-per-node
```

For example, to configure a maximum FIP login limit of **2000** sessions on a QFX3500 switch or on all Node devices in a QFabric system:

[edit **fc-options**]

```
user@switch# set max-login-sessions-per-node 2000
```

## Configuring VLANs for FCoE Traffic on an FCoE Transit Switch

When you configure a switch as a Fibre Channel over Ethernet (FCoE) transit switch, you must configure a VLAN that transports only FCoE traffic. FCoE traffic requires a dedicated VLAN and cannot share a VLAN with any other type of traffic. Because FCoE traffic is tagged traffic, the port (or interface) mode cannot be access mode, it must be either tagged-access port-mode (for switches that run the original CLI) or trunk interface-mode (for switches that run the Enhanced Layer 2 Software (ELS) CLI).

However, each interface that belongs to an FCoE VLAN must not only transport the tagged FCoE traffic, it must also transport the untagged FCoE Initialization Protocol (FIP) traffic. FIP communicates with the storage area network (SAN) Fibre Channel (FC) switch to set up the FCoE session for the FCoE client.

To transport untagged traffic on a tagged-access or trunk mode interface, the interface must have a native VLAN configured on it. Therefore, each interface that belongs to an FCoE VLAN must also have a native VLAN on it.

There are slight differences in the way you configure a native VLAN on an interface, depending on whether the switch uses the ELS CLI or the original CLI. This topic describes both methods.

**NOTE:** FCoE VLANs (any VLAN that carries FCoE traffic) support only Spanning Tree Protocol (STP) and link aggregation group (LAG) Layer 2 features.

FCoE traffic cannot use a standard LAG because traffic might be hashed to different physical LAG links on different transmissions. This breaks the (virtual) point-to-point link that Fibre Channel traffic requires. If you configure a standard LAG interface for FCoE traffic, FCoE traffic might be rejected by the FC SAN.

QFabric systems support a special LAG called an FCoE LAG, which enables you to transport FCoE traffic and regular Ethernet traffic (traffic that is not FCoE traffic) across the same link aggregation bundle. Standard LAGs use a hashing algorithm to determine which physical link in the LAG is used for a transmission, so communication between two devices might use different physical links in the LAG for different transmissions. An FCoE LAG ensures that FCoE traffic uses the same physical link in the LAG for requests and replies in order to preserve the virtual point-to-point link between the FCoE device converged network adapter (CNA) and the FC SAN switch across the QFabric system Node device. An FCoE LAG does not provide load balancing or link redundancy for FCoE traffic. However, regular Ethernet traffic uses the standard hashing algorithm and receives the usual LAG benefits of load balancing and link redundancy in an FCoE LAG.

**NOTE:** To configure an FCoE VLAN on a QFX3500 switch that you are using as an FCoE-FC gateway, you must also configure an FCoE VLAN interface as described in [“Configuring an FCoE VLAN Interface on an FCoE-FC Gateway”](#)

[on page 5528](#). (Only the QFX3500 switch supports FCoE-FC gateway configuration.)

.....

FCoE VLAN configuration includes:

- Configuring a VLAN to use as a dedicated FCoE VLAN
- Configuring the interface members of the FCoE VLAN.
- Configuring a native VLAN for FIP traffic.

This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

## Original CLI Configuration

To configure an FCoE VLAN on a non-ELS switch:

1. Configure a dedicated FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name vlan-id vlan-id
```

For example, to configure a VLAN named **fcoe\_vlan** with a VLAN ID of **100** as the FCoE VLAN:

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

2. Configure the FCoE VLAN on the interface (use **ethernet-switching** as the family and **tagged-access** as the port mode):

```
[edit interfaces]
user@switch# set interface-name unit unit family family port-mode mode vlan members
vlan-name
```

For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe\_vlan**:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching port-mode tagged-access vlan
members fcoe_vlan
```

3. Configure the Ethernet interface membership in the FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name interface interface-name
```

For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan interface xe-0/0/10.0
```

4. Configure a native VLAN for the untagged FIP traffic:

```
[edit vlans]
user@switch# set native vlan-id vlan-id
```

For example, to configure the native VLAN with a VLAN ID of 1:

```
[edit vlans]
user@switch# set native vlan-id 1
```

5. Assign member interfaces to the native VLAN:

```
[edit interfaces]
user@switch# set interface-name unit unit family family native-vlan-id vlan-id
```

For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID 1:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching native-vlan-id 1
```

## ELS CLI Configuration

To configure an FCoE VLAN on a switch running ELS:

1. Configure a dedicated FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name vlan-id vlan-id
```

For example, to configure a VLAN named **fcoe\_vlan** with a VLAN ID of **100** as the FCoE VLAN:

```
[edit vlans]
user@switch# set fcoe_vlan vlan-id 100
```

2. Configure the FCoE VLAN on the interface (use **ethernet-switching** as the family and **trunk** as the interface mode):

```
[edit interfaces]
user@switch# set interface-name unit unit family family interface-mode mode vlan members
vlan-name
```

For example, to configure the interface **xe-0/0/10** as a member of the FCoE VLAN **fcoe\_vlan**:

```
[edit interfaces]
user@switch# set xe-0/0/10 unit 0 family ethernet-switching interface-mode trunk vlan
members fcoe_vlan
```

3. Configure the Ethernet interface membership in the FCoE VLAN:

```
[edit vlans]
user@switch# set vlan-name interface interface-name
```

For example, to assign the interface **xe-0/0/10.0** to the FCoE VLAN named **fcoe\_vlan**:

```
[edit vlans]
user@switch# set fcoe_vlan interface xe-0/0/10.0
```

4. Configure a native VLAN on the physical Ethernet interface for the untagged FIP traffic:

```
[edit interfaces]
user@switch# set interface-name native-vlan-id vlan-id
```

For example, to configure the native VLAN on interface **xe-0/0/10** with a VLAN ID of **1**:

```
[edit interfaces]
user@switch# set xe-0/0/10 native-vlan-id 1
```

5. Configure the Ethernet interface as a member of the native VLAN:

```
[edit interfaces]
user@switch# set interface-name unit unit family family vlan members native-vlan-id
```

**NOTE:** The *native-vlan-id* number must be the same as the native VLAN ID number that you configured on the physical Ethernet interface (see step 4).

---

For example, to configure the interface **xe-0/0/10** as a member of the native VLAN with the native VLAN ID **1**:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/10 unit 0 family ethernet-switching vlan members 1
```

## Configuring VN2VF\_Port FIP Snooping and FCoE Trusted Interfaces on an FCoE Transit Switch

VN\_Port to VF\_Port (VN2VF\_Port) Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) snooping uses information gathered during FIP discovery and login to create firewall filters that provide security against unauthorized access to the FC switch or FCoE forwarder (FCF) through the switch when the switch is acting as an FCoE transit switch. The firewall filters allow only FCoE devices that successfully log in to the FC fabric to access the FCF through the transit switch. VN2VF\_Port FIP snooping provides security for the point-to-point virtual links that connect host FCoE Nodes (ENodes) and FCFs in the FCoE VLAN by denying access to any device that does not successfully log in to the FCF.

VN2VF\_Port FIP snooping is disabled by default. You enable VN2VF\_Port FIP snooping on a per-VLAN basis for VLANs that carry FCoE traffic. Ensure that a VLAN that carries FCoE traffic carries only FCoE traffic, because enabling VN2VF\_Port FIP snooping denies access for all other Ethernet traffic.

**NOTE:** All of the transit switch ports are untrusted by default. If an ENode on an FCoE device logs in to an FCF before you enable VN2VF\_Port FIP snooping on the VLAN and you then enable VN2VF\_Port FIP snooping, the transit switch denies traffic from the ENode because the transit switch has not snooped (learned) the ENode state. The following process automatically logs the ENode back in to the FCF to reestablish the connection:

1. VN2VF\_Port FIP snooping is enabled on an FCoE VLAN on the switch.
2. The switch denies existing connections between servers and the FCF on the FCoE VLAN by filtering the FCoE traffic and FIP traffic, so no keepalive messages from the ENodes reach the FCF.
3. The FCF port timer for each ENode and for each VN\_Port on each ENode expires.
4. The FCF sends each ENode whose port timer has expired a Clear Virtual Links (CVL) message.
5. The CVL message causes the ENode to log in again.

Because the FCF is a trusted source, you configure interfaces that connect to the FCF as FCoE trusted interfaces. FCoE trusted interfaces do not filter traffic (FIP snooping filtering should occur only at the FCoE access edge), but VN2VF\_Port FIP snooping continues to run on trusted interfaces so that the switch learns the FCF state.

**NOTE:** Do not configure ENode-facing interfaces both with FIP snooping enabled and as trusted interfaces. FCoE VLANs with interfaces that are directly connected to FCoE hosts should be configured with FIP snooping enabled and the interfaces should *not* be trusted interfaces. Ethernet interfaces that are connected to an FCF should be configured as trusted interfaces and should not have FIP snooping enabled. Interfaces that are connected to a transit switch that is performing FIP snooping can be configured as trusted interfaces if the FCoE VLAN is not enabled for FIP snooping.

Optionally, you can specify an FC-MAP value for each FCoE VLAN. On a given FCoE VLAN, the switch learns only FCFs that have a matching FC-MAP value. The default FC-MAP value is 0EFC00h for all FC devices. (Enter hexadecimal values for FC-MAP preceded by the hexadecimal indicator "0x"—for example, 0x0EFC00.) If you change the FC-MAP value of an FCF, change the FC-MAP value for the FCoE VLAN it belongs to on the switch and on the servers you want to communicate with the FCF. An FCoE VLAN can have one and only one FC-MAP value.

**NOTE:** The default enhanced FIP snooping scaling supports 2,500 sessions. On QFabric systems, starting with Junos OS Release 13.2X52, you can disable enhanced FIP snooping scaling on a per-VLAN basis if you want to do so, but only 376 sessions are supported if you disable enhanced FIP snooping scaling.

There are differences in the way you configure FIP snooping and FCoE trusted interfaces on a switch that depend on whether the switch uses the original CLI or the Enhanced Layer 2 Software (ELS) CLI. This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

### Original CLI Configuration

To enable VN2VF\_Port FIP snooping:

- To enable VN2VF\_Port FIP snooping on a single VLAN and specify the optional FC-MAP value:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan vlan-name examine-fip fc-map fc-map-value
```

For example, to enable VN2VF\_Port FIP snooping on a VLAN named **san1\_vlan** and change the FC-MAP value to **0x0EFC03**:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan san1_vlan examine-fip fc-map 0x0EFC03
```

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces ENodes to log in again.

- To enable VN2VF\_Port FIP snooping on all VLANs and use the default FC-MAP value:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan all examine-fip
```

- To configure an interface as an FCoE trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface interface-name fcoe-trusted
```

For example, to configure interface **xe-0/0/30** as an FCoE trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/30 fcoe-trusted
```

### ELS CLI Configuration

To enable VN2VF\_Port FIP snooping:

- To enable VN2VF\_Port FIP snooping on a VLAN and specify the optional FC-MAP value:

```
[edit]
user@switch# set vlans vlan-name forwarding-options fip-security fc-map fc-map-value
examine-vn2vf
```

For example, to enable VN2VF\_Port FIP snooping on a VLAN named **san1\_vlan** and change the FC-MAP value to **0x0EFC03**:

```
[edit]
user@switch# set vlans san1_vlan forwarding-options fip-security fc-map 0x0EFC03
examine-vn2vf
```

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces ENodes to log in again.

- To configure an interface as an FCoE trusted interface:

```
[edit]
user@switch# set vlans vlan-name forwarding-options fip-security interface interface-name
fcoe-trusted
```

For example, to configure interface **xe-0/0/30** on VLAN named **san1\_vlan** as an FCoE trusted interface:

```
[edit]
user@switch# set vlans san1_vlan forwarding-options fip-security interface xe-0/0/30
fcoe-trusted
```

## Disabling Enhanced FIP Snooping Scaling

Enhanced FIP snooping scaling (introduced in Junos OS Release 12.3) scales up to 2,500 sessions and is the default FIP snooping scaling mode. On QFabric systems only, you can disable enhanced FIP snooping scaling. Disabling FIP snooping scaling reduces the number of supported FIP snooping sessions to 376 sessions.

On QFabric system Node device in FCoE-FC gateway mode, you disable FIP snooping scaling globally, on all of the Fibre Channel (FC) fabrics (fc-fabrics) on the Node device. Either all FC fabrics on a Node device use enhanced FIP snooping scaling (2,500 sessions), or all FC fabrics on a Node device disable FIP snooping scaling (376 sessions). On an FCoE-FC gateway, you must disable FIP snooping scaling if the member interfaces of an FCoE VLAN are configured as members of an FCoE LAG *and* if the FC fabric is an FCoE untrusted fabric. If the FC fabric is an FCoE trusted fabric, then you do not need to disable FIP snooping scaling on the gateway.

On a QFabric system Node device in FCoE transit switch mode, you do not need to disable FIP snooping scaling. However, you can disable FIP snooping scaling on a per-VLAN basis if you want to do so.

Disabling FIP snooping scaling is done differently on an FCoE-FC gateway than on an FCoE transit switch. This document provides the method for each mode.

### Disabling Enhanced FIP Snooping Scaling on an FCoE-FC Gateway

If you configure an FCoE LAG on an FCoE untrusted gateway fabric, you must disable FIP snooping scaling. Disabling FIP snooping scaling is global and affects all FC fabrics on the gateway.

```
1. admin@qfabric# set fc-options no-fip-snooping-scaling
```

### Disabling Enhanced FIP Snooping Scaling on an FCoE Transit Switch

If you choose to disable FIP snooping scaling on an FCoE transit switch, you can disable it on individual FCoE VLANs:

```
1. admin@qfabric# set ethernet-switching-options secure-access-port vlan fcoe-vlan-name
  examine-fip no-fip-snooping-scaling
```

For example, if the FCoE VLAN name is **fcoe-vlan-blue**:

```
admin@qfabric# set ethernet-switching-options secure-access-port vlan fcoe-vlan-blue
  examine-fip no-fip-snooping-scaling
```

### Related Documentation

- [Configuring an FCoE LAG on page 5557](#)
- [Example: Configuring an FCoE LAG on a Redundant Server Node Group on page 5509](#)

- [Understanding VN\\_Port to VF\\_Port FIP Snooping on an FCoE Transit Switch on page 5341](#)
- [Understanding FCoE LAGs on page 5417](#)

## Disabling VN2VF\_Port FIP Snooping on an FCoE-FC Gateway Switch Interface

When the switch acts as an FCoE-FC gateway, the FCoE-network-facing Ethernet interfaces in the FCoE VLAN are automatically enabled for VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping. You can disable VN2VF\_Port FIP snooping on an individual Ethernet interface or you can disable VN2VF\_Port FIP snooping globally for all Ethernet interfaces in a gateway Fibre Channel (FC) fabric.

Disable VN2VF\_Port FIP snooping on an Ethernet interface by configuring it as an FCoE trusted interface. Disable VN2VF\_Port FIP snooping on all Ethernet interfaces in an FC fabric by configuring the FC fabric as FCoE trusted.

Do not disable VN2VF\_Port FIP snooping on an interface unless you are certain that the interface is connected to a trusted device. Do not disable VN2VF\_Port FIP snooping on an FC fabric unless all of the FCoE-network-facing interfaces in the fabric are either connected to a transit switch that is performing VN2VF\_Port FIP snooping on the FCoE devices as they log in to the FC network or all of the interfaces are connected to trusted devices.

VN2VF\_Port FIP snooping installs firewall filters that block FIP and FCoE frames from sources that have not logged in to the switch and prevents unauthorized access to the network. Disabling VN2VF\_Port FIP snooping disables these firewall filters and permits access to all FIP and FCoE frames transported on that interface.

- To disable VN2VF\_Port FIP snooping on an FCoE-device-facing Ethernet interface in an FCoE VLAN, configure that interface as a trusted interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface interface-name fcoe-trusted
```

For example, to configure interface **xe-0/0/7** as a trusted FC interface:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set interface xe-0/0/7 fcoe-trusted
```

- To disable VN2VF\_Port FIP snooping on all FCoE-device-facing interfaces in a gateway FC fabric, configure that fabric as a trusted fabric:

```
[edit]
user@switch# set fc-fabrics fabric-name protocols fip fcoe-trusted
```

For example, to configure an FC fabric named *santastic* as an FCoE trusted fabric:

```
[edit]
user@switch# set fc-fabrics santastic protocols fip fcoe-trusted
```

## Enabling VN2VN\_Port FIP Snooping and Configuring the Beacon Period on an FCoE Transit Switch

VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping on an FCoE transit switch provides security to help prevent unauthorized access and data transmission on a bridge that connects ENodes in the Ethernet network. VN2VN\_Port FIP snooping provides security for virtual links by creating filters based on information gathered (snooped) about FCoE devices during FIP transactions.

VN2VN\_Port FIP snooping is conceptually similar to VN2VF\_Port FIP snooping between VN\_Ports and VF\_Ports, but VN2VN\_Port FIP snooping does not require traffic between VN\_Ports to traverse the Fibre Channel (FC) switch or FCoE forwarder (FCF). Instead, a VN\_Port communicates transparently through the transit switch on a virtual link that emulates a direct connection to the VN\_Port at the other end of the virtual link.

VN2VN\_Port FIP snooping is disabled by default. You enable VN2VN\_Port FIP snooping on a per-VLAN basis on VLANs that carry VN2VN\_Port FCoE traffic. Ensure that the VLAN carries only FCoE traffic between VN\_Ports, because enabling VN2VN\_Port FIP snooping denies access for all other traffic, including VN2VF\_Port FIP snooping traffic.

All ENodes that you want to communicate using VN2VN\_Port FIP snooping must use an FCoE VLAN dedicated to VN2VN\_Port traffic. You cannot mix VN2VN\_Port FIP snooping traffic with VN2VF\_Port FIP snooping traffic in the same FCoE VLAN.

**NOTE:** An FCoE VLAN can support either VN2VF\_Port FIP snooping or VN2VN\_Port FIP snooping, but not both. Configure separate FCoE VLANs for VN2VF\_Port FIP snooping traffic and for VN2VN\_Port FIP snooping traffic. On FCoE VLANs that are configured as VN2VN\_Port FIP snooping VLANs, VN2VF\_Port traffic is dropped.

The *beacon period* is conceptually similar to the FIP keepalive period (timer) for VN2VF\_Port FIP snooping virtual link maintenance. The beacon period performs virtual link maintenance for VN2VN\_Port FIP snooping. It is the time interval between messages that verify the connection is still valid and the device at the other end of the virtual link is still reachable. You set the beacon period value for each FCoE VLAN that you configure to do VN2VN\_Port FIP snooping.

**NOTE:** In addition to enabling VN2VN\_Port FIP snooping and configuring the beacon period, you must also configure a dedicated FCoE VLAN for the VN2VN\_Port traffic, and set the FCoE transit switch ports in the proper port mode and trusted or untrusted state (interfaces are untrusted by default). See the VN2VN\_Port FIP snooping configuration example topics for complete configurations of several common network topologies.

There are differences in the way you configure a native VLAN on an interface that depend on whether the switch uses the original CLI or the Enhanced Layer 2 Software (ELS) CLI. This topic includes two configuration procedures, one for switches that run the original CLI, and one for switches that run the ELS CLI.

### Original CLI Configuration

To enable VN2VN\_Port FIP snooping and set the beacon period on an FCoE VLAN that is dedicated to VN2VN\_Port traffic:

- [edit ethernet-switching-options secure-access-port]  
user@switch# **set vlan *vlan-name* examine-fip examine-vn2vn beacon-period *milliseconds***

For example, to enable VN2VN\_Port FIP snooping on a VLAN named **vlan200** and set the beacon period to **90000** milliseconds:

```
[edit ethernet-switching-options secure-access-port]
user@switch# set vlan vlan200 examine-fip examine-vn2vn beacon-period 90000
```

### ELS CLI Configuration

To enable VN2VN\_Port FIP snooping and set the beacon period on an FCoE VLAN that is dedicated to VN2VN\_Port traffic:

- [edit]  
user@switch# **set vlans *vlan-name* forwarding-options fip-security examine-vn2vn beacon-period *milliseconds***

For example, to enable VN2VN\_Port FIP snooping on a VLAN named **vlan200** and set the beacon period to **90000** milliseconds:

```
[edit]
user@switch# set vlans vlan200 forwarding-options fip-security examine-vn2vn beacon-period 90000
```

## Configuring an FCoE LAG

A Fibre Channel over Ethernet (FCoE) link aggregation group (LAG) is a special LAG that enables you to transport FCoE traffic and regular Ethernet traffic across the same link aggregation bundle. Standard LAGs use a hashing algorithm to determine which physical link in the LAG is used for a transmission, so a series of communications between two devices might use different physical links in the LAG for different transmissions.

However, FCoE traffic requires a point-to-point link (or a virtual point-to-point link) between the FCoE device and the Fibre Channel (FC) storage area network (SAN) switch. This requirement means that communication between an FCoE device and a QFabric system Node device must use the same physical link in a LAG to maintain the virtual point-to-point connection.

An FCoE LAG solves the problem by ensuring that the same LAG link is used for communication between an FC SAN switch and a given FCoE device across a QFabric system Node device, preserving point-to-point link emulation. At the same time, regular Ethernet traffic (traffic that is not FCoE traffic) on the LAG is distributed across member interfaces in the same way as on a standard LAG. FCoE traffic is treated properly in terms of maintaining a virtual point-to-point link with the FC SAN, and regular Ethernet traffic enjoys the usual LAG benefits of load balancing and link redundancy.

**NOTE:** Configuring a LAG as an FCoE LAG does not provide link redundancy for FCoE traffic, and does not load balance FCoE traffic.

On FCoE-FC gateway untrusted Fibre Channel fabrics (fc-fabrics), if you configure an FCoE LAG, you must also disable enhanced FIP snooping scaling (scaling up to 2,500 sessions), which reduces the number of supported FIP snooping sessions to 376 sessions. On an FCoE-FC gateway, disabling enhanced FIP snooping scaling is global to the Node device. Trusted fc-fabrics on an FCoE-FC gateway support enhanced FIP snooping scaling.

This example shows how to configure an FCoE LAG with enhanced FIP snooping scaling enabled and also with enhanced FIP snooping scaling disabled.

The steps required to create the FCoE LAG are:

- Configuring an FCoE LAG interface.
- Assigning the Ethernet interfaces connected to the FCoE device to the FCoE LAG.
- Configuring FIP snooping.

In addition to configuring the FCoE LAG and FIP snooping scaling, you also need to configure:

- Configure a dedicated FCoE VLAN for the FCoE traffic.
- Configure a native VLAN for the untagged FIP traffic.
- Enable FIP snooping on the FCoE VLAN.
- Configure the FCoE LAG interface membership in the FCoE VLAN and the native VLAN.

- For FCoE-FC gateway switches, configure a Layer 3 FCoE VLAN interface, and add the FCoE VLAN interface to the Fibre Channel fabric.
- For FCoE-FC gateway switches, configure the fc-fabric as an FCoE trusted fabric if you are using enhanced FIP snooping scaling (and if the FCoE traffic is trusted).

[“Example: Configuring an FCoE LAG on a Redundant Server Node Group” on page 5509](#) includes an example of this configuration.

### Configuring an FCoE LAG When Enhanced FIP Snooping Scaling is Enabled

This example shows how to configure an FCoE LAG when you can use enhanced FIP snooping scaling, such as when the FCoE-FC gateway fabrics are trusted, or on an FCoE transit switch.

1. Specify the number of LAGs (Ethernet devices) the QFabric system Node group will support:

```
admin@qfabric# set chassis node-group node-group-name aggregated-devices ethernet device-count device-count
```

For example, to configure the Node group **RSNG1** to allow up to ten LAGs:

```
admin@qfabric# set chassis node-group RSNG1 aggregated-devices ethernet device-count 10
```

2. Configure the LAG interface on the RSNG:

```
admin@qfabric# set interfaces lag-interface-name unit unit family ethernet-switching port-mode trunk
```

For example, to configure a LAG interface named **ae3** on Node group **RSNG1**:

```
admin@qfabric# set interfaces RSNG1:ae3 unit 0 family ethernet-switching port-mode trunk
```

3. Configure the LAG interface as an FCoE LAG:

```
admin@qfabric# set interfaces lag-interface-name aggregated-ether-options fcoe-lag
```

For example, to configure LAG **ae3** on a Node group named **RSNG1** as an FCoE LAG:

```
admin@qfabric# set interfaces RSNG1:ae3 aggregated-ether-options fcoe-lag
```

4. Enable LACP on the FCoE LAG:

```
admin@qfabric# set interfaces fcoe-lag-interface-name aggregated-ether-options lacp active
```

For example, to configure LACP on FCoE LAG **RSNG1:ae3**:

```
admin@qfabric# set interfaces RSNG1:ae3 aggregated-ether-options lacp active
```

5. Assign the Ethernet interfaces connected to the FCoE device converged network adapter (CNA) to the FCoE LAG:

```
admin@qfabric# set interfaces interface-name ether-options 802.3ad fcoe-lag-name
```

For example, to assign interfaces **xe-0/0/20** and **xe-0/0/21** on Node device **row1-rack1** (which is part of the Node group **RSNG1**) to the FCoE LAG **ae3** (on Node group **RSNG1**):

```
admin@qfabric# set interfaces row1-rack1:xe-0/0/20 ether-options 802.3ad RSNG1:ae3
admin@qfabric# set interfaces row1-rack1:xe-0/0/21 ether-options 802.3ad RSNG1:ae3
```

**NOTE:** On QFabric system Node groups that have two or more member nodes, you can assign interfaces from any Node in the Node group to the FCoE LAG. Adding to the example, if Node device row2-rack1 is part of Node group RSNG1, then you can add interfaces from row2-rack1 to the FCoE LAG. For example, set interfaces row2-rack1:xe-0/0/20 ether-options 802.3ad RSNG1:ae3 adds an interface on a second Node device to the FCoE LAG.

6. Enable FIP snooping on the FCoE VLAN:

```
admin@qfabric# set ethernet-switching-options secure-access-port vlan fcoe-vlan-name
examine-fip
```

For example, to enable FIP snooping on an FCoE VLAN named **fcoe-vlan-blue**:

```
admin@qfabric# set ethernet-switching-options secure-access-port vlan fcoe-vlan-blue
examine-fip
```

7. On an FCoE-FC gateway only, enable FCoE trusted mode on the fc-fabric:

```
admin@qfabric# set fc-fabrics fc-fabric-name protocols fip fcoe-trusted
```

For example, to configure an fc-fabric named **sanfab1** as an FCoE trusted fabric:

```
admin@qfabric# set fc-fabrics sanfab1 protocols fip fcoe-trusted
```

### Configuring an FCoE LAG When Enhanced FIP Snooping Scaling Must be Disabled

This example shows how to configure an FCoE LAG when you need to disable enhanced FIP snooping scaling, for example, when an FCoE-FC gateway fabric is untrusted.

Follow steps 1-6 of the preceding example to configure the FCoE LAG and enable FIP snooping on the FCoE VLAN. Next, disable enhanced FIP snooping scaling:

1. On an FCoE-FC gateway switch, disable FIP snooping scaling on all FCoE LAGs in the Fibre Channel fabric options configuration:

```
admin@qfabric# set fc-options no-fip-snooping-scaling
```

This global statement disables FIP snooping scaling on all FCoE LAGs associated with all FC fabrics on the switch.

## Configuring the DCBX Mode

You can configure the DCBX mode that an interface uses to communicate with the connected peer. Three DCBX modes are supported:

- Autonegotiation—The interface negotiates with the connected peer to determine the DCBX mode. This is the default DCBX mode.
- IEEE DCBX—The interface uses IEEE DCBX type, length, and value (TLV) to exchange DCBX information with the connected peer. QFX3500 Node devices come up with IEEE DCBX enabled by default and then autonegotiate with the connected peer to determine the final DCBX mode.
- DCBX Version 1.01—The interface uses Converged Enhanced Ethernet (CEE) DCBX version 1.01 TLVs to exchange DCBX information with the connected peer. QFabric system Node devices other than QFX3500 switches come up with DCBX version 1.01 enabled by default and then autonegotiate with the connected peer to determine the final DCBX mode.

**NOTE:** Pre-CEE (pre-DCB) versions of DCBX such as DCBX version 1.00 are not supported. If an interface receives an LLDP frame with pre-CEE DCBX TLVs, the system drops the frame.

---

Configure the DCBX mode by specifying the mode for one interface or for all interfaces.

- To configure the DCBX mode, specify the interface and the mode:

```
[edit protocols dcbx]  
user@switch# set interface interface-name mode (auto-negotiate | ieee-dcbx |  
dcbx-version-1.01)
```

For example, to configure DCBX version 1.01 on interface **xe-0/0/21**:

```
user@switch# set protocols dcbx interface xe-0/0/21 mode dcbx-version-1.01
```

To configure IEEE DCBX on all interfaces:

```
user@switch# set protocols dcbx interface all mode ieee-dcbx
```

## Configuring DCBX Autonegotiation

Data Center Bridging Capability Exchange protocol (DCBX) discovers the data center bridging (DCB) capabilities of peers by exchanging feature configuration information. DCBX also detects feature misconfiguration and mismatches, and can configure DCB on peers. DCBX is an extension of the Link Layer Discovery Protocol (LLDP), and LLDP must remain enabled on every interface for which you want to use DCBX. If you attempt to enable DCBX on an interface on which LLDP is disabled, the configuration commit operation fails.

**NOTE:** LLDP and DCBX are enabled by default on all interfaces.

The switch supports DCBX autonegotiation for:

- Priority-based flow control (PFC) configuration
- Layer 2 and Layer 4 applications such as Fibre Channel over Ethernet (FCoE) and Internet Small Computer System Interface (iSCSI)
- Enhanced transmission selection (ETS) advertisement

DCBX autonegotiation is configured on a per-interface basis for each supported feature or application. The PFC and application DCBX exchanges use autonegotiation by default. The default autonegotiation behavior is:

- DCBX is enabled on the interface if the connected peer device also supports DCBX.
- DCBX is disabled on the interface if the connected peer device does not support DCBX.

You can override the default behavior for each feature by turning off autonegotiation to force an interface to enable or disable the feature.

Autonegotiation of ETS means that when ETS is enabled on an interface (priority groups are configured), the interface advertises its ETS configuration to the peer device. In this case, priorities (forwarding classes) that are not part of a priority group (forwarding class set) receive no bandwidth and are advertised in an automatically generated default forwarding class. If ETS is not enabled on an interface (no priority groups are configured), all of the priorities are advertised in one automatically generated default priority group that receives 100 percent of the port bandwidth.

Disabling ETS autonegotiation prevents the interface from sending the Recommendation TLV or the Configuration TLV to the connected peer.

On interfaces that use IEEE DCBX mode to exchange DCBX parameters, you can disable autonegotiation of the enhanced transmission selection (ETS) Recommendation TLV to the peer if you want an asymmetric ETS configuration between the peers. DCBX still exchanges the ETS Configuration TLV if you disable the ETS Recommendation TLV.

Autonegotiation of PFC means that when PFC is enabled on an interface, if the peer device connected to the interface supports PFC and is provisioned compatibly with the switch, DCBX sets the PFC operational state to enabled. If the peer device connected to

the interface does not support PFC or is not provisioned compatibly with the switch, DCBX sets the operational state to disabled.

In addition, if the peer advertises that it is “willing” to learn its PFC configuration from the switch, DCBX pushes the switch’s PFC configuration to the peer and does not check the peer’s administrative state. The switch does not learn PFC configuration from peers (the switch does not advertise its state as “willing”).

Disabling PFC autonegotiation prevents the interface from exchanging PFC configuration information with the peer. It forces the interface to enable PFC if PFC is configured on the interface or to disable PFC if PFC is not configured on the interface. If you disable PFC autonegotiation, the assumption is that the peer is also configured manually.

Autonegotiation of applications depends on whether or not you apply an application map to an interface. If you apply an application map to an interface, the interface autonegotiates DCBX for each application in the application map. PFC must be enabled on the FCoE priority (the FCoE IEEE 802.1p code point) for the interface to advertise the FCoE application. The interface only advertises applications that are included in the application map.

For example, if you apply an application map to an interface and the application map does not include the FCoE application, then that interface does not perform DCBX advertisement of FCoE.

If you do not apply an application map to an interface, DCBX does not advertise applications on that interface, with the exception of FCoE, which is handled differently than other applications.

**NOTE:** If you do not apply an application map to an interface, the interface performs autonegotiation of FCoE if the interface carries traffic in the FCoE forwarding class and also has PFC enabled on the FCoE priority. On such interfaces, if DCBX detects that the peer device connected to the interface supports FCoE, the switch advertises its FCoE capability and IEEE 802.1p code point on that interface. If DCBX detects that the peer device connected to the interface does not support FCoE, DCBX marks that interface as “FCoE down” and disables FCoE on the interface.

---

When DCBX marks an interface as “FCoE down,” the behavior of the switch depends on how you use it in the network:

- When the switch acts as an FCoE-FC gateway, it does not send or receive FCoE Initialization Protocol (FIP) packets.
- When the switch acts as an FCoE transit switch, the interface drops all of the FIP packets it receives. In addition, FIP packets received from an FCoE forwarder (FCF) are not forwarded to interfaces marked as “FCoE down.”

Disabling autonegotiation prevents the interface from exchanging application information with the peer. In this case, the assumption is that the peer is also configured manually.

To disable DCBX autonegotiation of PFC, applications (including FCoE), and ETS using the CLI:

1. Turn off autonegotiation for PFC.

```
[edit]
user@switch# set protocols dcbx interface interface-name priority-flow-control
no-auto-negotiation
```

2. Turn off autonegotiation for applications.

```
[edit]
user@switch# set protocols dcbx interface interface-name applications no-auto-negotiation
```

3. Turn off autonegotiation for ETS.

```
[edit]
user@switch# set protocols dcbx interface interface-name enhanced-transmission-selection
no-auto-negotiation
```

To disable autonegotiation of the ETS Recommendation TLV so that DCBX exchanges only the ETS Configuration TLV:

- [edit protocols dcbx interface *interface-name*]  
user@switch# set enhanced-transmission-selection no-recommendation-tlv

## Disabling the ETS Recommendation TLV

The enhanced transmission selection (ETS) Recommendation TLV communicates the ETS settings that the switch wants the connected peer interface to use. If the peer interface is “willing,” the peer interface changes its configuration to match the configuration in the ETS Recommendation TLV. By default, the switch interfaces send the ETS Recommendation TLV to the peer. The settings communicated are the egress ETS settings defined by configuring hierarchical scheduling on the interface.

We recommend that you use the same ETS settings on the connected peer that you use on the switch interface and that you leave the ETS Recommendation TLV enabled. However, on interfaces that use IEEE DCBX as the DCBX mode, if you want an asymmetric configuration between the switch interface and the connected peer, you can disable the ETS Recommendation TLV.

**NOTE:** Disabling the ETS Recommendation TLV on interfaces that use DCBX version 1.01 as the DCBX mode has no effect and does not change DCBX behavior.

If you disable the ETS Recommendation TLV, the switch still sends the ETS Configuration TLV to the connected peer. The result is that the connected peer is informed about the switch DCBX ETS configuration, but even if the peer is “willing,” the peer does not change its configuration to match the switch configuration. This is asymmetric configuration—the two interfaces can have different parameter values for the ETS attribute.

To disable the ETS Recommendation TLV:

- [edit protocols dcbx interface *interface-name*]  
user@switch# **set enhanced-transmission-selection no-recommendation-tlv**

## Defining an Application for DCBX Application Protocol TLV Exchange

Define each application for which you want DCBX to exchange application protocol information. You can define Layer 2 and Layer 4 applications. After you define applications, you map them to IEEE 802.1p code points, and then apply the application map to the interfaces on which you want DCBX to exchange application protocol information with connected peers. (See *Related Documentation* for how to configure application maps and apply them to interfaces, and for an example of the entire procedure that also includes classifier configuration.)

**NOTE:** In Junos OS Release 12.1, the FCoE application was configured by default, so you did not need to configure it in an application map. In Junos OS Release 12.2, if you want DCBX to advertise the FCoE application on an interface and you apply an application map to that interface, you must explicitly configure FCoE in the application map. You also must enable priority-based flow control (PFC) on the FCoE code point on all interfaces that you want to advertise FCoE. If you apply an application map to an interface, the interface sends DCBX TLVs only for the applications configured in the application map.

Define Layer 2 applications by mapping an application name to an EtherType. Define Layer 4 applications by mapping an application name to a protocol (TCP or UDP) and a destination port.

- To define a Layer 2 application, specify the name of the application and its EtherType:

```
[edit applications]
user@switch# set application application-name ether-type ether-type
```

For example, to configure an application named **PTP** (for Precision Time Protocol) that uses the EtherType **0x88F7**:

```
user@switch# set applications application ptp ether-type 0x88F7
```

- To define a Layer 4 application, specify the name of the application, its protocol (TCP or UDP), and its destination port:

```
[edit]
user@switch# set applications application application-name protocol (tcp | udp)
destination-port port-value
```

For example, to configure an application named **iscsi** (for Internet Small Computer System Interface) that uses the protocol **TCP** and the destination port **3260**:

```
user@switch# set applications application iscsi protocol tcp destination-port 3260
```

## Configuring an Application Map for DCBX Application Protocol TLV Exchange

After you define applications for which you want to exchange DCBX application protocol information, map the applications to IEEE 802.1p code points. The IEEE 802.1p code points identify incoming traffic and allow you to map that traffic to the desired application. You then apply the application map to the interfaces on which you want DCBX to exchange application protocol information with connected peers. (See *Related Documentation* for how to define applications and apply the application map to interfaces, and for an example of the entire procedure that also includes classifier configuration.)

**NOTE:** In Junos OS Release 12.1, the FCoE application was configured by default, so you did not need to configure it in an application map. In Junos OS Release 12.2, if you want DCBX to advertise the FCoE application on an interface and you apply an application map to that interface, you must explicitly configure FCoE in the application map. You also must enable priority-based flow control (PFC) on the FCoE code point on all interfaces that you want to advertise FCoE. If you apply an application map to an interface, the interface sends DCBX TLVs only for the applications configured in the application map.

Configure an application map by creating an application map name and mapping an application to one or more IEEE 802.1p code points.

- To define an application map, specify the name of the application map, the name of the application, and the IEEE 802.1p code points of the incoming traffic that you want to associate with the application in the application map:

```
[edit policy-options]
user@switch# set application-maps application-map-name application application-name
code-points [ aliases ] [ bit-patterns ]
```

For example, to configure an application map named **ptp-app-map** that includes an application named **PTP** (for Precision Time Protocol) and map the application to IEEE 802.1p code points **001** and **101**:

```
user@switch# set policy-options application-maps ptp-app-map application ptp code points
[ 001 101 ]
```

| <b>Release Information</b>      | Command introduced in Junos OS Release 12.3 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | Configure the system to rebalance NP_Port link loads automatically on an FCoE-FC gateway proxy fabric if the link loads become unbalanced. Load rebalancing is a disruptive action that forces some or all sessions (depending on the configured load-balancing algorithm) to log out and then log in again. When sessions log in again, they are placed on NP_Port interfaces so that the link loads are balanced.                                                                                                                                            |
| <b>Required Privilege Level</b> | storage—To view this statement in the configuration.<br>storage-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b>              | <p>Set the interval between periodic beacons. Beacons perform virtual link maintenance for VN_Ports in a way that is similar to FIP keepalive advertisements.</p> <p>The ENode sends periodic beacons every 90 seconds on behalf of the VN_Port. Each received beacon resets the session timer for the virtual link connection to the other VN_Port. If the FCF does not receive a beacon before the beacon timer expires, the VN_Port is considered as “down” and the virtual link is terminated. The beacon timer expires in 2.5 times the configured beacon timer value.</p>                                                                                                                                                                                                                                  |

## examine-vn2vn

**Syntax** `examine-vn2vn {  
    beacon-period milliseconds;  
}`

**Hierarchy Level** Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) **examine-fip**]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security]

**NOTE:** The `examine-vn2vn` configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

**Release Information** Statement introduced in Junos OS Release 12.2 for the QFX Series.  
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

**Description** Enable VN\_Port to VN\_Port (VN2VN) FIP snooping on a specified VLAN. The VLAN must be a dedicated FCoE VLAN that transports only FCoE traffic. A VLAN cannot support VN2VN FIP snooping and VN\_Port to VF\_Port FIP snooping (VN2VF) simultaneously. Configure separate VLANs for VN2VN FIP snooping and VN2VF FIP snooping.

When you enable VN2VN FIP snooping on a VLAN, the VN2VF session filters are removed and the all existing VN2VF sessions are terminated.

The remaining statement is explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

**Hierarchy Level** [edit]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure an FC fabric. You can configure a maximum of 12 FC fabrics, one per native FC port.

**NOTE:** Changing the name of an FC fabric causes all logins to drop and forces the ENodes to log in again.

**Options** *fc-fabric-name* —Unique name of the FC fabric.

The other statements are explained separately.

**Required Privilege Level** storage—To view this statement in the configuration.  
storage-control—To add this statement to the configuration.

## fc-map

**Syntax** `fc-map fc-map-value;`

**Hierarchy Level** Original CLI

[edit ethernet-switching options secure-access-port vlan (all | *vlan-name*) [examine-fip](#)]

ELS CLI for Platforms that Support FCoE

[edit vlans *vlan-name* forwarding-options fip-security]

**NOTE:** The `fc-map` configuration statement is in a different hierarchy on the original CLI than on the Enhanced Layer 2 Software (ELS) CLI.

QFX Series that Support FCoE-FC Gateway Configuration

[edit [fc-fabrics](#) *fc-fabric-name* [protocols fip](#)]

**Release Information** Statement introduced in Junos OS Release 10.4 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Statement introduced for the ELS CLI in Junos OS Release 13.2 for the QFX Series.

**Description** Set the FCoE mapped address prefix (FC-MAP) value for the FCoE VLAN to match the FC switch (or FCoE forwarder) FC-MAP value for the FC fabric. The FC-MAP value is a unique MAC address prefix an FC switch uses to identify FCoE traffic for a given FC fabric (traffic on a particular FCoE VLAN).

You can configure the FC-MAP value or use the default value. The default FC-MAP value is different for VN\_Port to VF\_Port (VN2VF\_Port) FIP snooping (0x0EFC00) than for VN\_Port to VN\_Port (VN2VN\_Port) FIP snooping.

The FC switch provides the FC-MAP value to FCoE nodes (ENodes) in the FIP discovery advertisement message. If the EX Series switch or the QFX Series FCoE VLAN FC-MAP value does not match the FC switch FC-MAP value, neither device discovers the FC switch on that VLAN, and the ENodes on that VLAN cannot access the FC switch. The FC switch accepts only FCoE traffic that uses the correct FC-MAP value as part of the VN\_Port MAC address.

When the QFX Series acts as an FCoE-FC gateway, the FC-MAP value for the gateway and the FCoE devices must match the FC switch FC-MAP value in order to communicate with the FC switch.

**NOTE:** Changing the FC-MAP value causes all logins to drop and forces the ENodes to log in again.

**Options** `fc-map-value`—FC-MAP value, hexadecimal value preceded by “0x”.

**Range:** 0x0EFC00 through 0x0EFCFF

**Default:** 0x0EFC00 for VN2VF\_Port FIP snooping 0x0EFD00 for VN2VN\_Port FIP snooping

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Configure a special link aggregation group (LAG) to transport Fibre Channel over Ethernet (FCoE) traffic and regular Ethernet traffic across the same link aggregation bundle.</p> <p>An FCoE LAG ensures that FCoE traffic uses the same link within a LAG to transmit and receive information between an FCoE device and a Fibre Channel (FC) SAN switch across a QFabric system Node device. This preserves the point-to-point link emulation that FC requires. A standard LAG uses a hashing algorithm to determine the LAG link used for each communication, so with a standard LAG, you cannot guarantee that communication between an FCoE device and the QFabric system Node device always uses the same link. If communication between the FCoE device and the QFabric system Node device uses different physical links, the SAN terminates the link.</p> <p>An FCoE LAG treats regular Ethernet traffic (traffic that is not FCoE traffic) in the same way as on a standard LAG, providing link redundancy and load-balancing for the regular Ethernet traffic. An FCoE LAG does not provide link redundancy or load balancing for FCoE traffic.</p> <p>On FCoE-FC gateways, if the gateway has one or more untrusted FC fabrics, you must also disable FIP snooping scaling on the gateway by including the <b>no-fip-snooping-scaling</b> option in the <a href="#">[edit fc-options]</a> hierarchy.</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b>              | Configure the specified 10-Gigabit Ethernet interface to trust Fibre Channel over Ethernet (FCoE) traffic. If an interface is connected to another switch such as an FCoE forwarder (FCF) or a transit switch, you can configure the interface as trusted so that the interface forwards FCoE traffic from the switch to the FCoE devices without installing FIP snooping filters.<br><br>(QFX Series FCoE-FC gateway) Configure the specified local Fibre Channel fabric to trust FCoE traffic on all ports in the fabric. Changing the fabric ports from untrusted to trusted removes any existing FIP snooping filters from the ports. Changing the fabric ports from trusted to untrusted by removing the <b>fcoe-trusted</b> configuration from the fabric forces all of the FCoE sessions on those ports to log out so that when the ENodes and VN_Ports log in again, the switch can build the appropriate FIP snooping filters. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## interface (Fibre Channel Fabric)

---

**Syntax**    interface {  
              interface-name {  
                  max-login-sessions max-login-sessions;  
              }  
              interface-name {  
                  max-login-sessions max-login-sessions;  
              }  
              <...> {  
                  max-login-sessions max-login-sessions;  
              }  
              vlan.interface-name;  
          }

**Hierarchy Level**    [edit [fc-fabrics](#) *fc-fabric-name*]

**Release Information**    Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description**    Associate one or more native Fibre Channel (FC) interfaces with an FC fabric and one VLAN interface for FCoE traffic. An FC interface can be associated with only one FC fabric.

**Options**    *interface-name*—Name of the native FC interface. You can assign one or more FC interfaces to an FC fabric.

*vlan.vlan-interface-name*—Name of the VLAN interface for FCoE traffic. You can assign one VLAN interface to an FC fabric.

The remaining statement is explained separately.

**Required Privilege**    storage—To view this statement in the configuration.

**Level**    storage-control—To add this statement to the configuration.

## load-balance-algorithm

---

|                            |                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | load-balance-algorithm (simple   enode-based   flogi-based);                                                                                                                                             |
| <b>Hierarchy Level</b>     | [edit <b>fc-fabrics</b> <i>fabric-name</i> <b>proxy</b> ]                                                                                                                                                |
| <b>Release Information</b> | Statement introduced in Junos OS Release 12.1 for the QFX Series.                                                                                                                                        |
| <b>Description</b>         | Set the load-balancing algorithm that the QFX Series uses to distribute FCoE sessions (FLOGI and FDISC sessions from the FCoE devices in the Ethernet network) among the NP_Port links to the FC switch. |

**NOTE:** Changing the load-balancing algorithm when FCoE sessions are running forces the FCoE sessions to log out, then log in again.

---

|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Options</b>                  | <p><b>simple</b>—Load balancing is based on the weighted utilization (load) of the NP_Ports connected to an FC fabric. Each new FLOGI or FDISC is assigned to the least-loaded link. When a link load rebalance occurs, the system minimizes disruption by using an algorithm to log out only the sessions that need to be moved to other links to balance the link load. To further minimize disruption, the algorithm logs out the sessions with the fewest dependencies (for example, FDISC sessions are logged out before FLOGI sessions). When the sessions log in again, they are placed on NP_Port interfaces in a manner that balances the link loads. This is the default load-balancing algorithm.</p> <p><b>enode-based</b>—Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions (VN_Port sessions) associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. When a link load rebalance occurs, the system logs off all sessions. The sessions log in again and are placed on NP_Port interfaces in a balanced manner.</p> <p><b>flogi-based</b>—FLOGI-based load balancing is similar to ENode-based load balancing, but the behavior when the loads are rebalanced is different. Load balancing is based on the ENode FLOGI. When an ENode logs in to the fabric, all subsequent FDISC sessions associated with that ENode are placed on the same link as the ENode FLOGI session, regardless of the link load. New ENode FLOGIs are placed on the least-loaded link. When a link load rebalance occurs, the system minimizes disruption by using an algorithm to log out only the sessions that need to be moved to other links to balance the link load. When the logged out sessions log back in, they are placed on NP_Port interfaces in a manner that balances the link loads.</p> |

| <b>Description</b>              | <p>Set the maximum number of FCoE initialization protocol (FIP) session logins permitted for an individual NP_Port interface in an FCoE-FC gateway fabric (FC fabric) or for the entire FCoE-FC gateway fabric. You can set a maximum FIP session limit for each NP_Port interface connected to an FC switch. You can also set a maximum FIP session limit for the entire FC fabric. The sum of the maximum login sessions permitted on the NP_Port interfaces in an FC fabric should not exceed the maximum login sessions configured for that FC fabric.</p> <p>The maximum number of FIP sessions (the combined total of all VN2VF_Port and VN2VN_Port sessions on the system) is 2500 sessions.</p> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.2 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | <p>Set the maximum number of FCoE initialization protocol (FIP) session logins permitted on a Node device. (This is the combined total of all VN2VF_Port and VN2VN_Port sessions on the Node device.)</p> <p>On a QFX3500 switch, the <b>max-login-sessions-per-node</b> command sets the maximum FIP session login limit for all of the FC fabrics configured on the device. The combined number of FIP sessions on all FC fabrics on the device should not exceed this limit.</p> <p>On a QFabric system, the <b>max-login-sessions-per-node</b> command globally sets the maximum FIP session login limit for each QFabric system Node device in the QFabric system. For example, if you set the Node limit to 2000 login sessions, then each QFabric Node device supports up to 2000 FIP login sessions. The total configured maximum number of login sessions of all of the FC fabrics on a Node device should not exceed the Node session limit.</p> |
|                                 | <div>  <p><b>NOTE:</b> FIP login session limits configured at the FC fabric level or at the FC fabric interface level might limit a Node device to fewer total sessions than the configured Node limit.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 13.2X52-D10 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | <p>Convert an FCoE LAG into a standard LAG. When you convert an FCoE LAG into a standard LAG, the standard LAG no longer works reliably for FCoE traffic. This is because FCoE traffic must use the same physical link within a LAG interface for communication between the FCoE device and the Fibre Channel SAN across a QFabric system Node device. A standard LAG uses a hashing algorithm to determine the link to use for each transmission, so there is no way to guarantee that a response will use the same link on which a device receives a request. An FCoE LAG guarantees that the same physical LAG link is used for communication between an FCoE device and the QFabric system Node device.</p> <p>If you convert an FCoE LAG into a standard LAG, do not use the standard LAG for FCoE traffic.</p> |

| <b>Release Information</b>                   | Statement introduced in Junos OS Release 13.2X52-D10 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>                           | <p>Disable FIP snooping scaling on all FCoE VLANs on an FCoE-FC gateway, or disable FIP snooping scaling on the specified FCoE VLAN on an FCoE transit switch.</p> <p>Disabling FIP snooping scaling reduces the maximum number of FIP snooping sessions from 2,500 sessions (the maximum with FIP snooping scaling enabled) to 376 sessions. FIP snooping scaling is enabled by default.</p> <p>Use this statement to disable FIP snooping scaling if you want to configure an FCoE LAG on an FCoE-FC gateway that contains one or more untrusted FC fabrics. Untrusted FC fabrics do not support FIP snooping scaling.</p> <p>On an FCoE transit switch, you can use this statement to disable FIP snooping scaling on a specified FCoE VLAN.</p> |
| <b>Default</b>                               | FIP snooping scaling is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.2 for the QFX Series.                                                                                                                                                                                                                                                                 |
| <b>Description</b>              | Disable DCBX to send the ETS Recommendation TLV (also known as the Information TLV) on egress. This feature is valid only if the interface DCBX mode is IEEE DCBX. If the interface DCBX mode is DCBX version 1.01, this statement has no effect. (DCBX version 1.01 does not advertise separate TLVs for individual attributes.) |
| <b>Default</b>                  | DCBX-enabled interfaces send the ETS recommendation TLV unless it is disabled.                                                                                                                                                                                                                                                    |

| <b>Description</b>                                                                                                                                                                                                                                  | <p>Configure a contiguous block of ports as FC ports. You can configure the FC-capable ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47 to create blocks of native FC interfaces. You cannot individually configure a single port as a native FC interface. Within these port blocks, you cannot mix FC interfaces with Ethernet interfaces. All of the ports in a block must be either native FC interfaces or Ethernet interfaces.</p> <p>You can configure:</p> <ul style="list-style-type: none"> <li>• Six native FC interfaces by configuring either ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5, or ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.</li> <li>• Twelve native FC interfaces by configuring ports xe-0/0/0 through xe-0/0/5 as fc-0/0/0 through fc-0/0/5 and ports xe-0/0/42 through xe-0/0/47 as fc-0/0/42 through fc-0/0/47.</li> <li>• No native FC interfaces by leaving ports xe-0/0/0 through xe-0/0/5 and ports xe-0/0/42 through xe-0/0/47 in their default state as Ethernet interfaces.</li> </ul> |
| <b>Options</b>                                                                                                                                                                                                                                      | <p><b><i>port-range-low</i></b>—Lowest-numbered port in the block of native FC interfaces, either 0 or 42.</p> <p><b><i>port-range-high</i></b>—Highest-numbered port in the block of native FC interfaces. The value is 5 if the <b><i>port-range-low</i></b> value is 0. The value is 47 if the <b><i>port-range-low</i></b> value is 42.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <div>  <p><b>NOTE:</b> Only a complete block of ports, xe-0/0/0 through xe-0/0/5, xe-0/0/42 through xe0/0/47, or both, can be configured as FC ports.</p> </div> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>              | Sets the global or interface-specific priority value associated with the switch FCF-MAC. CNAs use the priority value to determine the switch with which they will perform FIP FLOGI. The lower the value, the higher the priority. The switch advertises this value to the server ENodes on the FCoE network. A priority value set at the interface level overrides the global setting. |
| <b>Options</b>                  | <b><i>priority</i></b> —Value that determines the FCF an ENode selects to perform FIP FLOGI. The lower the priority number, the higher the priority of the FCF.<br><b>Range:</b> 0 through 255<br><b>Default:</b> 128                                                                                                                                                                   |

| <b>Description</b>              | Disable autonegotiation of priority-based flow control (PFC) on one or more Ethernet interfaces. Autonegotiation enables PFC on an interface only if the switch and the peer device connected to the switch both support PFC and have the same PFC configuration. Disabling autonegotiation on an interface forces the interface to use the PFC state (enabled or disabled) that is configured on the switch by the configuration and assignment of the congestion notification profile.                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <b>no-auto-negotiation</b> —Disable automatic negotiation of PFC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## protocols (FIP)

```
Syntax protocols {
    fip {
        fcoe-trusted;
        fc-map fc-map-value;
        fka-adv-period milliseconds;
        interface {
            interface-name {
                fka-adv-period milliseconds;
                priority priority;
            }
        }
        max-sessions-per-enode max-sessions-per-enode;
        priority priority;
        traceoptions {
            file filename <replace> <size size> <files number> <no-stamp>;
            <world-readable | no-world-readable>;
            flag flag <flag-modifier> <disable>;
        }
    }
}
```

**Hierarchy Level** [edit [fc-fabrics](#) *fc-fabric-name*]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure global or interface-specific FC protocol options. Individual interface settings override global settings.

**Options** The statements are explained separately.

**Required Privilege Level** storage—To view this statement in the configuration.  
storage-control—To add this statement to the configuration.

| Release Information      | Statement introduced in Junos OS Release 12.2 for the QFX Series.                                                                                                                                                                                                                                                                |
| Description              | Enable DCBX to send the ETS Recommendation TLV (also known as the Information TLV) on egress. This feature is valid only if the interface DCBX mode is IEEE DCBX. If the interface DCBX mode is DCBX version 1.01, this statement has no effect. (DCBX version 1.01 does not advertise separate TLVs for individual attributes.) |
| Default                  | DCBX-enabled interfaces send the ETS recommendation TLV unless it is disabled.                                                                                                                                                                                                                                                   |
| Options                  | <b>no-auto-negotiation</b> —Disable sending of the ETS recommendation TLV.                                                                                                                                                                                                                                                       |
| Required Privilege Level | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                              |

| <b>Release Information</b> | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                      |
| <b>Description</b>         | Set FC-2 protocol tracing options.                                                                                                                                                                                                                     |

**NOTE:** The **tracoptions** statement is not supported on the QFabric system.

**Default** Traceoptions is disabled.

**Options** **file *name***—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the **/var/log/** directory.

**files *number***—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**. The traceoption output continues in a second trace file named **trace-file.1**. When **trace-file.1** reaches its maximum size, output continues in a third file named **trace-file.2**, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

**Range:** 2 through 1000 files

**Default:** 1 trace file

**flag**—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements:

- **all**—Trace all operations.
- **error**—Trace all error events
- **normal**—Trace all normal events.

**Default:** If you do not specify the **normal** option, only unusual or abnormal operations are traced.

- **parse**—Trace configuration parsing.
- **rx-frame**—(Optional) Trace received frames.
- **rx-frame-header**—(Optional) Trace received frame headers.

- **tx-frame**—(Optional) Trace transmitted frames.
- **tx-frame-header**—(Optional) Trace transmitted frame headers.

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size *size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file.0***. Incoming tracefile data is logged in the now empty ***trace-file***. When ***trace-file*** again reaches its maximum size, ***trace-file.0*** is renamed ***trace-file.1*** and ***trace-file*** is renamed ***trace-file.0***. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

**Syntax:** ***xk*** to specify KB, ***xm*** to specify MB, or ***xg*** to specify GB

**Range:** 10 KB through the maximum file size of 4 GB (the maximum is lower if 4 GB is not supported on your system)

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| Release Information | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                             |
| Description         | Set FC protocol tracing options.                                                                                                                                                                                                                              |

**NOTE:** The **traceoptions** statement is not supported on the QFabric system.

**Default** Traceoptions is disabled.

**Options** **file *name***—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the **/var/log/** directory.

**files *number***—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file.0***. The traceoption output continues in a second trace file named ***trace-file.1***. When ***trace-file.1*** reaches its maximum size, output continues in a third file named ***trace-file.2***, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

**Range:** 2 through 1000 files

**Default:** 1 trace file

***flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements:

- **all**—Trace all operations.
- **fabric**—Trace virtual fabric events.
- **fc2**—Trace the FC2 (network layer protocols) events.
- **fip**—Trace the Fibre Channel over Ethernet (FCoE) Initialization Protocol events.
- **flogi**—Trace the fabric login server events.
- **forwarding-database**—Trace the forwarding database and next-hop events.
- **interface**—Trace the interface events.

- **krt**—Trace the communication over the routing socket.
- **lib**—Trace library calls.
- **lif**—Trace Fibre Channel logical interface (fc-lif) events.
- **vswitch**—Trace virtual switch events.

The following are the global tracing options:

- **all**—All trace operations.
- **config-internal**—Trace configuration internals.
- **general**—Trace general events.
- **normal**—All normal events.

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **parse**—Trace configuration parsing.
- **state**—Trace state transitions.
- **task**—Trace protocol task processing.
- **timer**—Trace protocol task timer processing.

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.O**. Incoming tracefile data is logged in the now empty **trace-file**. When **trace-file** again reaches its maximum size, **trace-file.O** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.O**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size of 4 GB (maximum is lower if 4 GB is not supported on your system)

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

|                           |                                                             |

## traceoptions (FIP Protocol Fibre Channel)

**Syntax** `traceoptions {  
     file filename <replace> <size size> <files number> <no-stamp>  
     <world-readable | no-world-readable>;  
     flag flag <flag-modifier>  
 }`

**Hierarchy Level** [edit [fc-fabrics](#) *fabric-name* [protocols](#) [fip](#)]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Set proxy FC protocol tracing options.

**NOTE:** The `traceoptions` statement is not supported on the QFabric system.

**Default** Traceoptions is disabled.

**Options** `file name`—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the `/var/log/` directory.

`files number` —(Optional) Maximum number of trace files. When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`. The traceoption output continues in a second trace file named `trace-file.1`. When `trace-file.1` reaches its maximum size, output continues in a third file named `trace-file.2`, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the `size` option.

**Range:** 2 through 1000 files

**Default:** 1 trace file

`flag`—Tracing operation to perform. To specify more than one tracing operation, include multiple `flag` statements:

- `all`—Trace all operations.
- `error`—Trace all error events
- `normal`—Trace all normal events.

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- `packet`—Trace packet decoding operations
- `parse`—Trace configuration parsing.
- `state`—Trace state transitions.

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**. Incoming tracefile data is logged in the now empty **trace-file**. When **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size of 4 GB (maximum is lower if 4 GB is not supported on your system)

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

|                                 |                                                                     |
|---------------------------------|---------------------------------------------------------------------|

|                                 | <b>storage-control</b> —To add this statement to the configuration. |

## traceoptions (Proxy Fibre Channel)

**Syntax** `traceoptions {  
     file filename <replace> <size size> <files number> <no-stamp>  
     <world-readable | no-world-readable>;  
     flag flag <flag-modifier>  
 }`

**Hierarchy Level** [edit `fc-fabrics fabric-name proxy`]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Set proxy FC protocol tracing options.

**NOTE:** The `traceoptions` statement is not supported on the QFabric system.

**Default** Traceoptions is disabled.

**Options** `file name`—Name of the file to receive the tracing operation output. Enclose the name in quotation marks. Traceoption output files are located in the `/var/log/` directory.

`files number`—(Optional) Maximum number of trace files. When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`. The traceoption output continues in a second trace file named `trace-file.1`. When `trace-file.1` reaches its maximum size, output continues in a third file named `trace-file.2`, and so on. When the maximum number of trace files is reached, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the `size` option.

**Range:** 2 through 1000 files

**Default:** 1 trace file

`flag`—Tracing operation to perform. To specify more than one tracing operation, include multiple `flag` statements:

- `all`—Trace all operations.
- `error`—Trace all error events.
- `interface`—Trace the interface events.
- `normal`—Trace all normal events.

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- `packet`—Trace packet decoding operations
- `parse`—Trace configuration parsing.

- **state**—Trace state transitions.

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**. Incoming tracefile data is logged in the now empty **trace-file**. When **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size of 4 GB (maximum is lower if 4 GB is not supported on your system)

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

# Administration

- [Routine Monitoring on page 5635](#)
- [Operational Commands on page 5640](#)

## Routine Monitoring

---

- [Monitoring Fibre Channel Interface Load Balancing on page 5635](#)

### Monitoring Fibre Channel Interface Load Balancing

You can use operational mode commands to monitor load balancing when the switch is in FCoE-FC gateway mode:

1. [Monitoring the Interface Load-Balancing State on page 5635](#)
2. [Monitoring the Fabric Load-Balancing Algorithm on page 5636](#)

#### Monitoring the Interface Load-Balancing State

---

**Purpose** Monitor the number of sessions, whether load balancing is enabled or disabled, and the load-balancing weight for each native Fibre Channel (FC) interface.

**NOTE:** A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.

**Action** To monitor the load-balancing state of the native FC interfaces in the CLI, enter the following CLI command:

```
user@switch> show fibre-channel proxy np-port
```

For example:

```
user@switch> show fibre-channel proxy np-port
Fabric: sanfab1, Fabric-id: 10
NP-Port   State      Sessions    LB state    LB weight
fc-0/0/0.0 online      5           ON           4
fc-0/0/1.0 online      5           ON           4
fc-0/0/2.0 online     10          ON           8

Fabric: fc_fab2, Fabric-id: 200
```

```

NP-Port      State      Sessions      LB state      LB weight
fc-0/0/44.0  isolated    0             OFF           0

Fabric: fc_fabric_100, Fabric-id: 100
NP-Port      State      Sessions      LB state      LB weight
fc-0/0/46.0  online     1             ON            8

```

**Meaning** [Table 402 on page 5636](#) summarizes key output fields for the FC interface load-balancing state.

**Table 402: Summary of Key FC Interface Load-Balancing Output Fields**

| Field     | Values                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fabric    | Name of the fabric.                                                                                                                                                                                                                                                                                                                                                                                                             |
| Fabric-id | Fabric ID number.                                                                                                                                                                                                                                                                                                                                                                                                               |
| NP-Port   | NP_Port interface connected to the FCoE forwarder (FCF) or the FC switch.                                                                                                                                                                                                                                                                                                                                                       |
| State     | FCID state of the NP_Port interface: <ul style="list-style-type: none"> <li>• <b>online</b>—The port is online and connected to the FC switch. FCoE devices can log in to the FC switch using this port.</li> <li>• <b>isolated</b>—The port is isolated and is not part of the load-balancing function. FCoE devices cannot log in to the FC switch using this port.</li> <li>• <b>offline</b>—The port is offline.</li> </ul> |
| Sessions  | Number of active sessions on the NP_Port interface.                                                                                                                                                                                                                                                                                                                                                                             |
| LB state  | Load-balancing state: <ul style="list-style-type: none"> <li>• <b>On</b>—Load balancing is on</li> <li>• <b>Off</b>—Load balancing is off.</li> </ul>                                                                                                                                                                                                                                                                           |
| LB weight | Load-balancing weight, which reflects the port speed: <ul style="list-style-type: none"> <li>• <b>2</b>—Port speed is 2 Gbps.</li> <li>• <b>4</b>—Port speed is 4 Gbps.</li> <li>• <b>8</b>—Port speed is 8 Gbps.</li> </ul>                                                                                                                                                                                                    |

The gateway determines the least-loaded interface using the following weighted round-robin (WRR) algorithm:

$$(\text{number-of-sessions} * \text{max-weight}) / \text{weight}$$

where *max-weight* is an internal constant. If the load on the FC interfaces is equal, the session is assigned to the interface with the highest link speed (the greatest weight).

### Monitoring the Fabric Load-Balancing Algorithm

**Purpose** Monitor the type of load-balancing algorithm (simple, ENode-based, or FLOGI-based) used on the native FC interfaces, whether or not automated load rebalancing is enabled, and the load rebalancing state of the fabric.

**Action** To monitor the load-balancing algorithm used on the native FC interfaces and the load rebalancing state in the CLI, enter the following CLI command:

```
user@switch> show fibre-channel proxy fabric-state
```

For example:

```
user@switch> show fibre-channel proxy fabric-state
Fabric: sanfab1, Fabric-id: 10
Proxy load balance algorithm: Simple, Fabric WWN verification: Yes
Auto load rebalance enabled : No
Last rebalance start-time   : Never
Last rebalance end-time     : Never
Last rebalance trigger      : Link-up
Last rebalance trigger-time  : Mon Sep 10 21:42:30 2012 usec: 814602
Last rebalance trigger-result: Not-configured

Fabric: fc_fab2, Fabric-id: 200
Proxy load balance algorithm: ENode based, Fabric WWN verification: Yes
Auto load rebalance enabled : No
Last rebalance start-time   : Never
Last rebalance end-time     : Never
Last rebalance trigger      : Link-up
Last rebalance trigger-time  : Mon Sep 17 17:23:35 2012 usec: 619684
Last rebalance trigger-result: Not-configured

Fabric: fc_fabric_100, Fabric-id: 100
Proxy load balance algorithm: FLOGI based, Fabric WWN verification: No
Auto load rebalance enabled : Yes
Last rebalance start-time   : Never
Last rebalance end-time     : Never
Last rebalance trigger      : Config-CLI
Last rebalance trigger-time  : Fri Nov 2 08:56:16 2012 usec: 004487
Last rebalance trigger-result: Not-required
```

**Meaning** You can configure each local FC fabric on an FCoE-FC gateway to use one of three types of load-balancing algorithms, *simple*, *ENode-based*, or *FLOGI-based*. All of the native FC interfaces (NP\_Ports) in a particular gateway FC fabric use the same load-balancing algorithm (the load-balancing algorithm is applied on a per-fabric basis).

[Table 403 on page 5637](#) summarizes key output fields for the FC interface load-balancing algorithm and state.

**Table 403: show fibre-channel proxy fabric-state Output Fields**

| Field Name       | Field Description   |
|------------------|---------------------|
| <b>Fabric</b>    | Name of the fabric. |
| <b>Fabric-id</b> | Fabric ID number.   |

**Table 403: show fibre-channel proxy fabric-state Output Fields (continued)**

| Field Name                          | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b>              | Clear Fibre Channel over Ethernet (FCoE) node (ENode) information for a specified ENode. This operation deletes the ENode state from the switch database and from the FIP snooping firewall filters, which causes the ENode to lose the connection to the Fibre Channel (FC) fabric and to log in to the fabric again. If you clear an ENode, all VN_Ports associated with that ENode are also cleared and lose their connection to the FC fabric and must log in to the fabric again. |
| <b>Options</b>                  | <i>enode-mac</i> —MAC address of the ENode.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## clear fip snooping vlan

---

|                                 |                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | <code>clear fip snooping vlan <i>vlan-name</i></code>                                                                                                                                                                                                                                                                                          |
| <b>Release Information</b>      | Command introduced in Junos OS Release 10.4 for EX Series switches.<br>Command introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                         |
| <b>Description</b>              | Clear FIP snooping information for the specified VLAN. This operation deletes all ENode and FCF information for the VLAN from the switch database and causes the ENodes to lose their connections to the FCFs. After clearing a VLAN, the switch relearns all of the FCFs and ENodes on the VLAN, and the ENodes must log in to the FCF again. |
| <b>Options</b>                  | <i>vlan-name</i> —Name of the VLAN.                                                                                                                                                                                                                                                                                                            |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                           |

| <b>Release Information</b>      | Command introduced in Junos OS Release 12.3 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | <p>Rebalance the link load on one or more FCoE-FC gateway proxy fabrics (local Fibre Channel fabrics on the gateway) on demand. Load rebalancing is a disruptive action that forces some or all sessions (depending on the configured load-balancing algorithm) to log out and then log in again. When sessions log in again, they are placed on NP_Port interfaces so that the link loads are balanced.</p> <p>Link load rebalancing occurs 10 seconds after you run the rebalancing command, unless another rebalancing trigger occurs before the 10 seconds elapse. If another rebalancing event occurs before the 10-second timer elapses, the timer is extended. Rebalancing occurs a maximum of 30 seconds after you run the rebalancing command, regardless of whether more rebalancing events occur.</p> <p>You can also perform a <i>dry run</i> to see a list of sessions that might be affected (logged out) if you request a load rebalance. A dry run does not rebalance the link loads; it only lists the sessions that might be affected if you rebalance.</p> |
| <b>Options</b>                  | <p><b>dry-run</b>—(Optional) Simulates performing link load rebalancing and displays a list of sessions that might be affected if you rebalance the link loads.</p> <p><b>fabric fabric-name</b>—Name of the fabric on which you want to rebalance the link loads. If you do not specify a fabric name with the fabric keyword, all fabrics on the FCoE-FC gateway rebalance their link loads.</p> <p><b>brief   detail</b>—(Optional) Display the specified level of output.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Additional Information</b>   | Requesting link load rebalancing is a one-time, on-demand operation. You must explicitly request load rebalancing every time you want to rebalance the link loads. Alternatively, you can configure automated load rebalancing if you want the NP_Port links to be rebalanced automatically whenever a load-rebalancing trigger occurs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

List of Sample Output [request fibre-channel proxy load-rebalance dry-run fabric fc\\_fabric\\_100 on page 5653](#)

Output Fields [Table 404 on page 5653](#) lists the output fields for the **request fibre-channel proxy load-rebalance dry-run** command. Output fields are listed in the approximate order in which they appear.

**Table 404: request fibre-channel proxy load-rebalance dry-run Output Fields**

| Field Name       | Field Description                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Fabric</b>    | Name of the fabric.                                                                                                                  |
| <b>Fabric-id</b> | Fabric ID number.                                                                                                                    |
| <b>F-Port</b>    | FCoE VLAN interface (VF_Port interface to the FCoE network).                                                                         |
| <b>FCID</b>      | VN_Port Fibre Channel identifier provided by the Fibre Channel over Ethernet Forwarder (FCoE forwarder) or the Fibre Channel switch. |
| <b>Port-WWN</b>  | Unique worldwide name (WWN) of the VN_Port.                                                                                          |
| <b>NP-Port</b>   | Name of the native Fibre Channel interface.                                                                                          |

## Sample Output

**request fibre-channel proxy load-rebalance dry-run fabric fc\_fabric\_100**

```

user@host> request fibre-channel proxy load-rebalance dry-run fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
F-Port          FCID      Port-WWN          NP-Port
vlan.100        0x8a013a  02:01:00:64:00:00:2a fc-0/0/1.0
vlan.100        0x8a013c  02:01:00:64:00:00:2b fc-0/0/1.0
vlan.100        0x8a0146  02:01:00:64:00:00:2e fc-0/0/1.0
vlan.100        0x8a014c  02:01:00:64:00:00:2f fc-0/0/1.0

```

**Release Information**

Command introduced before Junos OS Release 7.4.  
Command introduced in Junos OS Release 9.0 for EX Series switches.  
Command introduced in Junos OS Release 11.1 for the QFX Series.  
Command introduced in Junos OS Release 12.2 for ACX Series routers.  
Options added:

- **dynamic-flow-capture** in Junos OS Release 7.4.
- **dlsr** in Junos OS Release 7.5.
- **event-processing** in Junos OS Release 7.5.
- **ppp** in Junos OS Release 7.5.
- **l2ald** in Junos OS Release 8.0.
- **link-management** in Release 8.0.
- **pgcp-service** in Junos OS Release 8.4.
- **sbc-configuration-process** in Junos OS Release 9.5.
- **services pgcp gateway** in Junos OS Release 9.6.
- **sfc** and **all-sfc** for the TX Matrix Router in Junos OS Release 9.6.

**Description** Restart a Junos OS process.

**CAUTION:** Never restart a software process unless instructed to do so by a customer support engineer. A restart might cause the router or switch to drop calls and interrupt transmission, resulting in possible loss of data.

**Options** **none**—Same as **gracefully**.

**adaptive-services**—(Optional) Restart the configuration management process that manages the configuration for stateful firewall, Network Address Translation (NAT), intrusion detection services (IDS), and IP Security (IPsec) services on the Adaptive Services PIC.

**all-chassis**—(TX Matrix and TX Matrix Plus routers only) (Optional) Restart the software process on all chassis.

**all-lcc**—(TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process on all T640 routers connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process on all T1600 routers connected to the TX Matrix Plus router.

**all-members**—(MX Series routers only) (Optional) Restart the software process for all members of the Virtual Chassis configuration.

**all-sfc**—(TX Matrix Plus routers only) (Optional) For a TX Matrix Plus router, restart the software processes for the TX Matrix Plus router (or switch-fabric chassis).

**ancpd-service**—(Optional) Restart the Access Node Control Protocol (ANCP) process, which works with a special Internet Group Management Protocol (IGMP) session to collect outgoing interface mapping events in a scalable manner.

**application-identification**—(Optional) Restart the process that identifies an application using intrusion detection and prevention (IDP) to allow or deny traffic based on applications running on standard or nonstandard ports.

**audit-process**—(Optional) Restart the RADIUS accounting process that gathers statistical data that can be used for general network monitoring, analyzing, and tracking usage patterns, for billing a user based on the amount of time or type of services accessed.

**auto-configuration**—(Optional) Restart the Interface Auto-Configuration process.

**autoinstallation**—(EX Series switches only) (Optional) Restart the autoinstallation process.

**captive-portal-content-delivery**—(Optional) Restart the HTTP redirect service by specifying the location to which a subscriber's initial Web browser session is redirected, enabling initial provisioning and service selection for the subscriber.

**ce-l2tp-service**—(M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Universal Edge Layer 2 Tunneling Protocol (L2TP) process, which establishes L2TP tunnels and Point-to-Point Protocol (PPP) sessions through L2TP tunnels.

**chassis-control**—(Optional) Restart the chassis management process.

**class-of-service**—(Optional) Restart the class-of-service (CoS) process, which controls the router's or switch's CoS configuration.

**clksyncd-service**—(Optional) Restart the external clock synchronization process, which uses synchronous Ethernet (SyncE).

**database-replication**—(EX Series switches and MX Series routers only) (Optional) Restart the database replication process.

**datapath-trace-service**—(Optional) Restart the packet path tracing process.

**dhcp**—(J Series routers and EX Series switches only) (Optional) Restart the software process for a Dynamic Host Configuration Protocol (DHCP) server. A DHCP server allocates network IP addresses and delivers configuration settings to client hosts without user intervention.

**dhcp-service**—(Optional) Restart the Dynamic Host Configuration Protocol process.

**dialer-services**—(J Series routers and EX Series switches only) (Optional) Restart the ISDN dial-out process.

**diameter-service**—(Optional) Restart the diameter process.

**disk-monitoring**—(Optional) Restart disk monitoring, which checks the health of the hard disk drive on the Routing Engine.

**dlsw**—(J Series routers and QFX Series only) (Optional) Restart the data link switching (DLSw) service.

**dot1x-protocol**—(EX Series switches only) (Optional) Restart the port-based network access control process.

**dynamic-flow-capture**—(Optional) Restart the dynamic flow capture (DFC) process, which controls DFC configurations on Monitoring Services III PICs.

**ecc-error-logging**—(Optional) Restart the error checking and correction (ECC) process, which logs ECC parity errors in memory on the Routing Engine.

**ethernet-connectivity-fault-management**—(Optional) Restart the process that provides IEEE 802.1ag Operation, Administration, and Management (OAM) connectivity fault management (CFM) database information for CFM maintenance association end points (MEPs) in a CFM session.

**ethernet-link-fault-management**—(EX Series switches and MX Series routers only) (Optional) Restart the process that provides the OAM link fault management (LFM) information for Ethernet interfaces.

**ethernet-switching**—(EX Series switches only) (Optional) Restart the Ethernet switching process.

**event-processing**—(Optional) Restart the event process (eventd).

**fibre-channel**—(QFX Series only) (Optional) Restart the Fibre Channel process.

**firewall**—(Optional) Restart the firewall management process, which manages the firewall configuration and enables accepting or rejecting packets that are transiting an interface on a router or switch.

**general-authentication-service**—(EX Series switches and MX Series routers only) (Optional) Restart the general authentication process.

**gracefully**—(Optional) Restart the software process.

**iccp-service**—(Optional) Restart the Inter-Chassis Communication Protocol (ICCP) process.

**idp-policy**—(Optional) Restart the intrusion detection and prevention (IDP) protocol process.

**immediately**—(Optional) Immediately restart the software process.

**interface-control**—(Optional) Restart the interface process, which controls the router's or switch's physical interface devices and logical interfaces.

**ipsec-key-management**—(Optional) Restart the IPsec key management process.

**isdn-signaling**—(J Series routers and QFX Series only) (Optional) Restart the ISDN signaling process, which initiates ISDN connections.

**kernel-replication**—(Optional) Restart the kernel replication process, which replicates the state of the backup Routing Engine when graceful Routing Engine switchover (GRES) is configured.

**l2-learning**—(Optional) Restart the Layer 2 address flooding and learning process.

**l2cpd-service**—(Optional) Restart the Layer 2 Control Protocol process, which enables features such as Layer 2 protocol tunneling and nonstop bridging.

**l2tp-service**—(M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Layer 2 Tunneling Protocol (L2TP) process, which sets up client services for establishing Point-to-Point Protocol (PPP) tunnels across a network and negotiating Multilink PPP if it is implemented.

**l2tp-universal-edge**—(MX Series routers only) (Optional) Restart the L2TP process, which establishes L2TP tunnels and PPP sessions through L2TP tunnels.

**lACP**—(Optional) Restart the Link Aggregation Control Protocol (LACP) process. LACP provides a standardized means for exchanging information between partner systems on a link to allow their link aggregation control instances to reach agreement on the identity of the LAG to which the link belongs, and then to move the link to that LAG,

and to enable the transmission and reception processes for the link to function in an orderly manner.

**lcc *number***—(TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process for a specific T640 router that is connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process for a specific router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

**license-service**—(EX Series switches only) (Optional) Restart the feature license management process.

**link-management**—(TX Matrix and TX Matrix Plus routers and EX Series switches only) (Optional) Restart the Link Management Protocol (LMP) process, which establishes and maintains LMP control channels.

**lldpd-service**—(EX Series switches only) (Optional) Restart the Link Layer Discovery Protocol (LLDP) process.

**local**—(MX Series routers only) (Optional) Restart the software process for the local Virtual Chassis member.

**local-policy-decision-function**—(Optional) Restart the process for the Local Policy Decision Function, which regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

**mac-validation**—(Optional) Restart the Media Access Control (MAC) validation process, which configures MAC address validation for subscriber interfaces created on demux interfaces in dynamic profiles on MX Series routers.

**member *member-id***—(MX Series routers only) (Optional) Restart the software process for a specific member of the Virtual Chassis configuration. Replace *member-id* with a value of 0 or 1.

**mib-process**—(Optional) Restart the Management Information Base (MIB) version II process, which provides the router's MIB II agent.

**mobile-ip**—(Optional) Restart the Mobile IP process, which configures Junos OS Mobile IP features.

**mountd-service**—(EX Series switches and MX Series routers only) (Optional) Restart the service for NFS mount requests.

**mpls-traceroute**—(Optional) Restart the MPLS Periodic Traceroute process.

**mspd**—(Optional) Restart the Multiservice process.

**multicast-snooping**—(EX Series switches and MX Series routers only) (Optional) Restart the multicast snooping process, which makes Layer 2 devices, such as VLAN switches, aware of Layer 3 information, such as the media access control (MAC) addresses of members of a multicast group.

**named-service**—(Optional) Restart the DNS Server process, which is used by a router or a switch to resolve hostnames into addresses.

**network-access-service**—(J Series routers and QFX Series only) (Optional) Restart the network access process, which provides the router's Challenge Handshake Authentication Protocol (CHAP) authentication service.

**nfsd-service**—(Optional) Restart the Remote NFS Server process, which provides remote file access for applications that need NFS-based transport.

**packet-triggered-subscribers**—(Optional) Restart the packet-triggered subscribers and policy control (PTSP) process, which allows the application of policies to dynamic subscribers that are controlled by a subscriber termination device.

**peer-selection-service**—(Optional) Restart the Peer Selection Service process.

**pgcp-service**—(Optional) Restart the pgcpd service process running on the Routing Engine. This option does not restart pgcpd processes running on mobile station PICs. To restart pgcpd processes running on mobile station PICs, use the **services pgcp gateway** option.

**pgm**—(Optional) Restart the process that implements the Pragmatic General Multicast (PGM) protocol for assisting in the reliable delivery of multicast packets.

**pic-services-logging**—(Optional) Restart the logging process for some PICs. With this process, also known as fsad (the file system access daemon), PICs send special logging information to the Routing Engine for archiving on the hard disk.

**pki-service**—(Optional) Restart the PKI Service process.

**ppp**—(Optional) Restart the Point-to-Point Protocol (PPP) process, which is the encapsulation protocol process for transporting IP traffic across point-to-point links.

**ppp-service**—(Optional) Restart the Universal Edge PPP process, which is the encapsulation protocol process for transporting IP traffic across Universal Edge routers.

**pppoe**—(Optional) Restart the Point-to-Point Protocol over Ethernet (PPPoE) process, which combines PPP that typically runs over broadband connections with the Ethernet link-layer protocol that allows users to connect to a network of hosts over a bridge or access concentrator.

**protected-system-domain-service**—(Optional) Restart the Protected System Domain (PSD) process.

**redundancy-interface-process**—(Optional) Restart the ASP redundancy process.

**remote-operations**—(Optional) Restart the remote operations process, which provides the ping and traceroute MIBs.

**root-system-domain-service**—(Optional) Restart the Root System Domain (RSD) service.

**routing**—(ACX Series routers, QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the routing protocol process.

**routing <logical-system *logical-system-name*>**—(Optional) Restart the routing protocol process, which controls the routing protocols that run on the router or switch and maintains the routing tables. Optionally, restart the routing protocol process for the specified logical system only.

**sampling**—(Optional) Restart the sampling process, which performs packet sampling based on particular input interfaces and various fields in the packet header.

**sbc-configuration-process**—(Optional) Restart the session border controller (SBC) process of the border signaling gateway (BSG).

**scc**—(TX Matrix routers only) (Optional) Restart the software process on the TX Matrix router (or switch-card chassis).

**sdk-service**—(Optional) Restart the SDK Service process, which runs on the Routing Engine and is responsible for communications between the SDK application and Junos OS. Although the SDK Service process is present on the router, it is turned off by default.

**secure-neighbor-discovery**—(QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the secure Neighbor Discovery Protocol (NDP) process, which provides support for protecting NDP messages.

**sfc number**—(TX Matrix Plus routers only) (Optional) Restart the software process on the TX Matrix Plus router (or switch-fabric chassis). Replace **number** with **0**.

**service-deployment**—(Optional) Restart the service deployment process, which enables Junos OS to work with the Session and Resource Control (SRC) software.

**services**—(Optional) Restart a service.

**services pgcp gateway *gateway-name***—(Optional) Restart the pgcpd process for a specific border gateway function (BGF) running on an MS-PIC. This option does not restart the pgcpd process running on the Routing Engine. To restart the pgcpd process on the Routing Engine, use the **pgcp-service** option.

**sflow-service**—(EX Series switches only) (Optional) Restart the flow sampling (sFlow technology) process.

**snmp**—(Optional) Restart the SNMP process, which enables the monitoring of network devices from a central location and provides the router's or switch's SNMP master agent.

**soft**—(Optional) Reread and reactivate the configuration without completely restarting the software processes. For example, BGP peers stay up and the routing table stays constant. Omitting this option results in a graceful restart of the software process.

**static-subscribers**—(Optional) Restart the static subscribers process, which associates subscribers with statically configured interfaces and provides dynamic service activation and activation for these subscribers.

**statistics-service**—(Optional) Restart the process that manages the Packet Forwarding Engine statistics.

**subscriber-management**—(Optional) Restart the Subscriber Management process.

**subscriber-management-helper**—(Optional) Restart the Subscriber Management Helper process.

**tunnel-oamd**—(Optional) Restart the Tunnel OAM process, which enables the Operations, Administration, and Maintenance of Layer 2 tunneled networks. Layer 2 protocol tunneling (L2PT) allows service providers to send Layer 2 PDUs across the provider's cloud and deliver them to Juniper Networks EX Series Ethernet Switches that are not part of the local broadcast domain.

**usb-control**—(J Series routers and MX Series routers only) (Optional) Restart the USB control process.

**vrrp**—(ACX Series routers, EX Series switches, and MX Series routers only) (Optional) Restart the Virtual Router Redundancy Protocol (VRRP) process, which enables hosts on a LAN to make use of redundant routing platforms on that LAN without requiring more than the static configuration of a single default route on the hosts.

**web-management**—(J Series routers, QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the Web management process.

**Required Privilege Level** reset

**Related Documentation** [• Overview of Junos OS CLI Operational Mode Commands on page 52](#)

**List of Sample Output** [restart interfaces on page 5663](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request.

## Sample Output

### restart interfaces

```
user@host> restart interfaces
interfaces process terminated
interfaces process restarted
```

## show dcbx

| <b>Output Fields</b>            | <a href="#">Table 405 on page 5665</a> lists the output fields for the <b>show dcbx</b> command. Output fields are listed in the approximate order in which they appear.      |

Table 405: show dcbx output fields

| Field Name | Field Description                                                                                                                                                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DCBX       | Status of DCBX on the switch or for the specified interface: <ul style="list-style-type: none"> <li>• Enabled—DCBX is enabled on the switch or on the specified interface</li> <li>• Disabled—DCBX is disabled on the switch or on the specified interface</li> </ul> |
| Interface  | Name of the interface                                                                                                                                                                                                                                                 |

## Sample Output

### show dcbx

```

user@switch> show dcbx
DCBX                : Enabled
Interface           DCBX
xe-0/0/9.0          enabled
xe-0/0/32.0         enabled
xe-0/0/36.0         enabled

```

## show dcbx neighbors

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 407: show fibre-channel fabric Output Fields**

| Field Name            | Field Description                                                           | Level of Output  |
|-----------------------|-----------------------------------------------------------------------------|------------------|
| <b>Fabric</b>         | Name of the fabric.                                                         | All              |
| <b>Fabric-ID</b>      | Identification number of the fabric.                                        | All              |
| <b>Type</b>           | Type of fabric. All fabrics are <b>PROXY</b> fabrics.                       | All              |
| <b>Interfaces</b>     | Native Fibre Channel interfaces and FCoE interfaces assigned to the fabric. | All              |
| <b>Created at</b>     | Date and time the fabric was created.                                       | <b>extensive</b> |
| <b>Internal Index</b> | Fabric index internal to Junos OS.                                          | <b>extensive</b> |
| <b>Origin</b>         | Origin information internal to Junos OS.                                    | <b>extensive</b> |
| <b>Description</b>    | Text description of the fabric.                                             | <b>extensive</b> |

Table 407: show fibre-channel fabric Output Fields (*continued*)

| Field Name                           | Field Description                                                        | Level of Output  |
|--------------------------------------|--------------------------------------------------------------------------|------------------|
| <b>Fabric WWN</b>                    | Unique WWN of the fabric generated by the FCF.                           | <b>extensive</b> |
| <b>Login sessions</b>                | Number of FIP login sessions currently running on the fabric.            | <b>extensive</b> |
| <b>Configured max login sessions</b> | Configured maximum number of FIP login sessions permitted on the fabric. | <b>extensive</b> |

## Sample Output

### show fibre-channel fabric

```

user@switch> show fibre-channel fabric
Fabric          Fabric-ID      Type      Interfaces
-----
proxy2          200            PROXY     fc-0/0/0.0
                                     fc-0/0/1.0

```

### show fibre-channel fabric extensive

```

user@switch> show fibre-channel fabric extensive
Fabric: proxy2, Created at: Mon Apr 19 14:02:58 2010
Fabric-ID: 200, Internal index: 2, Origin: Static
Description: srv-fabric, Type: PROXY, Fabric WWN: 10:00:00:05:33:51:d7:cd
Login sessions: 200, Configured max login sessions: 500
      fc-0/0/0.0, (untagged)
      fc-0/0/1.0, (untagged)

```

## show fibre-channel fc2 sessions

**Syntax** `show fibre-channel fc2 sessions`  
`<fabric fabric-name>`  
`<brief | detail>`

**Release Information** Command introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Display Fibre Channel FC-2 information.

**NOTE:** A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.

**Options** `fabric fabric-name`—(Optional) Display output only for the specified fabric.  
`brief | detail`—(Optional) Display the specified level of output.

**Required Privilege Level** view

| <b>Output Fields</b>            | Table 410 on page 5694 lists the output fields for the <b>show fibre-channel fip</b> command. Output fields are listed in the approximate order in which they appear. A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.                                                                                                                                                                                                                                                                             |

| <b>ENode</b>                      | Information about a connected FCoE node (ENode).                                                                                         | All             |
| • <b>ENode-MAC</b>                | MAC address of the connected ENode.                                                                                                      | All             |
| • <b>Enode State</b>              | Login state internal to Junos OS.                                                                                                        | All             |
| • <b>Configured ENode timer</b>   | User-configured FIP keepalive advertisement interval in milliseconds.                                                                    | <b>detail</b>   |
| • <b>Running ENode timer</b>      | Runtime interval in milliseconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received. | <b>detail</b>   |
| • <b>Active FIP Sessions</b>      | Number of active FIP sessions on the ENode.                                                                                              | <b>detail</b>   |
| • <b>VN-Port-MAC</b>              | MAC address of a VN_Port on the ENode.                                                                                                   | All             |
| • <b>Session State</b>            | Session state internal to Junos OS.                                                                                                      | <b>detail</b>   |
| • <b>Configured FKA-ADV</b>       | User-configured FIP keepalive advertisement interval in milliseconds.                                                                    | <b>detail</b>   |
| • <b>Running FKA-ADV</b>          | Runtime interval in milliseconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received. | <b>detail</b>   |
| • <b>Configured VN-Port Timer</b> | Configured state of the VN_Port keepalive timer in milliseconds. This value is always 90 and is not user-configurable.                   | <b>detail</b>   |
| • <b>Running VN-Port Timer</b>    | Running state of the VN_Port keepalive timer in milliseconds.                                                                            | <b>detail</b>   |
| • <b>FCID</b>                     | Fibre Channel ID of the VN_Port.                                                                                                         | <b>detail</b>   |
| • <b>WWN</b>                      | Unique worldwide name of the VN_Port.                                                                                                    | <b>detail</b>   |

## Sample Output

### show fibre-channel fip

```

user@switch> show fibre-channel fip

| <b>Output Fields</b>            | Table 411 on page 5699 lists the output fields for the <b>show fibre-channel fip enode</b> command. Output fields are listed in the approximate order in which they appear. A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions.                                                                                                                                                                                                                                                            |

Table 411: show fibre-channel fip enode Output Fields

| Field Name            | Field Description                                                                                 | Level of Output |
|-----------------------|---------------------------------------------------------------------------------------------------|-----------------|
| <b>Fabric Name</b>    | Name of the fabric and in parentheses the fabric ID.                                              | All             |
| <b>FC-MAP</b>         | FCoE mapped address prefix of the FCoE forwarder for the fabric.                                  | <b>detail</b>   |
| <b>FKA-ADV-PERIOD</b> | Period of time in milliseconds between FIP keepalive advertisements configured for the FC fabric. | <b>detail</b>   |

Table 411: show fibre-channel fip enode Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                                                                                                                                           | Level of Output |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>MAX-SESSIONS-PER-ENODE</b> | Maximum number of concurrent sessions (FLOGI and FDISC combined) that each ENode can instantiate.                                                                                                                                                                           | <b>detail</b>   |
| <b>FCoE trusted</b>           | Whether ports on the FC fabric are trusted or untrusted: <ul style="list-style-type: none"> <li><b>Yes</b>—Ports on the FC fabric are trusted; FIP snooping is turned off.</li> <li><b>No</b>—Ports on the FC fabric are not trusted; FIP snooping is turned on.</li> </ul> | <b>detail</b>   |
| <b>Member</b>                 | Information about an FCF that is a member of the fabric.                                                                                                                                                                                                                    | All             |
| • <b>FCF-MAC</b>              | MAC address used in discovery advertisements.                                                                                                                                                                                                                               | All             |
| • <b>FKA-ADV-PERIOD</b>       | Period of time in milliseconds between FIP keepalive advertisements configured for the FC interface.                                                                                                                                                                        | <b>detail</b>   |
| • <b>FKA-ADV-D-BIT</b>        | Disable FIP keepalive advertisement monitoring bit. The state is always <b>off</b> .                                                                                                                                                                                        | <b>detail</b>   |
| • <b>Type</b>                 | Type of interface: <ul style="list-style-type: none"> <li><b>VF_Port Capable</b>—Interface can act as a VF_Port interface.</li> </ul>                                                                                                                                       | <b>detail</b>   |
| • <b>Priority</b>             | Priority value associated with the switch FCF-MAC. Converged network adapters (CNAs) use the priority value to determine the switch with which they will perform FIP FLOGI. The lower the value, the higher the priority.<br><br>Value range: 0 through 255.                | <b>detail</b>   |
| • <b>State</b>                | FIP state on the fabric: <ul style="list-style-type: none"> <li><b>Enable</b>—FIP is enabled on the fabric.</li> <li><b>Disable</b>—FIP is disabled on the fabric.</li> </ul>                                                                                               | <b>detail</b>   |

Table 411: show fibre-channel fip enode Output Fields (*continued*)

| Field Name                        | Field Description                                                                                                                        | Level of Output |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>ENode</b>                      | Information about a connected FCoE node (ENode).                                                                                         | All             |
| • <b>ENode-MAC</b>                | MAC address of the connected ENode.                                                                                                      | All             |
| • <b>ENode State</b>              | Login state internal to Junos OS.                                                                                                        | All             |
| • <b>Configured ENode timer</b>   | User-configured FIP keepalive advertisement interval in milliseconds.                                                                    | <b>detail</b>   |
| • <b>Running ENode timer</b>      | Runtime interval in milliseconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received. | <b>detail</b>   |
| • <b>Active FIP Sessions</b>      | Number of active FIP sessions on the ENode.                                                                                              | <b>detail</b>   |
| • <b>VN-Port-MAC</b>              | MAC address of a VN_Port on the ENode.                                                                                                   | <b>detail</b>   |
| • <b>Session State</b>            | Session state internal to Junos OS.                                                                                                      | <b>detail</b>   |
| • <b>Configured FKA-ADV</b>       | User-configured FIP keepalive advertisement interval in milliseconds.                                                                    | <b>detail</b>   |
| • <b>Running FKA-ADV</b>          | Runtime interval in seconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received.      | <b>detail</b>   |
| • <b>Configured VN-Port Timer</b> | Configured state of the VN_Port keepalive timer in seconds. This value is always 90 and is not user-configurable.                        | <b>detail</b>   |
| • <b>Running VN-Port Timer</b>    | Running state of the VN_Port keepalive timer in seconds.                                                                                 | <b>detail</b>   |
| • <b>FCID</b>                     | Fibre Channel ID of the VN_Port.                                                                                                         | <b>detail</b>   |
| • <b>WWN</b>                      | Unique worldwide name of the VN_Port.                                                                                                    | <b>detail</b>   |

## Sample Output

### show fibre-channel fip enode

```

user@switch> show fibre-channel fip enode 00:10:94:00:00:02

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                     |

**Table 412: show fibre-channel fip fabric Output Fields**

| Field Name            | Field Description                                                                                 | Level of Output |
|-----------------------|---------------------------------------------------------------------------------------------------|-----------------|
| <b>Fabric Name</b>    | Name of the fabric and in parentheses the fabric ID.                                              | All             |
| <b>FC-MAP</b>         | FCoE mapped address prefix of the FCoE forwarder for the fabric.                                  | <b>detail</b>   |
| <b>FKA-ADV-PERIOD</b> | Period of time in milliseconds between FIP keepalive advertisements configured for the FC fabric. | <b>detail</b>   |

Table 412: show fibre-channel fip fabric Output Fields (*continued*)

| Field Name                 | Field Description                                                                                                                   | Level of Output |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Member</b>              | Information about an FCF that is a member of the fabric.                                                                            | All             |
| • FCF-MAC                  | MAC address used in discovery advertisements.                                                                                       | All             |
| • FKA-ADV-PERIOD           | Period of time in milliseconds between FIP keepalive advertisements configured for the FC interface.                                | <b>detail</b>   |
| • FKA-ADV-D-BIT            | Disable FIP keepalive advertisement monitoring bit. The state is always <b>off</b> .                                                | <b>detail</b>   |
| • Type                     | Type of interface:<br><br>• <b>VF_Port Capable</b> —Interface can act as a VF_Port interface.                                       | <b>detail</b>   |
| <b>ENode</b>               | Information about a connected FCoE node (ENode).                                                                                    | All             |
| • ENode-MAC                | MAC address of the connected ENode.                                                                                                 | All             |
| • State                    | Login state internal to Junos OS.                                                                                                   | All             |
| • VN-Port-MAC              | MAC address of a VN_Port on the ENode.                                                                                              | <b>detail</b>   |
| • Session State            | Session state internal to Junos OS.                                                                                                 | <b>detail</b>   |
| • Configured FKA-ADV       | User-configured FIP keepalive advertisement interval in milliseconds.                                                               | <b>detail</b>   |
| • Running FKA-ADV          | Runtime interval in seconds of the last FIP keepalive advertisement received. This value changes every time an FKA_ADV is received. | <b>detail</b>   |
| • Configured VN-Port Timer | Configured state of the VN_Port keepalive timer in seconds. This value is always 90 and is not user-configurable.                   | <b>detail</b>   |
| • Running VN-Port Timer    | Running state of the VN_Port keepalive timer in seconds.                                                                            | <b>detail</b>   |

## Sample Output

| <b>Output Fields</b>            | <a href="#">Table 415 on page 5712</a> lists the output fields for the <b>show fibre-channel fip statistics</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                          |

Table 415: show fibre-channel fip statistics Output Fields

| Field Name     | Field Description                |
|----------------|----------------------------------|
| Fabric name    | Name of the fabric.              |
| Interface name | Name of the FCoE VLAN interface. |

Table 415: show fibre-channel fip statistics Output Fields (*continued*)

| Field Name              | Field Description                                         |
|-------------------------|-----------------------------------------------------------|
| <b>FIP Message Type</b> | Type of FIP message for the displayed row of statistics.. |
| • MDS                   | Number of multicast discovery solicitations.              |
| • UDS                   | Number of unicast discovery solicitations.                |
| • FLOGI                 | Number of fabric login (FLOGI) messages.                  |
| • FDISC                 | Number of fabric discovery (FDISC) messages.              |
| • LOGO                  | Number of fabric logout (LOGO) messages.                  |
| • ENODE KA              | Number of ENode keepalive messages.                       |
| • VN_Port KA            | Number of VN_Port keepalive messages.                     |
| • MDA                   | Number of multicast discovery advertisements.             |
| • UDA                   | Number of unicast discovery advertisements.               |
| • FLOGI ACC             | Number of fabric login requests accepted.                 |
| • FLOGI RJT             | Number of fabric login requests rejected.                 |
| • FDISC ACC             | Number of fabric discovery requests accepted.             |
| • FDISC RJT             | Number of fabric discovery requests rejected.             |
| • LOGO ACC              | Number of logout requests accepted.                       |
| • LOGO RJT              | Number of logout requests rejected.                       |
| • CVL                   | Number of clear virtual links (CVL) messages.             |
| • CVL ALL               | Number of CVL all messages.                               |
| <b>Received</b>         | Number of messages received.                              |
| <b>Sent</b>             | Number of messages sent.                                  |
| <b>Rx errors</b>        | Number of receive errors.                                 |

Table 415: show fibre-channel fip statistics Output Fields (*continued*)

| Field Name                |                                                    | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Dropped</b>            |                                                    | Number of dropped messages.<br><br><b>NOTE:</b> One cause of dropped messages is that the system limits the number of discovery solicitations (MDS and UDS) it accepts to a maximum of 100 outstanding requests at any given time. If the system has 100 discovery solicitations outstanding, the system does not respond to new discovery solicitations. Instead, the system drops new discovery solicitations and reports the number of dropped discovery solicitations in this field. When there are fewer than 100 outstanding discovery solicitations, the system responds to new requests as usual with a discovery advertisement. |
| <b>General Statistics</b> | <b>Number of frames recvd with invalid src-mac</b> | Number of frames received that have an invalid source media access control (MAC) address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                           | <b>Number of frames recvd with invalid version</b> | Number of FIP frames received with an Invalid FIP version.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                           | <b>Number of frames recvd with invalid opcode</b>  | Number of FIP validation descriptors with an invalid opcode received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                           | <b>Number of frames recvd with invalid subcode</b> | Number of FIP validation descriptors with an invalid subcode received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                           | <b>Number of frames recvd on inactive FCF</b>      | Number of frames received on a logical interface if FIP is not active on that logical interface (for example, if a WWN is not allocated to that logical interface).                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Last rebalance trigger</b>      | <p>Event that triggered the last link load rebalance on the FCoE-FC gateway fabric:</p> <ul style="list-style-type: none"> <li>• None—The link load has never been rebalanced.</li> <li>• Config-CLI—Configure (enable) automated load balancing.</li> <li>• Request-CLI—Rebalance requested from the CLI using the <b>request fibre-channel proxy load-rebalance fabric fabric-name</b> operational command.</li> <li>• Preview-CLI—Rebalancing <i>dry run</i> requested from the CLI using the <b>request fibre-channel proxy load-rebalance dry-run fabric fabric-name</b> operational command. Indicates that the switch completed the dry run. A dry run simulates a link load rebalance and displays a list of sessions that might be affected if you request an actual rebalance.</li> <li>• Link-up—New FC link (NP_Port) up on the FCoE-FC gateway fabric, which causes a rebalance to distribute sessions to the new link.</li> <li>• Restore-complete—If the FC process on the switch restarts, the switch attempts to restore the session state that existed before the restart. When automated rebalance is enabled, restore-complete indicates that the sessions have been restored and rebalanced.</li> </ul> |
| <b>Last rebalance trigger-time</b> | <p>Time that the last link load rebalance was triggered on the FCoE-FC gateway fabric:</p> <ul style="list-style-type: none"> <li>• Never—Link load rebalancing has never been triggered.</li> <li>• Timestamp value—Time the last link load rebalancing was triggered.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 422: show fibre-channel proxy fabric-state Output Fields (*continued*)

| Field Name                           | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Last rebalance trigger-result</b> | <p>Result of the last trigger event on the FCoE-FC gateway fabric:</p> <ul style="list-style-type: none"> <li>• Never—Link load rebalancing has never been triggered.</li> <li>• Not-configured—Automated rebalancing is not configured on the FCoE-FC gateway fabric.</li> <li>• Not-required—Last rebalance trigger did not require rebalancing the link load (the link load was already balanced across the active NP_Port links).</li> <li>• In-progress—Link load rebalancing is in progress and has not finished yet.</li> <li>• Restore-in-progress—The switch is recovering from an FC process restart and is in the process of restoring the sessions to the active NP_Port links.</li> <li>• Success—Link load rebalancing was successful.</li> <li>• Logged-out-all—All sessions have been logged out.</li> <li>• Preview-complete—The switch has finished simulating a dry run rebalancing request from the CLI (<code>request fibre-channel proxy load-rebalance dry-run fabric fabric-name</code> operational command) and reported the sessions that might be affected if you request an actual link load rebalance.</li> <li>• Fabric-deletion-in-progress—FCoE-FC gateway fabric is in the process of being deleted.</li> </ul> <p><b>NOTE:</b> A trigger event does not necessarily result in a rebalance action. Link load rebalancing only occurs if the NP_Port interface session load is not balanced at the time of the trigger event.</p> |

## Sample Output

### show fibre-channel proxy fabric-state

```

user@switch> show fibre-channel proxy fabric-state
Fabric: san_fab1, Fabric-id: 10
Proxy load balance algorithm: Simple, Fabric WVN verification: Yes
Auto load rebalance enabled : No
Last rebalance start-time   : Never
Last rebalance end-time     : Never
Last rebalance trigger      : Link-up
Last rebalance trigger-time  : Mon Sep 10 21:42:30 2012 usec: 814602
Last rebalance trigger-result: Not-configured

Fabric: san_fab2, Fabric-id: 20
Proxy load balance algorithm: ENode based, Fabric WVN verification: Yes
Auto load rebalance enabled : No
Last rebalance start-time   : Never
Last rebalance end-time     : Never
Last rebalance trigger      : Link-up
Last rebalance trigger-time  : Mon Sep 17 17:23:35 2012 usec: 619684
Last rebalance trigger-result: Not-configured

```

### show fibre-channel proxy fabric-state fabric

```

user@switch> show fibre-channel proxy fabric-state fabric fc_fabric_100
Fabric: fc_fabric_100, Fabric-id: 100
Proxy load balance algorithm: FLOGI based, Fabric WVN verification: No
Auto load rebalance enabled : Yes
Last rebalance start-time   : Never
Last rebalance end-time     : Never
Last rebalance trigger      : Config-CLI
Last rebalance trigger-time  : Fri Nov 2 08:56:16 2012 usec: 004487
Last rebalance trigger-result: Not-required

```

| <b>Output Fields</b>            | Table 424 on page 5737 lists the output fields for the <b>show fibre-channel proxy np-port</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                       |

Table 424: show fibre-channel proxy np-port Output Fields

| Field Name       | Field Description                                                                                                                                                    | Level of Output |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Fabric</b>    | Name of the fabric.                                                                                                                                                  | All             |
| <b>Fabric-id</b> | Fabric ID number.                                                                                                                                                    | All             |
| <b>NP-Port</b>   | NP_Port interface connected to the FCoE forwarder (FCF) or the Fibre Channel switch.                                                                                 | All             |
| <b>State</b>     | FCID state of the NP_Port interface.                                                                                                                                 | All             |
| <b>Sessions</b>  | Number of active sessions on the NP_Port interface. A session is a FLOGI or FDISC login to the FC SAN fabric. Session does not refer to end-to-end storage sessions. | All             |

Table 424: show fibre-channel proxy np-port Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                                                               | Level of Output |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Configured max login sessions | Configured maximum number of FIP login sessions permitted on the interface.                                                                                                                     | detail          |
| Enodes                        | Number of ENodes with sessions on the NP_Port.                                                                                                                                                  | detail          |
| LB state                      | Load-balancing state: <ul style="list-style-type: none"> <li>On—Load balancing is on</li> <li>Off—Load balancing is off.</li> </ul>                                                             | All             |
| LB weight                     | Load balance weight, which reflects the port speed: <ul style="list-style-type: none"> <li>2—Port speed is 2 Gbps.</li> <li>4—Port speed is 4 Gbps.</li> <li>8—Port speed is 8 Gbps.</li> </ul> | All             |
| Ref-count                     | Reference count internal to Junos OS.                                                                                                                                                           | detail          |
| Flags                         | Flags internal to Junos OS.<br><br>NOTE: When an NP_Port interface reaches its configured maximum number of FIP sessions, the <b>Flags</b> field displays the flag <b>MAX-LOGINS-REACHED</b> .  | detail          |

| <b>FC-MAP</b>                           | FCoE mapped address prefix of the FCoE forwarder for the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | All             |
| <b>FCF or FCF-MAC</b>                   | MAC address of the FCF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | All             |
| <b>Session Count or Active Sessions</b> | Current number of virtual link sessions with VN_Ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | All             |
| <b>VN_Port Count</b>                    | (QFX Series only)<br>Number of VN_Ports active on an ENode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <b>brief</b>    |
| <b>Configured FKA-ADV</b>               | FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258.<br><br>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module. | <b>detail</b>   |
| <b>Running FKA-ADV</b>                  | Runtime interval in seconds of the last FIP keepalive advertisement the FCF received. This value changes every time the FCF receives an FKA_ADV.<br><br>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.                                     | <b>detail</b>   |
| <b>Beacon Period</b>                    | (QFX Series only)<br>Beacon period interval in milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>detail</b>   |

Table 426: show fip snooping Output Fields (*continued*)

| Field Name                       | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>VN2VN Mode</b>                | (QFX Series only)<br>Mode of VN2VN_Port snooping: <ul style="list-style-type: none"> <li>Multi-Point—Multiple ENodes are connected to the network and form multiple virtual links. Each virtual link is created between one pair of VN_Ports. This is analogous to the loop mode in traditional FC networks.</li> <li>Point-to-Point—Two ENodes are connected to the network and form a single VN_Port to VN_Port virtual link. This is analogous to the point-to-point FC link between an FC initiator and an FC target.</li> </ul> | <b>detail</b>   |
| <b>ENode-MAC</b>                 | MAC address of the connected FCoE node (ENode).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | All             |
| <b>Interface</b>                 | Interface connected to the ENode.<br><br>(QFabric System only)<br>When an FCoE LAG has been configured, LAG interface connected to the ENode and LAG member interface connected to ENode.                                                                                                                                                                                                                                                                                                                                            | <b>detail</b>   |
| <b>VN-Port MAC</b>               | MAC address of a VN_Port on the ENode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | All             |
| <b>FKA-ADV</b>                   | Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF on behalf of the VN_Port (VN_Port FKA_ADV). This value changes every time the ENode sends a VN_Port FKA_ADV to the FCF.                                                                                                                                                                                                                                                                                                                | <b>detail</b>   |
| <b>Active VN_Ports</b>           | (QFX Series only)<br>Number of VN_Ports active on an ENode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>detail</b>   |
| <b>Vlink far-end VN-Port-MAC</b> | (QFX Series only)<br>Media access control (MAC) address of the VN_Port at the other end of the virtual link.                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>detail</b>   |

## Sample Output

### show fip snooping

```

user@switch> show fip snooping
VLAN : fcoevlan1      FC-MAP : 0e:fc:00
FCF : 00:10:94:00:00:01  Session Count : 2
ENode-MAC : 00:10:94:00:00:02
VN-Port-MAC : 0E:FC:00:01:00:05
VN-Port-MAC : 0E:FC:00:01:00:01

```

### show fip snooping brief (QFX Series)

```

user@switch> show fip snooping brief

| <b>Session Count</b>          | Current number of virtual link sessions with VN_Ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | All             |
| <b>Configured FKA-ADV</b>     | FIP keepalive interval in seconds configured on the FCoE forwarder (FCF) multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258. This value remains constant.<br><br>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module. | <b>detail</b>   |
| <b>Running FKA-ADV</b>        | Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF. This value changes every time the ENode sends an FKA_ADV to the FCF.<br><br>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.                                                                | <b>detail</b>   |
| <b>VN-Port or VN-Port-MAC</b> | MAC address of a VN_Port on the ENode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | All             |
| <b>FKA-ADV</b>                | Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF on behalf of the VN_Port (VN_Port FKA_ADV). This value changes every time the ENode sends a VN_Port FKA_ADV to the FCF.                                                                                                                                                                                                                                                                                                                                                                                               | <b>detail</b>   |
| <b>FCF or FCF-MAC</b>         | MAC address of the FCF to which the VN_Port is connected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | All             |

**Table 428: show fip snooping fcf Output Fields**

| Field Name     | Field Description                                      | Level of Output |
|----------------|--------------------------------------------------------|-----------------|
| FCF or FCF-MAC | MAC address of the FCoE forwarder.                     | All             |
| VLAN           | Name of the VLAN.                                      | All             |
| Session Count  | Current number of virtual link sessions with VN_Ports. | None            |

Table 428: show fip snooping fcf Output Fields (*continued*)

| Field Name           | Field Description                                                                                                                                                                                                     | Level of Output |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Configured FKA-ADV   | FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258.                                  | detail          |
| Running FKA-ADV      | Runtime interval in seconds of the last FIP keepalive advertisement the FCF received. This value changes every time the FCF receives an FKA_ADV.                                                                      | detail          |
| ENode-MAC            | MAC address of the connected ENode.                                                                                                                                                                                   | All             |
| • Interface          | Interface connected to the ENode.                                                                                                                                                                                     | detail          |
| • Configured FKA-ADV | FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258. This value remains constant.     | detail          |
| • Running FKA-ADV    | Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF. This value changes every time the ENode sends an FKA_ADV to the FCF.                                                   | detail          |
| • VN-Port MAC        | MAC address of a VN_Port on the ENode.                                                                                                                                                                                | All             |
| • FKA-ADV            | Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF on behalf of the VN_Port (VN_Port FKA_ADV). This value changes every time the ENode sends a VN_Port FKA_ADV to the FCF. | detail          |

## Sample Output

### show fip snooping fcf

```

user@switch> show fip snooping fcf 00:10:94:00:00:01
FCF : 00:10:94:00:00:01  VLAN : vlan1  Session Count : 2
  ENode-MAC : 00:10:94:00:00:02
    VN-Port-MAC : 0E:FC:00:00:00:05
    VN-Port-MAC : 0E:FC:00:00:00:01

```

### show fip snooping fcf detail

```

user@switch> show fip snooping fcf 00:10:94:00:00:01 detail
FCF-MAC : 00:10:94:00:00:01  VLAN : vlan1
Configured FKA-ADV : 258      Running FKA-ADV : 222
  ENode Information
    ENode-MAC : 00:10:94:00:00:02 Interface: xe-0/0/1
    Configured FKA-ADV : 258
    Running FKA-ADV : 226
    Session Information
      VN-Port MAC : 0E:FC:00:00:00:05  FKA-ADV : 242
      VN-Port MAC : 0E:FC:00:00:00:01  FKA-ADV : 238

```

## show fip snooping interface

Table 429: show fip snooping interface Output Fields (*continued*)

| Field Name                | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Level of Output |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Configured FKA-ADV</b> | <p>FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258.</p> <p>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.</p>                              | <b>detail</b>   |
| <b>Running FKA-ADV</b>    | <p>Runtime interval in seconds of the last FIP keepalive advertisement the FCF received. This value changes every time the FCF receives an FKA_ADV.</p> <p>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.</p>                                                                  | <b>detail</b>   |
| <b>ENode-MAC</b>          | MAC address of the connected FCoE node (ENode).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | All             |
| <b>Interface</b>          | Interface connected to the ENode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>detail</b>   |
| <b>Configured FKA-ADV</b> | <p>FIP keepalive interval in seconds configured on the FCF multiplied by three. For example, if the FKA_ADV period configured on the FCF is 86 seconds, the value of this field is 258. This value remains constant.</p> <p>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.</p> | <b>detail</b>   |
| <b>Running FKA-ADV</b>    | <p>Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF. This value changes every time the ENode sends an FKA_ADV to the FCF.</p> <p>For the QFX Series only, the output of this field is always 0 (zero) if the VLAN is an FCoE-FC gateway VLAN. If the VLAN is a FIP snooping VLAN (a transit switch VLAN), then the output is accurate. This is because for an FCoE-FC gateway VLAN, FIP snooping is performed internally and the keepalive advertisements are not tracked by the switch's Ethernet module.</p>                                               | <b>detail</b>   |
| <b>VN-Port MAC</b>        | MAC address of a VN_Port on the ENode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | All             |

Table 429: show fip snooping interface Output Fields (*continued*)

| Field Name | Field Description                                                                                                                                                                                                     | Level of Output |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| FKA-ADV    | Runtime interval in seconds of the last FIP keepalive advertisement the ENode sent to the FCF on behalf of the VN_Port (VN_Port FKA_ADV). This value changes every time the ENode sends a VN_Port FKA_ADV to the FCF. | <b>detail</b>   |

## Sample Output

### show fip snooping interface

```

user@switch> show fip snooping interface xe-0/0/9.0
VLAN: vlan_100,    FC-MAP: 0e:fc:00
FCF: 30:10:94:01:00:00    Session Count: 1
Enode-MAC: 10:10:94:01:00:01
VN-Port-MAC: 0e:fc:00:01:0a:01

```

### show fip snooping interface detail

```

user@switch> show fip snooping interface xe-0/0/9.0 detail
VLAN: vlan_100, FC-MAP: 0e:fc:00
FCF Information
FCF-MAC          : 30:10:94:01:00:00
Active Sessions  : 1
Configured FKA-ADV : 368640000
Running FKA-ADV   : 0
  Enode Information
  Enode-MAC: 10:10:94:01:00:01,      Interface: xe-0/0/9
  Configured FKA-ADV : 368640000
  Running FKA-ADV    : 0
    Session Information
    VN-Port MAC: 0e:fc:00:01:0a:01,  FKA-ADV : 0

```

## show fip snooping statistics

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Output Fields</b>            | Table 430 on page 5758 lists the output fields for the <b>show fip snooping statistics</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 430: show fip snooping statistics Output Fields**

| Field Name           | Field Description                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VLAN</b>          | Name of the VLAN for which a set of statistics is displayed.                                                                                                                                                                                                                                                                                  |
| <b>Mode</b>          | (QFX Series only)<br>Snooping mode enabled on the FCoE VLAN: <ul style="list-style-type: none"> <li>• VN2VF Snooping—The FCoE VLAN is configured for FIP snooping between an ENode VN_Port and a switch VF_Port.</li> <li>• VN2VN Snooping—The FCoE VLAN is configured for VN_Port to VN_Port FIP snooping between ENode VN_Ports.</li> </ul> |
| <b>Number of MDS</b> | Number of multicast discovery solicitation messages sent on the VLAN.                                                                                                                                                                                                                                                                         |

Table 430: show fip snooping statistics Output Fields (*continued*)

| Field Name                     | Field Description                                                                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of UDS                  | Number of unicast discovery solicitation messages sent on the VLAN.                                                                               |
| Number of FLOGI                | Number of fabric logins on the VLAN.                                                                                                              |
| Number of FDISC                | Number of fabric discovery logins on the VLAN.                                                                                                    |
| Number of LOGO                 | Number of fabric logouts on the VLAN.                                                                                                             |
| Number of ENode-keep-alive     | Number of ENode keepalive messages sent on the VLAN.                                                                                              |
| Number of VN_Port-keep-alive   | Number of VN_Port keepalive messages sent on the VLAN.                                                                                            |
| Number of MDA                  | Number of multicast discovery advertisement messages sent on the VLAN.                                                                            |
| Number of UDA                  | Number of unicast discovery advertisement messages sent on the VLAN.                                                                              |
| Number of FLOGI_ACC            | Number of fabric logins accepted on the VLAN.                                                                                                     |
| Number of FLOGI_RJT            | Number of fabric logins rejected on the VLAN.                                                                                                     |
| Number of FDISC_ACC            | Number of fabric discoveries accepted on the VLAN.                                                                                                |
| Number of FDISC_RJT            | Number of fabric discoveries rejected on the VLAN.                                                                                                |
| Number of LOGO_ACC             | Number of fabric logouts accepted on the VLAN.                                                                                                    |
| Number of LOGO_RJT             | Number of fabric logouts rejected on the VLAN.                                                                                                    |
| Number of CVL                  | Number of clear virtual links (CVL) actions on the VLAN.                                                                                          |
| Number of VN_Port Probes Req   | (QFX Series only)<br>Number of multicast N_Port_ID probes sent to the ALL-VN2VN-ENode-MACs multicast address on the VLAN.                         |
| Number of VN_Port Claim Notif  | (QFX Series only)<br>Number of multicast N_Port_ID claim notifications sent on the VLAN.                                                          |
| Number of VN_Port Beacons      | (QFX Series only)<br>Number of multicast beacons sent on the VLAN.                                                                                |
| Number of VN_Port Probes Reply | (QFX Series only)<br>Number of replies to N_Port_ID probes sent on the VLAN. Replies are unicast to the ENode MAC address of the probe requester. |

Table 430: show fip snooping statistics Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of VN_Port Claim Reply | (QFX Series only)<br>Number of replies to N_Port_ID claim notifications sent on the VLAN. Replies are unicast to the ENode MAC address of the claim notifier. |

## Sample Output

### show fip snooping statistics (FIP Snooping)

```

user@switch> show fip snooping statistics
VLAN: fcoevlan1      Mode: VN2VF Snooping

Number of MDS:          2
Number of UDS:          2
Number of FLOGI:        2
Number of FDISC:        2
Number of LOGO:         0
Number of Enode-keep-alive: 200
Number of VNPort-keep-alive: 200

Number of MDA:          25
Number of UDA:          2
Number of FLOGI_ACC:    2
Number of FLOGI_RJT:    0
Number of FDISC_ACC:    2
Number of FDISC_RJT:    0
Number of LOGO_ACC:     0
Number of LOGO_RJT:     0
Number of CVL:          0

```

### show fip snooping statistics (VN2VN\_Port Snooping)

```

user@switch> show fip snooping statistics
VLAN: vlan101      Mode: VN2VN Snooping

Number of VN_Port Probes Req:      3
Number of VN_Port Claim Notif:     3
Number of VN_Port Beacons:         0

Number of VN_Port Probes Reply:     3
Number of VN_Port Claim Reply:      3
Number of FLOGI:                    0
Number of FLOGI_ACC:                0
Number of FLOGI_RJT:                0
Number of FDISC:                    0
Number of FDISC_ACC:                0
Number of FDISC_RJT:                0
Number of LOGO:                     0
Number of LOGO_ACC:                 0
Number of LOGO_RJT:                 0

```
