Understanding TCP Port Scanning

A port scan occurs when one source IP address sends IP packets containing TCP SYN segments to 10 different destination ports within a defined interval (5000 microseconds is the default). The purpose of this attack is to scan the available services in the hopes that at least one port will respond, thus identifying a service to target.

Junos OS internally logs the number of different ports scanned from one remote source. Using the default settings, if a remote host scans 10 ports in 0.005 seconds (5000 microseconds), then the device flags this as a port scan attack and rejects all further packets from the remote source, regardless of the destination IP address, for the remainder of the specified timeout period. See [Figure 47](#).

Figure 47: Port Scan

NOTE: Junos OS supports port scanning for both IPv4 and IPv6 traffic.

Enhancing Traffic Management by Blocking Port Scans

This example shows how to enhance traffic management by configuring a screen to block port scans originating from a particular security zone.

- [Requirements on page 906](#)
- [Overview on page 906](#)
- [Configuration on page 906](#)
- [Verification on page 907](#)

Requirements

Before you begin, understand how port scanning works. See [“Understanding TCP Port Scanning” on page 904](#).

Overview

You can use a port scan to block IP packets containing TCP SYN segments or UDP segments sent to different ports from the same source address within a defined interval. The purpose of this attack is to scan the available services in the hopes that at least one port will respond. Once a port responds, it is identified as a service to target.

In this example, you configure a 5000 port-scan screen to block port scans originating from a particular security zone and then assign the screen to the zone called zone-1.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option 5000-port-scan tcp port-scan threshold 5000
set security screen ids-option 10000-port-scan udp port-scan threshold 10000
set security zones security-zone zone-1 screen 5000-port-scan
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a screen to block port scans:

1. Configure the screen.

```
[edit security]
user@host# set security screen ids-option 5000-port-scan tcp port-scan threshold
5000
user@host# set security screen ids-option 10000-port-scan udp port-scan threshold
10000
```

2. Enable the screen in the security zone.

```
[edit security]
user@host# set security zones security-zone zone-1 screen 5000-port-scan
```

Results From configuration mode, confirm your configuration by entering the **show security screen ids-option 5000-port-scan** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen ids-option 5000-port-scan
tcp {
```

```

    port-scan threshold 5000;
}
udp {
    port-scan threshold 10000;
}

[edit]
user@host# show security zones
security-zone zone-1 {
    screen 5000-port-scan;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Screens in the Security Zone on page 907](#)
- [Verifying the Security Screen Configuration on page 907](#)

Verifying the Screens in the Security Zone

Purpose Verify that the screen is enabled in the security zone.

Action From operational mode, enter the **show security zones** command.

```

[edit]
user@host> show security zones
Security zone: zone-1
  Send reset for non-SYN session TCP packets: Off
  Policy configurable: Yes
  Screen: 5000-port-scan
  Interfaces bound: 0
  Interfaces:

```

Meaning The sample output shows that the screen for zone-1 is enabled for port scan blocking.

Verifying the Security Screen Configuration

Purpose Verify the configuration information about the security screen.

Action From operational mode, enter the **show security screen ids-option screen-name** command.

```

[edit]
user@host> show security screen ids-option 5000-port-scan
Screen object status:
Name                                     Value
TCP port scan threshold                 5000
UDP port scan threshold                 10000

```

Meaning The sample output shows that the port scan blocking is operational with TCP and UDP threshold.

- Related Documentation**
- [Understanding TCP Port Scanning on page 904](#)

Understanding UDP Port Scanning

UDP port scan gives statistical information on a session threshold. As the incoming packets traverse the screen, the sessions are established. The number of sessions threshold enforced is based on zone, source IP, and the threshold period and does not allow more than 10 new sessions in the configured threshold period, for each zone and source IP address. The UDP port scan is disabled by default. When the UDP port scan is enabled, the default threshold period is 5000 microseconds. This value can be manually set to a range of 1000-1,000,000 microseconds. This feature protects some exposed public UDP services against DDoS attacks. See [Figure 48](#).

Understanding Network Reconnaissance Using IP Options

The IP standard RFC 791, *Internet Protocol*, specifies a set of options for providing special routing controls, diagnostic tools, and security.

RFC 791 states that these options are “unnecessary for the most common communications” and, in reality, they rarely appear in IP packet headers. These options appear after the destination address in an IP packet header, as shown in [Figure 49](#). When they do appear, they are frequently being put to some illegitimate use.

Figure 49: Routing Options

Version	Header	Type of Service	Total Packet Length (in Bytes)			
Identification			O	D	M	Fragment Offset
Time to Live (TTL)	Protocol		Header Checksum			
Source Address						
Destination Address						
Options						
Payload						

9030007

9030607

This topic contains the following sections:

- [Uses for IP Packet Header Options on page 909](#)
- [Screen Options for Detecting IP Options Used for Reconnaissance on page 911](#)

Uses for IP Packet Header Options

[Table 67](#) lists the IP options and their accompanying attributes.

Table 67: IP Options and Attributes

Type	Class	Number	Length	Intended Use	Nefarious Use
End of Options	0*	0	0	Indicates the end of one or more IP options.	None.
No Options	0	1	0	Indicates there are no IP options in the header.	None.
Security	0	2	11 bits	Provides a way for hosts to send security, TCC (closed user group) parameters, and Handling Restriction Codes compatible with Department of Defense (DoD) requirements. (This option, as specified in RFC 791, <i>Internet Protocol</i> , and RFC 1038, <i>Revised IP Security Option</i> , is obsolete.) Currently, this screen option is applicable only to IPv4.	Unknown. However, because it is obsolete, its presence in an IP header is suspect.

Table 67: IP Options and Attributes (*continued*)

Type	Class	Number	Length	Intended Use	Nefarious Use
Loose Source Route	0	3	Varies	Specifies a partial route list for a packet to take on its journey from source to destination. The packet must proceed in the order of addresses specified, but it is allowed to pass through other devices in between those specified.	Evasion. The attacker can use the specified routes to hide the true source of a packet or to gain access to a protected network.
Record Route	0	7	Varies	<p>Records the IP addresses of the network devices along the path that the IP packet travels. The destination machine can then extract and process the route information. (Due to the size limitation of 40 bytes for both the option and storage space, this can only record up to 9 IP addresses.)</p> <p>Currently, this screen option is applicable only to IPv4.</p>	Reconnaissance. If the destination host is a compromised machine in the attacker's control, he or she can glean information about the topology and addressing scheme of the network through which the packet passed.
Stream ID	0	8	4 bits	<p>(Obsolete) Provided a way for the 16-bit SATNET stream identifier to be carried through networks that did not support the stream concept.</p> <p>Currently, this screen option is applicable only to IPv4.</p>	Unknown. However, because it is obsolete, its presence in an IP header is suspect.
Strict Source Route	0	9	Varies	<p>Specifies the complete route list for a packet to take on its journey from source to destination. The last address in the list replaces the address in the destination field.</p> <p>Currently, this screen option is applicable only to IPv4.</p>	Evasion. An attacker can use the specified routes to hide the true source of a packet or to gain access to a protected network.
Timestamp	2**	4		<p>Records the time (in coordinated universal time [UTC]***) when each network device receives the packet during its trip from the point of origin to its destination. The network devices are identified by IP address.</p> <p>This option develops a list of IP addresses of the devices along the path of the packet and the duration of transmission between each one.</p> <p>Currently, this screen option is applicable only to IPv4.</p>	Reconnaissance. If the destination host is a compromised machine in the attacker's control, he or she can glean information about the topology and addressing scheme of the network through which the packet has passed.

Table 67: IP Options and Attributes (*continued*)

Type	Class	Number	Length	Intended Use	Nefarious Use
------	-------	--------	--------	--------------	---------------

* The class of options identified as 0 was designed to provide extra packet or network control.

** The class of options identified as 2 was designed for diagnostics, debugging, and measurement.

*** The timestamp uses the number of milliseconds since midnight UTC. UTC is also known as Greenwich Mean Time (GMT), which is the basis for the international time standard.

Screen Options for Detecting IP Options Used for Reconnaissance

The following screen options detect IP options that an attacker can use for reconnaissance or for some unknown but suspect purpose:

- **Record Route**—Junos OS detects packets where the IP option is 7 (record route) and records the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
- **Timestamp**—Junos OS detects packets where the IP option list includes option 4 (Internet timestamp) and records the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
- **Security**—Junos OS detects packets where the IP option is 2 (security) and records the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
- **Stream ID**—Junos OS detects packets where the IP option is 8 (stream ID) and records the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.

If a packet with any of the previous IP options is received, Junos OS flags this as a network reconnaissance attack and records the event for the ingress interface.

Example: Detecting Packets That Use IP Screen Options for Reconnaissance

This example shows how to detect packets that use IP screen options for reconnaissance.

- [Requirements on page 911](#)
- [Overview on page 912](#)
- [Configuration on page 912](#)
- [Verification on page 913](#)

Requirements

Before you begin, understand how network reconnaissance works. See “[Understanding Network Reconnaissance Using IP Options](#)” on page 908.

Overview

RFC 791, *Internet Protocol*, specifies a set of options for providing special routing controls, diagnostic tools, and security. The screen options detect IP options that an attacker can use for reconnaissance, including record route, timestamp, security, and stream ID.

In this example, you configure an IP screen screen-1 and enable it in a security zone called zone-1.

NOTE: You can enable only one screen in one security zone.

Configuration

CLI Quick Configuration To quickly detect packets with the record route, timestamp, security, and stream ID IP screen options, copy the following commands and paste them into the CLI.

```
[edit]
set security screen ids-option screen-1 ip record-route-option
set security screen ids-option screen-1 ip timestamp-option
set security screen ids-option screen-1 ip security-option
set security screen ids-option screen-1 ip stream-option
set security zones security-zone zone-1 screen screen-1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To detect packets that use IP screen options for reconnaissance:

1. Configure IP screen options.

NOTE: Currently, these screen options support IPv4 only.

```
[edit security screen]
user@host# set ids-option screen-1 ip record-route-option
user@host# set ids-option screen-1 ip timestamp-option
user@host# set ids-option screen-1 ip security-option
user@host# set ids-option screen-1 ip stream-option
```

2. Enable the screen in the security zone.

```
[edit security zones ]
user@host# set security-zone zone-1 screen screen-1
```

Results From configuration mode, confirm your configuration by entering the **show security screen** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
```

```

[user@host]show security screen
ids-option screen-1 {
    ip {
        record-route-option;
        timestamp-option;
        security-option;
        stream-option;
    }
}
[edit]
[user@host]show security zones
zones {
    security-zone zone-1 {
        screen screen-1;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Example: Blocking Packets with No Flags Set on page 922](#)

Understanding Operating System Probes

Before launching an exploit, attackers might try to probe the targeted host to learn its operating system (OS). With that knowledge, they can better decide which attack to launch and which vulnerabilities to exploit. Junos OS can block reconnaissance probes commonly used to gather information about OS types.

Related Documentation

- [Reconnaissance Deterrence Overview on page 901](#)

Understanding Domain Name System Resolve

Prior to Junos OS Release 12.1X47, DNS resolution was performed with only UDP as a transport. Messages carried by UDP are restricted to 512 bytes; longer messages are truncated and the traffic class (TC) bit is set in the header. The maximum length of UDP DNS response messages is 512 bytes, but the maximum length of TCP DNS response messages is 65,535 bytes. A DNS resolver knows whether the response is complete if the TC bit is set in the header. Hence, a TCP DNS response can carry more information than a UDP DNS response.

There are three types of DNS resolve behaviors:

- UDP DNS resolve
- TCP DNS resolve

- UDP/TCP DNS resolve

NOTE: A policy uses UDP/TCP DNS resolve to resolve IP addresses. In UDP/TCP DNS resolve, UDP DNS resolve is first used, and when it gets truncated TCP DNS resolve is used.

NOTE: A Routing Engine policy supports a maximum of 1024 IPv4 address prefixes and 256 IPv6 address prefixes that can be sent to the PFE. If the maximum number of IPv4 or IPv6 address prefixes exceeds the limits, the addresses over the limitations will not be sent to the PFE and a syslog message is generated. The maximum number of addresses in a TCP DNS response is 4094 for IPv4 addresses and 2340 for IPv6 addresses, but only 1024 IPv4 addresses and 256 IPv6 addresses are loaded to the PFE.

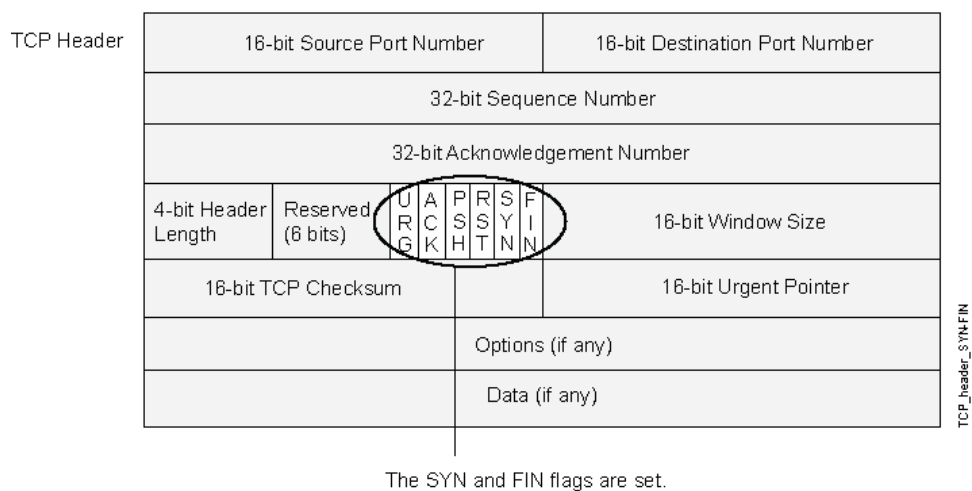

Related Documentation

- [Reconnaissance Deterrence Overview on page 901](#)

Understanding TCP Headers with SYN and FIN Flags Set

Both the SYN and FIN control flags are not normally set in the same TCP segment header. The SYN flag synchronizes sequence numbers to initiate a TCP connection. The FIN flag indicates the end of data transmission to finish a TCP connection. Their purposes are mutually exclusive. A TCP header with the SYN and FIN flags set is anomalous TCP behavior, causing various responses from the recipient, depending on the OS. See [Figure 50](#).

Figure 50: TCP Header with SYN and FIN Flags Set

An attacker can send a segment with both flags set to see what kind of system reply is returned and thereby determine what kind of OS is on the receiving end. The attacker can then use any known system vulnerabilities for further attacks.

When you enable this screen option, Junos OS checks if the SYN and FIN flags are set in TCP headers. If it discovers such a header, it drops the packet.

NOTE: Junos OS supports TCP header with SYN and FIN flags set protection for both IPv4 and IPv6 traffic.

Related Documentation

- [Reconnaissance Deterrence Overview on page 901](#)

Example: Blocking Packets with SYN and FIN Flags Set

This example shows how to create a screen to block packets with the SYN and FIN flags set.

- [Requirements on page 917](#)
- [Overview on page 917](#)
- [Configuration on page 917](#)
- [Verification on page 918](#)

Requirements

Before you begin, understand how TCP headers with SYN and FIN flags work. See “[Understanding TCP Headers with SYN and FIN Flags Set](#)” on page 916.

Overview

The TCP header with the SYN and FIN flags set cause different responses from a targeted device depending on the OS it is running. The syn-fin screen is enabled for the security zone.

In this example, you create a screen called screen-1 in a security zone to block packets with the SYN and FIN flags set.

Configuration

Step-by-Step Procedure

To block packets with both the SYN and FIN flags set:

1. Configure the screen.

```
[edit]
user@host# set security screen ids-option screen-1 tcp syn-fin
```
2. Enable the screen in the security zone.

```
[edit ]
user@host# set security zones security-zone zone-1 screen screen-1
```
3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

Confirm that the configuration is working properly.

- [Verifying the Screens in the Security Zone on page 918](#)
- [Verifying the Security Screen Configuration on page 918](#)

Verifying the Screens in the Security Zone

Purpose Verify that the screen is enabled in the security zone.

Action From operational mode, enter the **show security zones** command.

```
[edit]
user@host> show security zones

Security zone: zone-1
  Send reset for non-SYN session TCP packets: Off
  Policy configurable: Yes
  Screen: screen-1
  Interfaces bound: 1
  Interfaces:
    ge-1/0/0.0
```

Verifying the Security Screen Configuration

Purpose Display the configuration information about the security screen.

Action From operational mode, enter the **show security screen ids-option screen-name** command.

```
[edit]
user@host> show security screen ids-option screen-1
Screen object status:

      Name                               Value
      TCP SYN FIN                        enabled
```

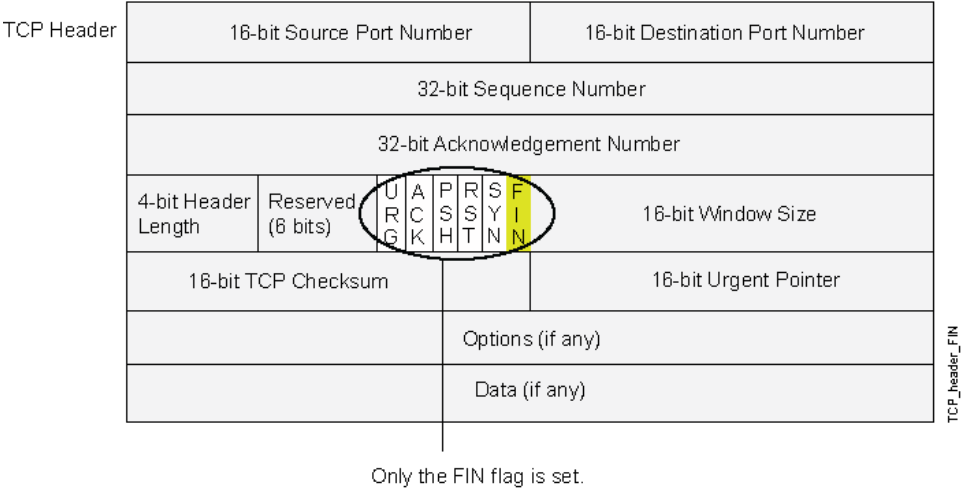

Understanding TCP Headers With FIN Flag Set and Without ACK Flag Set

Figure 51 shows TCP segments with the FIN control flag set (to signal the conclusion of a session and terminate the connection). Normally, TCP segments with the FIN flag set also have the ACK flag set (to acknowledge the previous packet received). Because a TCP header with the FIN flag set but not the ACK flag is anomalous TCP behavior, there is no uniform response to this. The OS might respond by sending a TCP segment with the RST flag set. Another might completely ignore it. The victim's response can provide the attacker with a clue as to its OS. (Other purposes for sending a TCP segment with the FIN flag set are to evade detection while performing address and port scans and to evade defenses on guard for a SYN flood by performing a FIN flood instead.)

NOTE: Vendors have interpreted RFC 793, *Transmission Control Protocol*, variously when designing their TCP/IP implementations. When a TCP segment arrives with the FIN flag set but not the ACK flag, some implementations send RST segments, while others drop the packet without sending an RST.

Figure 51: TCP Header with FIN Flag Set

When you enable this screen option, Junos OS checks if the FIN flag is set but not the ACK flag in TCP headers. If it discovers a packet with such a header, it drops the packet.

NOTE: Junos OS supports TCP header with SYN and FIN flags set protection for both IPv4 and Ipv6 traffic.

Related Documentation

- [Reconnaissance Deterrence Overview on page 901](#)

Example: Blocking Packets With FIN Flag Set and Without ACK Flag Set

This example shows how to create a screen to block packets with the FIN flag set but the ACK flag not set.

- [Requirements on page 919](#)
- [Overview on page 920](#)
- [Configuration on page 920](#)
- [Verification on page 920](#)

Requirements

Before you begin, understand how TCP headers work. See “[Understanding TCP Headers With FIN Flag Set and Without ACK Flag Set](#)” on page 918.

Overview

The TCP segments with the FIN flag set also have the ACK flag set to acknowledge the previous packet received. Because a TCP header with the FIN flag set but the ACK flag not set is anomalous TCP behavior, there is no uniform response to this. When you enable the fin-no-ack screen option, Junos OS checks if the FIN flag is set but not the ACK flag in TCP headers. If it discovers a packet with such a header, it drops the packet.

In this example, you create a screen called screen-1 to block packets with the FIN flag set but the ACK flag not set.

Configuration

Step-by-Step Procedure

To block packets with the FIN flag set but the ACK flag not set:

1. Configure the screen.

```
[edit]  
user@host# set security screen ids-option screen-1 tcp fin-no-ack
```
2. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

Confirm that the configuration is working properly.

- [Example: Detecting Packets with Either a Loose or a Strict Source Route Option Set on page 936](#)

Understanding Attacker Evasion Techniques

Whether gathering information or launching an attack, it is generally expected that the attacker avoids detection. Although some IP address and port scans are blatant and easily detectable, more wily attackers use a variety of means to conceal their activity. Techniques such as using FIN scans instead of SYN scans—which attackers know most firewalls and intrusion detection programs detect—indicate an evolution of reconnaissance and exploit techniques for evading detection and successfully accomplishing their tasks.

Related Documentation

- [Reconnaissance Deterrence Overview on page 901](#)

Understanding FIN Scans

A FIN scan sends TCP segments with the FIN flag set in an attempt to provoke a response (a TCP segment with the RST flag set) and thereby discover an active host or an active port on a host. Attackers might use this approach rather than perform an address sweep with ICMP echo requests or an address scan with SYN segments, because they know that many firewalls typically guard against the latter two approaches but not necessarily against FIN segments. The use of TCP segments with the FIN flag set might evade detection and thereby help the attackers succeed in their reconnaissance efforts.

Related Documentation

- [Reconnaissance Deterrence Overview on page 901](#)

Thwarting a FIN Scan

To thwart FIN scans, take either or both of the following actions:

- Enable the screen option that specifically blocks TCP segments with the FIN flag set but not the ACK flag, which is anomalous for a TCP segment:

```
user@host#set security screen fin-no-ack tcp fin-no-ack
user@host#set security zones security-zone name screen fin-no-ack
```

where ***name*** is the name of the zone to which you want to apply this screen option .

- Change the packet processing behavior to reject all non-SYN packets that do not belong to an existing session. The SYN check flag is set as the default.

NOTE: Changing the packet flow to check that the SYN flag is set for packets that do not belong to existing sessions also thwarts other types of non-SYN scans, such as a null scan (when no TCP flags are set).

Understanding TCP SYN Checking

By default, Junos OS checks for SYN flags in the first packet of a session and rejects any TCP segments with non-SYN flags attempting to initiate a session. You can leave this packet flow as is or change it so that Junos OS does not enforce SYN flag checking before creating a session. [Figure 53](#) illustrates packet flow sequences both when SYN flag checking is enabled and when it is disabled.

Figure 53: SYN Flag Checking

When Junos OS with SYN flag checking enabled receives a non-SYN TCP segment that does not belong to an existing session, it drops the packet. By default, Junos OS does not send a TCP RST to the source host on receiving the non-SYN segment. You can configure the device to send TCP RST to the source host by using the **set security zones security-zone trust tcp-rst** command. If the code bit of the initial non-SYN TCP packet is RST, the device does not send a TCP-RST.

Not checking for the SYN flag in the first packets offers the following advantages:

- **NSRP with Asymmetric Routing**—In an active/active NSRP configuration in a dynamic routing environment, a host might send the initial TCP segment with the SYN flag set to one device (Device-A), but the SYN/ACK might be routed to the other device in the cluster (Device-B). If this asymmetric routing occurs after Device-A has synchronized its session with Device-B, all is well. On the other hand, if the SYN/ACK response reaches Device-B before Device-A synchronizes the session and SYN checking is enabled, Device-B rejects the SYN/ACK, and the session cannot be established. With SYN checking disabled, Device-B accepts the SYN/ACK response—even though there is no existing session to which it belongs—and creates a new session table entry for it.
- **Uninterrupted Sessions**—If you reset the device or even change a component in the core section of a policy and SYN checking is enabled, all existing sessions or those sessions to which the policy change applies are disrupted and must be restarted. Disabling SYN checking avoids such disruptions to network traffic flows.

NOTE: A solution to this scenario is to install the device with SYN checking disabled initially. Then, after a few hours—when established sessions are running through the device—enable SYN checking. The core section in a policy contains the following main components: source and destination zones, source and destination addresses, one or more services, and an action.

However, the previous advantages exact the following security sacrifices:

- **Reconnaissance Holes**—When an initial TCP segment with a non-SYN flag—such as ACK, URG, RST, FIN—arrives at a closed port, many operating systems (Windows, for example) respond with a TCP segment that has the RST flag set. If the port is open, then the recipient does not generate any response.

By analyzing these responses or lack thereof, an intelligence gatherer can perform reconnaissance on the protected network and also on the Junos OS policy set. If a TCP segment is sent with a non-SYN flag set and the policy permits it through, the destination host receiving such a segment might drop it and respond with a TCP segment that has the RST flag set. Such a response informs the perpetrator of the presence of an active host at a specific address and that the targeted port number is closed. The intelligence gatherer also learns that the firewall policy permits access to that port number on that host.

By enabling SYN flag checking, Junos OS drops TCP segments without a SYN flag if they do not belong to an existing session. It does not return a TCP RST segment. Consequently, the scanner gets no replies regardless of the policy set or whether the port is open or closed on the targeted host.

- **Session Table Floods**—If SYN checking is disabled, an attacker can bypass the Junos OS SYN flood protection feature by flooding a protected network with a barrage of TCP segments that have non-SYN flags set. Although the targeted hosts drop the packets—and possibly send TCP RST segments in reply—such a flood can fill up the session table of the Juniper Networks device. When the session table is full, the device cannot process new sessions for legitimate traffic.

By enabling SYN checking and SYN flood protection, you can thwart this kind of attack. Checking that the SYN flag is set on the initial packet in a session forces all new sessions to begin with a TCP segment that has the SYN flag set. SYN flood protection then limits the number of TCP SYN segments per second so that the session table does not become overwhelmed.

If you do not need SYN checking disabled, Juniper Networks strongly recommends that it be enabled (its default state for an initial installation of Junos OS). You can enable it with the **set flow tcp-syn-check** command. With SYN checking enabled, the device rejects TCP segments with non-SYN flags set unless they belong to an established session.

**Related
Documentation**

- [Reconnaissance Deterrence Overview on page 901](#)

Setting TCP SYN Checking

With SYN checking enabled, the device rejects TCP segments with non-SYN flags set unless they belong to an established session. Enabling SYN checking can help prevent attacker reconnaissance and session table floods. TCP SYN checking is enabled by default.

To disable SYN checking:

```
user@host#set security flow tcp-session no-syn-check
```

Setting Strict SYN Checking

With strict SYN checking enabled, the device enables the strict three-way handshake check for the TCP session. It enhances security by dropping data packets before the three-way handshake is done. TCP strict SYN checking is disabled by default.

NOTE: The `strict-syn-check` option cannot be enabled if `no-syn-check` or `no-syn-check-in-tunnel` is enabled.

To enable strict SYN checking:

```
user@host#set security flow tcp-session strict-syn-check
```

Understanding IP Spoofing

One method of attempting to gain access to a restricted area of the network is to insert a false source address in the packet header to make the packet appear to come from a trusted source. This technique is called IP spoofing. The mechanism to detect IP spoofing relies on route table entries. For example, if a packet with source IP address 10.1.1.6 arrives at ge-0/0/1, but Junos OS has a route to 10.1.1.0/24 through ge-0/0/0, a check for IP spoofing discovers that this address arrived at an invalid interface as defined in the route table. A valid packet from 10.1.1.6 can only arrive via ge-0/0/0, not ge-0/0/1. Therefore, Junos OS concludes that the packet has a spoofed source IP address and discards it.

NOTE: Junos OS detects and drops both IPv4 and IPv6 spoofed packets.

Example: Blocking IP Spoofing

This example shows how to configure a screen to block IP spoof attacks.

- [Requirements on page 929](#)
- [Overview on page 930](#)
- [Configuration on page 930](#)
- [Verification on page 930](#)

Requirements

Before you begin, understand how IP Spoofing works. See “[Understanding IP Spoofing](#)” on page 929.

Overview

One method of attempting to gain access to a restricted area of a network is to insert a bogus source address in the packet header to make the packet appear to come from a trusted source. This technique is called IP spoofing.

In this example, you configure a screen called screen-1 to block IP spoof attacks and enable the screen in the zone-1 security zone.

Configuration

Step-by-Step Procedure

To block IP spoofing:

1. Configure the screen.

```
[edit]  
user@host# set security screen ids-option screen-1 ip spoofing
```
2. Enable the screen in the security zone.

```
[edit]  
user@host# set security zone security-zone zone-1 screen screen-1
```
3. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

Confirm that the configuration is working properly.

- [Verifying the Screens in the Security Zone on page 930](#)
- [Verifying the Security Screen Configuration on page 930](#)

Verifying the Screens in the Security Zone

Purpose Verify that the screen is enabled in the security zone.

Action From operational mode, enter the **show security zones** command.

```
[edit]  
user@host> show security zones  
  
Security zone: zone-1  
Send reset for non-SYN session TCP packets: Off  
Policy configurable: Yes  
Screen: screen-1  
Interfaces bound: 1  
Interfaces:  
ge-1/0/0.0
```

Verifying the Security Screen Configuration

Purpose Display the configuration information about the security screen.

Action From operational mode, enter the **show security screen ids-option screen-name** command.

```
[edit]
user@host> show security screen ids-option screen-1
Screen object status:
```

Name	Value
IP spoofing	enabled

Understanding IP Spoofing in Layer 2 Transparent Mode

In an IP spoofing attack, the attacker gains access to a restricted area of the network and inserts a false source address in the packet header to make the packet appear to come from a trusted source. IP spoofing is most frequently used in denial-of-service (DoS) attacks. When SRX Series devices are operating in transparent mode, the IP spoof-checking mechanism makes use of address book entries. Address books only exist on the Routing Engine. IP spoofing in Layer 2 transparent mode is performed on the Packet Forwarding Engine. Address book information cannot be obtained from the Routing Engine each time a packet is received by the Packet Forwarding Engine. Therefore, address books attached to the Layer 2 zones must be pushed to the Packet Forwarding Engine.

NOTE: IP spoofing in Layer 2 transparent mode does not support DNS and wildcard addresses.

When a packet is received by the Packet Forwarding Engine, the packet's source IP address is checked to determine if it is in the incoming zone's address-book. If the packet's source IP address is in the incoming zone's address book, then this IP address is allowed on the interface, and traffic is passed.

If the source IP address is not present in the incoming zone's address-book, but exists in other zones, then the IP address is considered a spoofed IP. Accordingly, actions such as drop and logging can be taken depending on the screen configuration (alarm-without-drop).

NOTE: If the alarm-without-drop option is configured, the Layer 2 spoofing packet only triggers an alarm message, but the packet is not dropped.

If a packet's source IP address is not present in the incoming zone's address book or other zones, then you cannot determine if the IP is spoofed or not. In such instances, the packet is passed.

Junos OS takes into account the following match conditions while it searches for source IP addresses in the address book:

- **Host-match**—The IP address match found in the address-book is an address without a prefix.
- **Prefix-match**—The IP address match found in the address-book is an address with a prefix.
- **Any-match**—The IP address match found in the address-book is “any”, “any-IPv4”, or “any-IPv6”.
- **No-match**—No IP address match is found.

Documentation**

- [Configuring IP Spoofing in Layer 2 Transparent Mode on page 932](#)

Configuring IP Spoofing in Layer 2 Transparent Mode

You can configure the IP spoof-checking mechanism to determine whether or not an IP is being spoofed.

To configure IP spoofing in Layer 2 transparent mode:

1. Set the interface in Layer 2 transparent mode.

```
[edit]
user@host# set interfaces ge-0/0/1 unit 0 family ethernet-switching
```

2. (Optional) Set the zone in Layer 2 transparent mode.

```
[edit]
user@host# set security zones security-zone untrust interfaces ge-0/0/1.0
```

3. Configure the address book.

```
[edit]
user@host# set security address-book my-book address myadd1 10.1.1.0/24
user@host# set security address-book my-book address myadd2 10.1.2.0/24
```

4. Apply the address book to the zone.

```
[edit]
user@host# set security address-book my-book attach zone untrust
```

5. Configure screen IP spoofing.

```
[edit]
user@host# set security screen ids-option my-screen ip spoofing
```

6. Apply the screen to the zone.

```
[edit]
user@host# set security zones security-zone untrust screen my-screen
```

7. (Optional) Configure the **alarm-without-drop** option.

```
[edit]
user@host# set security screen ids-option my-screen alarm-without-drop
```

NOTE: If the **alarm-without-drop** option is configured, the Layer 2 spoofing packet only triggers an alarm message, but the packet is not dropped.

Understanding IP Source Route Options

Source routing was designed to allow users at the source of an IP packet transmission to specify the IP addresses of the devices (also referred to as “hops”) along the path that they want an IP packet to take on its way to its destination. The original intent of the IP source route options was to provide routing control tools to aid diagnostic analysis. If, for example, the transmission of a packet to a particular destination meets with irregular success, you might first use either the record route or the timestamp IP option to discover the addresses of devices along the path or paths that the packet takes. You can then use either the loose or the strict source route option to direct traffic along a specific path, using the addresses you learned from the results that the record route or timestamp options produced. By changing device addresses to alter the path and sending several packets along different paths, you can note changes that either improve or lessen the success rate. Through analysis and the process of elimination, you might be able to deduce where the trouble lies. See [Figure 54](#).

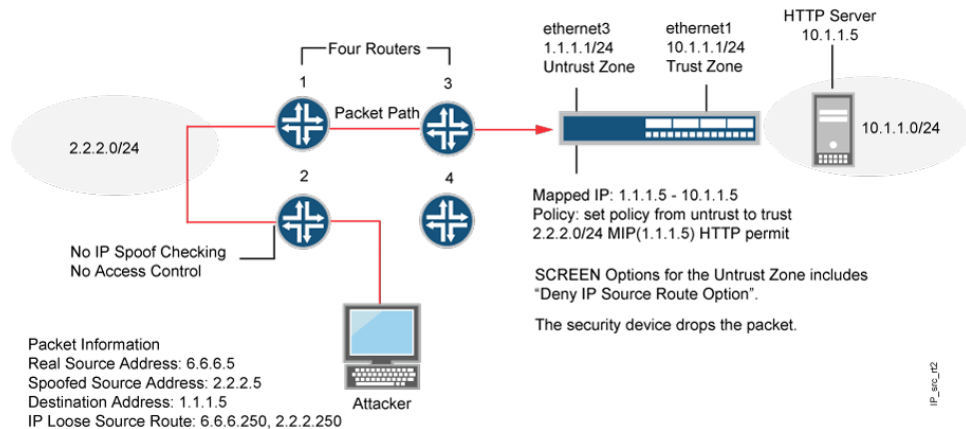

Figure 54: IP Source Routing

Although the uses of IP source route options were originally benign, attackers have learned to put them to more devious uses. They can use IP source route options to hide their true

address and access restricted areas of a network by specifying a different path. For an example showing how an attacker can put both deceptions to use, consider the following scenario as illustrated in Figure 55.

Figure 55: Loose IP Source Route Option for Deception

Junos OS only allows traffic 2.2.2.0/24 if it comes through ethernet1, an interface bound to zone_external. Devices 3 and 4 enforce access controls but devices 1 and 2 do not. Furthermore, device 2 does not check for IP spoofing. The attacker spoofs the source address and, by using the loose source route option, directs the packet through device 2 to the 2.2.2.0/24 network and from there out device 1. Device 1 forwards it to device 3, which forwards it to the Juniper Networks device. Because the packet came from the 2.2.2.0/24 subnet and has a source address from that subnet, it seems to be valid. However, one remnant of the earlier chicanery remains: the loose source route option. In this example, you have enabled the deny IP source route screen option for zone_external. When the packet arrives at ethernet3, the device rejects it.

You can enable the device to either block any packets with loose or strict source route options set or detect such packets and then record the event in the counters list for the ingress interface. The screen options are as follows:

- **Deny IP Source Route Option**—Enable this option to block all IP traffic that employs the loose or strict source route option. Source route options can allow an attacker to enter a network with a false IP address.
- **Detect IP Loose Source Route Option**—The device detects packets where the IP option is 3 (Loose Source Routing) and records the event in the screen counters list for the ingress interface. This option specifies a partial route list for a packet to take on its journey from source to destination. The packet must proceed in the order of addresses specified, but it is allowed to pass through other devices in between those specified.
- **Detect IP Strict Source Route Option**—The device detects packets where the IP option is 9 (Strict Source Routing) and records the event in the screen counters list for the ingress interface. This option specifies the complete route list for a packet to take on its journey from source to destination. The last address in the list replaces the address in the destination field. Currently, this screen option is applicable to IPv4 only.

Example: Blocking Packets with Either a Loose or a Strict Source Route Option Set

This example shows how to block packets with either a loose or a strict source route option set.

- [Requirements on page 935](#)
- [Overview on page 935](#)
- [Configuration on page 935](#)
- [Verification on page 936](#)

Requirements

Before you begin, understand how IP source route options work. See “[Understanding IP Source Route Options](#)” on page 933.

Overview

Source routing allows users at the source of an IP packet transmission to specify the IP addresses of the devices (also referred to as “hops”) along the path that they want an IP packet to take on its way to its destination. The original intent of the IP source route options was to provide routing control tools to aid diagnostic analysis.

You can enable the device to either block any packets with loose or strict source route options set or detect such packets and then record the event in the counters list for the ingress interface.

In this example you create the screen called screen-1 to block packets with either a loose or a strict source route option set and enable the screen in the zone-1 security zone.

Configuration

Step-by-Step Procedure

To block packets with either the loose or the strict source route option set:

1. Configure the screen.

```
[edit ]
user@host# set security screen ids-option screen-1 ip source-route-option
```
2. Enable the screen in the security zone.

```
[edit ]
user@host# set security zones security-zone zone-1 screen screen-1
```
3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

Confirm that the configuration is working properly.

Verifying the Screens in the Security Zone

Purpose Verify that the screen is enabled in the security zone.

Action From operational mode, enter the **show security zones** command.

```
[edit]
user@host> show security zones
Security zone: zone-1
  Send reset for non-SYN session TCP packets: Off
  Policy configurable: Yes
  Screen: screen-1
  Interfaces bound: 1
  Interfaces:
    ge-1/0/0.0
```

Verifying the Security Screen Configuration

Purpose Display the configuration information about the security screen.

Action From operational mode, enter the **show security screen ids-option *screen-name*** command.

```
[edit]
user@host> show security screen ids-option screen-1
Screen object status:

Name                                     Value
IP source route option                 enabled
```

Example: Detecting Packets with Either a Loose or a Strict Source Route Option Set

This example shows how to detect packets with either a loose or a strict source route option set.

- [Requirements on page 936](#)
- [Overview on page 937](#)
- [Configuration on page 937](#)
- [Verification on page 937](#)

Requirements

Before you begin, understand how IP source route options work. See “[Understanding IP Source Route Options](#)” on page 933.

Overview

Source routing allows users at the source of an IP packet transmission to specify the IP addresses of the devices (also referred to as “hops”) along the path that they want an IP packet to take on its way to its destination. The original intent of the IP source route options was to provide routing control tools to aid diagnostic analysis.

You can enable the device to either block any packets with loose or strict source route options set or detect such packets and then record the event in the counters list for the ingress interface.

In this example, you create two screens called screen-1 and screen-2 to detect and record, but not block, packets with a loose or strict source route option set and enable the screens in zones zone-1 and zone-2.

Configuration

Step-by-Step Procedure To detect and record, but not block, packets with a loose or strict source route option set:

1. Configure the loose source screen.

```
[edit]
user@host# set security screen ids-option screen-1 ip loose-source-route-option
```

2. Configure the strict source route screen.

```
[edit]
user@host# set security screen ids-option screen-2 ip strict-source-route-option
```

NOTE: Currently, this screen option supports IPv4 only.

3. Enable the screens in the security zones.

```
[edit]
user@host# set security zones security-zone zone-1 screen screen-1
user@host# set security zones security-zone zone-2 screen screen-2
```

4. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

Confirm that the configuration is working properly.

- [Understanding SYN Fragment Protection on page 944](#)
- [Example: Dropping IP Packets Containing SYN Fragments on page 945](#)

Suspicious Packet Attributes Overview

Attackers can craft packets to perform reconnaissance or launch denial-of-service (DoS) attacks. Sometimes it is unclear what the intent of a crafted packet is, but the very fact that it is crafted suggests that it is being put to some kind of insidious use.

The following topics describe screen options that block suspicious packets that might contain hidden threats:

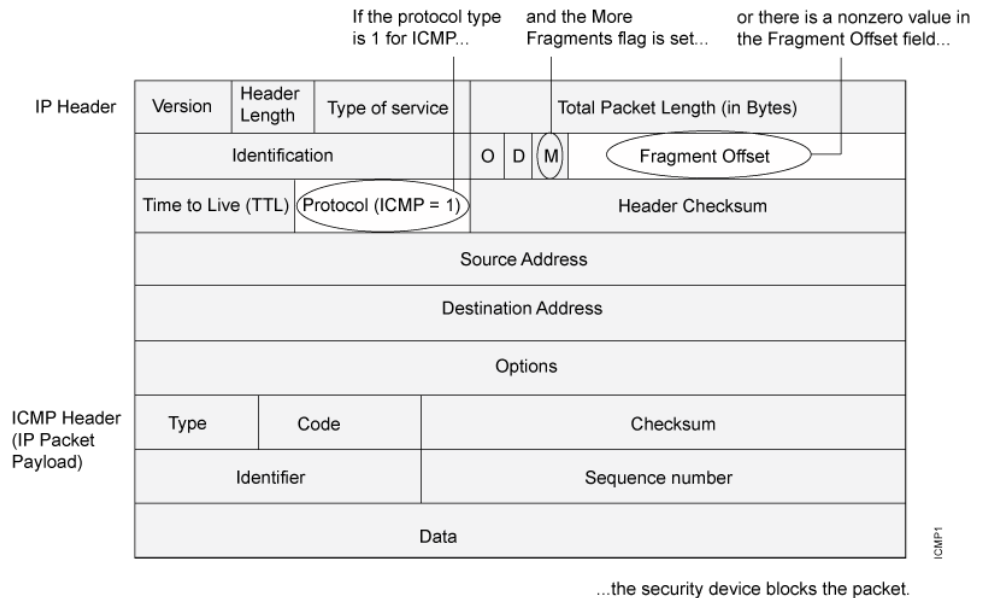

- [Understanding ICMP Fragment Protection on page 941](#)
- [Understanding Large ICMP Packet Protection on page 943](#)
- [Understanding Bad IP Option Protection on page 947](#)
- [Understanding Unknown Protocol Protection on page 949](#)
- [Understanding IP Packet Fragment Protection on page 950](#)
- [Understanding SYN Fragment Protection on page 944](#)

Understanding ICMP Fragment Protection

Internet Control Message Protocol (ICMP) provides error reporting and network probe capabilities. Because ICMP packets contain very short messages, there is no legitimate reason for ICMP packets to be fragmented. If an ICMP packet is so large that it must be fragmented, something is amiss.

When you enable the ICMP fragment protection screen option, Junos OS blocks any ICMP packet that has the More Fragments flag set or that has an offset value indicated in the offset field. See [Figure 56](#).

Figure 56: Blocking ICMP Fragments

NOTE: Junos OS supports ICMP fragment protection for ICMPv6 packets.

Example: Blocking Fragmented ICMP Packets

This example shows how to block fragmented ICMP packets.

Requirements

Before you begin, Understand ICMP fragment protection. See [“Suspicious Packet Attributes Overview”](#) on page 941.

Overview

When you enable the ICMP fragment protection screen option, Junos OS blocks any ICMP packet that has the more fragments flag set or that has an offset value indicated in the offset field.

In this example, you configure the ICMP fragment screen to block fragmented ICMP packets originating from the zone1 security zone.

Configuration

Step-by-Step Procedure To block fragmented ICMP packets:

1. Configure the screen.

```
[edit]
user@host# set security screen ids-option icmp-fragment icmp fragment
```

2. Configure a security zone.

```
[edit]
user@host# set security zones security-zone zone1 screen icmp-fragment
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

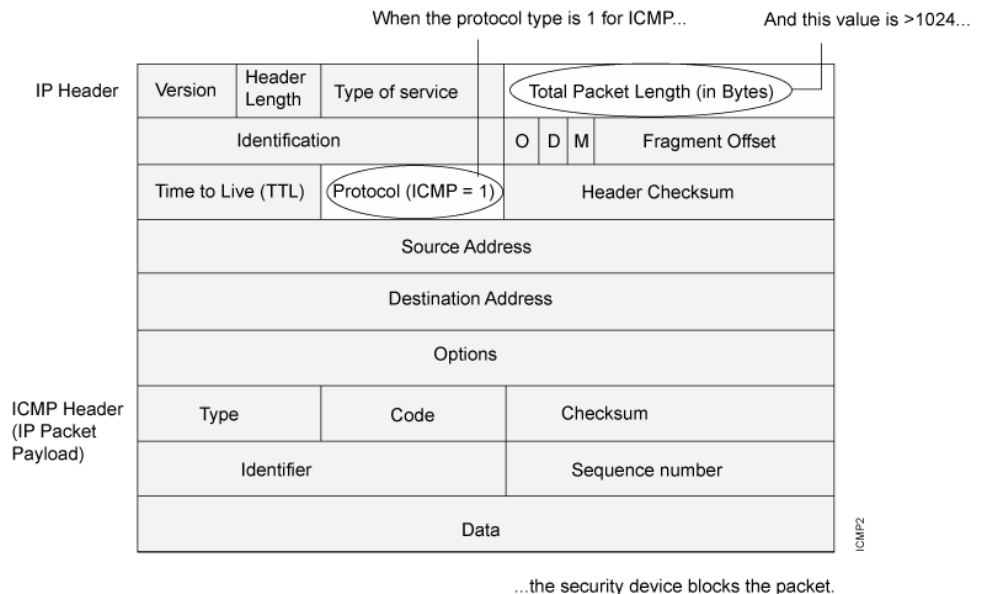

To verify the configuration is working properly, enter the **show security screen statistics zone zone-name** command.

Understanding Large ICMP Packet Protection

Internet Control Message Protocol (ICMP) provides error reporting and network probe capabilities. Because ICMP packets contain very short messages, there is no legitimate reason for large ICMP packets. If an ICMP packet is unusually large, something is amiss.

For example, the SRX 210 uses ICMP as a channel for transmitting covert messages. The presence of large ICMP packets might expose a compromised machine acting as a SRX 210 agent. It also might indicate some other kind of questionable activity. See [Figure 57](#).

Figure 57: Blocking Large ICMP Packets

When you enable the large size ICMP packet protection screen option, Junos OS drops ICMP packets with a length greater than 1024 bytes.

NOTE: Junos OS supports large ICMP packet protection for both ICMP and ICMPv6 packets.

Example: Blocking Large ICMP Packets

This example shows how to block large ICMP packets.

Requirements

Before you begin, Understand large ICMP packet protection. See [“Suspicious Packet Attributes Overview”](#) on page 941.

Overview

When you enable the large ICMP packet protection screen option, Junos OS drops ICMP packets that are larger than 1024 bytes.

In this example, you configure the ICMP large screen to block large ICMP packets originating from the zone1 security zone.

Configuration

Step-by-Step Procedure

To block large ICMP packets:

1. Configure the screen.

```
[edit]
user@host# set security screen ids-option icmp-large icmp large
```

2. Configure a security zone.

```
[edit]
user@host# set security zones security-zone zone1 screen icmp-large
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

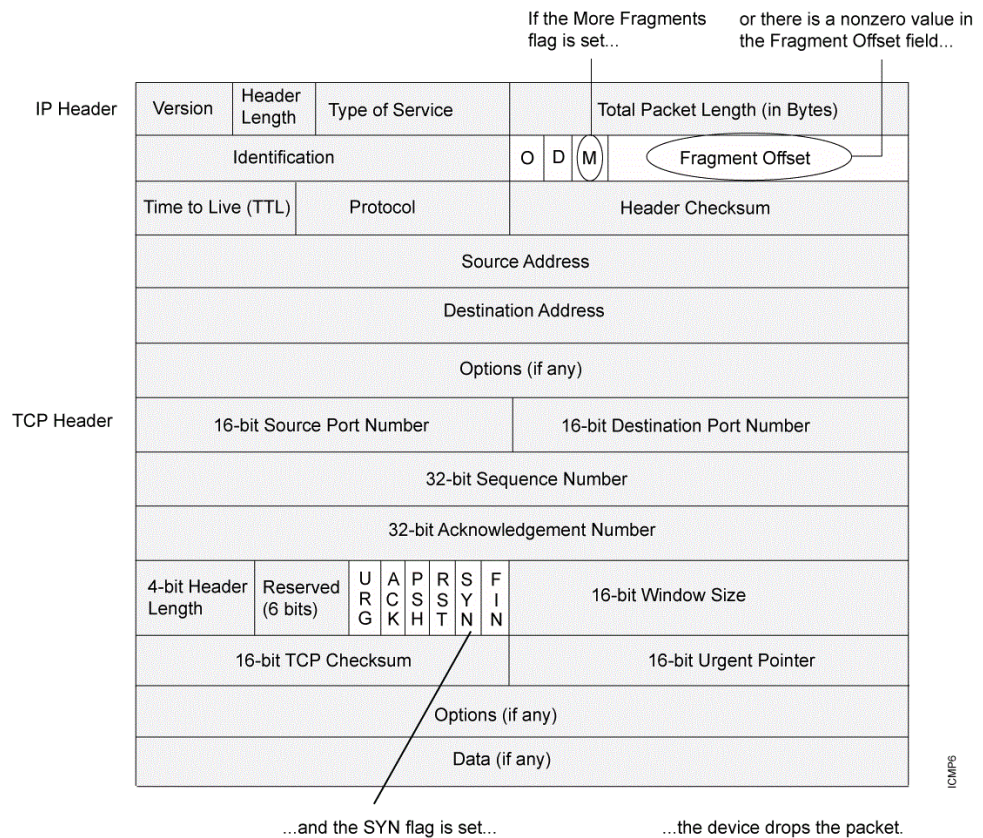

To verify the configuration is working properly, enter the **show security screen statistics zone zone-name** command.

Understanding SYN Fragment Protection

The IP encapsulates a TCP SYN segment in the IP packet that initiates a TCP connection. Because the purpose of this packet is to initiate a connection and invoke a SYN/ACK segment in response, the SYN segment typically does not contain any data. Because the IP packet is small, there is no legitimate reason for it to be fragmented.

A fragmented SYN packet is anomalous, and, as such, it is suspect. To be cautious, block such unknown elements from entering your protected network. See [Figure 58](#).

Figure 58: SYN Fragments

When you enable the SYN fragment detection screen option, Junos OS detects packets when the IP header indicates that the packet has been fragmented and the SYN flag is set in the TCP header. Junos OS records the event in the screen counters list for the ingress interface.

NOTE: Junos OS supports SYN fragment protection for both IPv4 and IPv6 packets.

Example: Dropping IP Packets Containing SYN Fragments

This example shows how to drop IP packets containing SYN fragments.

Requirements

Before you begin, Understand IP packet fragment protection. See [“Suspicious Packet Attributes Overview”](#) on page 941.

Overview

When you enable the SYN fragment detection screen option, Junos OS detects packets when the IP header indicates that the packet has been fragmented and the SYN flag is

set in the TCP header. Also, Junos OS records the event in the screen counters list for the ingress interface.

In this example, you configure the SYN fragment screen to drop fragmented SYN packets originating from the zone1 security zone.

Configuration

Step-by-Step Procedure

To drop IP packets containing SYN fragments:

1. Configure the screen.

```
[edit]  
user@host# set security screen ids-option syn-frag tcp syn-frag
```

2. Configure the security zone.

```
[edit]  
user@host# set security zones security-zone zone1 screen syn-frag
```

3. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security screen statistics zone *zone-name*** command.

Protecting Against IP Attacks

- [Example: Dropping Packets Using an Unknown Protocol on page 950](#)
- [Understanding IP Packet Fragment Protection on page 950](#)
- [Example: Dropping Fragmented IP Packets on page 951](#)

Understanding Bad IP Option Protection

The IP standard RFC 791, *Internet Protocol*, specifies a set of eight options that provide special routing controls, diagnostic tools, and security. Although the original, intended uses for these options served worthy ends, people have figured out ways to twist these options to accomplish less commendable objectives.

Either intentionally or accidentally, attackers sometimes configure IP options incorrectly, producing either incomplete or malformed fields. Regardless of the intentions of the person who crafted the packet, the incorrect formatting is anomalous and potentially harmful to the intended recipient. See [Figure 59](#).

Figure 59: Incorrectly Formatted IP Options

If the IP options are incorrectly formatted, the security device records the event in the screen counters for the ingress interface.

When you enable the bad IP option protection screen option, Junos OS blocks packets when any IP option in the IP packet header is incorrectly formatted. Additionally, Junos OS records the event in the event log.

NOTE: Junos OS supports bad IP option protection for both IPv4 and IPv6 packets.

Example: Blocking IP Packets with Incorrectly Formatted Options

This example shows how to block large ICMP packets with incorrectly formatted options.

Requirements

Before you begin, Understand bad IP option protection. See [“Suspicious Packet Attributes Overview” on page 941](#).

Overview

When you enable the bad IP option protection screen option, Junos OS blocks packets when any IP option in the IP packet header is incorrectly formatted. Additionally, Junos OS records the event in the event log.

In this example, you configure the IP bad option screen to block large ICMP packets originating from the zone1 security zone.

Configuration

Step-by-Step Procedure

To detect and block IP packets with incorrectly formatted IP options:

1. Configure the screen.

[edit]

```
user@host# set security screen ids-option ip-bad-option ip bad-option
```

NOTE: Currently this screen option is applicable only to IPv4.

2. Configure a security zone.

```
[edit]
```

```
user@host# set security zones security-zone zone1 screen ip-bad-option
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
```

```
user@host# commit
```

Verification

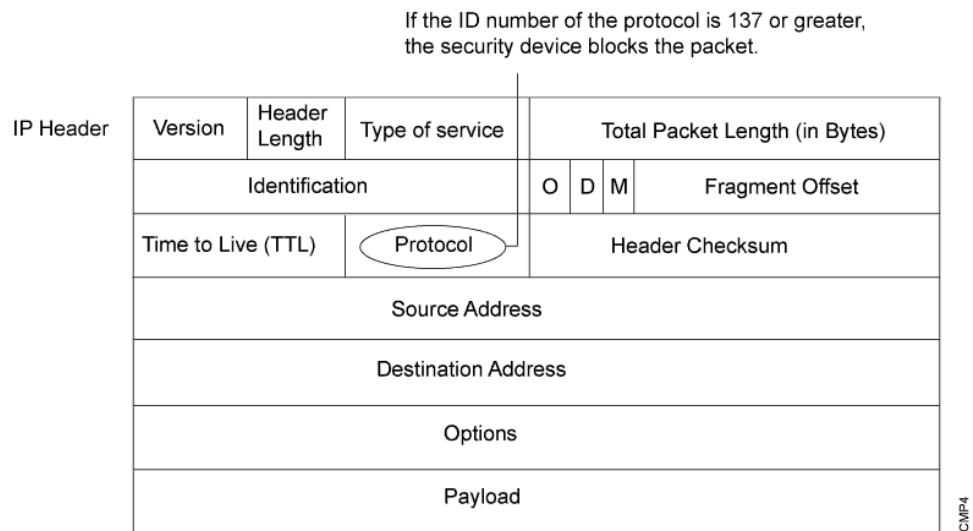

To verify the configuration is working properly, enter the **show security screen statistics zone zone-name** command.

Understanding Unknown Protocol Protection

Based on RFC 1700, the protocol types with ID numbers of 137 or greater are reserved and undefined at this time. Precisely because these protocols are undefined, there is no way to know in advance if a particular unknown protocol is benign or malicious.

Unless your network makes use of a nonstandard protocol with an ID number of 137 or greater, a cautious stance is to block such unknown elements from entering your protected network. See [Figure 60](#).

Figure 60: Unknown Protocols

When you enable the unknown protocol protection screen option, Junos OS drops packets when the protocol field contains a protocol ID number of 137 or greater by default.

NOTE: When you enable the unknown protocol protection screen option for IPv6 protocol, Junos OS drops packets when the protocol field contains a protocol ID number of 139 or greater by default.

Example: Dropping Packets Using an Unknown Protocol

This example shows how to drop packets using an unknown protocol.

Requirements

Before you begin, Understand unknown protocol protection. See [“Suspicious Packet Attributes Overview” on page 941](#).

Overview

When you enable the unknown protocol protection screen option, Junos OS drops packets when the protocol field contains a protocol ID number of 137 or greater by default.

In this example, you configure the unknown protocol screen to block packets with an unknown protocol originating from the zone1 security zone.

Configuration

Step-by-Step Procedure

To drop packets that use an unknown protocol:

1. Configure the unknown protocol screen.

```
[edit]  
user@host# set security screen ids-option unknown-protocol ip unknown-protocol
```
2. Configure a security zone.

```
[edit]  
user@host# set security zones security-zone zone1 screen unknown-protocol
```
3. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

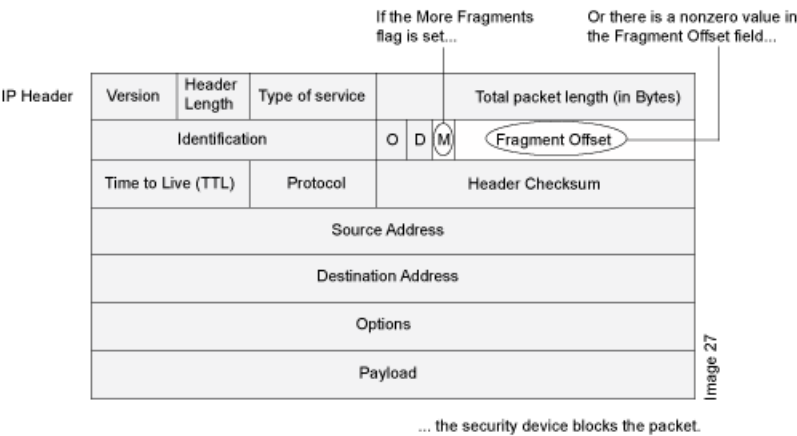

To verify the configuration is working properly, enter the **show security screen statistics zone zone-name** command.

Understanding IP Packet Fragment Protection

As packets traverse different networks, it is sometimes necessary to break a packet into smaller pieces (fragments) based upon the maximum transmission unit (MTU) of each network. IP fragments might contain an attacker's attempt to exploit the vulnerabilities in the packet reassembly code of specific IP stack implementations. When the victim

receives these packets, the results can range from processing the packets incorrectly to crashing the entire system. See [Figure 61](#).

Figure 61: IP Packet Fragments

When you enable Junos OS to deny IP fragments on a security zone, it blocks all IP packet fragments that it receives at interfaces bound to that zone.

NOTE: Junos OS supports IP fragment protection for both IPv4 and IPv6 packets.

In IPv6 packets, fragment information is not present in the IPv6 header. The fragment information is present in the fragment extension header, which is responsible for IPv6 fragmentation and reassembly. The source node inserts the fragment extension header between the IPv6 header and the payload header if fragmentation is required. See [Figure 62](#).

Figure 62: IPv6 Packet

The general format of the fragment extension header is shown in [Figure 63](#).

Figure 63: Fragment Extension Header

FRAGMENT EXTENSION HEADER FORMAT																																
Offsets	Octet	0							1							2							3									
Octet	Bit	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0	0	Next Header							Reserved							Fragment Offset							Res M									
4	32	Identification																														

Example: Dropping Fragmented IP Packets

This example shows how to drop fragmented IP packets.

Requirements

Before you begin, Understand IP packet fragment protection. See [“Suspicious Packet Attributes Overview” on page 941](#).

Overview

When this feature is enabled, Junos OS denies IP fragments on a security zone and blocks all IP packet fragments that are received at interfaces bound to that zone.

In this example, you configure the block fragment screen to drop fragmented IP packets originating from the zone1 security zone.

Configuration

Step-by-Step Procedure

To drop fragmented IP packets:

1. Configure the screen.

```
[edit]
user@host# set security screen ids-option block-frag ip block-frag
```

2. Configure the security zone.

```
[edit]
user@host# set security zones security-zone zone1 screen block-frag
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security screen statistics zone *zone-name*** command.

Security Configuration Statement Hierarchy

Use the statements in the **security** configuration hierarchy to configure actions, certificates, dynamic virtual private networks (VPNs), firewall authentication, flow, forwarding options, group VPNs, Intrusion Detection Prevention (IDP), Internet Key Exchange (IKE), Internet Protocol Security (IPsec), logging, Network Address Translation (NAT), public key infrastructure (PKI), policies, resource manager, rules, screens, secure shell known hosts, trace options, user identification, Unified Threat Management (UTM), and zones. Statements that are exclusive to the SRX Series devices running Junos OS are described in this section.

Each of the following topics lists the statements at a sub-hierarchy of the **[edit security]** hierarchy.

fin-no-ack

Syntax	<code>fin-no-ack;</code>
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Enable detection of an illegal combination of flags, and reject packets that have this combination.
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Attack Detection and Prevention Overview on page 813 • Example: Configuring Multiple Screening Options on page 827 • Security Configuration Statement Hierarchy on page 595

flood (Security ICMP)

Syntax	flood { threshold <i>number</i> ; }
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> icmp]
Release Information	Statement modified in Junos OS Release 9.2.
Description	Configure the device to detect and prevent Internet Control Message Protocol (ICMP) floods. An ICMP flood occurs when ICMP echo requests are broadcast with the purpose of flooding a system with so much data that it first slows down, and then times out and is disconnected. The threshold defines the number of ICMP packets per second allowed to ping the same destination address before the device rejects further ICMP packets.
Options	<p>threshold <i>number</i> —Number of ICMP packets per second allowed to ping the same destination address before the device rejects further ICMP packets.</p> <p>Range: 1 through 1,000,000 per second</p> <p>Default: 1,000 per second</p>
<div>  <p>NOTE: For SRX Series devices the applicable range is 1 through 4,000,000 per second.</p> </div>	
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

Hierarchy Level [edit security screen]

Release Information Statement introduced in Junos OS Release 8.5. Support for the **description** option added in Junos OS Release 12.1. UDP supports **port-scan** option starting from Junos OS Release 12.1X47-D10.

Description Define screens for the intrusion detection service (IDS).

Options **description text**—Descriptive text about a screen.

loose-source-route-option—The device detects packets where the IP option is 3 (Loose Source Routing) and records the event in the screen counters list for the ingress interface. This option specifies a partial route list for a packet to take on its journey from source to destination. The packet must proceed in the order of addresses specified, but it is allowed to pass through other devices in between those specified.

source-route-option—Enable this option to block all IP traffic that employs the loose or strict source route option. Source route options can allow an attacker to enter a network with a false IP address.

strict-source-route-option—The device detects packets where the IP option is 9 (Strict Source Routing) and records the event in the screen counters list for the ingress interface. This option specifies the complete route list for a packet to take on its journey from source to destination. The last address in the list replaces the address in the destination field. Currently, this screen option is applicable to IPv4 only.

NOTE: Loose source route option and strict source route option will only alarm and will not be dropped when there is overflow of traffic. When only IP source option is configured, the attacked packets are dropped.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

}  
}
```

Hierarchy Level [edit security screen ids-option *screen-name*]

Release Information Statement introduced in Junos OS Release 8.5. Support for IPv6 bad-option extension header screens added in Junos OS Release 12.1X46-D10.

Description Configure IP layer IDS options.

- Options**
- **bad-option**—Detect and drop any packet with an incorrectly formatted IP option in the IP packet header. The device records the event in the screen counters list for the ingress interface. This screen option is applicable to IPv4 and IPv6.
 - **block-frag**—Enable IP packet fragmentation blocking.
 - **loose-source-route-option**—Detect packets where the IP option is 3 (loose source routing), and record the event in the screen counters list for the ingress interface. This option specifies a partial route list for a packet to take on its journey from source to destination. The packet must proceed in the order of addresses specified, but it is allowed to pass through other devices in between those specified. The type 0 routing header of the loose source route option is the only related header defined in IPv6 .
 - **record-route-option**—Detect packets where the IP option is 7 (record route), and record the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
 - **security-option**—Detect packets where the IP option is 2 (security), and record the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
 - **source-route-option**—Detect packets, and record the event in the screen counters list for the ingress interface.
 - **spoofing**—Prevent spoofing attacks. Spoofing attacks occur when unauthorized agents attempt to bypass firewall security by imitating valid client IP addresses. Using the spoofing option invalidates such false source IP address connections.

The default behavior is to base spoofing decisions on individual interfaces.
 - **stream-option**—Detect packets where the IP option is 8 (stream ID), and record the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
 - **strict-source-route-option**—Detect packets where the IP option is 9 (strict source routing), and record the event in the screen counters list for the ingress interface. This option specifies the complete route list for a packet to take on its journey from source to destination. The last address in the list replaces the address in the destination field. Currently, this screen option is applicable only to IPv4.
 - **tear-drop**—Block the teardrop attack. Teardrop attacks occur when fragmented IP packets overlap and cause the host attempting to reassemble the packets to crash. The teardrop option directs the device to drop any packets that have such a discrepancy.
 - **timestamp-option**—Detect packets where the IP option list includes option 4 (Internet timestamp), and record the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
 - **unknown-protocol**—Discard all received IP frames with protocol numbers greater than 137 for IPv4 and 139 for IPv6. Such protocol numbers are undefined or reserved.

Required Privilege	security—To view this statement in the configuration.
Level	security-control—To add this statement to the configuration.

ip-sweep

Syntax	ip-sweep { threshold <i>number</i> ; }
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> icmp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure the device to detect and prevent an IP Sweep attack. An IP Sweep attack occurs when an attacker sends ICMP echo requests (pings) to multiple destination addresses. If a target host replies, the reply reveals the target's IP address to the attacker. If the device receives 10 ICMP echo requests within the number of microseconds specified in this statement, it flags this as an IP Sweep attack, and rejects the 11th and all further ICMP packets from that host for the remainder of the second.
Options	<p>threshold <i>number</i>—Maximum number of microseconds during which up to 10 ICMP echo requests from the same host are allowed into the device. More than 10 requests from a host during this period triggers an IP Sweep attack response on the device during the remainder of the second.</p> <p>Range: 1000 through 1,000,000 microseconds</p> <p>Default: 5000 microseconds</p>
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Attack Detection and Prevention Overview on page 813 • Example: Configuring Multiple Screening Options on page 827 • Security Configuration Statement Hierarchy on page 595

ip-in-udp

Syntax	<pre>ip-in-udp { teredo; }</pre>
Hierarchy Level	[edit security screen ids-option <i>ids-option-name</i> ip tunnel]
Release Information	Statement introduced in Junos OS Release 12.3X48-D10.
Description	Configure IP tunnel IPinUDP IDS option.
Options	teredo — Enable IP tunnel IPinUDP Teredo IDS option.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Security Configuration Statement Hierarchy on page 595

land

Syntax	<pre>land;</pre>
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Enable prevention of Land attacks by combining the SYN flood defense with IP spoofing protection. Land attacks occur when an attacker sends spoofed IP packets with headers containing the target's IP address for the source and destination IP addresses. The attacker sends these packets with the SYN flag set to any available port. The packets induce the target to create empty sessions with itself, filling its session table and overwhelming its resources.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827• Security Configuration Statement Hierarchy on page 595

large

Syntax	large;
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> icmp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure the device to detect and drop any ICMP frame with an IP length greater than 1024 bytes.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

limit-session

Syntax	limit-session { destination-ip-based <i>number</i> ; source-ip-based <i>number</i> ; }
Hierarchy Level	[edit security screen ids-option <i>screen-name</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Limit the number of concurrent sessions the device can initiate from a single source IP address or the number of sessions it can direct to a single destination IP address.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Attack Detection and Prevention Overview on page 813 • Example: Configuring Multiple Screening Options on page 827 • Security Configuration Statement Hierarchy on page 595

no-syn-check

Syntax	no-syn-check;
Hierarchy Level	[edit security flow tcp-session]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Disable checking of the TCP SYN bit before creating a session. By default, the device checks that the SYN bit is set in the first packet of a session. If the bit is not set, the device drops the packet.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827

no-syn-check-in-tunnel

Syntax	no-syn-check-in-tunnel;
Hierarchy Level	[edit security flow tcp-session]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Disable checking of the TCP SYN bit before creating a session for tunneled packets. By default, the device checks that the SYN bit is set in the first packet of a VPN session. If the bit is not set, the device drops the packet.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827

ping-death

Syntax	ping-death;
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> icmp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure the device to detect and reject oversized and irregular ICMP packets. Although the TCP/IP specification requires a specific packet size, many ping implementations allow larger packet sizes. Larger packets can trigger a range of adverse system reactions, including crashing, freezing, and restarting.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827• Security Configuration Statement Hierarchy on page 595

port-scan

Syntax	<pre>port-scan { threshold <i>number</i>; }</pre>
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	<p>Prevent port scan attacks. A port scan attack occurs when an attacker sends packets with different port numbers to scan available services. The attack succeeds if a port responds. To prevent this attack, the device internally logs the number of different ports scanned from a single remote source. For example, if a remote host scans 10 ports in 0.005 seconds (equivalent to 5000 microseconds, the default threshold setting), the device flags this behavior as a port scan attack, and rejects further packets from the remote source.</p>
Options	<p>threshold <i>number</i> —Number of microseconds during which the device accepts packets from the same remote source with up to 10 different port numbers. If the number of ports during the threshold period reaches 10 or more, the device rejects additional packets from the source.</p> <p>Range: 1000 through 1,000,000 microseconds</p> <p>Default: 5000 microseconds</p>
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827• Security Configuration Statement Hierarchy on page 595

screen (Security Zones)

Syntax	<code>screen <i>screen-name</i>;</code>
Hierarchy Level	[edit security zones functional-zone management], [edit security zones security-zone <i>zone-name</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify a security screen for a security zone.
Options	<i>screen-name</i> —Name of the screen.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Attack Detection and Prevention Overview on page 813 • Example: Configuring Multiple Screening Options on page 827

source-ip-based

Syntax	<code>source-ip-based <i>number</i>;</code>
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> limit-session]
Release Information	Statement modified in Junos OS Release 9.2.
Description	Limit the number of concurrent sessions the device can initiate from a single source IP address.
Options	<i>number</i> —Maximum number of concurrent sessions that can be initiated from a source IP address. Range: 1 through 1,000,000 Default: 128

NOTE: For SRX Series devices the applicable range is 1 through 8,000,000.

Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Attack Detection and Prevention Overview on page 813 • Example: Configuring Multiple Screening Options on page 827 • Security Configuration Statement Hierarchy on page 595

source-threshold

Syntax	source-threshold <i>number</i> ;
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp syn-flood]
Release Information	Statement modified in Junos OS Release 9.2.
Description	Specify the number of SYN segments that the device can receive per second from a single source IP address (regardless of the destination IP address and port number) before the device begins dropping connection requests from that source.
Options	<p><i>number</i> —Number of SYN segments to be received per second before the device starts dropping connection requests.</p> <p>Range: 4 through 500,000 per second</p> <p>Default: 4000 per second</p>

NOTE: For SRX Series devices the applicable range is 4 through 1,000,000 per second.

Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Attack Detection and Prevention Overview on page 813 • Example: Configuring Multiple Screening Options on page 827 • Security Configuration Statement Hierarchy on page 595

strict-syn-check

Syntax	strict-syn-check;
Hierarchy Level	[edit security flow tcp-session]
Release Information	Statement introduced in Junos OS Release 9.4.
Description	Enable the strict three-way handshake check for the TCP session. It enhances security by dropping data packets before the three-way handshake is done. By default, strict-syn-check is disabled.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Attack Detection and Prevention Overview on page 813 • Example: Configuring Multiple Screening Options on page 827

syn-ack-ack-proxy

Syntax	syn-ack-ack-proxy; { threshold <i>number</i> , }
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5; support for IPv6 addresses added in Junos OS Release 10.4.
Description	Prevent the SYN-ACK-ACK attack, which occurs when the attacker establishes multiple telnet sessions without allowing each session to terminate. This behavior consumes all open slots, generating a denial-of-service (DoS) condition.
Options	threshold <i>number</i> — Number of connections from any single IP address. Range: 1 through 250,000 Default: 512
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827• Security Configuration Statement Hierarchy on page 595

syn-check-required

Syntax	syn-check-required;
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit tcp-options]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Enable sync check per policy. The syn-check-required value overrides the global value no-syn-check.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827

syn-fin

Syntax	syn-fin;
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Enable detection of an illegal combination of flags that attackers can use to consume sessions on the target device, thus resulting in a denial-of-service (DoS) condition.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827• Security Configuration Statement Hierarchy on page 595

syn-flood

Syntax	<pre> syn-flood { alarm-threshold <i>number</i>; attack-threshold <i>number</i>; destination-threshold <i>number</i>; source-threshold <i>number</i>; timeout <i>seconds</i>; white-list <i>name</i> { destination-address <i>destination-address</i>; source-address <i>source-address</i>; } } </pre>
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure detection and prevention of SYN flood attacks. Such attacks occur when the connecting host continuously sends TCP SYN requests without replying to the corresponding ACK responses.
<div>  <p>NOTE: On all SRX Series devices, the TCP synchronization flood alarm threshold value does not indicate the number of packets dropped, however the value does show the packet information after the alarm threshold has been reached.</p> <p>The synchronization cookie or proxy never drops packets; therefore the alarm-without-drop (not drop) action is shown in the system log.</p> </div>	
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> Security Configuration Statement Hierarchy on page 595

syn-flood-protection-mode

Syntax	syn-flood-protection-mode (syn-cookie syn-proxy);
Hierarchy Level	[edit security flow]
Release Information	Statement introduced in Junos OS Release 8.5; support for IPv6 addresses added in Junos OS Release 10.4.
Description	Enable SYN cookie or SYN proxy defenses against SYN attacks. SYN flood protection mode is enabled globally on the device and is activated when the configured syn-flood attack-threshold value is exceeded.
Options	<ul style="list-style-type: none"> • syn-cookie—Uses a cryptographic hash to generate a unique Initial Sequence Number (ISN). This is enabled by default. • syn-proxy—Uses a proxy to handle the SYN attack.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

syn-frag

Syntax	syn-frag;
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Enable detection of a SYN fragment attack and drops any packet fragments used for the attack. A SYN fragment attack floods the target host with SYN packet fragments. The host caches these fragments, waiting for the remaining fragments to arrive so it can reassemble them. The flood of connections that cannot be completed eventually fills the host's memory buffer. No further connections are possible, and damage to the host's operating system can occur.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Configuration Statement Hierarchy on page 595

tcp (Security Screen)

```
Syntax  tcp {
        fin-no-ack;
        land;
        port-scan {
            threshold number;
        }
        syn-ack-ack-proxy {
            threshold number;
        }
        syn-fin;
        syn-flood {
            alarm-threshold number;
            attack-threshold number;
            destination-threshold number;
            source-threshold number;
            timeout seconds;
            white-list name {
                destination-address destination-address;
                source-address source-address;
            }
        }
        syn-frag;

        tcp-sweep {
            threshold threshold number;
        }
        winnuke;
    }
```

Hierarchy Level [edit security screen ids-option *screen-name*]

Release Information Statement introduced in Junos OS Release 8.5.

Description Configure TCP-layer intrusion detection service (IDS) options.

NOTE: On all SRX Series devices, the TCP synchronization flood alarm threshold value does not indicate the number of packets dropped, however the value does show the packet information after the alarm threshold has been reached.

The synchronization cookie or proxy never drops packets; therefore the **alarm-without-drop (not drop)** action is shown in the system log.

Options The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Related Documentation • [Security Configuration Statement Hierarchy on page 595](#)

tcp-no-flag

Syntax	tcp-no-flag;
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Enable the device to drop illegal TCP packets with a missing or malformed flag field.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	• Security Configuration Statement Hierarchy on page 595

tcp-sweep

Syntax	tcp-sweep { threshold <i>number</i> ; }
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp]
Release Information	Statement introduced in Junos OS Release 10.2.
Description	<p>Configure the device to detect and prevent TCP sweep attack. In a TCP sweep attack, an attacker sends TCP SYN packets to the target device as part of the TCP handshake. If the device responds to those packets, the attacker gets an indication that a port in the target device is open, which makes the port vulnerable to attack. If a remote host sends TCP packets to 10 addresses in 0.005 seconds (5000 microseconds), then the device flags this as a TCP sweep attack.</p> <p>If the alarm-without-drop option is not set, the device rejects the eleventh and all further TCP packets from that host for the remainder of the specified threshold period.</p>
Options	<p>threshold <i>number</i>—Maximum number of microseconds during which up to 10 TCP SYN packets from the same host are allowed into the device. More than 10 requests from a host during this period triggers TCP Sweep attack response on the router during the remainder of the second.</p> <p>Range: 1000 through 1,000,000 microseconds</p> <p>Default: 5000 microseconds</p>
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827• Security Configuration Statement Hierarchy on page 595

timeout (Security Screen)

Syntax	<code>timeout <i>seconds</i>;</code>
Hierarchy Level	[edit security screen ids-option <i>screen-name</i> tcp syn-flood]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the maximum length of time before a half-completed connection is dropped from the queue. You can decrease the timeout value until you see any connections dropped during normal traffic conditions.
Options	<i>seconds</i> —Time interval before a half-completed connection is dropped from the queue. Range: 1 through 50 seconds Default: 20 seconds
Required Privilege Level	security —To view this statement in the configuration. security-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Attack Detection and Prevention Overview on page 813• Example: Configuring Multiple Screening Options on page 827• Security Configuration Statement Hierarchy on page 595

traceoptions (Security Screen)

Syntax	<pre> traceoptions { file { filename; files number; match regular-expression; size maximum-file-size; (world-readable no-world-readable); } flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit security screen]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	<p>Configure screen tracing options.</p> <p>To specify more than one tracing option, include multiple flag statements.</p>
Options	<ul style="list-style-type: none"> • file—Configure the trace file options. <ul style="list-style-type: none"> • filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log. By default, the name of the file is the name of the process being traced. • files number—Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed to trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten. <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> • match regular-expression—Refine the output to include lines that contain the regular expression. • size maximum-file-size—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named trace-file reaches this size, it is renamed trace-file.0. When the trace-file again reaches its maximum size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten. <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the files option and a filename.</p> <p>Syntax: x K to specify KB, x m to specify MB, or x g to specify GB</p>

Range: 10 KB through 1 GB

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.
 - **all**—Trace all screen events
 - **configuration**—Trace screen configuration events
 - **flow**—Trace flow events
- **no-remote-trace**—Set remote tracing as disabled.

Required Privilege Level trace—To view this statement in the configuration.
 trace-control—To add this statement to the configuration.

udp (Security Screen)

Syntax	<pre> udp { flood { threshold <i>number</i>; } udp-sweep { threshold <i>threshold number</i>; } } </pre>
Hierarchy Level	[edit security screen ids-option <i>screen-name</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the number of packets allowed per second to the same destination IP address/port pair. When the number of packets exceeds this value within any 1-second period, the device generates an alarm and drops subsequent packets for the remainder of that second.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

CHAPTER 44

Operational Commands

- `clear security screen statistics`
- `clear security screen statistics interface`
- `clear security screen statistics zone`
- `show security screen ids-option`
- `show security screen statistics`
- `show security screen status`

clear security screen statistics

Syntax	clear security screen statistics <node (<i>node-id</i> all local primary)>
Release Information	Command introduced in Junos OS Release 9.0.
Description	Clear intrusion detection service (IDS) security screen statistics on the device.
Options	<p>node—(Optional) For chassis cluster configurations, clear security screen statistics on a specific node.</p> <ul style="list-style-type: none">• <i>node-id</i> —Identification number of the node. It can be 0 or 1.• all —Clear all nodes.• local —Clear the local node.• primary—Clear the primary node.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show security screen statistics on page 1012• Example: Configuring Multiple Screening Options on page 827
List of Sample Output	clear security screen statistics node 0 on page 1002
Output Fields	This command produces no output.

Sample Output

clear security screen statistics node 0

```
user@host> clear security screen statistics node 0
```

clear security screen statistics interface

Syntax	clear security screen statistics interface <i>interface-name</i>
Release Information	Command introduced in Junos OS Release 8.5; node options added in Junos OS Release 9.0.
Description	Clear intrusion detection service (IDS) security screen statistics for an interface.
Options	<ul style="list-style-type: none"> • interface <i>interface-name</i> —Name of the interface on which to clear security screen statistics. • node—(Optional) For chassis cluster configurations, clear security screen statistics on a specific node. <ul style="list-style-type: none"> • node-id —Identification number of the node. It can be 0 or 1. • all —Clear all nodes. • local —Clear the local node. • primary—Clear the primary node.
Required Privilege Level	clear

List of Sample Output	clear security screen statistics interface fab0 on page 1003 clear security screen statistics interface fab0 node 0 on page 1003
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

clear security screen statistics interface fab0

```

user@host> clear security screen statistics interface fab0
node0:
-----
IDS statistics has been cleared.
node1:
-----
IDS statistics has been cleared.
```

Sample Output

clear security screen statistics interface fab0 node 0

```

user@host> clear security screen statistics interface fab0 node 0
node0:
-----
IDS statistics has been cleared.
```

clear security screen statistics zone

Syntax	clear security screen statistics zone <i>zone-name</i> <node (<i>node-id</i> all local primary)>
Release Information	Command introduced in Junos OS Release 8.5; node options added in Junos OS Release 9.0.
Description	Clear IDS security screen statistics for a security zone.
Options	<ul style="list-style-type: none"> • zone <i>zone-name</i>—Name of the security zone for which to clear security screen statistics. • node—(Optional) For chassis cluster configurations, clear security screen statistics for a security zone on a specific node. <ul style="list-style-type: none"> • <i>node-id</i>—Identification number of the node. It can be 0 or 1. • all—Clear all nodes. • local—Clear the local node. • primary—Clear the primary node.

node0:
-----
IDS statistics has been cleared.
```

show security screen ids-option

Syntax	show security screen ids-option screen-name <node (<i>node-id</i> all local primary)>
Release Information	Command introduced in Junos OS Release 8.5. Support for node options added in Junos OS Release 9.0. Support for IPv6 extension header screens added in Junos OS Release 12.1X46-D10. Support for UDP port scan added in Junos OS Release 12.1X47-D10.
Description	Display configuration information about the specified security screen.
Options	<ul style="list-style-type: none"> • screen-name —Name of the screen. • node—(Optional) For chassis cluster configurations, display the configuration status of the security screen on a specific node. <ul style="list-style-type: none"> • node-id —Identification number of the node. It can be 0 or 1. • all—Display information about all nodes. • local—Display information about the local node. • primary—Display information about the primary node.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • ids-option on page 968 • Example: Configuring Multiple Screening Options on page 827
List of Sample Output	show security screen ids-option jscreen on page 1009 show security screen ids-option jscreen (IPv6) on page 1010 show security screen ids-option jscreen1 node all on page 1010
Output Fields	Table 68 lists the output fields for the show security screen ids-option command. Output fields are listed in the approximate order in which they appear.

Table 68: show security screen ids-option Output Fields

Field Name	Field Description
TCP address sweep threshold	Number of microseconds for which the device accepts 10 TCP packets from the same remote source to different destination addresses.
TCP port scan threshold	Number of microseconds during which the device accepts packets from the same remote source with up to 10 different port numbers.
ICMP address sweep threshold	Maximum number of microseconds during which up to 10 ICMP echo requests from the same host are allowed into the device.

Table 68: show security screen ids-option Output Fields (*continued*)

Field Name	Field Description
UDP flood threshold	Number of UDP packets per second allowed to ping the same destination address before the device rejects further UDP packets.
UDP port scan threshold	Number of microseconds during which the device accepts packets from the same remote source IP with up to 10 different destination port numbers.
TCP winnuke	Enable or disable the detection of TCP WinNuke attacks.
TCP SYN flood attack threshold	Number of SYN packets per second required to trigger the SYN proxy response.
TCP SYN flood alarm threshold	Number of half-complete proxy connections per second at which the device makes entries in the event alarm log.
TCP SYN flood source threshold	Number of SYN segments to be received per second before the device begins dropping connection requests.
TCP SYN flood destination threshold	Number of SYN segments received per second before the device begins dropping connection requests.
TCP SYN flood timeout	Maximum length of time before a half-completed connection is dropped from the queue.
TCP SYN flood queue size	Number of proxy connection requests that can be held in the proxy connection queue before the device begins rejecting new connection requests.
ICMP large packet	Enable or disable the detection of any ICMP frame with an IP length greater than 1024 bytes.
UDP address sweep threshold	Number of microseconds for which the device accepts 10 UDP packets from the same remote source to different destination addresses.
IPv6 extension routing	Enable or disable the IPv6 extension routing screen option.
IPv6 extension shim6	Enable or disable the IPv6 extension shim6 screen option.
IPv6 extension fragment	Enable or disable the IPv6 extension fragment screen option.
IPv6 extension AH	Enable or disable the IPv6 extension Authentication Header Protocol screen option.
IPv6 extension ESP	Enable or disable the IPv6 extension Encapsulating Security Payload screen option.
IPv6 extension mobility	Enable or disable the IPv6 extension mobility screen option.
IPv6 extension HIP	Enable or disable the IPv6 extension Host Identify Protocol screen option.
IPv6 extension no next	Enable or disable the IPv6 extension no-next screen option.
IPv6 extension user-defined	Enable or disable the IPv6 extension user-defined screen option.

Table 68: show security screen ids-option Output Fields (*continued*)

Field Name	Field Description
IPv6 extension HbyH jumbo	Enable or disable the IPv6 extension HbyH jumbo screen option.
IPv6 extension HbyH RPL	Enable or disable the IPv6 extension HbyH RPL screen option.
IPv6 extension HbyH router alert	Enable or disable the IPv6 extension HbyH router screen option.
IPv6 extension HbyH quick start	Enable or disable the IPv6 extension HbyH quick-start screen option.
IPv6 extension HbyH CALIPSO	Enable or disable the IPv6 extension HbyH Common Architecture Label IPv6 Security Screen option.
IPv6 extension HbyH SMF DPD	Enable or disable the IPv6 extension HbyH Simplified Multicast Forwarding IPv6 Duplicate Packet Detection screen option.
IPv6 extension HbyH user-defined	Enable or disable the IPv6 extension HbyH user-defined screen option.
IPv6 extension Dst tunnel encap limit	Enable or disable the IPv6 extension distributed (network) storage tunnel encapsulation limit screen option.
IPv6 extension Dst home address	Enable or disable the IPv6 extension DST home address screen option.
IPv6 extension Dst ILNP nonce	Enable or disable the IPv6 extension DST Identifier-Locator Network Protocol nonce screen option.
IPv6 extension Dst line-id	Enable or disable the IPv6 extension DST line-ID screen option.
IPv6 extension Dst user-defined	Enable or disable the IPv6 extension DST user-defined screen option.
IPv6 extension header limit	Threshold for the number of IPv6 extension headers that can pass through the screen.
IPv6 malformed header	Enable or disable the IPv6 malformed header screen option.
ICMPv6 malformed header	Enable or disable the ICMPv6 malformed packet screen option.

Sample Output

show security screen ids-option jscreen

```

user@host> show security screen ids-option jscreen
Screen object status:
Name                                     Value
TCP port scan threshold                 5000
UDP port scan threshold                 10000
ICMP address sweep threshold            5000

```

Sample Output

show security screen ids-option jscreen (IPv6)

```
user@host> show security screen ids-option jscreen
```

```
Screen object status:
```

Name	Value
ICMP ping of death	enabled
.....	
IPv6 extension routing	enabled
IPv6 extension shim6	enabled
IPv6 extension fragment	enabled
IPv6 extension AH	enabled
IPv6 extension ESP	enabled
IPv6 extension mobility	enabled
IPv6 extension HIP	enabled
IPv6 extension no next	enabled
IPv6 extension user-defined	enabled
IPv6 extension HbyH jumbo	enabled
IPv6 extension HbyH RPL	enabled
IPv6 extension HbyH router alert	enabled
IPv6 extension HbyH quick start	enabled
IPv6 extension HbyH CALIPSO	enabled
IPv6 extension HbyH SMF DPD	enabled
IPv6 extension HbyH user-defined	enabled
IPv6 extension Dst tunnel encap limit	enabled
IPv6 extension Dst home address	enabled
IPv6 extension Dst ILNP nonce	enabled
IPv6 extension Dst line-id	enabled
IPv6 extension Dst user-defined	enabled
IPv6 extension header limit	20
IPv6 Malformed header	enabled
ICMPv6 malformed packet	enabled

Sample Output

show security screen ids-option jscreen1 node all

```
user@host> show security screen ids-option jscreen1 node all
```

```
node0:
```

```
Screen object status:
```

Name	Value
UDP flood threshold	1000
TCP winnuke	enabled
TCP SYN flood attack threshold	200
TCP SYN flood alarm threshold	512
TCP SYN flood source threshold	4000
TCP SYN flood destination threshold	4000
TCP SYN flood timeout	20
TCP SYN flood queue size	1024
ICMP large packet	enabled

```
node1:
```

```
Screen object status:
```

Name	Value
UDP flood threshold	1000

TCP winnuke	enabled
TCP SYN flood attack threshold	200
TCP SYN flood alarm threshold	512
TCP SYN flood source threshold	4000
TCP SYN flood destination threshold	4000
TCP SYN flood timeout	20
TCP SYN flood queue size	1024
ICMP large packet	enabled

show security screen statistics

Syntax	show security screen statistics (zone <i>zone-name</i> interface <i>interface-name</i>) <logical-system (<i>logical-system-name</i> all)> <node (<i>node-id</i> all local primary)> <root-logical-system>
Release Information	Command introduced in Junos OS Release 8.5. node options added in Junos OS Release 9.0. logical-system all option added in Junos OS Release 11.2R6. Support for IPv6 extension header screens added in Junos OS Release 12.1X46-D10.
Description	Display intrusion detection service (IDS) security screen statistics.
Options	<ul style="list-style-type: none"> • zone <i>zone-name</i>—Display screen statistics for this security zone. • interface <i>interface-name</i>—Display screen statistics for this interface. • logical-system—(Optional) Display screen statistics for configured logical systems. <ul style="list-style-type: none"> • <i>logical-system-name</i>—Display screen statistics for the named logical system. • all—Display screen statistics for all logical systems, including the master (root) logical system. • node—(Optional) For chassis cluster configurations, display screen statistics on a specific node. <ul style="list-style-type: none"> • <i>node-id</i>—Identification number of a node. It can be 0 or 1. • all—Display information about all nodes. • local—Display information about the local node. • primary—Display information about the primary node. • root-logical-system—(Optional) Display screen statistics for the master logical system only.
Required Privilege Level	view

Output Fields Table 69 lists the output fields for the **show security screen statistics** command. Output fields are listed in the approximate order in which they appear.

Table 69: show security screen statistics Output Fields

Field Name	Field Description
ICMP flood	Internet Control Message Protocol (ICMP) flood counter. An ICMP flood typically occurs when ICMP echo requests use all resources in responding, such that valid network traffic can no longer be processed.
UDP flood	User Datagram Protocol (UDP) flood counter. UDP flooding occurs when an attacker sends IP packets containing UDP datagrams with the purpose of slowing down the resources, such that valid connections can no longer be handled.
TCP winnuke	Number of Transport Control Protocol (TCP) WinNuke attacks. WinNuke is a denial-of-service (DoS) attack targeting any computer on the Internet running Windows.
TCP port scan	Number of TCP port scans. The purpose of this attack is to scan the available services in the hopes that at least one port will respond, thus identifying a service to target.
ICMP address sweep	Number of ICMP address sweeps. An IP address sweep can occur with the intent of triggering responses from active hosts.
IP tear drop	Number of teardrop attacks. Teardrop attacks exploit the reassembly of fragmented IP packets.
TCP SYN flood	Number of TCP SYN attacks.
IP spoofing	Number of IP spoofs. IP spoofing occurs when an invalid source address is inserted in the packet header to make the packet appear to come from a trusted source.
ICMP ping of death	ICMP ping of death counter. Ping of death occurs when IP packets are sent that exceed the maximum legal length (65,535 bytes).
IP source route option	Number of IP source route attacks.
TCP address sweep	Number of TCP address sweeps.
TCP land attack	Number of land attacks. Land attacks occur when an attacker sends spoofed SYN packets containing the IP address of the victim as both the destination and source IP address.
TCP SYN fragment	Number of TCP SYN fragments.
TCP no flag	Number of TCP headers without flags set. A normal TCP segment header has at least one control flag set.
IP unknown protocol	Number of IPs.
IP bad options	Number of invalid options.
IP record route option	Number of packets with the IP record route option enabled. This option records the IP addresses of the network devices along the path that the IP packet travels.

Table 69: show security screen statistics Output Fields (*continued*)

Field Name	Field Description
IP timestamp option	Number of IP timestamp option attacks. This option records the time (in Universal Time) when each network device receives the packet during its trip from the point of origin to its destination.
IP security option	Number of IP security option attacks.
IP loose source route option	Number of IP loose source route option attacks. This option specifies a partial route list for a packet to take on its journey from source to destination.
IP strict source route option	Number of IP strict source route option attacks. This option specifies the complete route list for a packet to take on its journey from source to destination.
IP stream option	Number of stream option attacks. This option provides a way for the 16-bit SATNET stream identifier to be carried through networks that do not support streams.
ICMP fragment	Number of ICMP fragments. Because ICMP packets contain very short messages, there is no legitimate reason for ICMP packets to be fragmented. If an ICMP packet is so large that it must be fragmented, something is amiss.
ICMP large packet	Number of large ICMP packets.
TCP SYN FIN	Number of TCP SYN FIN packets.
TCP FIN no ACK	Number of TCP FIN flags without the acknowledge (ACK) flag.
Source session limit	Number of concurrent sessions that can be initiated from a source IP address.
TCP SYN-ACK-ACK proxy	Number of TCP flags enabled with SYN-ACK-ACK. To prevent flooding with SYN-ACK-ACK sessions, you can enable the SYN-ACK-ACK proxy protection screen option. After the number of connections from the same IP address reaches the SYN-ACK-ACK proxy threshold and SRX Series devices running Junos OS reject further connection requests from that IP address.
IP block fragment	Number of IP block fragments.
Destination session limit	Number of concurrent sessions that can be directed to a single destination IP address.
UDP address sweep	Number of UDP address sweeps.
IPv6 extension header	Number of packets filtered for the defined IPv6 extension headers.
IPv6 extension hop by hop option	Number of packets filtered for the defined IPv6 hop-by-hop option types.
IPv6 extension destination option	Number of packets filtered for the defined IPv6 destination option types.
IPv6 extension header limit	Number of packets filtered for crossing the defined IPv6 extension header limit.
IPv6 malformed header	Number of IPv6 malformed headers defined for the intrusion detection service (IDS).

Table 69: show security screen statistics Output Fields (*continued*)

ICMPv6 malformed packet	Number of ICMPv6 malformed packets defined for the IDS options.
-------------------------	-----------------------------------------------------------------

Sample Output

show security screen statistics zone scrzone

```

user@host> show security screen statistics zone scrzone
Screen statistics:
IDS attack type                               Statistics

Introduction to Security Building Blocks

- [Understanding Security Building Blocks for Security Devices on page 1025](#)

Understanding Security Building Blocks for Security Devices

This guide provides information about the building blocks used to configure features for security devices.

- A security zone is a collection of one or more network segments requiring the regulation of inbound and outbound traffic through policies. Security zones are logical entities to which one or more interfaces are bound. With many types of Juniper Networks devices, you can define multiple security zones, the exact number of which you determine based on your network needs.
- An address book is a collection of addresses and address sets. Junos OS allows you to configure multiple address books. Address books are like components, or building blocks, that are referenced in other configurations such as security policies or NAT. You can add addresses to address books or use the predefined addresses available to each address book by default.
- A security policy is a stateful firewall policy that provides a set of tools to network administrators, enabling them to implement network security for their organizations. Security policies enforce rules for transit traffic, in terms of what traffic can pass through the firewall, and the actions that need to take place on traffic as it passes through the firewall.
- An application set is a group of applications. Junos OS simplifies the process by allowing you to manage a small number of application sets, rather than a large number of individual application entries. The application (or application set) is referred to by security policies as match criteria for packets initiating sessions.

Security Zones and Interfaces Overview

Interfaces act as a doorway through which traffic enters and exits a Juniper Networks device. Many interfaces can share exactly the same security requirements; however, different interfaces can also have different security requirements for inbound and outbound data packets. Interfaces with identical security requirements can be grouped together into a single security zone.

A *security zone* is a collection of one or more network segments requiring the regulation of inbound and outbound traffic through policies.

Security zones are logical entities to which one or more interfaces are bound. With many types of Juniper Networks devices, you can define multiple security zones, the exact number of which you determine based on your network needs.

On a single device, you can configure multiple security zones, dividing the network into segments to which you can apply various security options to satisfy the needs of each segment. At a minimum, you must define two security zones, basically to protect one area of the network from the other. On some security platforms, you can define many security zones, bringing finer granularity to your network security design—and without deploying multiple security appliances to do so.

From the perspective of security policies, traffic enters into one security zone and goes out on another security zone. This combination of a **from-zone** and a **to-zone** is defined as a *context*. Each context contains an ordered list of policies. For more information on policies, see [“Security Policies Overview” on page 1065](#).

This topic includes the following sections:

- [Understanding Security Zone Interfaces on page 1030](#)

Understanding Security Zone Interfaces

An interface for a security zone can be thought of as a doorway through which TCP/IP traffic can pass between that zone and any other zone.

Through the policies you define, you can permit traffic between zones to flow in one direction or in both. With the routes that you define, you specify the interfaces that traffic from one zone to another must use. Because you can bind multiple interfaces to a zone, the routes you chart are important for directing traffic to the interfaces of your choice.

An interface can be configured with an IPv4 address, IPv6 address, or both.

Understanding Functional Zones

A functional zone is used for special purposes, like management interfaces. Currently, only the management (MGT) zone is supported. Management zones have the following properties:

- Management zones host management interfaces.
- Traffic entering management zones does not match policies; therefore, traffic cannot transit out of any other interface if it was received in the management interface.
- Management zones can only be used for dedicated management interfaces.

Related Documentation

- [Security Zones and Interfaces Overview on page 1029](#)
- [Example: Creating Security Zones on page 1031](#)

Understanding Security Zones

Security zones are the building blocks for policies; they are logical entities to which one or more interfaces are bound. Security zones provide a means of distinguishing groups of hosts (user systems and other hosts, such as servers) and their resources from one another in order to apply different security measures to them.

Security zones have the following properties:

- Policies—Active security policies that enforce rules for the transit traffic, in terms of what traffic can pass through the firewall, and the actions that need to take place on the traffic as it passes through the firewall. For more information, see [“Security Policies Overview” on page 1065](#).
- Screens—A Juniper Networks stateful firewall secures a network by inspecting, and then allowing or denying, all connection attempts that require passage from one security

zone to another. For every security zone, you can enable a set of predefined screen options that detect and block various kinds of traffic that the device determines as potentially harmful. For more information, see [“Reconnaissance Deterrence Overview” on page 901](#).

- Address books—IP addresses and address sets that make up an address book to identify its members so that you can apply policies to them. Address book entries can include any combination of IPv4 addresses, IPv6 addresses, and Domain Name System (DNS) names. For more information, see [“Example: Configuring Address Books and Address Sets” on page 1056](#).
- TCP-RST—When this feature is enabled, the system sends a TCP segment with the RESET flag set when traffic arrives that does not match an existing session and does not have the SYNchronize flag set.
- Interfaces—List of interfaces in the zone.

Security zones have the following preconfigured zone:

- Trust zone—Available only in the factory configuration and is used for initial connection to the device. After you commit a configuration, the trust zone can be overridden.

Example: Creating Security Zones

This example shows how to configure zones and assign interfaces to them. When you configure a security zone, you can specify many of its parameters at the same time.

- [Requirements on page 1031](#)
- [Overview on page 1031](#)
- [Configuration on page 1032](#)
- [Verification on page 1033](#)

Requirements

Before you begin, configure network interfaces. See the *Interfaces Feature Guide for Security Devices*.

Overview

An interface for a security zone can be thought of as a doorway through which TCP/IP traffic can pass between that zone and any other zone.

NOTE: By default, interfaces are in the null zone. The interfaces will not pass traffic until they have been assigned to a zone.

NOTE: You can configure 2000 interfaces within a security zone on SRX3400, SRX3600, SRX5600, and SRX5800 devices.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/1 unit 0 family inet address 10.12.12.1/24
set interfaces ge-0/0/1 unit 0 family inet6 address fa:43::21/96
set security security-zone ABC interfaces ge-0/0/1.0
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To create zones and assign interfaces to them:

1. Configure an Ethernet interface and assign an IPv4 address to it.

```
[edit]
user@host# set interfaces ge-0/0/1 unit 0 family inet address 10.12.12.1/24
```
2. Configure an Ethernet interface and assign an IPv6 address to it.

```
user@host# set interfaces ge-0/0/1 unit 0 family inet6 address fa:43::21/96
```
3. Configure a security zone and assign it to an Ethernet interface.

```
user@host# set security security-zone ABC interfaces ge-0/0/1.0
```

Results From configuration mode, confirm your configuration by entering the **show security zones security-zone ABC** and **show interfaces ge-0/0/1** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show security zones security-zone ABC
...
    interfaces {
        ge-0/0/1.0 {
            ...
        }
    }

[edit]
user@host# show interfaces ge-0/0/1
...
    unit 0 {
        family inet {
            address 10.12.12.1/24;
```

```
    }  
    family inet6 {  
        address fe:43::21/96;  
    }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

- [Troubleshooting with Logs on page 1033](#)

Troubleshooting with Logs

Purpose	Use these logs to identify any issues.
Action	From operational mode, enter the show log messages command and the show log dcd command.

Understanding How to Control Inbound Traffic Based on Traffic Types

This topic describes how to configure zones to specify the kinds of traffic that can reach the device from systems that are directly connected to its interfaces.

Note the following:

- You can configure these parameters at the zone level, in which case they affect all interfaces of the zone, or at the interface level. (Interface configuration overrides that of the zone.)
- You must enable all expected host-inbound traffic. Inbound traffic destined to this device is dropped by default.
- You can also configure a zone's interfaces to allow for use by dynamic routing protocols.

This feature allows you to protect the device against attacks launched from systems that are directly or indirectly connected to any of its interfaces. It also enables you to selectively configure the device so that administrators can manage it using certain applications on certain interfaces. You can prohibit use of other applications on the same or different interfaces of a zone. For example, most likely you would want to ensure that outsiders not use the Telnet application from the Internet to log into the device because you would not want them connecting to your system.

Example: Controlling Inbound Traffic Based on Traffic Types

This example shows how to configure inbound traffic based on traffic types.

- [Requirements on page 1036](#)
- [Overview on page 1036](#)
- [Configuration on page 1036](#)
- [Verification on page 1038](#)

Requirements

Before you begin:

- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.
- Understand Inbound traffic types. See “[Understanding How to Control Inbound Traffic Based on Traffic Types](#)” on page 1035.

Overview

By allowing system services to run, you can configure zones to specify different types of traffic that can reach the device from systems that are directly connected to its interfaces. You can configure the different system services at the zone level, in which case they affect all interfaces of the zone, or at the interface level. (Interface configuration overrides that of the zone.)

You must enable all expected host-inbound traffic. Inbound traffic from devices directly connected to the device's interfaces is dropped by default.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security zones security-zone ABC host-inbound-traffic system-services all
set security zones security-zone ABC interfaces ge-0/0/1.3 host-inbound-traffic
  system-services telnet
set security zones security-zone ABC interfaces ge-0/0/1.3 host-inbound-traffic
  system-services ftp
set security zones security-zone ABC interfaces ge-0/0/1.3 host-inbound-traffic
  system-services snmp
set security zones security-zone ABC interfaces ge-0/0/1.0 host-inbound-traffic
  system-services all
set security zones security-zone ABC interfaces ge-0/0/1.0 host-inbound-traffic
  system-services ftp except
set security zones security-zone ABC interfaces ge-0/0/1.0 host-inbound-traffic
  system-services http except
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure inbound traffic based on traffic types:

1. Configure a security zone.

```
[edit]
user@host# edit security zones security-zone ABC
```
2. Configure the security zone to support inbound traffic for all system services.

```
[edit security zones security-zone ABC]
user@host# set host-inbound-traffic system-services all
```
3. Configure the Telnet, FTP, and SNMP system services at the interface level (not the zone level) for the first interface.

```
[edit security zones security-zone ABC]
user@host# set interfaces ge-0/0/1.3 host-inbound-traffic system-services telnet
user@host# set interfaces ge-0/0/1.3 host-inbound-traffic system-services ftp
user@host# set interfaces ge-0/0/1.3 host-inbound-traffic system-services snmp
```
4. Configure the security zone to support inbound traffic for all system services for a second interface.

```
[edit security zones security-zone ABC]
user@host# set interfaces ge-0/0/1.0 host-inbound-traffic system-services all
```
5. Exclude the FTP and HTTP system services from the second interface.

```
[edit security zones security-zone ABC]
user@host# set interfaces ge-0/0/1.0 host-inbound-traffic system-services ftp
except
user@host# set interfaces ge-0/0/1.0 host-inbound-traffic system-services http
except
```

Results From configuration mode, confirm your configuration by entering the **show security zones security-zone ABC**. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security zones security-zone ABC
host-inbound-traffic {
    system-services {
        all;
    }
}
interfaces {
    ge-0/0/1.3 {
        host-inbound-traffic {
            system-services {
                ftp;
                telnet;
                snmp;
            }
        }
    }
    ge-0/0/1.0 {
```

```

    host-inbound-traffic {
      system-services {
        all;
        ftp {
          except;
        }
        http {
          except;
        }
      }
    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

- [Troubleshooting with Logs on page 1038](#)

Troubleshooting with Logs

Purpose Use these logs to identify any issues.

Action From operational mode, enter the **show log messages** command and the **show log dcd** command.

Related Documentation • [Understanding How to Control Inbound Traffic Based on Traffic Types on page 1035](#)

Understanding How to Control Inbound Traffic Based on Protocols

This topic describes the inbound system protocols on the specified zone or interface.

Any host-inbound traffic that corresponds to a protocol listed under the host-inbound traffic option is allowed. For example, if anywhere in the configuration, you map a protocol to a port number other than the default, you can specify the protocol in the host-inbound traffic option, and the new port number will be used. [Table 70](#) lists the supported protocols. A value of **all** indicates that traffic from all of the following protocols is allowed inbound on the specified interfaces (of the zone, or a single specified interface).

Table 70: Supported Inbound System Protocols

Supported System Services			
all	igmp	pim	sap
bfd	ldp	rip	vrrp
bgp	msdp	ripng	nhrp

Table 70: Supported Inbound System Protocols (*continued*)

Supported System Services			
router-discovery	dvmrp	ospf	rsvp
pgm	ospf3		

NOTE: If DVMRP or PIM is enabled for an interface, IGMP and MLD host-inbound traffic is enabled automatically. Because IS-IS uses OSI addressing and should not generate any IP traffic, there is no host-inbound traffic option for the IS-IS protocol.

NOTE: You do not need to configure Neighbor Discovery Protocol (NDP) on host-inbound traffic, because the NDP is enabled by default.

Configuration option for IPv6 Neighbor Discovery Protocol (NDP) is available. The configuration option is **set protocol neighbor-discovery onlink-subnet-only** command. This option will prevent the device from responding to a Neighbor Solicitation (NS) from a prefix which was not included as one of the device interface prefixes.

NOTE: The Routing Engine needs to be rebooted after setting this option to remove any possibility of a previous IPv6 entry from remaining in the forwarding-table.

Example: Controlling Inbound Traffic Based on Protocols

This example shows how to enable inbound traffic for an interface.

- [Requirements on page 1040](#)
- [Overview on page 1040](#)
- [Configuration on page 1040](#)
- [Verification on page 1041](#)

Requirements

Before you begin:

- Configure security zones. See [“Example: Creating Security Zones” on page 1031](#).
- Configure network interfaces. See the *Interfaces Feature Guide for Security Devices*.

Overview

Any host-inbound traffic that corresponds to a protocol listed under the host-inbound traffic option is allowed. For example, if anywhere in the configuration you map a protocol to a port number other than the default, you can specify the protocol in the host-inbound traffic option, and the new port number will be used.

A value of **all** indicates that traffic from all of the protocols is allowed inbound on the specified interfaces (of the zone, or a single specified interface).

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security zones security-zone ABC interfaces ge-0/0/1.0 host-inbound-traffic protocols ospf
set security zones security-zone ABC interfaces ge-0/0/1.0 host-inbound-traffic protocols ospf3
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure inbound traffic based on protocols:

1. Configure a security zone.

```
[edit]
user@host# edit security zones security-zone ABC
```

2. Configure the security zone to support inbound traffic based on the ospf protocol for an interface.

```
[edit security zones security-zone ABC]
user@host# set interfaces ge-0/0/1.0 host-inbound-traffic protocols ospf
```

3. Configure the security zone to support inbound traffic based on the ospf3 protocol for an interface.

```
[edit security zones security-zone ABC]
user@host# set interfaces ge-0/0/1.0 host-inbound-traffic protocols ospf3
```

Results From configuration mode, confirm your configuration by entering the **show security zones security-zone ABC**. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security zones security-zone ABC
interfaces {
  ge-0/0/1.0 {
    host-inbound-traffic {
      protocols {
        ospf;
        ospf3;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

- [Troubleshooting with Logs on page 1041](#)

Troubleshooting with Logs

Purpose Use these logs to identify any issues.

Action From operational mode, enter the **show log messages** command and the **show log dcd** command.

Related Documentation

Supported System Services for Host Inbound Traffic

This topic describes the supported system services for host inbound traffic on the specified zone or interface.

For example, suppose a user whose system was connected to interface **1.3.1.4** in zone **ABC** wanted to telnet into interface **2.1.2.4** in zone **ABC**. For this action to be allowed, the Telnet application must be configured as an allowed inbound service on both interfaces and a policy must permit the traffic transmission.

[Table 71](#) shows the system services that can be used for host inbound traffic.

Table 71: System Services for Host Inbound Traffic

Host Inbound System Services	
all	any-service
dns	finger

Table 71: System Services for Host Inbound Traffic (*continued*)

Host Inbound System Services	
ftp	http
https	indent-reset
ike	netconf
ntp	ping
reverse-ssh	reverse-telnet
rlogin	rpm
rsh	sip
snmp	snmp-trap
ssh	telnet
tftp	traceroute
xnm-clear-text	xnm-ssl

NOTE: On the SRX Series Services Gateways, the `xnm-clear-text` field is enabled in the factory default configuration. This setting enables incoming Junos XML protocol traffic in the trust zone for the device when the device is operating with factory default settings. We recommend you to replace the factory default settings with user-defined configuration which provides additional security once the box is configured. You must delete the `xnm-clear-text` field manually by using the CLI command `delete system services xnm-clear-text`.

Table 72 shows the supported protocols that can be used for host inbound traffic.

Table 72: Protocols for Host Inbound Traffic

Protocols	
all	bfd
bgp	dvmrp
igmp	msdp
ospf	nhrp

Table 72: Protocols for Host Inbound Traffic (*continued*)

Protocols	
pgm	ospf3
rip	pim
sap	ripng
	vrrp

NOTE: All services (except DHCP and BOOTP) can be configured either per zone or per interface. A DHCP server is configured only per interface because the incoming interface must be known by the server to be able to send out DHCP replies.

NOTE: You do not need to configure Neighbor Discovery Protocol (NDP) on host-inbound traffic, because the NDP is enabled by default.

Configuration option for IPv6 Neighbor Discovery Protocol (NDP) is available. The configuration option is **set protocol neighbor-discovery onlink-subnet-only** command. This option will prevent the device from responding to a Neighbor Solicitation (NS) from a prefix which was not included as one of the device interface prefixes.

NOTE: The Routing Engine needs to be rebooted after setting this option to remove any possibility of a previous IPv6 entry from remaining in the forwarding-table.

Example: Configuring the TCP-Reset Parameter

This example shows how to configure the TCP-Reset parameter for a zone.

- [Requirements on page 1045](#)
- [Overview on page 1046](#)
- [Configuration on page 1046](#)
- [Verification on page 1046](#)

Requirements

Before you begin, configure security zones. See “[Example: Creating Security Zones](#)” on [page 1031](#).

Overview

When the TCP-Reset parameter feature is enabled, the system sends a TCP segment with the RESET flag set when traffic arrives that does not match an existing session and does not have the SYN flag set.

Configuration

Step-by-Step Procedure

To configure the TCP-Reset parameter for a zone:

1. Configure a security zone.

```
[edit]  
user@host# edit security zones security-zone ABC
```
2. Configure the TCP-Reset parameter for the zone.

```
[edit security zones security-zone ABC]  
user@host# set tcp-rst
```
3. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security zones** command.

- [Understanding Address Sets on page 1051](#)
- [Understanding Global Address Books on page 1051](#)
- [Configuring Addresses and Address Sets on page 1052](#)
- [Example: Configuring Address Books and Address Sets on page 1056](#)
- [Limitations of Addresses and Address Sets in a Security Policy on page 1061](#)

Understanding Address Books

An address book is a collection of addresses and address sets. Junos OS allows you to configure multiple address books. Address books are like components, or building blocks, that are referenced in other configurations such as security policies or NAT. You can add addresses to address books or use the predefined addresses available to each address book by default.

Address book entries include addresses of hosts and subnets whose traffic is either allowed, blocked, encrypted, or user-authenticated. These addresses can be any combination of IPv4 addresses, IPv6 addresses, wildcard addresses, or Domain Name System (DNS) names.

- [Predefined Addresses on page 1049](#)
- [Network Prefixes in Address Books on page 1050](#)
- [Wildcard Addresses in Address Books on page 1050](#)
- [DNS Names in Address Books on page 1050](#)

Predefined Addresses

You can either create addresses or use any of the following predefined addresses that are available by default:

- **Any**—This address matches any IP address. When this address is used as a source or destination address in a policy configuration, it matches the source and destination address of any packet.

- **Any-ipv4**—This address matches any IPv4 address.
- **Any-ipv6**—This address matches any IPv6 address.

Network Prefixes in Address Books

You can specify addresses as network prefixes in the prefix/length format. For example, 1.2.3.0/24 is an acceptable address book address because it translates to a network prefix. However, 1.2.3.4/24 is not acceptable for an address book because it exceeds the subnet length of 24 bits. Everything beyond the subnet length must be entered as 0 (zero). In special scenarios, you can enter a hostname because it can use the full 32-bit address length.

An IPv6 address prefix is a combination of an IPv6 prefix (address) and a prefix length. The prefix takes the form `ipv6-prefix/prefix-length` and represents a block of address space (or a network). The `ipv6-prefix` variable follows general IPv6 addressing rules. The `/prefix-length` variable is a decimal value that indicates the number of contiguous, higher-order bits of the address that make up the network portion of the address. For example, 10FA:6604:8136:6502::/64 is a possible IPv6 prefix. For more information on text representation of IPv6 addresses and address prefixes, see RFC 4291, *IP Version 6 Addressing Architecture*.

Wildcard Addresses in Address Books

Besides IP addresses and domain names, you can specify a wildcard address in an address book. A wildcard address is represented as `A.B.C.D/wildcard-mask`. The wildcard mask determines which of the bits in the IP address `A.B.C.D` should be ignored. For example, the source IP address 192.168.0.11/255.255.0.255 in a security policy implies that the security policy match criteria can discard the third octet in the IP address (symbolically represented as 192.168.*.11). Therefore, packets with source IP addresses such as 192.168.1.11 and 192.168.22.11 conform to the match criteria. However, packets with source IP addresses such as 192.168.0.1 and 192.168.1.21 do not satisfy the match criteria.

The wildcard address usage is not restricted to full octets only. You can configure any wildcard address. For example, the wildcard address 192.168. 7.1/255.255.7.255 implies that you need to ignore only the first 5 bits of the third octet of the wildcard address while making the policy match. If the wildcard address usage is restricted to full octets only, then wildcard masks with either 0 or 255 in each of the four octets only will be permitted.

DNS Names in Address Books

By default, you can resolve IPv4 and IPv6 addresses for a DNS. If IPv4 or IPv6 addresses are designated, you can resolve only those addresses by using the keywords `ipv4-only` and `ipv6-only`, respectively.

Before you can use domain names for address entries, you must configure the security device for DNS services. For information about DNS, see *DNS Overview*.

Related Documentation

- [Understanding Global Address Books on page 1051](#)
- [Understanding Address Sets on page 1051](#)
- [Configuring Addresses and Address Sets on page 1052](#)

Understanding Address Sets

An address book can grow to contain large numbers of addresses and become difficult to manage. You can create groups of addresses called address sets to manage large address books. Using address sets, you can organize addresses in logical groups and use them to easily configure other features, such as policies and NAT rules.

The predefined address set, **any**, which contains both **any-ipv4** and **any-ipv6** addresses, is automatically created for each security zone.

You can create address sets with existing users, or create empty address sets and later fill them with users. When creating address sets, you can combine IPv4 and IPv6 addresses, but the addresses must be in the same security zone.

You can also create an address set within an address set. This allows you to apply policies more effectively. For example, if you want to apply a policy to two address sets, **set1** and **set2**, instead of using two statements, you can use just one statement to apply the policy to a new address set, **set3**, that includes address sets **set1** and **set2**.

When you add addresses to policies, sometimes the same subset of addresses can be present in multiple policies, making it difficult to manage how policies affect each address entry. Reference an address set entry in a policy like an individual address book entry to allow you to manage a small number of address sets, rather than manage a large number of individual address entries.

Understanding Global Address Books

An address book called “global” is always present on your system. Similar to other address books, the global address book can include any combination of IPv4 addresses, IPv6 addresses, wildcard addresses, or Domain Name System (DNS) names.

You can create addresses in the global address book or use the predefined addresses (**any**, **any-ipv4**, and **any-ipv6**). However, to use the addresses in the global address book, you do not need to attach the security zones to it. The global address book is available to all security zones that have no address books attached to them.

Global address books are used in the following cases:

- NAT configurations—NAT rules can use address objects only from the global address book. They cannot use addresses from zone-based address books.
- Global policies—Addresses used in a global policy must be defined in global address book. Global address book objects do not belong to any particular zone.

- Related Documentation**
- [Understanding Address Books on page 1049](#)
 - [Understanding Address Sets on page 1051](#)
 - [Configuring Addresses and Address Sets on page 1052](#)

Configuring Addresses and Address Sets

You can define addresses and address sets in an address book and then use them when configuring different features. You can also use predefined addresses **any**, **any-ipv4**, and **any-ipv6** that are available by default. However, you cannot add the predefined address **any** to an address book.

After address books and sets are configured, they are used in configuring different features, such as security policies, security zones, and NAT.

- [Addresses and Address Sets on page 1052](#)
- [Address Books and Security Zones on page 1053](#)
- [Address Books and Security Policies on page 1053](#)
- [Address Books and NAT on page 1055](#)

Addresses and Address Sets

You can define IPv4 addresses, IPv6 addresses, wildcard addresses, or Domain Name System (DNS) names as address entries in an address book.

The following sample address book called **book1** contains different types of addresses and address sets. Once defined, you can leverage these addresses and address sets when you configure security zones, policies, or NAT rules.

```
[edit security address-book book1]
user@host# set address a1 1.1.1.1
user@host# set address a2 1.1.1.4/30
user@host# set address a4 fe80::210:dbff:feff:1000/64
user@host# set address a5 0001:db8:1::1/127
user@host# set address abc dns-name www.example.com
user@host# set address-set set1 address a1
user@host# set address-set set1 address a2
user@host# set address-set set1 address a2
user@host# set address-set set2 address bbc
```

When defining addresses and address sets, follow these guidelines:

- Address sets can only contain address names that belong to the same security zone.
- Address names **any**, **any-ipv4** and **any-ipv6** are reserved; you cannot use them to create any addresses.
- Addresses and address sets in the same zone must have distinct names.

- Address names cannot be the same as address set names. For example, if you configure an address with the name **add1**, do not create the address set with the name **add1**.
- When deleting an individual address book entry from the address book, you must remove the address (wherever it is referred) from all the address sets; otherwise, the system will cause a commit failure.

Address Books and Security Zones

A security zone is a logical group of interfaces with identical security requirements. You attach security zones to address books that contain entries for the addressable networks and end hosts (and, thus, users) belonging to the zone.

A zone can use two address books at a time—the global address book and the address book that the zone is attached to. When a security zone is not attached to any address book, it automatically uses the global address book. Thus, when a security zone is attached to an address book, the system looks up addresses from this attached address book; otherwise, the system looks up addresses from the default global address book. The global address book is available to all security zones by default; you do not need to attach zones to the global address book.

The following guidelines apply when attaching security zones to address books:

- Addresses attached to a security zone conform to the security requirements of the zone.
- The address book that you attach to a security zone must contain all IP addresses that are reachable within that zone.
- When you configure policies between two zones, you must define the addresses for each of the zone's address books.
- Addresses in a user-defined address book have a higher lookup priority than addresses in the global address book. Thus, for a security zone that is attached to a user-defined address book, the system searches the user-defined address book first; if no address is found, then it searches the global address book.

Address Books and Security Policies

Addresses and address sets are used when specifying the match criteria for a policy. Before you can configure policies to permit, deny, or tunnel traffic to and from individual hosts and subnets, you must make entries for them in address books. You can define different types of addresses, such as IPv4 addresses, IPv6 addresses, wildcard addresses, and DNS names, as match criteria for security policies.

Policies contain both source and destination addresses. You can refer to an address or address set in a policy by the name you give to it in the address book attached to the zone specified in the policy.

- When traffic is sent to a zone, the zone and address to which the traffic is sent are used as the destination zone and address-matching criteria in policies.

- When traffic is sent from a zone, the zone and address from which the traffic is sent are used as the source zone and address-matching criteria in policies.

Addresses Available for Security Policies

When configuring the source and destination addresses for a policy rule, you can type a question mark in the CLI to list all the available addresses that you can choose from.

You can use the same address name for different addresses that are in different address books. However, the CLI lists only one of these addresses—the address that has the highest lookup priority.

For example, suppose you configure addresses in two address books—**global** and **book1**. Then, display the addresses that you can configure as source or destination addresses in a policy (see [Table 73](#)).

Table 73: Available Addresses Displayed in the CLI

Addresses Configured	Addresses Displayed in the CLI
<pre>[edit security address-book] set global address a1 1.1.2.0/24; set global address a2 2.2.2.0/24; set global address a3 3.3.3.0/24; set book1 address a1 1.1.1.0/24;</pre>	<pre>[edit security policies from-zone trust to-zone untrust] user@host# set policy p1 match set match source-address ?</pre> <p>Possible completions:</p> <pre>[Open a set of values a1 The address in address book book1 a2 The address in address book global a3 The address in address book global any Any IPv4 or IPv6 address any-ipv4 Any IPv4 address any-ipv6 Any IPv6 address</pre>

The addresses displayed in this example illustrate:

- Addresses in a user-defined address book have a higher lookup priority than addresses in the global address book.
- Addresses in a global address book have a higher priority than the predefined addresses **any**, **any-ipv4**, and **any-ipv6**.
- When the same address name is configured for two or more different addresses, only the highest priority address, based on the address lookup, is available. In this example, the CLI displays address **a1** from **book1** (1.1.1.0/24) because that address has a higher lookup priority than the global address **a1** (1.1.2.0/24).

Applying Policies to Address Sets

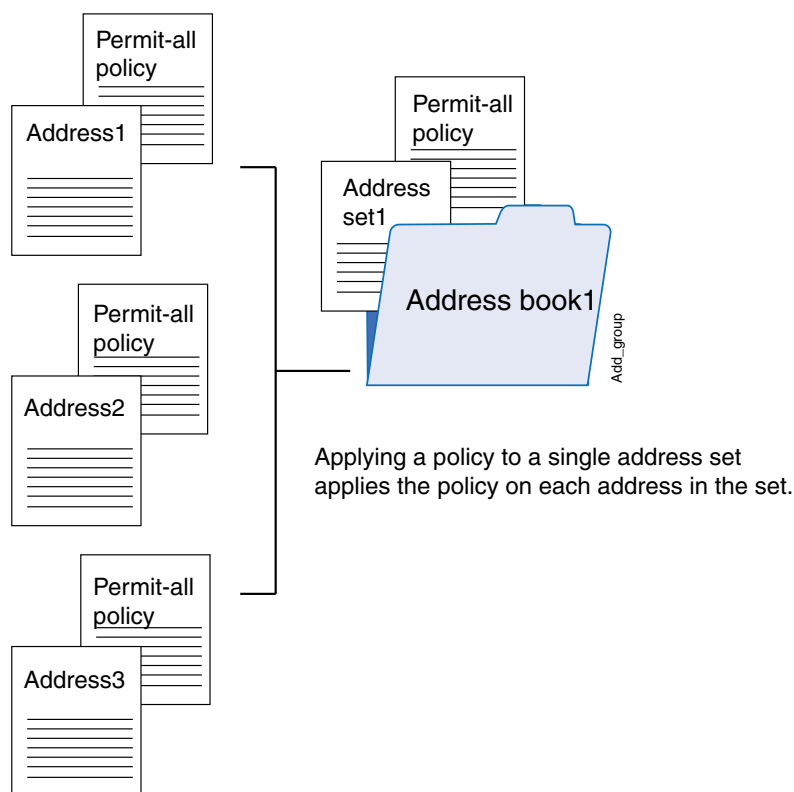

When you specify an address set in policies, Junos OS applies the policies automatically to each address set member, so you do not have to create them one by one for each address. Also, if an address set is referenced in a policy, the address set cannot be removed without removing its reference in the policy. It can, however, be edited.

NOTE: Consider that for each address set, the system creates individual rules for its members. It creates an internal rule for each member in the group as well as for each service configured for each user. If you configure address books without taking this into account, you can exceed the number of available policy resources, especially if both the source and destination addresses are address groups and the specified service is a service group.

Figure 64 shows how policies are applied to address sets.

Figure 64: Applying Policies to Address Sets

Address Books and NAT

Once you define addresses in address books, you can specify them in the source, destination, or static NAT rules. It is simpler to specify meaningful address names instead of IP prefixes as source and destination addresses in the NAT rule configuration. For example, instead of specifying 10.208.16.0/22 as source address, you can specify an address called **local** that includes address 10.208.16.0/22.

You can also specify address sets in NAT rules, allowing you to add multiple addresses within an address set and therefore manage a small number of address sets, rather than manage a large number of individual address entries. When you specify an address set in a NAT rule, Junos OS applies the rule automatically to each address set member, so you do not have to specify each address one by one.

NOTE: The following address and address set types are not supported in NAT rules—wildcard addresses, DNS names, and a combination of IPv4 and IPv6 addresses.

When configuring address books with NAT, follow these guidelines:

- In a NAT rule, you can specify addresses from a global address book only. User-defined address books are not supported with NAT.
- You can configure an address set as a source address name in a source NAT rule. However, you cannot configure an address set as a destination address name in a destination NAT rule.

The following sample NAT statements show the address and address set types that are supported with source and destination NAT rules:

```
[edit security nat source rule-set src-nat rule src-rule1]
set match source-address 2000::/64
set match source-address-name add1
set match source-address-name add-set1
set match destination-address 2001::/64
set match destination-address-name add2
set match destination-address-name add-set2

[edit security nat destination rule-set dst-nat rule dst-rule1]
set match source-address 2001::/64
set match source-address-name add2
set match source-address-name add-set2
set match destination-address-name add1
```

- In a static NAT rule, you cannot configure an address set as a source or destination address name. The following sample NAT statements show the types of address that are supported with static NAT rules:

```
[edit security nat static rule-set stat]
set rule stat-rule1 match destination-address 3.3.3.0/24
set rule stat-rule2 match destination-address-name add1
```

Example: Configuring Address Books and Address Sets

This example shows how to configure addresses and address sets in address books. It also shows how to attach address books to security zones.

- [Requirements on page 1057](#)
- [Overview on page 1057](#)

- [Configuration on page 1058](#)
- [Verification on page 1060](#)

Requirements

Before you begin:

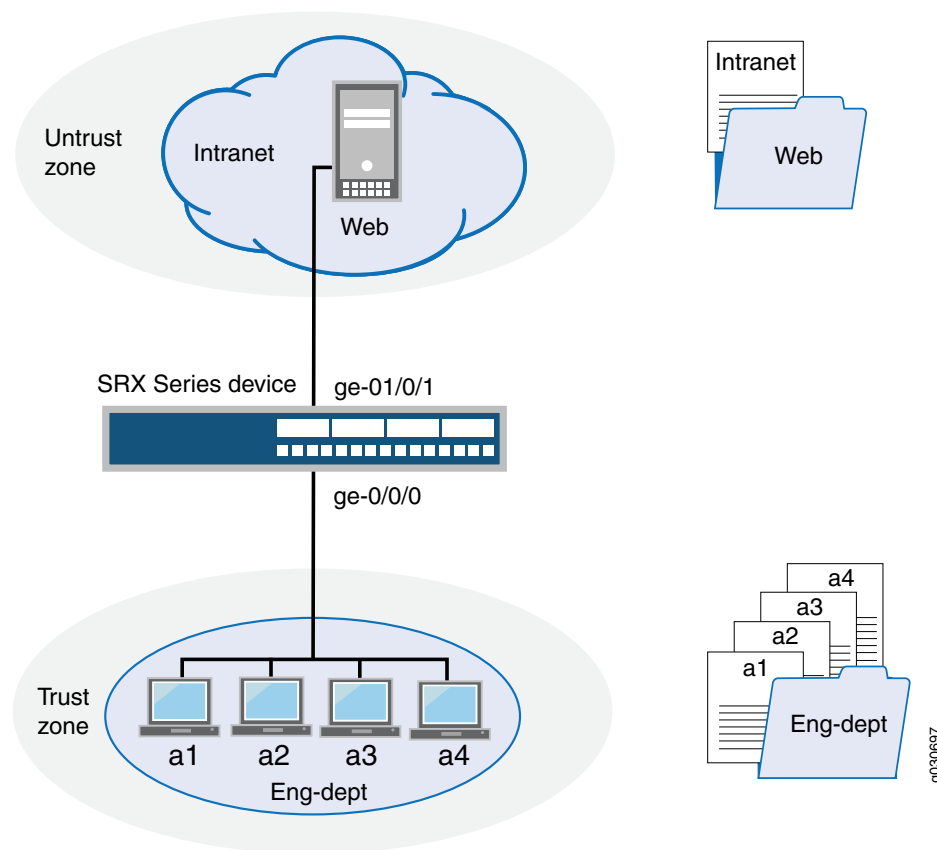

- Configure the Juniper Networks security devices for network communication.
- Configure network interfaces on server and member devices. See the *Interfaces Feature Guide for Security Devices*.
- Configure Domain Name System (DNS) services. For information about DNS, see *DNS Overview*.

Overview

In this example, you configure an address book with addresses and address sets (see [Figure 65](#)) to simplify configuring your company's network. You create an address book called **Eng-dept** and add addresses of members from the Engineering department. You create another address book called **Web** and add a DNS name to it. Then you attach a security zone trust to the **Eng-dept** address book and security zone untrust to the **Web** address book. You also create address sets to group software and hardware addresses in the Engineering department. You plan to use these addresses as source address and destination addresses in your future policy configurations.

In addition, you add an address to the global address book, to be available to any security zone that has no address book attached to it.

Figure 65: Configuring Addresses and Address Sets

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security zones security-zone trust interfaces ge-0/0/0
set security zones security-zone untrust interfaces ge-0/0/1
set security address-book Eng-dept address a1 1.1.1.1
set security address-book Eng-dept address a2 1.1.1.2
set security address-book Eng-dept address a3 1.1.1.3
set security address-book Eng-dept address a4 1.1.1.4
set security address-book Eng-dept address-set sw-eng address a1
set security address-book Eng-dept address-set hw-eng address a2
set security address-book Eng-dept address-set hw-eng address a3
set security address-book Eng-dept address-set hw-eng address a4
set security address-book Eng-dept attach zone trust
set security address-book Web address Intranet dns-name www-int.example.net
set security address-book Web attach zone untrust
set security address-book global address g1 2.2.2.2/24
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure addresses and address sets:

1. Create security zones and assign interfaces to them.

```
[edit]
user@host# set security zones security-zone trust interfaces ge-0/0/0
user@host# set security zones security-zone untrust interfaces ge-0/0/1
```

2. Create an address book and define addresses in it.

```
[edit security address-book Eng-dept ]
user@host# set address a1 1.1.1.1
user@host# set address a2 1.1.1.2
user@host# set address a3 1.1.1.3
user@host# set address a4 1.1.1.4
```

3. Create address sets.

```
[edit security address-book Eng-dept]
user@host# set address-set sw-eng address a1
user@host# set address-set sw-eng address a2
user@host# set address-set hw-eng address a3
user@host# set address-set hw-eng address a4
```

4. Attach the address book to a security zone.

```
[edit security address-book Eng-dept]
user@host# set attach zone trust
```

5. Create another address book and attach it to a security zone.

```
[edit security address-book Web ]
user@host# set address Intranet dns-name www-int.example.net
user@host# set attach zone untrust
```

6. Define an address in the global address book.

```
[edit]
user@host# set security address-book global address g1 2.2.2.2/24
```

Results From configuration mode, confirm your configuration by entering the **show security zones** and **show security address-book** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security zones
security-zone untrust {
  interfaces {
    ge-0/0/1.0;
  }
}
security-zone trust {
  interfaces {
    ge-0/0/0.0;
  }
}
```

```
    }  
[edit]  
user@host# show security address-book  
Eng-dept {  
    address a1 1.1.1.1/32;  
    address a2 1.1.1.2/32;  
    address a3 1.1.1.3/32;  
    address a4 1.1.1.4/32;  
    address-set sw-eng {  
        address a1;  
        address a2;  
    }  
    address-set hw-eng {  
        address a3;  
        address a4;  
    }  
    attach {  
        zone trust;  
    }  
}  
Web {  
    address Intranet {  
        dns-name www-int.example.net ;  
    }  
    attach {  
        zone untrust;  
    }  
}  
global {  
    address g1 2.2.2.2/24;  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying Address Book Configuration on page 1060](#)
- [Verifying Global Address Book Configuration on page 1060](#)

Verifying Address Book Configuration

Purpose Display information about configured address books and addresses.

Action From configuration mode, enter the **show security address-book** command.

Verifying Global Address Book Configuration

Purpose Display information about configured addresses in the global address book.

Action From configuration mode, enter the **show security address-book global** command.

Limitations of Addresses and Address Sets in a Security Policy

On SRX Series devices, one policy can reference multiple address sets, multiple address entries, or both. One address set can reference a maximum of 1024 address entries and a maximum of 256 address sets. There is a limit to the number of address objects that a policy can reference; the maximum number of address objects per policy is 1024.

For example, if policy p1 references 10 address entries and 10 address sets (which in turn reference 3 address entries), then the number of address objects under this policy is 40 (10 address entries + [10 address sets x 3 address entries] = 40).

Note that every IPv6 address entry is equal to 4 IPv4 address entries. For example, a policy configured for 1000 IPv4 address entries and 5 IPv6 address entries has 1020 address objects ($1000 + [5 \times 4] = 1020$), which is within the 1024 value, and can be committed. However, a policy configured for 1000 IPv4 address entries and 7 IPv6 address entries has 1028 address objects ($1000 + [7 \times 4] = 1028$), which exceeds the 1024 value, cannot be committed, and consequently generates an error message.

Security Policies Overview

To secure their business, organizations must control access to their LAN and their resources. Security policies are commonly used for this purpose. Secure access is required both within the company across the LAN and in its interactions with external networks such as the Internet. Junos OS provides powerful network security features through its stateful firewall, application firewall, and user identity firewall. All three types of firewall enforcement are implemented through security policies. The stateful firewall policy syntax is widened to include additional tuples for the application firewall and the user identity firewall.

In a Junos OS stateful firewall, the security policies enforce rules for transit traffic, in terms of what traffic can pass through the firewall, and the actions that need to take place on traffic as it passes through the firewall. From the perspective of security policies, the traffic enters one security zone and exits another security zone. This combination of a *from-zone* and *to-zone* is called a *context*. Each context contains an *ordered list* of policies. Each policy is processed in the order that it is defined within a context.

A security policy, which can be configured from the user interface, controls the traffic flow from one zone to another zone by defining the kind(s) of traffic permitted from specified IP sources to specified IP destinations at scheduled times.

Policies allow you to deny, permit, reject (deny and send a TCP RST or ICMP port unreachable message to the source host), encrypt and decrypt, authenticate, prioritize, schedule, filter, and monitor the traffic attempting to cross from one security zone to another. You decide which users and what data can enter and exit, and when and where they can go.

NOTE: For an SRX Series device that supports virtual systems, policies set in the root system do not affect policies set in virtual systems.

An SRX Series device secures a network by inspecting, and then allowing or denying, all connection attempts that require passage from one security zone to another.

Logging capability can also be enabled with security policies during session initialization (**session-init**) or session close (**session-close**) stage.

- To view logs from denied connections, enable log on **session-init**.
- To log sessions after their conclusion/tear-down, enable log on **session-close**.

NOTE: Session log is enabled at real time in the flow code which impacts the user performance. If both **session-close** and **session-init** are enabled, performance is further degraded as compared to enabling **session-init** only.

For SRX Series branch devices, a factory default security policy is provided that:

- Allows all traffic from the trust zone to the untrust zone.
- Allows all traffic between trusted zones, that is from the trust zone to intrazone trusted zones.
- Denies all traffic from the untrust zone to the trust zone.

Through the creation of policies, you can control the traffic flow from zone to zone by defining the kinds of traffic permitted to pass from specified sources to specified destinations at scheduled times.

At the broadest level, you can allow all kinds of traffic from any source in one zone to any destination in all other zones without any scheduling restrictions. At the narrowest level, you can create a policy that allows only one kind of traffic between a specified host in one zone and another specified host in another zone during a scheduled interval of time. See [Figure 66](#).

Figure 66: Security Policy

Broadly defined Internet access: Any service from any point in the trust zone to any point in the untrust zone at any time.

Narrowly defined Internet access: SMTP service from a mail server in the trust zone to a mail server in the untrust zone from 5:00 AM to 7:00 PM.

Every time a packet attempts to pass from one zone to another or between two interfaces bound to the same zone, the device checks for a policy that permits such traffic (see [“Understanding Security Zones” on page 1030](#) and [“Policy Application Sets Overview” on page 1152](#)). To allow traffic to pass from one security zone to another—for example, from zone A to zone B—you must configure a policy that permits zone A to send traffic to zone B. To allow traffic to flow the other way, you must configure another policy permitting traffic from zone B to zone A.

To allow data traffic to pass between zones, you must configure firewall policies.

Understanding Security Policy Rules

The security policy applies the security rules to the transit traffic within a context (**from-zone** to **to-zone**). Each policy is uniquely identified by its name. The traffic is classified by matching its source and destination zones, the source and destination addresses, and the application that the traffic carries in its protocol headers with the policy database in the data plane.

Each policy is associated with the following characteristics:

- A source zone
- A destination zone
- One or many source address names or address set names
- One or many destination address names or address set names
- One or many application names or application set names

These characteristics are called the *match criteria*. Each policy also has actions associated with it: permit, deny, reject, count, log, and VPN tunnel. You have to specify the match condition arguments when you configure a policy, source address, destination address, and application name.

You can specify to configure a policy with IPv4 or IPv6 addresses using the wildcard entry **any**. When flow support is not enabled for IPv6 traffic, **any** matches IPv4 addresses. When flow support is enabled for IPv6 traffic, **any** matches both IPv4 and IPv6 addresses. To enable flow-based forwarding for IPv6 traffic, use the **set security forwarding-options family inet6 mode flow-based** command. You can also specify the wildcard **any-ipv4** or **any-ipv6** for the source and destination address match criteria to include only IPv4 or only IPv6 addresses, respectively.

When flow support for IPv6 traffic is enabled, the maximum number of IPv4 or IPv6 addresses that you can configure in a security policy is based on the following match criteria:

- $\text{Number_of_src_IPv4_addresses} + \text{number_of_src_IPv6_addresses} * 4 \leq 1024$
- $\text{Number_of_dst_IPv4_addresses} + \text{number_of_dst_IPv6_addresses} * 4 \leq 1024$

The reason for the match criteria is that an IPv6 address uses four times the memory space that an IPv4 address uses.

NOTE: You can configure a security policy with IPv6 addresses only if flow support for IPv6 traffic is enabled on the device.

If you do not want to specify a specific application, enter **any** as the default application. To look up the default applications, from configuration mode, enter **show groups junos-defaults | find applications (predefined applications)**. For example, if you do not supply an application name, the policy is installed with the application as a wildcard (default). Therefore, any data traffic that matches the rest of the parameters in a given policy would match the policy regardless of the application type of the data traffic.

NOTE: If a policy is configured with multiple applications, and more than one of the applications match the traffic, then the application that best meets the match criteria is selected.

The action of the first policy that the traffic matches is applied to the packet. If there is no matching policy, the packet is dropped. Policies are searched from top to bottom, so it is a good idea to place more specific policies near the top of the list. You should also place IPsec VPN tunnel policies near the top. Place the more general policies, such as one that would allow certain users access to all Internet applications, at the bottom of the list. For example, place deny-all or reject-all policies at the bottom after all of the specific policies have been parsed before and legitimate traffic has been allowed/count/logged.

NOTE: Support for IPv6 addresses added in Release 10.2 of Junos OS and support for IPv6 addresses in active/active chassis cluster configurations (in addition to the existing support of active/passive chassis cluster configurations) has been added in Junos OS Release 10.4.

Policies are looked up during flow processing after firewall filters and screens have been processed and route look up has been completed by the Services Processing Unit (SPU) (for high-end SRX Series devices). Policy look up determines the destination zone, destination address, and egress interface.

When you are creating a policy, the following policy rules apply:

- Security policies are configured in a **from-zone** to **to-zone** direction. Under a specific zone direction, each security policy contains a name, match criteria, an action, and miscellaneous options.
- The policy name, match criteria, and action are required.
- The policy name is a keyword.
- The source address in the match criteria is composed of one or more address names or address set names in the **from-zone**.
- The destination address of the match criteria is composed of one or more address names or address set names in the **to-zone**.
- The application name in the match criteria is composed of the name of one or more applications or application sets.
- One of the following actions is required: permit, deny, or reject.
- Accounting and auditing elements can be specified: count and log.
- You can enable logging at the end of a session with the **session-close** command, or at the beginning of the session with the **session-init** command.
- When the count alarm is turned on, specify alarm thresholds in bytes per second or kilobytes per minute.
- You cannot specify **global** as either the **from-zone** or the **to-zone** except under following condition:

Any policy configured with the **to-zone** as a global zone must have a single destination address to indicate that either static NAT or incoming NAT has been configured in the policy.

- In SRX Series Services Gateways, the policy permit option with NAT is simplified. Each policy will optionally indicate whether it allows NAT translation, does not allow NAT translation, or does not care.
- Address names cannot begin with the following reserved prefixes. These are used only for address NAT configuration:
 - `static_nat_`
 - `incoming_nat_`
 - `junos_`
- Application names cannot begin with the `junos_` reserved prefix.

Understanding Wildcard Addresses

Source and destination addresses are two of the five match criteria that should be configured in a security policy. You can now configure wildcard addresses for the source and destination address match criteria in a security policy. A wildcard address is represented as A.B.C.D/wildcard-mask. The wildcard mask determines which of the bits in the IP address A.B.C.D should be ignored by the security policy match criteria. For example, the source IP address 192.168.0.11/255.255.0.255 in a security policy implies that the security policy match criteria can discard the third octet in the IP address (symbolically represented as 192.168.*.11). Therefore, packets with source IP addresses such as 192.168.1.11 and 192.168.22.11 conform to the match criteria. However, packets with source IP addresses such as 192.168.0.1 and 192.168.1.21 do not satisfy the match criteria.

The wildcard address usage is not restricted to full octets only. You can configure any wildcard address. For example, the wildcard address 192.168. 7.1/255.255.7.255 implies that you need to ignore only the first 5 bits of the third octet of the wildcard address while making the policy match. If the wildcard address usage is restricted to full octets only, then wildcard masks with either 0 or 255 in each of the four octets only will be permitted.

NOTE: The first octet of the wildcard mask should be greater than 128. For example, a wildcard mask represented as 0.255.0.255 or 1.255.0.255 is invalid.

A wildcard security policy is a simple firewall policy that allows you to permit, deny, and reject the traffic trying to cross from one security zone to another. You should not configure security policy rules using wildcard addresses for services such as Unified Threat Management (UTM).

NOTE: Only Intrusion and Prevention (IDP) for IPv6 sessions is supported for all high-end SRX Series devices. UTM for IPv6 sessions is not supported. If your current security policy uses rules with the IP address wildcard any, and UTM features are enabled, you will encounter configuration commit errors because UTM features do not yet support IPv6 addresses. To resolve the errors, modify the rule returning the error so that the any-ipv4 wildcard is used; and create separate rules for IPv6 traffic that do not include UTM features.

Configuring wildcard security policies on a device affects performance and memory usage based on the number of wildcard policies configured per from-zone and to-zone context. Therefore, you can only configure a maximum of 480 wildcard policies for a specific from-zone and to-zone context.

Understanding Security Policy Elements

A security policy is a set of statements that controls traffic from a specified source to a specified destination using a specified service. A policy permits, denies, or tunnels specified types of traffic unidirectionally between two points.

Each policy consists of:

- A unique name for the policy.
- A **from-zone** and a **to-zone**, for example: `user@host# set security policy from-zone untrust to-zone untrust`
- A set of match criteria defining the conditions that must be satisfied to apply the policy rule. The match criteria are based on a source IP address, destination IP address, and applications. The user identify firewall provides greater granularity by including an additional tuple, source-identity, as part of the policy statement.
- A set of actions to be performed in case of a match—permit, deny, or reject.
- Accounting and auditing elements—counting, logging, or structured system logging.

If the SRX Series receives a packet that matches those specifications, it performs the action specified in the policy.

Security policies enforce a set of rules for transit traffic, identifying which traffic can pass through the firewall and the actions taken on the traffic as it passes through the firewall. Actions for traffic matching the specified criteria include permit, deny, reject, log, or count.

For SRX Series branch devices, a factory default security policy is provided that:

- permits all traffic from the trust zone to the untrust zone.
- denies all traffic from the untrust zone to the trust zone.
- allows all traffic from the trust zone to the untrust zone.

Understanding Security Policies for Self Traffic

Security policies are configured on the devices to apply services to the traffic flowing through the device. For example UAC and UTM policies are configured to apply services to the transient traffic.

Self-traffic or host traffic, is the host-inbound traffic; that is, the traffic terminating on the device or the host-outbound traffic that is the traffic originating from the device. You can now configure policies to apply services on self traffic. Services like the SSL stack service that must terminate the SSL connection from a remote device and perform some processing on that traffic, IDP services on host-inbound traffic, or IPsec encryption on host-outbound traffic must be applied through the security policies configured on self-traffic.

When you configure a security policy for self-traffic, the traffic flowing through the device is first checked against the policy, then against the **host-inbound-traffic** option configured for the interfaces bound to the zone.

You can configure the security policy for self-traffic to apply services to self-traffic. The host-outbound policies will work only in cases where the packet that originated in the host device goes through the flow and the incoming interface of this packet is set to local.

The advantages of using the self-traffic are:

- You can leverage most of the existing policy or flow infrastructure used for the transit traffic.
- You do not need a separate IP address to enable any service.
- You can apply services or policies to any host-inbound traffic with the destination IP address of any interface on the device.

NOTE: You can configure the security policy for self-traffic with relevant services only. For example, it is not relevant to configure the fwauth service on host-outbound traffic, and gprs-gtp services are not relevant to the security policies for self-traffic.

The security policies for the self traffic are configured under the new default security zone called the *junos-host* zone. The *junos-host* zone will be part of the *junos-defaults* configuration, so users can delete it. The existing zone configurations such as interfaces, screen, tcp-rst, and host-inbound-traffic options are not meaningful to the *junos-host* zone. Therefore there is no dedicated configuration for the *junos-host* zone.

NOTE: You can use *host-inbound-traffic* to control incoming connections to a device; however it does not restrict traffic going out of the device. Whereas, *junos-host-zone* allows you to select the application of your choice and also restrict outgoing traffic. For example, services like NAT, IDP, UTM, and so forth can now be enabled for traffic going in or out of the SRX Series device using *junos-host-zone*.

Security Policies Configuration Overview

You must complete the following tasks to create a security policy:

1. Create zones. See [“Example: Creating Security Zones” on page 1031](#).
2. Configure an address book with addresses for the policy. See [“Example: Configuring Address Books and Address Sets” on page 1056](#).
3. Create an application (or application set) that indicates that the policy applies to traffic of that type. See [“Example: Configuring Applications and Application Sets” on page 1152](#).
4. Create the policy. See [“Example: Configuring a Security Policy to Permit or Deny All Traffic” on page 1074](#), [“Example: Configuring a Security Policy to Permit or Deny Selected Traffic” on page 1078](#), and [“Example: Configuring a Security Policy to Permit or Deny Wildcard Address Traffic” on page 1082](#).
5. Create schedulers if you plan to use them for your policies. See [“Example: Configuring Schedulers for a Daily Schedule Excluding One Day” on page 1104](#).

The Firewall Policy Wizard enables you to perform basic security policy configuration. For more advanced configuration, use the J-Web interface or the CLI.

Configuring Policies Using the Firewall Wizard

The Firewall Policy Wizard enables you to perform basic security policy configuration. For more advanced configuration, use the J-Web interface or the CLI.

To configure policies using the Firewall Policy Wizard:

1. Select **Configure>Tasks>Configure FW Policy** in the J-Web interface.
2. Click the Launch Firewall Policy Wizard button to launch the wizard.
3. Follow the prompts in the wizard.

The upper-left area of the wizard page shows where you are in the configuration process. The lower-left area of the page shows field-sensitive help. When you click a link under the Resources heading, the document opens in your browser. If the document opens in a new tab, be sure to close only the tab (not the browser window) when you close the document.

Example: Configuring a Security Policy to Permit or Deny All Traffic

This example shows how to configure a security policy to permit or deny all traffic.

- [Requirements on page 1074](#)
- [Overview on page 1074](#)
- [Configuration on page 1075](#)
- [Verification on page 1077](#)

Requirements

Before you begin:

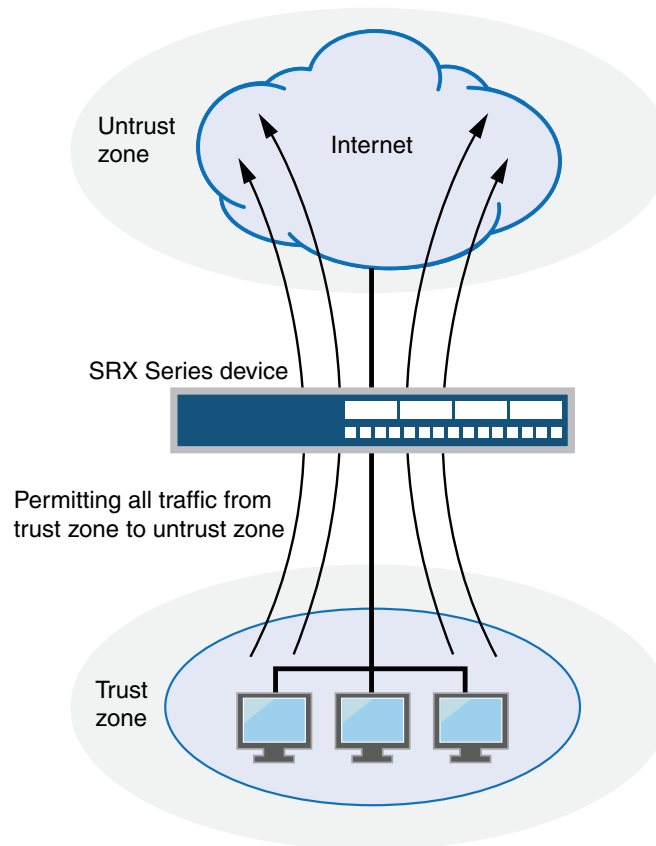

- Create zones. See [“Example: Creating Security Zones” on page 1031](#).
- Configure an address book and create addresses for use in the policy. See [“Example: Configuring Address Books and Address Sets” on page 1056](#).
- Create an application (or application set) that indicates that the policy applies to traffic of that type. See [“Example: Configuring Applications and Application Sets” on page 1152](#).

Overview

In the Junos OS, security policies enforce rules for transit traffic, in terms of what traffic can pass through the device, and the actions that need to take place on traffic as it passes through the device. From the perspective of security policies, the traffic enters one security

zone and exits another security zone. In this example, you configure the trust and untrust interfaces, ge-0/0/2 and ge-0/0/1. See [Figure 67](#).

Figure 67: Permitting All Traffic

This configuration example shows how to:

- Permit or deny all traffic from the trust zone to the untrust zone but block everything from the untrust zone to the trust zone.
- Permit or deny selected traffic from a host in the trust zone to a server in the untrust zone at a particular time.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security zones security-zone trust interfaces ge-0/0/2 host-inbound-traffic
system-services all
set security zones security-zone untrust interfaces ge-0/0/1 host-inbound-traffic
system-services all
set security policies from-zone trust to-zone untrust policy permit-all match
source-address any
```

```

set security policies from-zone trust to-zone untrust policy permit-all match
  destination-address any
set security policies from-zone trust to-zone untrust policy permit-all match application
  any
set security policies from-zone trust to-zone untrust policy permit-all then permit
set security policies from-zone untrust to-zone trust policy deny-all match source-address
  any
set security policies from-zone untrust to-zone trust policy deny-all match
  destination-address any
set security policies from-zone untrust to-zone trust policy deny-all match application
  any
set security policies from-zone untrust to-zone trust policy deny-all then deny

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure a security policy to permit or deny all traffic:

1. Configure the interfaces and security zones.

```

[edit security zones]
user@host# set security-zone trust interfaces ge-0/0/2 host-inbound-traffic
system-services all
user@host# set security-zone untrust interfaces ge-0/0/1 host-inbound-traffic
system-services all

```
2. Create the security policy to permit traffic from the trust zone to the untrust zone.

```

[edit security policies from-zone trust to-zone untrust]
user@host# set policy permit-all match source-address any
user@host# set policy permit-all match destination-address any
user@host# set policy permit-all match application any
user@host# set policy permit-all then permit

```
3. Create the security policy to deny traffic from the untrust zone to the trust zone.

```

[edit security policies from-zone untrust to-zone trust]
user@host# set policy deny-all match source-address any
user@host# set policy deny-all match destination-address any
user@host# set policy deny-all match application any
user@host# set policy deny-all then deny

```

Results From configuration mode, confirm your configuration by entering the **show security policies** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

NOTE: The configuration example is a default permit-all from the trust zone to the untrust zone.

```

[edit]
user@host# show security policies
from-zone trust to-zone untrust {

```

```

policy permit-all {
  match {
    source-address any;
    destination-address any;
    application any;
  }
  then {
    permit;
  }
}
}
from-zone untrust to-zone trust {
  policy deny-all {
    match {
      source-address any;
      destination-address any;
      application any;
    }
    then {
      deny;
    }
  }
}
}

user@host# show security zones
security-zone trust {
  interfaces {
    ge-0/0/2.0 {
      host-inbound-traffic {
        system-services {
          all;
        }
      }
    }
  }
}
security-zone untrust {
  interfaces {
    ge-0/0/1.0 {
      host-inbound-traffic {
        system-services {
          all;
        }
      }
    }
  }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

Verifying Policy Configuration

Purpose	Verify information about security policies.
Action	From operational mode, enter the show security policies detail command to display a summary of all security policies configured on the device.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security zones security-zone trust interfaces ge-0/0/2 host-inbound-traffic
system-services all
set security zones security-zone untrust interfaces ge-0/0/1 host-inbound-traffic
system-services all
set security address-book book1 address mail-untrust 1.1.1.24/32
set security address-book book1 attach zone untrust
set security address-book book2 address mail-trust 192.168.1.1/32
set security address-book book2 attach zone trust
set security policies from-zone trust to-zone untrust policy permit-mail match
source-address mail-trust
```

```

set security policies from-zone trust to-zone untrust policy permit-mail match
destination-address mail-untrust
set security policies from-zone trust to-zone untrust policy permit-mail match application
junos-mail
set security policies from-zone trust to-zone untrust policy permit-mail then permit

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure a security policy to allow selected traffic:

1. Configure the interfaces and security zones.

```

[edit security zones]
user@host# set security-zone trust interfaces ge-0/0/2 host-inbound-traffic
system-services all
user@host# set security-zone untrust interfaces ge-0/0/1 host-inbound-traffic
system-services all

```

2. Create address book entries for both the client and the server. Also, attach security zones to the address books.

```

[edit security address-book book1]
user@host# set address mail-untrust 1.1.1.24/32
user@host# set attach zone untrust

[edit security address-book book2]
user@host# set address mail-trust 192.168.1.1/32
user@host# set attach zone trust

```

3. Define the policy to permit mail traffic.

```

[edit security policies from-zone trust to-zone untrust]
user@host# set policy permit-mail match source-address mail-trust
user@host# set policy permit-mail match destination-address mail-untrust
user@host# set policy permit-mail match application junos-mail
user@host# set policy permit-mail then permit

```

Results From configuration mode, confirm your configuration by entering the **show security policies** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show security policies
from-zone trust to-zone untrust {
  policy permit-mail {
    match {
      source-address mail-trust;
      destination-address mail-untrust;
      application junos-mail;
    }
    then {
      permit;
    }
  }
}

```

```
user@host# show security zones
security-zone trust {
  host-inbound-traffic {
    system-services {
      all;
    }
    interfaces {
      ge-0/0/2 {
        host-inbound-traffic {
          system-services {
            all;
          }
        }
      }
    }
  }
}
security-zone untrust {
  interfaces {
    ge-0/0/1 {
      host-inbound-traffic {
        system-services {
          all;
        }
      }
    }
  }
}

user@host# show security address-book
book1 {
  address mail-untrust 1.1.1.24/32;
  attach {
    zone untrust;
  }
}
book2 {
  address mail-trust 192.168.1.1/32;
  attach {
    zone trust;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

- [Requirements on page 1082](#)
- [Overview on page 1082](#)
- [Configuration on page 1083](#)
- [Verification on page 1085](#)

Requirements

Before you begin:

- Understand wildcard addresses. See “[Understanding Wildcard Addresses](#)” on page 1070.
- Create zones. See “[Example: Creating Security Zones](#)” on page 1031.
- Configure an address book and create addresses for use in the policy. See “[Example: Configuring Address Books and Address Sets](#)” on page 1056.
- Create an application (or application set) that indicates that the policy applies to traffic of that type. See “[Example: Configuring Applications and Application Sets](#)” on page 1152.
- Permit traffic to and from trust and untrust zones. See “[Example: Configuring a Security Policy to Permit or Deny All Traffic](#)” on page 1074.
- Permit e-mail traffic to and from trust and untrust zones. See “[Example: Configuring a Security Policy to Permit or Deny Selected Traffic](#)” on page 1078

Overview

In the Junos operating system (Junos OS), security policies enforce rules for the transit traffic, in terms of what traffic can pass through the device, and the actions that need to take place on the traffic as it passes through the device. From the perspective of security policies, the traffic enters one security zone and exits another security zone. In this

example, you configure a specific security to allow only wildcard address traffic from a host in the trust zone to the untrust zone. No other traffic is allowed.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** in configuration mode.

```
set security zones security-zone trust interfaces ge-0/0/2 host-inbound-traffic
system-services all
set security zones security-zone untrust interfaces ge-0/0/1 host-inbound-traffic
system-services all
set security address-book book1 address wildcard-trust wildcard-address
192.168.0.11/255.255.0.255
set security address-book book1 attach zone trust
set security policies from-zone trust to-zone untrust policy permit-wildcard match
source-address wildcard-trust
set security policies from-zone trust to-zone untrust policy permit-wildcard match
destination-address any
set security policies from-zone trust to-zone untrust policy permit-wildcard match
application any
set security policies from-zone trust to-zone untrust policy permit-wildcard then permit
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure a security policy to allow selected traffic:

1. Configure the interfaces and security zones.

```
[edit security zones]
user@host# set security-zone trust interfaces ge-0/0/2 host-inbound-traffic
system-services all
user@host# set security-zone untrust interfaces ge-0/0/1 host-inbound-traffic
system-services all
```

2. Create an address book entry for the host and attach the address book to a zone.

```
[edit security address-book book1]
user@host# set address wildcard-trust wildcard-address 192.168.0.11/255.255.0.255
user@host# set attach zone trust
```

3. Define the policy to permit wildcard address traffic.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy permit-wildcard match source-address wildcard-trust
user@host# set policy permit-wildcard match destination-address any
user@host# set policy permit-wildcard match application any
user@host# set policy permit-wildcard then permit
```

Results From configuration mode, confirm your configuration by entering the **show security policies** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security policies
from-zone trust to-zone untrust {
  policy permit-wildcard {
    match {
      source-address wildcard-trust;
      destination-address any;
      application any;
    }
    then {
      permit;
    }
  }
}

user@host# show security zones
security-zone trust {
  host-inbound-traffic {
    system-services {
      all;
    }
  }
  interfaces {
    ge-0/0/2 {
      host-inbound-traffic {
        system-services {
          all;
        }
      }
    }
  }
}

security-zone untrust {
  interfaces {
    ge-0/0/1 {
      host-inbound-traffic {
        system-services {
          all;
        }
      }
    }
  }
}

user@host# show security address-book
book1 {
  address wildcard-trust {
    wildcard-address 192.168.0.11/255.255.0.255;
  }
  attach {
    zone trust;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Policy Configuration on page 1085](#)

Verifying Policy Configuration

Purpose	Verify information about security policies.
Action	From operational mode, enter the show security policies policy-name permit-wildcard detail command to display details about the permit-wildcard security policy configured on the device.
Meaning	<p>The output displays information about the permit-wildcard policy configured on the system. Verify the following information:</p> <ul style="list-style-type: none">• From and To zones• Source and destination addresses• Match criteria
Related Documentation	<ul style="list-style-type: none">• Security Policies Configuration Overview on page 1073• Understanding Security Policy Rules on page 1067• Example: Configuring a Security Policy to Permit or Deny All Traffic on page 1074• Example: Configuring a Security Policy to Permit or Deny Selected Traffic on page 1078

Example: Configuring a Security Policy to Redirect Traffic Logs to an External System Log Server

This example shows how to configure a security policy to send traffic logs generated on the device to an external system log server.

- [Requirements on page 1085](#)
- [Overview on page 1086](#)
- [Configuration on page 1086](#)
- [Verification on page 1088](#)

Requirements

This example uses the following hardware and software components:

- A client connected to an SRX5600 device at the interface ge-4/0/5
- A server connected to the SRX5600 device at the interface ge-4/0/4

The logs generated on the SRX5600 device are stored in a Linux-based system log server.

- An SRX5600 device connected to the Linux-based server

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you configure a security policy on the SRX5600 device to send traffic logs, generated by the device during data transmission, to a Linux-based server. Traffic logs record details of every session. The logs are generated during session establishment and termination between the source and the destination device that are connected to the SRX5600 device.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** in configuration mode.

```
set security log source-address 1.1.1.1
set security log stream trafficlogs severity debug
set security log stream trafficlogs host 14.1.1.2
set security zones security-zone client host-inbound-traffic system-services all
set security zones security-zone client host-inbound-traffic protocols all
set security zones security-zone client interfaces ge-4/0/5.0
set security zones security-zone server host-inbound-traffic system-services all
set security zones security-zone server interfaces ge-4/0/4.0
```

```

set security zones security-zone server interfaces ge-4/0/1.0
set security policies from-zone client to-zone server policy match source-address any
set security policies from-zone client to-zone server policy match destination-address
  any
set security policies from-zone client to-zone server policy match application any
set security policies from-zone client to-zone server policy match then permit
set security policies from-zone client to-zone server policy match then log session-init
set security policies from-zone client to-zone server policy match then log session-close

```

**Step-by-Step
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure a security policy to send traffic logs to an external system log server:

1. Configure security logs to transfer traffic logs generated at the SRX5600 device to an external system log server with the IP address 14.1.1.2. The IP address 1.1.1.1 is the loopback address of the SRX5600 device.

```

[edit security log]
user@host# set source-address 1.1.1.1
user@host# set stream trafficlogs severity debug
user@host# set stream trafficlogs host 14.1.1.2

```

2. Configure a security zone and specify the types of traffic and protocols that are allowed on interface ge-4/0/5.0 of the SRX5600 device.

```

[edit security zones]
user@host# set security-zone client host-inbound-traffic system-services all
user@host# set security-zone client host-inbound-traffic protocols all
user@host# set security-zone client interfaces ge-4/0/5.0

```

3. Configure another security zone and specify the types of traffic that are allowed on the interfaces ge-4/0/4.0 and ge-4/0/1.0 of the SRX5600 device.

```

[edit security zones]
user@host# set security-zone server host-inbound-traffic system-services all
user@host# set security-zone server interfaces ge-4/0/4.0
user@host# set security-zone server interfaces ge-4/0/1.0

```

4. Create a policy and specify the match criteria for that policy. The match criteria specifies that the device can allow traffic from any source, to any destination, and on any application.

```

[edit security policies from-zone client to-zone server]
user@host# set policy match source-address any
user@host# set policy match destination-address any
user@host# set policy match application any
user@host# set policy match then permit any

```

5. Enable the policy to log traffic details at the beginning and at the end of the session.

```

[edit security policies from-zone client to-zone server]
user@host# set policy match then log session-init
user@host# set policy match then log session-close

```

Results From configuration mode, confirm your configuration by entering the **show security log** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security log
format syslog;
source-address 1.1.1.1;
stream trafficlogs {
  severity debug;
  host {
    14.1.1.2;
  }
}
```

If you are done configuring the device, enter **commit** from the configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying Zones on page 1088](#)
- [Verifying Policies on page 1088](#)

Verifying Zones

Purpose Verify that the security zone is enabled or not.

Action From operational mode, enter the **show security zones** command.

Verifying Policies

Purpose Verify that the policy is working.

Action From operational mode, enter the **show security policies** command on all the devices.

CHAPTER 51

Configuring Negated Addresses

- [Understanding Negated Address Support on page 1089](#)
- [Example: Configuring Negated Addresses on page 1090](#)

Understanding Negated Address Support

Junos OS allows users to add any number of source and destination addresses to a policy. If you need to exclude certain addresses from a policy, you can configure them as negated addresses. When an address is configured as a negated address, it is excluded from a policy. You cannot, however, exclude the following IP addresses from a policy:

- Wildcard
- IPv6
- any
- any-ipv4
- any-ipv6
- 0.0.0.0

When a range of addresses or a single address is negated, it can be divided into multiple addresses. These negated addresses are shown as a prefix or a length that requires more memory for storage on a Packet Forwarding Engine.

Each platform has a limited number of policies with negated addresses. A policy can contain 10 source or destination addresses. The capacity of the policy depends on the maximum number of policies that the platform supports.

Before you configure a negated source address, destination address, or both, perform the following tasks:

1. Create a source, destination, or both address book.
2. Create address names and assign source and destination addresses to the address names.
3. Create address sets to group source, destination, or both address names.
4. Attach source and destination address books to security zones. For example, attach the source address book to the from-zone **trust** and the destination address book to the to-zone **untrust**.
5. Specify the match source, destination, or both address names.
6. Execute source-address-excluded, destination-address excluded, or both commands. A source, destination, or both addresses added in the source, destination, or both address books will be excluded from the policy.

NOTE: The global address book does not need to be attached to any security zone.

**Related
Documentation**

- [Example: Configuring Negated Addresses on page 1090](#)

Example: Configuring Negated Addresses

This example shows how to configure negated source and destination addresses. It also shows how to configure address books and address sets.

- [Requirements on page 1090](#)
- [Overview on page 1091](#)
- [Configuration on page 1091](#)
- [Verification on page 1093](#)

Requirements

This example uses the following hardware and software components:

- An SRX Series device
- A PC
- Junos OS Release 12.1X45-D10

Before you begin, configure address books and address sets. See [“Example: Configuring Address Books and Address Sets” on page 1056](#).

Overview

In this example, you create source and destination address books, SOUR-ADDR and DES-ADDR, and add source and destination addresses to it. You create source and destination address sets, as1 and as2, and group source and destination addresses to them. Then you attach source address book to the security zone trust and the destination address book to the security zone untrust.

You create security zones from-zone trust and to-zone untrust. You specify the policy name to p1 and then you set the name of the match source address to as1 and the match destination address to as2. You specify the commands **source -address-excluded** and **destination -address-excluded** to exclude source and destination addresses configured in the policy p1. Finally, you set the policy p1 to permit traffic from-zone trust to to-zone untrust.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security address-book SOU-ADDR address ad1 255.255.255.255/32
set security address-book SOU-ADDR address ad2 1.1.1.1/32
set security address-book SOU-ADDR address ad3 range-address 15.100.199.56 to
  15.200.100.16
set security address-book SOU-ADDR address ad4 15.100.196.0/22
set security address-book SOU-ADDR address-set as1 address ad1
set security address-book SOU-ADDR address-set as1 address ad2
set security address-book SOU-ADDR address-set as1 address ad3
set security address-book SOU-ADDR address-set as1 address ad4
set security address-book SOU-ADDR attach zone trust
set security address-book DES-ADDR address ad8 2.1.1.1/32
set security address-book DES-ADDR address ad9 range-address 20.1.1.11 to 50.1.5.199
set security address-book DES-ADDR address ad10 50.1.4.0/22
set security address-book DES-ADDR address ad11 range-address 20.1.7.199 to 20.1.8.19
set security address-book DES-ADDR address-set as2 address ad8
set security address-book DES-ADDR address-set as2 address ad9
set security address-book DES-ADDR address-set as2 address ad10
set security address-book DES-ADDR address-set as2 address ad11
set security address-book DES-ADDR attach zone untrust
set security policies from-zone trust to-zone untrust policy p1 match source-address as1
set security policies from-zone trust to-zone untrust policy p1 match
  source-address-excluded
set security policies from-zone trust to-zone untrust policy p1 match destination-address
  as2
set security policies from-zone trust to-zone untrust policy p1 match
  destination-address-excluded
set security policies from-zone trust to-zone untrust policy p1 match application any
set security policies from-zone trust to-zone untrust policy p1 then permit
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure negated addresses:

1. Create a source address book and address names. Add the source addresses to the address book.

```
[edit security address book ]
user@host#set SOU-ADDR address ad1 255.255.255.255/32
user@host#set SOU-ADDR address ad2 1.1.1.1/32
user@host#set SOU-ADDR ad3 range-address 15.100.199.56 to 15.200.100.16
user@host#set SOU-ADDR address ad4 15.100.196.0/22
```

2. Create an address set to group source address names.

```
[edit security address book ]
user@host# set SOU-ADDR address-set as1 address ad1
user@host# set SOU-ADDR address-set as1 address ad2
user@host# set SOU-ADDR address-set as1 address ad3
user@host# set SOU-ADDR address-set as1 address ad4
```

3. Attach the source address book to the security from zone.

```
[edit security address book ]
user@host# set SOU-ADDR attach zone trust
```

4. Create a destination address book and address names. Add the destination addresses to the address book.

```
[edit security address book ]
user@host#set DES-ADDR address ad8 2.1.1.1/32
user@host#set DES-ADDR address ad9 range-address 20.1.1.11 to 50.1.5.199
user@host#set DES-ADDR address ad10 50.1.4.0/22
user@host#set DES-ADDR address ad11 range-address 20.1.7.199 to 20.1.8.19
```

5. Create another address set to group destination address names.

```
[edit security address book ]
user@host# set DES-ADDR address-set as1 address ad8
user@host# set DES-ADDR address-set as1 address ad9
user@host# set DES-ADDR address-set as1 address ad10
user@host# set DES-ADDR address-set as1 address ad11
```

6. Attach the destination address book to the security to zone.

```
[edit security address book ]
user@host# set DES-ADDR attach zone untrust
```

7. Specify the policy name and source address.

```
[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 match source-address
as1
```

8. Exclude source addresses from the policy.

```
[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 match
source-address-excluded
```

9. Specify the destination address.

```
[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 match destination-address
as2
```

10. Exclude destination addresses from the policy.

```
[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 match
destination-address-excluded
```

11. Configure the security policy application.

```
[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 match application any
```

12. Permit the traffic from-zone trust to to-zone untrust.

```
[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 then permit
```

Results From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security policies
from-zone trust to-zone untrust {
  policy p1 {
    match {
      source-address as1;
      destination-address as2;
      source-address-excluded;
      destination-address-excluded;
      application any;
    }
    then {
      permit;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Policy Configuration on page 1093](#)
- [Verifying the Policy Configuration Detail on page 1094](#)

Verifying the Policy Configuration

Purpose Verify that the policy configuration is correct.

Action From operational mode, enter the **show security policies policy-name p1** command.

```
user@host>show security policies policy-name p1
node0:
-----
From zone: trust, To zone: untrust
Policy: p1, State: enabled, Index: 4, Scope Policy: 0, Sequence number: 1
Source addresses(excluded): as1
Destination addresses(excluded): as2
Applications: any
Action: permit
```

This output summarizes the policy configuration.

Verifying the Policy Configuration Detail

Purpose Verify that the policy and the negated source and destination address configurations are correct.

Action From operational mode, enter the **show security policies policy-name p1 detail** command.

```
user@host>show security policies policy-name p1 detail
Policy: p1, action-type: permit, State: enabled, Index: 4, Scope Policy: 0
Policy Type: Configured
Sequence number: 1
From zone: trust, To zone: untrust
Source addresses(excluded):
  ad1(SOU-ADDR): 255.255.255.255/32
  ad2(SOU-ADDR): 1.1.1.1/32
  ad3(SOU-ADDR): 15.100.199.56 ~ 15.200.100.16
  ad4(SOU-ADDR): 15.100.196.0/22
Destination addresses(excluded):
  ad8(DES-ADDR): 20.1.7.199 ~ 20.1.8.19
  ad9(DES-ADDR): 50.1.4.0/22
  ad10(DES-ADDR): 20.1.1.11 ~ 50.1.5.199
  ad11(DES-ADDR): 2.1.1.1/32
Application: any
IP protocol: 0, ALG: 0, Inactivity timeout: 0
Source port range: [0-0]
Destination port range: [0-0]
Per policy TCP Options: SYN check: No, SEQ check: No
```

This output summarizes the policy configuration and shows the names of negated source and destination addresses excluded from the policy.

Configuring Global Security Policy

- [Global Policy Overview on page 1095](#)
- [Example: Configuring a Global Policy with No Zone Restrictions on page 1097](#)
- [Example: Configuring a Global Policy with Multiple Zones on page 1099](#)

Global Policy Overview

In a Junos OS stateful firewall, security policies enforce rules for transit traffic, in terms of what traffic can pass through the firewall, and the actions that need to take place on traffic as it passes through the firewall. Security policies require traffic to enter one security zone and exit another security zone. This combination of a from-zone and to-zone is called a *context*. Each context contains an ordered list of policies. Each policy is processed in the order that it is defined within a context. Traffic is classified by matching the policy's from-zone, to-zone, source address, destination address, and the application that the traffic carries in its protocol header. Each global policy, as with any other security policy, has the following actions: permit, deny, reject, log, count.

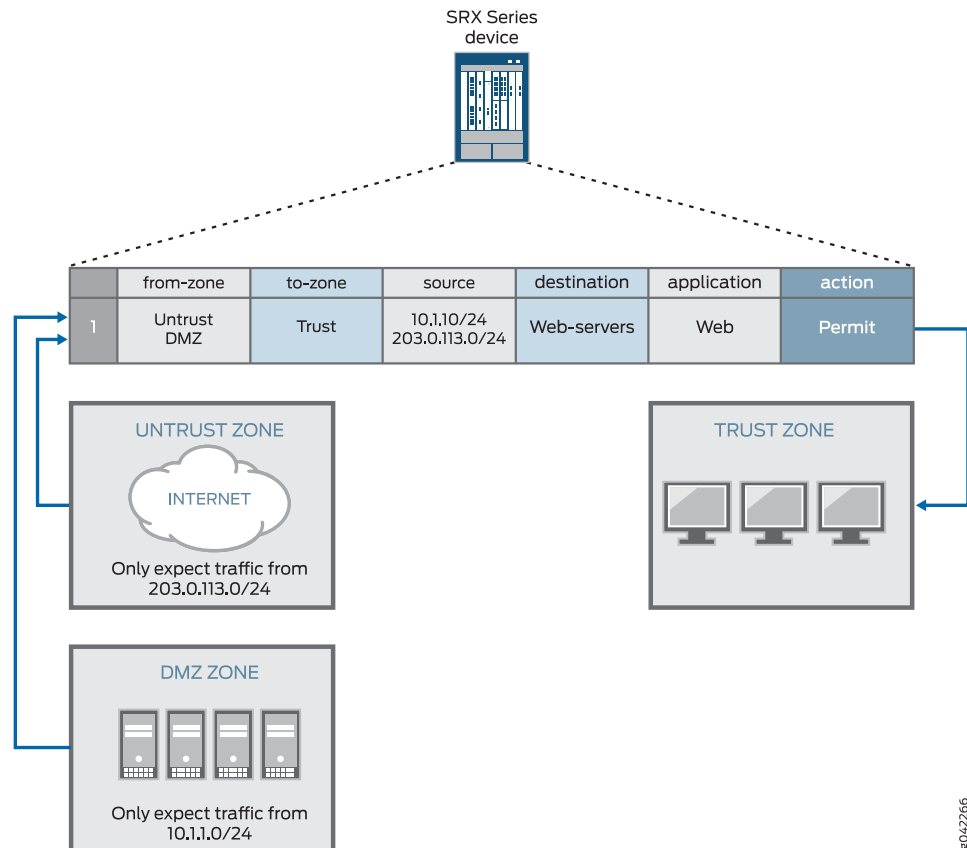

You can configure a security policy from the user interface. Security policies control traffic flow from one zone to another zone by defining the kind(s) of traffic permitted from specific IP sources to specific IP destinations at scheduled times. This works well in most cases, but it is not flexible enough. For example, if you want to perform actions on traffic you have to configure policies for each possible context. To avoid creating multiple policies across every possible context, you can create a global policy that encompasses all zones, or a multizone policy that encompasses several zones.

Using a global policy, you can regulate traffic with addresses and applications, regardless of their security zones, by referencing user-defined addresses or the predefined address “any.” These addresses can span multiple security zones. For example, if you want to provide access to or from multiple zones, you can create a global policy with the address “any,” which encompasses all addresses in all zones. Selecting the “any” address matches any IP address, and when “any” is used as a source/destination address in any global policy configuration, it matches the source/destination address of any packet.

Using a global policy you can also provide access to multiple source zones and multiple destination zones in one policy. However, we recommend that, for security reasons and to avoid spoofing traffic, when you create a multizone policy you use identical matching criteria (source address, destination address, application) and an identical action. In [Figure 69](#), for example, if you create a multizone policy that includes DMZ and Untrust

from-zones, spoofing traffic from 203.0.113.0/24 from the DMZ zone could match the policy successfully and reach the protected host in the Trust to-zone.

Figure 69: Multizone Global Policy Security Consideration

NOTE: Global policies without from-zone and to-zone information do not support VPN tunnels because VPN tunnels require specific zone information.

When policy lookup is performed, policies are checked in the following order: intra-zone (trust-to-trust), inter-zone (trust-to-untrust), then global. Similar to regular policies, global policies in a context are ordered, such that the first matched policy is applied to the traffic.

NOTE: If you have a global policy, make sure you have not defined a “catch-all” rule such as, match source any, match destination any, or match application any in the intra-zone or inter-zone policies because the global policies will not be checked. If you do not have a global policy, then it is recommended that you include a “deny all” action in your intra-zone or inter-zone policies. If you do have a global policy, then you should include a “deny all” action in the global policy.

In logical systems, you can define global policies for each logical system. Global policies in one logical system are in a separate context than other security policies, and have a lower priority than regular security policies in a policy lookup. For example, if a policy lookup is performed, regular security policies have priority over global policies. Therefore, in a policy lookup, regular security policies are searched first and if there is no match, global policy lookup is performed.

Related Documentation

- [Understanding Security Policy Rules on page 1067](#)
- [Understanding Security Policy Elements on page 1071](#)
- [Example: Configuring a Global Policy with No Zone Restrictions on page 1097](#)

Example: Configuring a Global Policy with No Zone Restrictions

Unlike other security policies in Junos OS, global policies do not reference specific source and destination zones. Global policies reference the predefined address “any” or user-defined addresses that can span multiple security zones. Global policies give you the flexibility of performing actions on traffic without any zone restrictions. For example, you can create a global policy so that every host in every zone can access the company website, for example, www.example.net. Using a global policy is a convenient shortcut when there are many security zones. Traffic is classified by matching its source address, destination address, and the application that the traffic carries in its protocol header.

This example shows how to configure a global policy to deny or permit traffic.

- [Requirements on page 1097](#)
- [Overview on page 1098](#)
- [Configuration on page 1098](#)
- [Verification on page 1099](#)

Requirements

Before you begin:

- Review the firewall security policies.

See “Security Policies Overview” on page 1065, “Global Policy Overview” on page 1095, “Understanding Security Policy Rules” on page 1067, and “Understanding Security Policy Elements” on page 1071.

- Configure an address book and create addresses for use in the policy.

See “Example: Configuring Address Books and Address Sets” on page 1056.

- Create an application (or application set) that indicates that the policy applies to traffic of that type.

See “Example: Configuring Applications and Application Sets” on page 1152.

Overview

This configuration example shows how to configure a global policy that accomplishes what multiple security policies (using zones) would have accomplished. Global policy gp1 permits all traffic while policy gp2 denies all traffic.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security address-book global address server1 www.example.net
set security address-book global address server2 www.mail.com
set security policies global policy gp1 match source-address server1
set security policies global policy gp1 match destination-address server2
set security policies global policy gp1 match application any
set security policies global policy gp1 then permit
set security policies global policy gp2 match source-address server2
set security policies global policy gp2 match destination-address server1
set security policies global policy gp2 match application junos-ftp
set security policies global policy gp2 then deny
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure a global policy to permit or deny all traffic:

1. Create addresses.

```
[edit security]
user@host# set security address-book global address server1 www.example.net
user@host# set security address-book global address server2 www.mail.com
```

2. Create the global policy to permit all traffic.

```
[edit security]
user@host# set policy global policy gp1 match source-address server1
user@host# set policy global policy gp1 match destination-address server2
user@host# set policy global policy gp1 match application any
user@host# set policy global policy gp1 then permit
```

3. Create the global policy to deny all traffic.

```
[edit security]
user@host# set policy global policy gp2 match source-address server2
user@host# set policy global policy gp2 match destination-address server1
user@host# set policy global policy gp2 match application junos-ftp
user@host# set policy global policy gp2 then deny
```

Results From configuration mode, confirm your configuration by entering the **show security policies** and **show security policies <global>** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host> show security policies
Default policy: permit-all
Global policies:
  Policy: gp1, State: enabled, Index: 4, Scope Policy: 0, Sequence number: 1
    Source addresses: server1
    Destination addresses: server2
    Applications: any
    Action: permit
  Policy: gp2, State: enabled, Index: 5, Scope Policy: 0, Sequence number: 2
    Source addresses: server2
    Destination addresses: server1
    Applications: junos-ftp
    Action: deny
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying Global Policy Configuration

Purpose Verify that global policies gp1 and gp2 are configured as required.

Action From operational mode, enter the **show security policies <global>** command.

Related Documentation

- [Global Policy Overview on page 1095](#)

Example: Configuring a Global Policy with Multiple Zones

Unlike other security policies in Junos OS, global policies allow you to create multizone policies. A global policy is a convenient shortcut when there are many security zones, because it enables you to configure multiple source zones and multiple destination zones in one global policy instead of having to create a separate policy for each

from-zone/to-zone pair, even when other attributes, such as source-address or destination-address, are identical.

- [Requirements on page 1100](#)
- [Overview on page 1100](#)
- [Configuration on page 1100](#)
- [Verification on page 1101](#)

Requirements

Before you begin:

- Review the firewall security policies.

See “Security Policies Overview” on page 1065, “Global Policy Overview” on page 1095, “Understanding Security Policy Rules” on page 1067, and “Understanding Security Policy Elements” on page 1071.

- Create security zones.

See “Example: Creating Security Zones” on page 1031

Overview

This configuration example shows how to configure a global policy that accomplishes what multiple security policies would have accomplished. Global policy Pa permits all traffic from zones 1 and 2 to zones 3 and 4.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security policies global policy Pa match source-address any
set security policies global policy Pa match destination-address any
set security policies global policy Pa match application any
set security policies global policy Pa match from-zone zone1
set security policies global policy Pa match from-zone zone2
set security policies global policy Pa match to-zone zone3
set security policies global policy Pa match to-zone zone4
set security policies global policy Pa then permit
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a global policy with multiple zones:

1. Create a global policy to allow any traffic from zones 1 and 2 to zones 3 and 4.

```
[edit security]
set security policies global policy Pa match source-address any
```

```
set security policies global policy Pa match destination-address any
set security policies global policy Pa match application any
set security policies global policy Pa match from-zone zone1
set security policies global policy Pa match from-zone zone2
set security policies global policy Pa match to-zone zone3
set security policies global policy Pa match to-zone zone4
set security policies global policy Pa then permit
```

Results From configuration mode, confirm your configuration by entering the **show security policies global** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show security policies global
policy Pa {
  match {
    source-address any;
    destination-address any;
    application any;
    from-zone [ zone1 zone2 ];
    to-zone [ zone3 zone4 ];
  }
  then {
    permit;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying Global Policy Configuration

Purpose Verify that the global policy is configured as required.

Action From operational mode, enter the **show security policies global** command.

Managing Security Policy Activation By Configuring Schedulers

- [Security Policy Schedulers Overview on page 1103](#)
- [Example: Configuring Schedulers for a Daily Schedule Excluding One Day on page 1104](#)

Security Policy Schedulers Overview

Schedulers are powerful features that allow a policy to be activated for a specified duration. You can define schedulers for a single (nonrecurrent) or recurrent time slot within which a policy is active. You can create schedulers irrespective of a policy, meaning that a scheduler cannot be used by any policies. However, if you want a policy to be active within a scheduled time, then you must first create a scheduler.

When a scheduler times out, the associated policy is deactivated and all sessions associated with the policy are also timed out.

If a policy contains a reference to a scheduler, the schedule determines when the policy is active, that is, when it can be used as a possible match for traffic. Schedulers allow you to restrict access to a resource for a period of time or remove a restriction.

The following guidelines apply to schedulers:

- A scheduler can have multiple policies associated with it; however, a policy cannot be associated with multiple schedulers.
- A policy is active during the time when the scheduler it refers to is also active.
- When a scheduler is off, the policy is unavailable for policy lookup.
- A scheduler can be configured as one of the following:
 - Scheduler can be active for a single time slot, as specified by a start date and time and a stop date and time.
 - Scheduler can be active forever (recurrent), but as specified by the daily schedule. The schedule on a specific day (time slot) takes priority over the daily schedule.
 - Scheduler can be active within a time slot as specified by the weekday schedule.
 - Scheduler can have a combination of two time slots (daily and timeslot).

Example: Configuring Schedulers for a Daily Schedule Excluding One Day

This example shows how to configure schedulers for packet match checks every day except Sunday.

- [Requirements on page 1104](#)
- [Overview on page 1104](#)
- [Configuration on page 1104](#)
- [Verification on page 1106](#)

Requirements

Before you begin:

- Understand security policies schedulers. See "[Security Policies Overview](#)" on page 1065.
- Configure security zones before applying this configuration. See "[Example: Creating Security Zones](#)" on page 1031.

Overview

Schedulers are powerful features that allow a policy to be activated for a specified duration. You can define schedulers for a single (nonrecurrent) or recurrent time slot within which a policy is active. If you want a policy to be active within a scheduled time, then you must first create a scheduler.

To configure a scheduler, you enter a meaningful name and a start and stop time for the scheduler. You can also attach comments.

In this example, you:

- Specify the scheduler, `sch1`, that allows a policy, which refers to it, to be used for packet match checks every day except Sundays.
- Create a policy, `abc`, and specify the match conditions and action to be taken on traffic that matches the specified conditions, and bind the schedulers to the policy to allow access during the specified days.

Configuration

- CLI Quick Configuration**
- To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set schedulers scheduler sch1 daily all-day
```

```
set schedulers scheduler sch1 sunday exclude
set security policies from-zone green to-zone red policy abc match source-address any
set security policies from-zone green to-zone red policy abc match destination-address
  any
set security policies from-zone green to-zone red policy abc match application any
set security policies from-zone green to-zone red policy abc then permit
set security policies from-zone green to-zone red policy abc scheduler-name sch1
set security policies default-policy permit-all
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure a scheduler:

1. Set a scheduler.

```
[edit schedulers ]
user@host# set scheduler sch1 daily all-day
user@host# set scheduler sch1 sunday exclude
```
2. Specify the match conditions for the policy.

```
[edit security policies from-zone green to-zone red policy abc]
user@host# set match source-address any destination-address any application
  any
```
3. Specify the action.

```
[edit security policies from-zone green to-zone red policy abc]
user@host# set then permit
```
4. Associate the scheduler to the policy.

```
[edit security policies from-zone green to-zone red policy abc ]
user@host# set scheduler-name sch1
```

Results From configuration mode, confirm your configuration by entering the **show schedulers** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
[user@host]show schedulers
scheduler sch1 {
  daily all-day;
  sunday exclude;
}
[edit]
[user@host]show security policies
from-zone green to-zone red {
  policy abc {
    match {
      source-address any;
      destination-address any;
      application any;
    }
    then {
```

```
        permit;  
    }  
    scheduler-name sch1;  
}  
default-policy {  
    permit-all;  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Schedulers are Active on page 1106](#)
- [Verifying Policies on page 1106](#)

Verifying Schedulers are Active

Purpose Verify if schedulers are enabled or not.

Action From operational mode, enter the **show schedulers** command.

Verifying Policies

Purpose Verify if the policies are working.

Action From operational mode, enter the **show security policies** command.

Understanding User Role Firewalls

Network security enforcement, monitoring, and reporting based solely on IP information soon will not be sufficient for today's dynamic and mobile workforce. By integrating user firewall policies, administrators can permit or restrict network access of employees, contractors, partners, and other users based on the roles they are assigned. User role firewalls enable greater threat mitigation, provide more informative forensic resources, improve record archiving for regulatory compliance, and enhance routine access provisioning.

User role firewalls trigger two actions:

- Retrieve user and role information associated with the traffic
- Determine the action to take based on six match criteria within the context of the zone pair

The source-identity field distinguishes a user role firewall from other types of firewalls. If the source identity is specified in any policy for a particular zone pair, it is a user role firewall. The user and role information must be retrieved before policy lookup occurs. If the source identity is not specified in any policy, user and role lookup is not required.

To retrieve user and role information, authentication tables are searched for an entry with an IP address corresponding to the traffic. If an entry is found, the user is classified as an authenticated user. If not found, the user is classified as an unauthenticated user.

The username and roles associated with an authenticated user are retrieved for policy matching. Both the authentication classification and the retrieved user and role information are used to match the source-identity field.

Characteristics of the traffic are matched to the policy specifications. Within the zone context, the first policy that matches the user or role and the five standard match criteria determines the action to be applied to the traffic.

The following sections describe the interaction of user and role retrieval and the policy lookup process, methods for acquiring user and role assignments, techniques for configuring user role firewall policies, and an example of configuring user role firewall policies.

User Role Retrieval and the Policy Lookup Process

For policy lookup, firewall policies are grouped by zone pair (the from zone and to zone). Within the context of the zone pair, IP-based firewall policies are matched to traffic based on five criteria—source IP, source port, destination IP, destination port, and protocol.

User role firewall policies include a sixth match criteria—source identity. The source-identity field specifies the users and roles to which the policy applies. When the source-identity field is specified in any policy within the zone pair, user and role information must be retrieved before policy lookup can proceed. (If all policies in the zone pair are set to **any** or have no entry in the source-identity field, user and role information is not required and the five standard match criteria are used for policy lookup.)

The user identification table (UIT) provides user and role information for an active user who has already been authenticated. Each entry in the table maps an IP address to an authenticated user and any roles associated with that user.

When traffic requires user and role data, each registered UIT is searched for an entry with the same IP address. If a user has not been authenticated, there is no entry for that IP address in the table. If no UIT entry exists, the user is considered an unauthenticated user.

Policy lookup resumes after the user and role information has been retrieved. The characteristics of the traffic are matched against the match criteria in the policies. The source-identity field of a policy can specify one or more users or roles, and the following keywords:

authenticated-user—Users that have been authenticated.

unauthenticated-user—Users that have not been authenticated.

any—All users regardless of authentication. If the source-identity field is not configured or is set to any in all of the policies for the zone pair, only five criteria are matched.

unknown-user—Users unable to be authenticated due to an authentication server disconnection, such as a power outage.

For example, consider user-c who is assigned to the mgmt role. When traffic from the trust zone to the untrust zone is received from user-c at IP address 1.1.2.3, policy lookup is initiated. Table 74 represents three policies in a user role firewall for the trust to untrust zone pair.

Table 74: Trust Zone to Untrust Zone Policy Sequence

src-zone	src-zone	dest-zone	src-IP	dest-IP	source-identity	Application	Action	Services
P1	trust	untrust	1.1.1.0	2.2.2.0	any	http	deny	–
P2	trust	untrust	any	any	mgmt	any	permit	–
P3	trust	untrust	1.1.2.3	any	employee	http	deny	–

All policies for the zone pair are checked first for a source-identity option. If any of the policies specifies a user, a role, or a keyword, user and role retrieval must occur before policy lookup continues. Table 74 shows that policy P2 specifies mgmt as the source identity, making this a user role firewall. User and roles must be retrieved before policy lookup can continue.

NOTE: User and role retrieval would not be performed if the keyword any or if no source identity was specified in all of the policies in the zone context. In such cases, only the five remaining values are matched to the policy criteria.

The UIT represented in Table 75 is checked for the IP address. Because the address is found, the username user-c, all roles listed for user-c (in this case, mgmt and employee), and the keyword authenticated-user become data used to match the traffic to the **source-identity** field of a policy.

Table 75: UIT Authentication Details

Source IP Address	Username	Roles
1.1.2.4	user-a	employee
1.1.2.3	user-c	mgmt, employee
1.2.3.2	user-s	contractor

Policy lookup resumes and compares the match criteria in each policy in Table 74 to the incoming traffic. Assuming all other criteria match, the first policy that specifies user-c, mgmt, employee, authenticated-user, or any in the source-identity field could be a match

for this traffic. Policy P1 matches one of the retrieved roles for user-c, but the source IP address does not match; therefore policy lookup continues. For policy P2, all criteria match the traffic; therefore the policy action is followed and the traffic is permitted. Note that the traffic also matches policy P3, but user firewall policies are terminal—policy lookup ends when the first policy match is found. Because policy P2 matches all criteria, policy lookup ends and policy P3 is not checked.

Policies can also be based on the classification assigned to a user from the user and role retrieval results. Consider a different set of policies for the same zone pair represented by [Table 76](#). If traffic is received from user-q at IP 1.1.2.5, user and role retrieval is required because the source-identity field is specified in at least one of the policies.

Table 76: Trust Zone to Untrust Zone Policy Sequence

policy-name	src-zone	dest-zone	src-IP	dest-IP	source-identity	application	action	Services
P1	trust	untrust	any	any	unauthenticated	http	deny	–
P2	trust	untrust	any	any	mgmt	any	permit	–
P3	trust	untrust	1.1.2.3	any	employee	http	deny	–

When the UIT entries in [Table 75](#) are checked, no entry is found for IP address 1.1.2.5. Therefore, the user is considered an unauthenticated user. When policy lookup resumes, the traffic matches policy P1 and the traffic is denied.

Understanding the User Identification Table

On the SRX Series device, the user identification table (UIT) contains the IP address, username, and role information for each authenticated user. Entries are ordered by IP address. When username and role information is required by a security policy, all UITs are checked. Finding the IP address in an entry in one of the UITs means that the user at that address has already been successfully authenticated.

Each authentication source maintains its own UIT independently and provides query functions for accessing data. Three types of UITs are supported—the local authentication table, the Unified Access Control (UAC) authentication table, and the firewall authentication table.

Local authentication table—A static UIT created on the SRX Series device either manually or programmatically using CLI commands. All users included in the local authentication table are considered authenticated users. When a matching IP address

is found, user and role information is retrieved from the table entry and associated with the traffic. User and role information can be created on the device manually or ported from a third-party authentication server, but the data in the local authentication table is not updated in real time.

UAC authentication table—A dynamic UIT pushed from the Junos Pulse Access Control Service to the SRX Series device. The UAC authentication table of a Junos Pulse Access Control Service contains an entry for each authenticated user. The data in this table is updated and pushed to the SRX Series device whenever its authentication table is updated. Depending on the device configuration, authentication could occur on the Junos Pulse Access Control Service itself or on a third-party authentication server. If the Access Control Service is relaying data from a third-party server, the data is restructured by the Access Control Service to match the file format of its authentication table and pushed to the SRX Series device.

Firewall authentication table—A dynamic UIT created on the SRX when **user-firewall** is specified as the firewall authentication type in a security policy. This UIT provides an alternative user role source to UAC when firewall authentication is already in use on your SRX device. In this way, users defined for pass-through authentication can also be used as a source for usernames and roles when the **user-firewall** option is specified as the firewall authentication type in a policy.

The **user-firewall** authentication type initiates firewall authentication to verify the user by using either local authentication information or external authentication servers supporting RADIUS, LDAP, or SecureID authentication methods. When this type is specified for firewall authentication, the username and associated groups (roles) from the authentication source are mapped to the IP address and added to the firewall authentication UIT.

- [Local Authentication Table on page 1111](#)
- [UAC Authentication Table on page 1113](#)
- [Firewall Authentication Table on page 1114](#)
- [Policy Provisioning With Users and Roles on page 1115](#)

Local Authentication Table

The local authentication table is managed with CLI commands that insert or delete entries. A local authentication table can be used as a backup solution when a dynamic UIT is not available, or to assign user and role information to devices that cannot authenticate to the network, such as printers or file servers. The local authentication table can be used for testing or to demonstrate how a user role firewall works without firewall authentication or the Access Control Service configured.

The IP addresses, user names, and roles from a third-party authentication source can be downloaded and added to the local authentication table programmatically using CLI commands. If an authentication source defines users and groups, the groups can be configured as roles and associated with the user as usual.

To be compliant with the UAC authentication table, user names are limited to 65 characters and role names are limited to 64 characters. The local authentication table has a maximum of 10,000 authentication entries on SRX1400 devices and above, and

5000 authentication entries on SRX650 devices and below. Each authentication entry can be associated with up to 200 roles. The maximum capacity is based on an average of 10 roles assigned to each user. This is the same capacity specified for a UAC authentication table.

Use the following command to add an entry to a local authentication table. Note that each entry is keyed by IP address.

```
user@host> request security user-identification local-authentication-table add user
user-name ip-address ip-address role [role-name role-name ]
```

The role option in a single CLI command accepts up to 40 roles. To associate more than 40 roles with a single user, you need to enter multiple commands. Keep the following characteristics in mind when adding or modifying authentication user and role entries.

- Role names cannot be the same as usernames.
- Using the **add** option with an existing IP address and username aggregates the role entries. The table can support up to 200 roles per user.
- Using the **add** option with an existing IP address and a new username overwrites the existing username for that IP address.
- Role aggregation does not affect existing sessions.
- To change the role list of an existing entry, you need to delete the existing entry and add an entry with the new role list.
- To change the IP address of an existing entry, you need to delete the existing entry and add an entry with the new IP address.

An entry can be deleted by IP address or by username.

```
user@host> request security user-identification local-authentication-table delete
(ip-address | user-name)
```

The local authentication table can be cleared with the following command:

```
user@host> clear security user-identification local-authentication-table
```

To display the content of the local authentication table, use the following **show...** command:

```
user@host> show security user-identification local-authentication-table all (brief |
extensive)
```

The **brief** option (the default) displays information in a tabular format sequenced by IP address. User names and role lists are truncated to fit the format.

```
user@host> show security user-identification local-authentication-table all
```

```
Total entries: 2
Source IP      Username      Roles
1.1.1.1        user1         role1
2.2.2.2        user2         role2, role3
```

The **extensive** option displays the full content for each field. Other options limit the display to a single username, IP address, or role.

```

user@host> show security user-identification local-authentication-table all extensive

Total entries: 3
Ip-address: 1.1.1.1
Username: user1
Roles: role1

Ip-address: 2.2.2.2
Username: user1
Roles: role2

Ip-address: 3.3.3.3
Username: user3
Roles: role1, role2

```

UAC Authentication Table

An SRX Series device can act as an enforcer for a Junos Pulse Access Control Service. In this implementation, the SRX Series device acts as a Layer 3 enforcement point and controls access to resources with IP-based resource policies that have been pushed down from the Access Control Service.

When implemented as a user role firewall, the SRX Series device can access the UAC network in a similar way for user role retrieval. In this instance, user and role information for all authenticated users is pushed from the Access Control Service.

The SRX Series device configuration is similar to that of an enforcer. To establish communication, both devices require configuration and password settings to recognize the other. From the SRX Series device, connect the Access Control Service as an infranet controller.

```

[edit]
user@host# set services unified-access-control infranet-controller ic-name address
ip-address
user@host# set services unified-access-control infranet-controller ic-name interface
interface-name
user@host# set services unified-access-control infranet-controller ic-name password
password

```

From the Access Control Service, define the SRX Series device as a New Enforcer. Use the same password specified on the SRX Series device.

Users and passwords are defined on the Access Control Service as in a standard authentication configuration. One or more roles can also be associated with users. When a user is authenticated, an entry containing the IP address, username, and associated roles is added to the UAC authentication table on the Access Control Service.

The UAC authentication table is pushed from the Access Control Service to the SRX Series device when the connection between the two devices is initialized. Whenever an entry is added, removed, or updated on the Access Control Service, the updated UAC authentication table is pushed to the SRX Series device.

Resource access policies are not necessary on the Access Control Service for a user role firewall implementation. The access behavior is provided in the policy configurations on the SRX Series device. If resource access policies are defined on the Access Control

Service, they are pushed to the SRX Series device, but they are not used unless a specific firewall policy implements UAC policies in the policy's action field.

NOTE: On SRX1400, SRX3400, SRX3600, SRX5400, SRX5600, and SRX5800 devices, the default authentication table capacity is 45,000; the administrator can increase the capacity to a maximum of 50,000.

On SRX100, SRX110, SRX210, SRX220, SRX240, SRX550, and SRX650 devices, the default authentication table capacity is 10,000; the administrator can increase the capacity to a maximum of 15,000.

The following **show services** command displays the content of the UAC authentication table on the SRX Series device, confirming that the table has been pushed from the Access Control Service successfully:

```
user@host> show services unified-access-control authentication-table extended
```

Id	Source IP	Username	Age	Role name
3	10.214.161.195	prasanta	60	Users
6	10.214.161.183	june	60	Employees
Total: 2				

The SRX Series device monitors connections and detects if communication to the Access Control Service has been lost. Based on the UAC configuration, the SRX Series device waits for a response for a configured interval before issuing another request. If a response is received, the Access Control Service is considered functional. If no response is received after a specified timeout period, communication is considered lost and the timeout action is applied. The following UAC command syntax configures the interval, timeout, and timeout action:

```
user@host# set services unified-access-control interval seconds
user@host# set services unified-access-control timeout seconds
user@host# set services unified-access-control timeout-action (close | no-change | open)
```

During a disconnection, if user and role lookup is attempted for the disconnected device, it returns a failure code regardless of the timeout action. If access to all authentication sources is lost, the keyword `unknown-user` is associated with the IP address. When policy lookup resumes, a policy with `unknown-user` as the source identity would match the traffic. By implementing a specific policy for `unknown-user`, you can create a method for handling the loss of authentication sources.

Firewall Authentication Table

Firewall authentication requires users to authenticate to the SRX firewall before permitting access between zones and devices. When traffic is received, the user is prompted for a username and password, and verified against a specified profile of valid users. Depending on the device configuration, firewall authentication verifies that telnet, HTTP, HTTPS (for high-end SRX devices), and FTP traffic has been authenticated locally or by a RADIUS, LDAP, or SecureID authentication server.

If firewall authentication is in use on a device, the authentication process can also provide the username and role information needed for user role firewall match criteria. In this

case, the information is collected and maintained in a UIT called the firewall authentication table. One or more access policies in the **edit access** hierarchy define authentication methods to be used for firewall authentication.

The firewall authentication table must be enabled as the authentication source for user role information retrieval. The **priority** option specifies the sequence in which all UITs will be checked.

```
user@host# set security user-identification authentication-source firewall-authentication
priority priority
```

In a firewall policy for a given zone pair, the **firewall-authentication** service specified for the **permit** action initiates authentication of matching traffic. The **user-firewall** authentication type generates the UIT entry for the authenticated user. The name specified in the **access-profile** option identifies the profile to be used to authenticate valid users.

```
[edit security policies from-zone zone to-zone zone policy policy-name]
user@host# set match source-identity unauthenticated-user
user@host# set then permit firewall-authentication user-firewall access-profile
profile-name
```

The UIT table entry contains the IP address of the traffic mapped to the authenticated user and the user's associated groups. When the user is no longer active, the entry is removed from the table. Because entries are continuously added and removed as the traffic and authenticated users change, the firewall authentication table is considered dynamic.

When policies within the same zone pair specify the **source-identity** field as part of its match criteria, all enabled UITs are searched for an entry corresponding to the IP address of the traffic. If found, the associated username and groups are retrieved for source-identity matching. (User authentication group names are considered role names for source-identity matching.)

Policy Provisioning With Users and Roles

All users and roles, whether defined on the SRX Series device or on the Access Control Service, are maintained in a user role file on the SRX Series device. To display all users and roles available for provisioning, use the following **show security...** commands.

NOTE: Usernames and roles in the firewall authentication table are not included in the following displays.

- To display all of the roles that are available for provisioning, use the **show security user-identification role-provision all** command. Note that the roles from all UITs are listed together.
- To display all of the users that are available for provisioning, use the **show security user-identification user-provision all** command.
- To display all of the users and roles that are available for provisioning, use the **show security user-identification source-identity-provision all** command.

When a policy configuration is committed, the user role file is checked to determine if all users and roles specified in the policy are available for provisioning. If a user or role is not found, a warning identifies the missing user or role so that you can define it later.

NOTE: The policy is committed even if a user or role is not yet defined.

Obtaining Username and Role Information Through Firewall Authentication

User role firewall policies can be integrated with firewall authentication both to authenticate users and to retrieve username and role information. The information is mapped to the IP address of the traffic, stored in the firewall authentication table, and used for user role firewall policy enforcement.

The following CLI statements configure firewall authentication for user role firewall enforcement.

1. If not already established, define the access profile to be used for firewall authentication. You can skip this step if an existing access profile provides the client data needed for your implementation.

The access profile is configured in the **[edit access profile]** hierarchy as with other firewall authentication types. It defines clients as firewall users and the passwords that provide them access. Use the following command to define a profile and add client names and passwords for firewall authentication.

```
set access profile profile-name client client-name firewall-user password pwd
```

2. If HTTPS traffic is expected, define the access profile to be used for SSL termination services. You can skip this step if an existing SSL termination profile provides the services needed for your implementation.

The SSL termination profile is configured in the **[edit services ssl]** hierarchy.

```
set services ssl termination profile ssl-profile-name server-certificate certificate-type
```

3. Enable the firewall authentication table as an authentication source.

```
set security user-identification authentication-source firewall-authentication priority priority
```

The priority value determines the sequence in which authentication sources are checked. The default value is 150 for the firewall authentication table. (It is 100 for the local authentication table and 200 for the Unified Access Control authentication table.) By default, the local authentication table is checked first, the firewall authentication table is next, and the UAC authentication table is third if it is enabled. You can change this sequence by changing the priority value of one or more of the tables.

4. Configure policies that permit traffic for user firewall authentication.

```
edit security policies from-zone zone to-zone zone policy policy-name
set match source-identity unauthenticated-user
set then permit firewall-authentication user-firewall access-profile profile-name
  ssl-termination-profile profile-name
```

When unauthenticated traffic is permitted for firewall authentication, the user is authenticated based on the access profile configured in this statement. The **ssl-termination-profile** option is needed only for HTTPS traffic.

By specifying the authentication type **user-firewall**, the firewall authentication table is propagated with the IP address, username, and any group names associated with the authenticated user. (Group names from firewall authentication are interpreted as roles by the user role firewall.) Any further traffic from this IP address will match the IP address in the firewall authentication table, and not require authentication. The associated username and roles are retrieved from the table for use as potential match criteria in subsequent security policies.

Configuring a User Role Firewall For Captive Portal Redirection

To automatically redirect unauthenticated users to the Access Control Service, use the UAC captive portal feature. The following syntax defines the profile for the captive portal:

```
set services unified-access-control captive-portal profile-name redirect-traffic
  [unauthenticated | all]
set services unified-access-control captive-portal profile-name redirect-url host-url
```

The Kerberos protocol, used for authentication encryption, identifies the Access Control Service only by its service principal name (SPN). The protocol does not accept an IP address. Therefore, the format for the redirect URL must be

service://hostname/options

In this implementation, the service is HTTP and the hostname is the FQDN of the Access Control Service. Options specified after the hostname pass additional information to the Access Control Service directing the user back to the original destination, to the SRX Series device, or to the policy that originated the redirection. You can configure the options using the following keyword and variable pairs:

?target=%dest-url%—Specifies the protected resource which the user is trying to access.

`&enforcer=%enforcer-id%`—Specifies the ID assigned to the SRX Series device when it is configured as an enforcer by the Access Control Service.

`&policy=%policy-id%`—Specifies the encrypted policy ID for the security policy that redirected the traffic.

The following statements define the profile of the captive portal named `auth-redirect`. The captive portal redirects unauthenticated users to the URL of the Access Control Service for authentication. After successful authentication, the traffic will be directed back to the SRX Series device.

```
[edit]
user@host# set services unified-access-control captive-portal auth-redirect redirect-traffic
unauthenticated
user@host# set services unified-access-control captive-portal auth-redirect redirect-url
"http://ic6000.ucdc.com/?target=%dest-url%&policy=%policy-id%"
```

A defined captive-portal profile is displayed as part of the UAC configuration.

```
...
services unified-access-control captive-portal auth-redirect {
    redirect-traffic unauthenticated;
    redirect-url "http://ic6000.ucdc.com/?target=%dest-url%&policy=%policy-id%";
}
```

After the profile is defined, a policy can apply the captive portal as an application service when certain criteria are matched. The following example defines policy P1 to apply the `auth-redirect` captive portal profile to any HTTP traffic from the trust to untrust zones whenever the role is `unauthenticated-user`:

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy P1 match
application http
user@host# set security policies from-zone trust to-zone untrust policy P1 match
source-identity unauthenticated-user
user@host# set security policies from-zone trust to-zone untrust policy P1 then permit
application-services uac-policy captive-portal auth-redirect
```

Example: Configuring a User Role Firewall on an SRX Series Device

The following example configures a user role firewall on an SRX Series device. The firewall controls access from the trust zone to the untrust zone based on active, authenticated

users or their associated roles. User role firewall policies establish the following restrictions:

- Only authenticated users are permitted from the trust zone to the untrust zone.
Unauthenticated users are redirected to an Access Control Service for authentication.
 - Traffic from IP 1.1.1.0 to IP 2.2.2.0 within the zone context is restricted. Only the traffic from users with the dev-abc, http-juniper-accessible, or ftp-accessible role is permitted. Permitted traffic is further evaluated by AppFW rules.
 - Permitted traffic identified as junos:FACEBOOK-ACCESS, junos:GOOGLE-TALK, or junos:MEEBO application traffic is denied.
 - Permitted traffic for any other application is permitted.
 - All other traffic from the trust zone to the untrust zone is permitted.
- [Requirements on page 1119](#)
 - [Overview on page 1119](#)
 - [Configuration on page 1120](#)

Requirements

Before you begin, ensure that the SRX Series device with Junos OS Release 12.1 or later is configured and initialized.

In this example, user and role information associated with the IP address of the traffic is provided by an Access Control Service. For instructions on configuring the Access Control Server, see “[Acquiring User Role Information from an Active Directory Authentication Server](#)” on page 5573.

Overview

[Table 77](#) outlines a firewall that meets the requirements for this example. The user role firewall consists of four policies.

Table 77: User Role Firewall Policies

policy-name	src-zone	dest-zone	src-IP	dest-IP	source-identity	application	action	Services
user-role-fw1	trust	untrust	any	any	authenticated	http	permit	UAC captive portal
user-role-fw2	trust	untrust	1.1.1.0	2.2.2.0	dev-abc http-juniper-accessible ftp-accessible	http	permit	AppFW ruleset RS1
user-role-fw3	trust	untrust	1.1.1.0	2.2.2.0	any	http	deny	
user-role-fw4	trust	untrust	any	any	any	http	permit	

Because the **source-identity** field is specified for at least one of the policies in this firewall, user and role information must be retrieved before policy lookup is conducted. The source IP of the traffic is compared to the items in the UIT. If the source IP address is found, the keyword **authenticated**, the username, and any roles associated with this user are stored for later use in policy lookup. If a matching entry for the IP address is not found in the UIT, the keyword **unauthenticated-user** is stored for policy lookup.

After retrieving the username, roles, and keywords, policy lookup begins. Characteristics of the incoming traffic are compared to each policy's match criteria. If a match is found, the action specified in that policy is taken.

A policy match is a terminal event, and no policies after the match are checked. Policy sequence influences the action to be taken for matching traffic. In this example, policies are applied in the following sequence:

user-role-fw1—Applies the UAC captive portal service to matching HTTP traffic with the unauthenticated-user keyword, and redirects it to the Access Control Service for authentication. A UAC profile must also be configured to identify the captive portal specifications.

user-role-fw2—Applies an AppFW rule set to any HTTP traffic from address 1.1.1.0 to address 2.2.2.0 that has a matching username or role. An application firewall must also be configured to define the rule set.

user-role-fw3—Denies all remaining HTTP traffic from address 1.1.1.0 to address 2.2.2.0 for this zone pair.

user-role-fw4—Permits all remaining HTTP traffic for this zone pair.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

Configuring Redirection For Unauthenticated Users

Step-by-Step Procedure

When an IP address is not listed in the UIT, the unauthenticated-user keyword is used in policy lookup. Instead of denying access to this traffic, a policy can redirect the traffic to a UAC captive portal for authentication.

NOTE: It is important to position a redirection policy for unauthenticated-user before a policy for “any” user so that UAC authentication is not shadowed by a policy intended for authenticated users.

To configure redirection from the SRX Series device to the Access Control Service:

1. From configuration mode, configure the UAC profile for the captive portal acs-device.
[edit]

```
user@host# set services unified-access-control captive-portal acs-device
redirect-traffic unauthenticated-user
```

2. Configure the redirection URL for the Access Control Service or a default URL for the captive portal.

```
[edit]
user@host# set services unified-access-control captive-portal acs-device
redirect-url "https://%ic-url%/?target=%dest-url%&enforcer=%enforcer-id%"
```

This policy specifies the default target and enforcer variables to be used by the Access Control Service to direct the user back after authentication. This ensures that changes to system specifications will not affect configuration results.

NOTE: When variables, such as `?target=`, are included in the command line, you must enclose the URL and variables in quotation marks.

3. Configure a user role firewall policy that redirects HTTP traffic from zone trust to zone untrust if the source-identity is unauthenticated-user. The captive portal profile name is specified as the action to be taken for traffic matching this policy.

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw1
match source-address any
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw1
match destination-address any
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw1
match application http
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw1
match source-identity unauthenticated-user
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw1
then permit application-services uac-policy captive-portal acs-device
```

4. If you are done configuring the policies, commit the changes.

```
[edit]
user@host# commit
```

Results From configuration mode, confirm your configuration by entering the **show services** and **show security policies** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show services

...
unified-access-control {
  captive-portal acs-device {
    redirect-traffic unauthenticated;
    redirect-url "https://%ic-ip%/?target=%dest-url%&enforcer=%enforcer-id%"
  }
}
```

```

user@host# show security policies
...
from-zone trust to-zone untrust {
  policy user-role-fw1 {
    match {
      source-address any;
      destination-address any;
      application http;
      source-identity unauthenticated-user
    }
    then {
      permit {
        application-services {
          uac-policy {
            captive-portal acs-device;
          }
        }
      }
    }
  }
}
...

```

Creating a User Role Policy With an Application Firewall

Step-by-Step Procedure

This policy restricts traffic from IP 1.1.1.0 to IP 2.2.2.0 based on its user and roles, and also its application. The configuration defines an application rule set and applies it to matching user role traffic.

1. Configure the AppFW rule set rs1. The following rule set denies junos:FACEBOOK-ACCESS, junos:GOOGLE-TALK, or junos:MEEBO application traffic. It applies the default setting, permit, to the remaining traffic.

```

[edit]
user@host# set security application-firewall rule-sets rs1
[edit security application-firewall rule-sets rs1]
user@host# set rule r1 match dynamic-application [junos:FACEBOOK-ACCESS
junos:GOOGLE-TALK junos:MEEBO]
user@host# set rule r1 then deny
user@host# set default-rule permit

```

2. Configure a policy to apply the rs1 application firewall rule set to traffic from IP 1.1.1.0 to IP 2.2.2.0 with the dev-abc, http-mgmt-accessible, or ftp-accessible user role.

```

[edit]
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw2
  match source-address 1.1.1.0
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw2
  match destination-address 2.2.2.0
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw2
  match application http
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw2
  match source-identity [dev-abc http-mgmt-accessible ftp-accessible]
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw2
  then permit application-services application-firewall rule-set rs1

```

3. If you are done configuring the policy, commit the changes.

```
[edit]
user@host# commit
```

Results Verify that the AppFW rule set is configured properly. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show security application-firewall

...
rule-sets rs1 {
  rule r1 {
    match {
      dynamic-application [junos:FACEBOOK-ACCESS junos:GOOGLE-TALK junos:MEEB0]
    }
    then {
      deny;
    }
  }
  default-rule {
    permit;
  }
}
```

Creating Remaining Security Policies Based on User and Role

Step-by-Step Procedure

The following procedure configures policies for the remaining traffic.

1. Configure a policy to deny traffic with the same source and destination address but with different user and role criteria than specified in the user-role-fw2 policy.

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw3
match source-address 1.1.1.0
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw3
match destination-address 2.2.2.0
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw3
match application http
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw3
match source-identity any
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw3
then deny
```

2. Configure a security policy to permit all other HTTP traffic from zone trust to zone untrust.

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw4
match source-address any
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw4
match destination-address any
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw4
match application http
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw4
match source-identity any
user@host# set security policies from-zone trust to-zone untrust policy user-role-fw4
then permit
```

Results Verify the content and sequence of the user role firewall policies. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

[edit]

user@host# show security policies

```
...
from-zone trust to-zone untrust {
  policy user-role-fw1 {
    match {
      source-address any;
      destination-address any;
      application http;
      source-identity unauthenticated-user
    }
    then {
      permit {
        application-services {
          uac-policy {
            captive-portal acs-device;
          }
        }
      }
    }
  }
}
from-zone trust to-zone untrust {
  policy user-role-fw2 {
    match {
      source-address 1.1.1.0;
      destination-address 2.2.2.0;
      application http;
      source-identity [dev-abc http-juniper-accessible ftp-accessible]
    }
    then {
      permit {
        application-services {
          application-firewall {
            rule-set rs1
          }
        }
      }
    }
  }
}
from-zone untrust to-zone trust {
  policy user-role-fw3 {
    match {
      source-address 1.1.1.0;
      destination-address 2.2.2.0;
      application http;
      source-identity any
    }
    then {
      deny
    }
  }
}
from-zone trust to-zone untrust {
  policy user-role-fw4 {
```

```

match {
  source-address any;
  destination-address any;
  application http;
  source-identity any
}
then {
  permit
}
}
}

```

Configuring Resource Policies Using UAC

When using the user role firewall feature, resource policies are not necessary on the Access Control Service. If, however, resource policies exist, they are pushed to the SRX Series device at connection. You can create policies that use these resource policies by applying the UAC application service in the policy configuration. [Table 78](#) shows three firewall policies that use the UAC resource policies exclusively:

Table 78: User Role Firewall Usage

policy-name	src-zone	dest-zone	src-IP	dest-IP	source-identity	application	action	Services
P1	zone1	zone2	any	3.3.3.3	any	http	permit	UTM
P2	zone1	zone2	any	net2	any	http	permit	IDP
P3	zone1	zone2	any	any	any	any	permit	UAC

The policies for traffic from zone1 to zone2 do not initiate user and role retrieval because any is specified in the source-identity field of every policy. In this example, traffic to the IP address 3.3.3.3 is permitted, but must meet processing requirements for the specified application service, in this case, UTM. Traffic to net2 is permitted and processed by the IDP processing requirements. Any remaining traffic is permitted and processed by the UAC processing requirements.

The configuration for this firewall policy would be as follows:

```

[edit]
user@host# show security policies

from-zone zone1 to-zone zone2 {
  policy P1 {
    match {
      source-address any;
      destination-address 3.3.3.3;
      source-identity any;

```

```

        application http;
    }
    then {
        permit {
            application-services {
                idp;
            }
        }
    }
}
from-zone zone1 to-zone zone2 {
    policy P2 {
        match {
            source-address any;
            destination-address net2;
            source-identity any;
            application http;
        }
        then {
            permit {
                application-services {
                    utm;
                }
            }
        }
    }
}
from-zone zone1 to-zone zone2 {
    policy P3 {
        match {
            source-address any;
            destination-address any;
            source-identity any;
            application any;
        }
        then {
            permit {
                application-services {
                    uac-policy;
                }
            }
        }
    }
}
...

```

In this sample configuration, the action fields in P1 and P2 apply any requirements that have been configured for IDP and UTM respectively. By specifying the `uac-policy` option, the resource policies pushed to the SRX Series device determine whether the destination is accessible.

A user role firewall can implement both user role policies and the resource policies pushed from the Access Control Service. [Table 79](#) shows the policies for three zone pairs.

Table 79: User Role Firewall Usage

policy-name	src-zone	dest-zone	src-IP	dest-IP	source-identity	application	action	Services
-------------	----------	-----------	--------	---------	-----------------	-------------	--------	----------

Table 79: User Role Firewall Usage (*continued*)

P1	zone1	zone2	any	any	unauthenticated-user	any	permit	UAC captive portal
P2	zone1	zone2	any	3.3.3.3	role2	http	permit	IDP
P3	zone1	zone2	any	net2	authenticated-user	http	permit	UTM
P4	zone1	zone2	any	any	any	any	permit	
P5	zone1	zone3	any	any	any	any	permit	UAC
P6	zone2	zone3	any	any	any	any	permit	UAC

Traffic from zone1 to zone2 is subject to one of four user role policies. The first of these policies uses the UAC captive portal to redirect unauthenticated users to the Access Control Service for authentication.

The access of traffic from zone1 to zone3 and from zone2 to zone3 is controlled by the resource policies pushed from the Access Control Service.

Setting Security Policy Reorder

- [Understanding Security Policy Ordering on page 1129](#)
- [Example: Reordering the Policies on page 1131](#)

Understanding Security Policy Ordering

Junos OS offers a tool for verifying that the order of policies in the policy list is valid.

It is possible for one policy to eclipse, or *shadow*, another policy. Consider the following examples:

Example 1

```
[edit]
user@host# set security zones security-zone trust interfaces ge-0/0/2 host-inbound-traffic
system-services all
user@host# set security zones security-zone untrust interfaces ge-0/0/1
host-inbound-traffic system-services all
user@host# set security policies from-zone trust to-zone untrust policy permit-all match
source-address any
user@host# set security policies from-zone trust to-zone untrust match
destination-address any
user@host# set security policies from-zone trust to-zone untrust match application any
user@host# set security policies from-zone trust to-zone untrust set then permit
user@host# set security policies from-zone untrust to-zone trust policy deny-all match
source-address any
user@host# set security policies from-zone untrust to-zone trust policy deny-all match
destination-address any
user@host# set security policies from-zone untrust to-zone trust policy deny-all match
application any
user@host# set security policies from-zone untrust to-zone trust policy deny-all then
deny
```

Example 2

```
[edit]
user@host# set security zones security-zone trust interfaces ge-0/0/2.0
host-inbound-traffic system-services all
user@host# set security zones security-zone untrust interfaces ge-0/0/1.0
host-inbound-traffic system-services all
user@host# set security address-book book1 address mail-untrust 1.1.1.24/32
user@host# set security address-book book1 attach zone untrust
```

```

user@host# set security address-book book2 address mail-trust 192.168.1.1/32
user@host# set security address-book book2 attach zone trust
user@host# set security policies from-zone trust to-zone untrust policy permit-mail match
    source-address mail-trust
user@host# set security policies from-zone trust to-zone untrust policy permit-mail match
    destination-address mail-untrust
user@host# set security policies from-zone trust to-zone untrust policy permit-mail match
    application junos-mail
user@host# set security policies from-zone trust to-zone untrust policy permit-mail then
    permit

```

In examples 1 and 2, where policy **permit-mail** is configured after policy **permit-all** from zone **trust** to zone **untrust**. All traffic coming from zone **untrust** matches the first policy **permit-all** and is allowed by default. No traffic matches policy **permit-mail**.

Because Junos OS performs a policy lookup starting from the top of the list, when it finds a match for traffic received, it does not look any lower in the policy list. To correct the previous example, you can simply reverse the order of the policies, putting the more specific one first:

```

[edit]
user@host# insert security policies from-zone trust to-zone untrust policy permit-mail
    before policy permit-all

```

In cases where there are dozens or hundreds of policies, the eclipsing of one policy by another might not be so easy to detect. To check if policies are being shadowed, enter any of the following commands:

```

[edit]
user@host# run show security shadow-policies logical-system lsys-name from-zone
    from-zone-name to-zone to-zone-name

```

```

[edit]
user@host# run show security shadow-policies logical-system lsys-name global

```

This command reports the shadowing and shadowed policies. It is then the administrator's responsibility to correct the situation.

NOTE: The concept of policy *shadowing* refers to the situation where a policy higher in the policy list always takes effect before a subsequent policy. Because the policy lookup always uses the first policy it finds that matches the five-part tuple of the source and destination zone, source and destination address, and application type, if another policy applies to the same tuple (or a subset of the tuple), the policy lookup uses the first policy in the list and never reaches the second one.

- [Example: Configuring a Security Policy to Permit or Deny All Traffic on page 1074](#)
- [Example: Configuring a Security Policy to Permit or Deny Selected Traffic on page 1078](#)

Example: Reordering the Policies

This example shows how to move policies around after they have been created.

- [Requirements on page 1131](#)
- [Overview on page 1131](#)
- [Configuration on page 1131](#)
- [Verification on page 1131](#)

Requirements

Before you begin:

- Create zones. See [“Example: Creating Security Zones” on page 1031](#).
- Configure the address book and create addresses for use in the policy. See [“Example: Configuring Address Books and Address Sets” on page 1056](#).

Overview

To reorder policies to correct shadowing, you can simply reverse the order of the policies, putting the more specific one first.

Configuration

Step-by-Step Procedure

To reorder existing policies:

1. Reorder two existing policies by entering the following command:

```
[edit]
user@host# insert security policies from-zone trust to-zone untrust policy
permit-mail before policy permit-all
```
2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security policies** command.

Matching Security Policies

The **show security match-policies** command allows you to troubleshoot traffic problems using the match criteria: source port, destination port, source IP address, destination IP address, and protocol. For example, if your traffic is not passing because either an appropriate policy is not configured or the match criteria is incorrect, the **show security match-policies** command allows you to work offline and identify where the problem actually exists. It uses the search engine to identify the problem and thus enables you to use the appropriate match policy for the traffic.

The **result-count** option specifies how many policies to display. The first enabled policy in the list is the policy that is applied to all matching traffic. Other policies below it are “shadowed” by the first and are never encountered by matching traffic.

NOTE: The **show security match-policies** command is applicable only to security policies; IDP policies are not supported.

Example 1: show security match-policies

```
user@host> show security match-policies from-zone z1, to-zone z2 source-ip 10.10.10.1
destination-ip 30.30.30.1 source-port 1 destination-port 21 protocol tcp
```

```

Policy: p1, action-type: permit, State: enabled, Index: 4
Sequence number: 1
From zone: z1, To zone: z2
Source addresses:
  a2: 20.20.0.0/16
  a3: 10.10.10.1/32
Destination addresses:
  d2: 40.40.0.0/16
  d3: 30.30.30.1/32
Application: junos-ftp
IP protocol: tcp, ALG: ftp, Inactivity timeout: 1800
Source port range: [0-0]
Destination port range: [21-21]

```

Example 2: Using the result-count Option

By default, the output list contains the policy that will be applied to traffic with the specified characteristics. To list more than one policy that match the criteria, use the **result-count** option. The first policy listed is always the policy that will be applied to matching traffic. If the **result-count** value is from 2 to 16, the output includes all policies that match the criteria up to the specified **result-count**. All policies listed after the first are “shadowed” by the first policy and are never applied to matching traffic.

Use this option to test the positioning of a new policy or to troubleshoot a policy that is not applied as expected for particular traffic.

In the following example, the traffic criteria matches two policies. The first policy listed, **p1**, contains the action applied to the traffic. Policy **p15** is shadowed by the first policy, and its action, therefore, will not be applied to matching traffic.

```

user@host> show security match-policies source-ip 10.10.10.1 destination-ip 20.20.20.5
source_port 1004 destination_port 80 protocol tcp result_count 5
Policy: p1, action-type: permit, State: enabled, Index: 4
Sequence number: 1
From zone: zone-A, To zone: zone-B
Source addresses:
  sa1: 10.10.0.0/16
Destination addresses:
  da5: 20.20.0.0/16
Application: any
IP protocol: 1, ALG: 0, Inactivity timeout: 0
Source port range: [1000-1030]
Destination port range: [80-80]

Policy: p15, action-type: deny, State: enabled, Index: 18
Sequence number: 15
From zone: zone-A, To zone: zone-B
Source addresses:
  sa11: 10.10.10.1/32
Destination addresses:
  da15: 20.20.20.5/32
Application: any
IP protocol: 1, ALG: 0, Inactivity timeout: 0
Source port range: [1000-1030]
Destination port range: [80-80]

```

Tracking Policy Hit Counts

Use the **show security policies hit-count** command to display the utility rate of security policies according to the number of hits they receive. You can use this feature to determine which policies are being used on the device, and how frequently they are used. Depending on the command options that you choose, the number of hits can be listed without an order or sorted in either ascending or descending order, and they can be restricted to the number of hits that fall above or below a specific count or within a range. Data is shown for all zones associated with the policies or named zones.

Best Practices for Defining Policies on High-End SRX Series Devices

A secure network is vital to a business. To secure a network, a network administrator must create a security policy that outlines all of the network resources within that business and the required security level for those resources. The security policy applies the security rules to the transit traffic within a context (from-zone to to-zone) and each policy is uniquely identified by its name. The traffic is classified by matching the source and destination zones, the source and destination addresses, and the application that the traffic carries in its protocol headers with the policy database in the data plane.

[Table 80](#) provides the policy limitations for high-end SRX Series devices.

Table 80: Policy Limitations for High-End SRX Series Devices

Policy Limitations	SRX1400 SRX1500	SRX3400 SRX3600	SRX5400 SRX5600 SRX5800
Address objects	1024	1024	1024
Application objects	3072	3072	3072
Security policies	40,000	40,000	80,000
Policy contexts (zone pairs)	4096	4096	8192
Policies per context	10,000	10,000	10,000

Table 80: Policy Limitations for High-End SRX Series Devices (*continued*)

Policy Limitations	SRX1400 SRX1500	SRX3400 SRX3600	SRX5400 SRX5600 SRX5800
Policies with counting enabled	1024	1024	1024

NOTE: The number of source and destination address objects allowed per firewall rule is 1024. The systemwide maximum allowed is 32,000 address objects.

Therefore, as you increase the number of addresses and applications in each rule, the amount of memory that is used by the policy definition increases, and sometimes the system runs out of memory with fewer than 80,000 policies.

To get the actual memory utilization of a policy on the Packet Forwarding Engine (PFE) and the Routing Engine (RE), you need to take various components of the memory tree into consideration. The memory tree includes the following two components:

- Policy context—Used to organize all policies in this context. Policy context includes variables such as source and destination zones.
- Policy entity—Used to hold the policy data. Policy entity calculates memory using parameters such as policy name, IP addresses, address count, applications, firewall authentication, WebAuth, IPsec, count, application services, and Junos Services Framework (JSF).

Additionally, the data structures used to store policies, rule sets, and other components use different memory on the Packet Forwarding Engine and on the Routing Engine. For example, address names for each address in the policy are stored on the Routing Engine, but no memory is allocated at the Packet Forwarding Engine level. Similarly, port ranges are expanded to prefix and mask pairs and are stored on the Packet Forwarding Engine, but no such memory is allocated on the Routing Engine.

Accordingly, depending on the policy configuration, the policy contributors to the Routing Engine are different from those to the Packet Forwarding Engine, and memory is allocated dynamically.

Memory is also consumed by the “deferred delete” state. In the deferred delete state, when an SRX Series device applies a policy change, there is transitory peak usage whereby both the old and new policies are present. So for a brief period, both old and new policies exist on the Packet Forwarding Engine, taking up twice the memory requirements.

Therefore, there is no definitive way to infer clearly how much memory is used by either component (Packet Forwarding Engine or Routing Engine) at any given point in time, because memory requirements are dependent on specific configurations of policies, and memory is allocated dynamically.

The following best practices for policy implementation enable you to better use system memory and to optimize policy configuration:

- Use single prefixes for source and destination addresses. For example, instead of using /32 addresses and adding each address separately, use a large subnet that covers most of the IP addresses you require.
- Use application “any” whenever possible. Each time you define an individual application in the policy, you can use an additional 52 bytes.
- Use fewer IPv6 addresses because IPv6 addresses consume more memory.
- Use fewer zone pairs in policy configurations. Each source or destination zone uses about 16,048 bytes of memory.
- The following parameters can change how memory is consumed by the bytes as specified:
 - Firewall authentication—About 16 bytes or more (unfixed)
 - Web authentication—About 16 bytes or more (unfixed)
 - IPsec—12 bytes
 - Application services—28 bytes
 - Count—64 bytes
- Check memory utilization before and after compiling policies.

NOTE: The memory requirement for each device is different. Some devices support 512,000 sessions by default and the bootup memory is usually at 72 to 73 percent. Other devices can have up to 1 million sessions and the bootup memory can be up to 83 to 84 percent. In the worst-case scenario, to support about 80,000 policies in the SPU, the SPU should boot with a flowd kernel memory consumption of up to 82 percent, and with at least 170 megabytes of memory available.

- [Global Policy Overview on page 1095](#)
- [Example: Configuring a Global Policy with No Zone Restrictions on page 1097](#)
- [Checking Memory Status on page 1137](#)

Checking Memory Status

Memory for flow entities (for example, policies, zones, addresses) on SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices is dynamically allocated. However, certain

practices can help monitor the current memory usage on the device and optimize parameters to better size system configuration, especially during policy implementation.

You can isolate memory issues by comparing memory values before and after policy configurations.

To check memory usage:

- Use the **show chassis routing-engine** command to check overall Routing Engine (RE) memory usage. The following output from this command shows memory utilization at 39 percent:

```
user@host# show chassis routing-engine
Routing Engine status:
Slot 0:
  Current state           Master
  Election priority       Master (default)
  DRAM                    1024 MB
  Memory utilization       39 percent
  CPU utilization:
    User                  0 percent
    Background            0 percent
    Kernel                 2 percent
    Interrupt              0 percent
    Idle                   97 percent
  Model                   RE-PPC-1200-A
  Start time              2011-07-09 19:19:49 PDT
  Uptime                  37 days, 15 hours, 44 minutes, 13 seconds
  Last reboot reason      0x3:power cycle/failure watchdog
  Load averages:         1 minute   5 minute   15 minute
                        0.22        0.16        0.07
```

- Use the **show system processes extensive** command to acquire information on the processes running on the Routing Engine.

Use the **find nsd** option in the **show system processes extensive** command to see direct usage on the Network Security Daemon (NSD) with its total memory in use as 10 megabytes and CPU utilization of 0 percent.

```
user@host# show system processes extensive | find nsd
1182 root      1  96    0 10976K 5676K select  2:08 0.00% nsd
1191 root      4   4    0  8724K 3764K select  1:57 0.00% slbd
1169 root      1  96    0  8096K 3520K select  1:51 0.00% jsrpd
1200 root      1   4    0      0K   16K peer_s  1:10 0.00% peer proxy
1144 root      1  96    0  9616K 3528K select  1:08 0.00% lacpd
1138 root      1  96    0  6488K 2932K select  1:02 0.00% ppmdd
1130 root      1  96    0  7204K 2208K select  1:02 0.00% craftd
1163 root      1  96    0 16928K 5188K select  0:58 0.00% cosd
1196 root      1   4    0      0K   16K peer_s  0:54 0.00% peer proxy
  47 root      1 -16    0      0K   16K sdflls  0:54 0.00% softdepflush
1151 root      1  96    0 15516K 9580K select  0:53 0.00% appidd
  900 root      1  96    0  5984K 2876K select  0:41 0.00% eventd
```

- Check the configuration file size. Save your configuration file with a unique name before exiting the CLI. Then, enter the **ls -l filename** command from the shell prompt in the UNIX-level shell to check the file size as shown in the following sample output:

```
user@host> start shell
% ls -l config
-rw-r--r--  1 remote  staff  12681 Feb 15 00:43 config
```

Synchronizing a Security Policy on SRX Series Devices

Security policies are stored in both the Routing Engine (RE), and the Packet Forwarding Engine (PFE). When you modify the policies on the Routing Engine side, the policies are synchronized to the Packet Forwarding Engine side when you commit the configuration.

The policies in the Routing Engine and Packet Forwarding Engine must always be in sync for the configuration to commit successfully. Under certain circumstances, policies in the Routing Engine and the Packet Forwarding Engine might be out of sync resulting in generation of system core files upon commit completion.

When the policy configuration is modified and policies are out of sync, the following error message is displayed when you attempt to commit a configuration:

```
Policy is out of sync between RE and PFE <SPU-name(s)>. Please resync before commit.
```

```
error: configuration check-out failed
```

To synchronize policies between the Routing Engine and the Packet Forwarding Engine, you must:

- Reboot the device (device in standalone mode)
- Reboot both devices (devices in a chassis cluster mode)

Verifying Scheduled Policies

Purpose Display information about address books and zones.

Action Use the **show schedulers** CLI command to display information about schedulers configured on the system. If a specific scheduler is identified, detailed information is displayed for that scheduler only.

```
user@host# show schedulers
scheduler sche1 {
    /* This is sched1 */
    start-date 2006-11-02.12:12 stop-date 2007-11-02.12:11;
}
scheduler sche2 {
    daily {
        all-day;
    }
    sunday {
        start-time 16:00 stop-time 17:00;
    }
    friday {
        exclude;
    }
}
scheduler sche3 {
    start-date 2006-11-02.12:12 stop-date 2007-11-02.12:11;
    daily {
        start-time 10:00 stop-time 17:00
    }
    sunday {
        start-time 12:00 stop-time 14:00;
        start-time 16:00 stop-time 17:00;
    }
    monday {
        all-day;
    }
    friday {
        exclude;
    }
}
```

Meaning The output displays information about schedulers configured on the system. Verify the following information:

- Daily (recurrent) and one-time only (nonrecurrent) schedulers are configured correctly.
- Schedulers are active if policies are associated.

Verifying Shadow Policies

- [Verifying All Shadow Policies on page 1141](#)
- [Verifying a Policy Shadows One or More Policies on page 1141](#)
- [Verifying a Policy Is Shadowed by One or More Policies on page 1141](#)

Verifying All Shadow Policies

Purpose Verify all the policies that shadows one or more policies.

Action From the operational mode, enter the following commands:

- For logical systems, enter the **show security shadow-policies logical-system *lsys-name* from-zone *from-zone-name* to-zone *to-zone-name*** command.
- For global policies, enter the **show security shadow-policies logical-system *lsys-name* global** command.

```
root@host> show security shadow-policies from-zone zone-a to-zone zone-b
Policies          Shadowed policies
P1                P3
P1                P4
P2                P5
```

Meaning The output displays the list of all policies that shadows other policies. In this example, P1 policy shadows P3 and P4 policies and P2 policy shadows P5 policy.

Verifying a Policy Shadows One or More Policies

Purpose Verify if a given policy shadows one or more policies positioned after it.

Action From the operational mode, enter the following commands:

- For logical systems, enter the **show security shadow-policies logical-system *lsys-name* from-zone *from-zone-name* to-zone *to-zone-name* policy *policy-name*** command.
- For global policies, enter the **show security shadow-policies logical-system *lsys-name* global policy *policy-name*** command.

```
root@host> show security shadow-policies from-zone zone-a to-zone zone-b policy P1
Policies          Shadowed policies
P1                P3
P1                P4
```

Meaning The output displays all the policies that are shadowed by the given policy. In this example, P1 policy shadows P3 and P4 policies.

Verifying a Policy Is Shadowed by One or More Policies

Purpose Verify if a given policy is shadowed by one or more positioned before it.

Action From the operational mode, enter the following commands:

- For logical systems, enter the **show security shadow-policies logical-system *lsys-name* from-zone *from-zone-name* to-zone *to-zone-name* policy *policy-name* reverse** command.

- For global policies, enter the **show security shadow-policies logical-system *lsys-name* global policy *policy-name* reverse** command.

```
root@host> show security shadow-policies from-zone zone-a to-zone zone-b policy P4 reverse
Policies                               Shadowed policies
P1                                     P4
```

Meaning The output displays the given policy shadowed by one or more policies. In this example, P4 policy is shadowed by P1 policy.

Monitoring Policy Statistics

Purpose Monitor and record traffic that Junos OS permits or denies based on previously configured policies.

Action To monitor traffic, enable the count and log options.

Count—Configurable in an individual policy. If count is enabled, statistics are collected for sessions that enter the device for a given policy, and for the number of packets and bytes that pass through the device in both directions for a given policy. For counts (only for packets and bytes), you can specify that alarms be generated whenever the traffic exceeds specified thresholds. See [count \(Security Policies\)](#).

Log—Logging capability can be enabled with security policies during session initialization (**session-init**) or session close (**session-close**) stage. See [log \(Security Policies\)](#).

- To view logs from denied connections, enable log on **session-init**.
- To log sessions after their conclusion/tear-down, enable log on **session-close**.

NOTE: Session log is enabled at real time in the flow code which impacts the user performance. If both **session-close** and **session-init** are enabled, performance is further degraded as compared to enabling **session-init** only.

For details about information collected for session logs, see [“Information Provided in Session Log Entries for SRX Series Services Gateways” on page 1761](#).

- [Verifying a Security Policy Commit on page 1143](#)
- [Debugging Policy Lookup on page 1144](#)

Checking a Security Policy Commit Failure

Problem **Description:** Most policy configuration failures occur during a commit or runtime. Commit failures are reported directly on the CLI when you execute the CLI command **commit-check** in configuration mode. These errors are configuration errors, and you cannot commit the configuration without fixing these errors.

Solution To fix these errors, do the following:

1. Review your configuration data.
2. Open the file `/var/log/nsd_chk_only`. This file is overwritten each time you perform a commit check and contains detailed failure information.

Verifying a Security Policy Commit

Problem **Description:** Upon performing a policy configuration commit, if you notice that the system behavior is incorrect, use the following steps to troubleshoot this problem:

Solution

1. **Operational show Commands**—Execute the operational commands for security policies and verify that the information shown in the output is consistent with what you expected. If not, the configuration needs to be changed appropriately.
2. **Traceoptions**—Set the **traceoptions** command in your policy configuration. The flags under this hierarchy can be selected as per user analysis of the **show** command output. If you cannot determine what flag to use, the flag option **all** can be used to capture all trace logs.

```
user@host# set security policies traceoptions <flag all>
```

You can also configure an optional filename to capture the logs.

```
user@host# set security policies traceoptions <filename>
```

If you specified a filename in the trace options, you can look in the `/var/log/<filename>` for the log file to ascertain if any errors were reported in the file. (If you did not specify a filename, the default filename is `eventd`.) The error messages indicate the place of failure and the appropriate reason.

After configuring the trace options, you must recommit the configuration change that caused the incorrect system behavior.

Debugging Policy Lookup

Problem **Description:** When you have the correct configuration, but some traffic was incorrectly dropped or permitted, you can enable the **lookup** flag in the security policies traceoptions. The **lookup** flag logs the lookup related traces in the trace file.

Solution `user@host# set security policies traceoptions <flag lookup>`

Handling Security Policy Violations

- [Understanding Searching and Sorting Audit Logs on page 1145](#)
- [Understanding Packet Flow Alarms and Auditing on page 1146](#)
- [Example: Generating a Security Alarm in Response to Policy Violations on page 1147](#)

Understanding Searching and Sorting Audit Logs

An audit administrator analyzes the audit trail, reviews the audit record, and deletes the audit trail for maintenance purposes. The search and sort capability provides an efficient mechanism to the audit administrator for viewing pertinent audit information. This helps the audit administrator to identify potential security violations and take action against possible security breaches. The audit log can be viewed by all the administrators (such as Audit, Cryptographic, Security, and IDS administrators) . An IDS audit log can be viewed only by IDS audit administrator.

The security administrator can configure audit events and set thresholds that could indicate a potential security violation. The device monitors the occurrences of these events and notifies the administrator after an event has occurred or a set threshold has been met.

The audit administrator can search or group the audit log data based on the following:

- Destination subject identity
- Source subject identity
- Range of date, time, user identities, subject service identifiers, or Transport Layer protocol
- Rule identity
- User identity
- Network interface
- Success of auditable security events
- Failure of auditable security events

NOTE:

- The device sends an alarm to the console or the security alarm system when the in-memory audit event log exceeds the limit configured by the security administrator. The device then overwrites the oldest log messages with the new audit event log messages.
 - During system reboot the device does a commit of the existing configuration including login classes. Therefore, there will be audit log entries for all user-defined classes indicating that they have been modified.
-

**Related
Documentation**

- [Understanding Packet Flow Alarms and Auditing on page 1146](#)
- [Example: Generating a Security Alarm in Response to Policy Violations on page 1147](#)

Understanding Packet Flow Alarms and Auditing

Alarms are triggered when packets are dropped because of a policy violation. A policy violation occurs when a packet matches a reject or deny policy. A policy violation alarm is generated when the system monitors any of the following audited events:

- Number of policy violations by a source network identifier within a specified period
- Number of policy violations to a destination network identifier within a specified period
- Number of policy violations to an application within a specified period
- Policy rule or group of rule violations within a specified period

There are four types of alarms corresponding to these four events. The alarms are based on source IP, destination IP, application, and policy.

When a packet encounters a reject or deny policy, the policy violation counters for all enabled types of alarm are increased. When any counter reaches the specified threshold within a specified period, an alarm is generated. After a specified period, the policy violation counter is reset and reused to start another counting cycle.

To view the alarm information, run the **show security alarms** command. The violation count and the alarm do not persist across system reboots. After a reboot, the violation count resets to zero and the alarm is cleared from the alarm queue.

After taking appropriate actions, you can clear the alarm. The alarm remains in the queue until you clear it (or until you reboot the device). To clear the alarm, run the **clear security alarms** command. After you clear the alarm, a subsequent series of flow policy violations can cause a new alarm to be raised.

**Related
Documentation**

- [Example: Setting an Audible Alert as Notification of a Security Alarm on page 6945](#)
- [Example: Generating a Security Alarm in Response to Policy Violations on page 1147](#)

Example: Generating a Security Alarm in Response to Policy Violations

This example shows how to configure the device to generate a system alarm when a policy violation occurs. By default, no alarm is raised when a policy violation occurs.

- [Requirements on page 1147](#)
- [Overview on page 1147](#)
- [Configuration on page 1147](#)
- [Verification on page 1148](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you configure an alarm to be raised when:

- The application size is 10240 units.
- The source IP violation exceeds 1000 within 20 seconds.
- The destination IP violations exceeds 1000 within 10 seconds.
- The policy match violation exceeds 100, with a size of 100 units.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security alarms potential-violation policy application size 10240
set security alarms potential-violation policy source-ip threshold 1000 duration 20
set security alarms potential-violation policy destination-ip threshold 1000 duration 10
set security alarms potential-violation policy policy-match threshold 100 size 100
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To configure policy violation alarms:

1. Enable security alarms.

```
[edit]
user@host# edit security alarms
```
2. Specify that an alarm should be raised when an application violation occurs.

```
[edit security alarms potential-violation policy]
user@host# set application size 10240
```

3. Specify that an alarm should be raised when a source IP violation occurs.
`[edit security alarms potential-violation policy]
user@host# set source-ip threshold 1000 duration 20`
4. Specify that an alarm should be raised when a destination IP violation occurs.
`[edit security alarms potential-violation policy]
user@host# set destination-ip threshold 1000 duration 10`
5. Specify that an alarm should be raised when a policy match violation occurs.
`[edit security alarms potential-violation policy]
user@host# set policy-match threshold 100 size 100`

Results From configuration mode, confirm your configuration by entering the **show security alarms** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
policy {  
  source-ip {  
    threshold 1000;  
    duration 20;  
  }  
  destination-ip {  
    threshold 1000;  
    duration 10;  
  }  
  application {  
    size 10240;  
  }  
  policy-match {  
    threshold 100;  
    size 100;  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, from operational mode, enter the **show security alarms** command.

Security Policy Applications Overview

Applications are types of traffic for which protocol standards exist. Each application has a transport protocol and destination port number(s) associated with it, such as TCP/port 21 for FTP and TCP/port 23 for Telnet. When you create a policy, you must specify an application for it.

You can select one of the predefined applications from the application book, or a custom application or application set that you created. You can see which application you can use in a policy by using the **show application** CLI command.

NOTE: Each predefined application has a source port range of 1–65535, which includes the entire set of valid port numbers. This prevents potential attackers from gaining access by using a source port outside of the range. If you need to use a different source port range for any predefined application, create a custom application. For information, see [“Understanding Custom Policy Applications” on page 1155](#).

Policy Application Sets Overview

When you create a policy, you must specify an application, or service, for it to indicate that the policy applies to traffic of that type. Sometimes the same applications or a subset of them can be present in multiple policies, making it difficult to manage. Junos OS allows you to create groups of applications called application sets. Application sets simplify the process by allowing you to manage a small number of application sets, rather than a large number of individual application entries.

The application (or application set) is referred to by security policies as match criteria for packets initiating sessions. If the packet matches the application type specified by the policy and all other criteria match, then the policy action is applied to the packet.

You can specify the name of an application set in a policy. In this case, if all of the other criteria match, any one of the applications in the application set serves as valid matching criteria; **any** is the default application name that indicates all possible applications.

Applications are created in the `.../applications/application/application-name` directory. You do not need to configure an application for any of the services that are predefined by the system.

In addition to predefined services, you can configure a custom service. After you create a custom service, you can refer to it in a policy.

Example: Configuring Applications and Application Sets

This example shows how to configure applications and application sets.

- [Requirements on page 1152](#)
- [Overview on page 1152](#)
- [Configuration on page 1153](#)
- [Verification on page 1153](#)

Requirements

Before you begin, configure the required applications. See [“Policy Application Sets Overview” on page 1152](#).

Overview

Rather than creating or adding multiple individual application names to a policy, you can create an application set and refer to the name of the set in a policy. For example, for a

group of employees, you can create an application set that contains all the approved applications.

In this example, you create an application set that are used to log into the servers in the ABC (intranet) zone, to access the database, and to transfer files.

- Define the applications in the configured application set.
- Managers in zone A and managers in zone B use these services. Therefore, give the application set a generic name, such as MgrAppSet.
- Create an application set for the applications that are used for e-mail and Web-based applications that are delivered by the two servers in the external zone.

Configuration

Step-by-Step Procedure

To configure an application and application set:

1. Create an application set for managers.

```
[edit applications]
user@host# set application-set MgrAppSet application junos-ssh
user@host# set application-set MgrAppSet application junos-telnet
```
2. Create another application set for e-mail and Web-based applications.

```
[edit applications]
user@host# set application-set WebMailApps application junos-smtp
user@host# set application-set WebMailApps application junos-pop3
```
3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show applications** command.

Verifying the Configuration

- [Example: Configuring Custom Policy Application Term Options on page 1157](#)

Understanding Custom Policy Applications

If you do not want to use predefined applications in your policy, you can easily create custom applications.

You can assign each custom application the following attributes:

- Name
- Transport protocol
- Source and destination port numbers for applications using TCP or UDP
- Type and code values for applications using ICMP
- Timeout value

Related Documentation

- [Custom Application Mappings on page 1155](#)
- [Understanding Policy Application Timeout Configuration and Lookup on page 1161](#)
- [Understanding Policy Application Timeouts Contingencies on page 1162](#)
- [Example: Adding and Modifying Custom Policy Applications on page 1156](#)

Custom Application Mappings

The application option specifies the Layer 7 application that maps to the Layer 4 application that you reference in a policy. A predefined application already has a mapping to a Layer 7 application. However, for custom applications, you must link the application to an application explicitly, especially if you want the policy to apply an Application Layer Gateway (ALG) or deep inspection to the custom application.

NOTE: Junos OS supports ALGs for numerous applications, including DNS, FTP, H.323, HTTP, RSH, SIP, Telnet, and TFTP.

Applying an ALG to a custom application involves the following two steps:

- Define a custom application with a name, timeout value, transport protocol, and source and destination ports.
- When configuring a policy, reference that application and the application type for the ALG that you want to apply.

**Related
Documentation**

- [Understanding Custom Policy Applications on page 1155](#)

Example: Adding and Modifying Custom Policy Applications

This example shows how to add and modify custom policy applications.

- [Requirements on page 1156](#)
- [Overview on page 1156](#)
- [Configuration on page 1157](#)
- [Verification on page 1157](#)

Requirements

Before you begin, create addresses and security zones. See [“Example: Creating Security Zones” on page 1031](#).

Overview

In this example, you create a custom application using the following information:

- A name for the application: **cust-telnet**.
- A range of source port numbers: 1 through **65535**.
- A destination port number: 23000.
- The protocol used by the application: TCP.

Configuration

Step-by-Step Procedure The following example requires you to navigate through various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To add and modify a custom policy application:

1. Configure TCP and specify the source port and destination port.

```
[edit applications application cust-telnet]
user@host# set protocol tcp source-port 1-65535 destination-port 23000
```
2. Specify the length of time that the application is inactive.

```
[edit applications application cust-telnet]
user@host# set inactivity-timeout 1800
```
3. Modify a custom policy application.

```
[edit applications application cust-telnet]
user@host# delete protocol tcp
user@host# set application-protocol ftp
```
4. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show applications application** command.

NOTE: The timeout value is in seconds. If you do not set it, the timeout value of a custom application is 1800 seconds. If you do not want an application to time out, type never.

Example: Configuring Custom Policy Application Term Options

This example shows how to configure applications properties and term options for application protocols.

- [Requirements on page 1158](#)
- [Overview on page 1158](#)

- [Configuration on page 1158](#)
- [Verification on page 1160](#)

Requirements

This example uses the following hardware and software components:

- An SRX Series device
- A PC

Before you begin:

- Configure the required applications. See [“Example: Adding and Modifying Custom Policy Applications” on page 1156](#).

Overview

In this example, you create an application name, app-name, and a term called custom-options to define your custom policy application term options.

You configure Domain Name Service (DNS) as the Application Layer Gateway (ALG) type and UDP as the networking protocol type. You set the source port to 24000 and the destination port to 23000. Then you set the Internet Control Message Protocol (ICMP) packet type value to 5 and the ICMP code value to 0. You set the remote procedure call (RPC) program number value to 50 and the Universal Unique Identifier (UUID) value to 1be617c0-31a5-11cf-a7d8-00805f48a135. Finally, you set the inactivity-timeout value to 60.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
user@host# set applications application app-name term custom-options
user@host# set applications application app-name term custom-options alg dns
user@host#set applications application app-name term custom-options protocol udp
user@host#set applications application app-name term custom-options source-port
24000
user@host#set applications application app-name term custom-options destination-port
23000
user@host#set applications application app-name term custom-options icmp-type 5
user@host#set applications application app-name term custom-options icmp-code 0
user@host#set applications application app-name term custom-options
rpc-program-number 50
user@host#set applications application app-name term custom-options uuid
1be617c0-31a5-11cf-a7d8-00805f48a135
user@host#set applications application app-name term custom-options inactivity-timeout
60
```

Step-by-Step Procedure

To configure custom policy application term options:

1. Configure the term name.

```
[edit applications]
user@host# set application app-name term custom-options
```
2. Configure the ALG type.

```
[edit applications]
user@host# set application app-name term custom-options alg dns
```
3. Configure the networking protocol type.

```
[edit applications]
user@host# set application app-name term custom-options protocol udp
```
4. Configure the source port number.

```
[edit applications]
user@host# set application app-name term custom-options source-port 24000
```
5. Configure the TCP or UDP destination port number.

```
[edit applications]
user@host# set application app-name term custom-options destination-port 23000
```
6. Specify the application type value.

```
[edit applications]
user@host# set application app-name term custom-options icmp-type 5
```
7. Specify the application code value.

```
[edit applications]
user@host# set application app-name term custom-options icmp-code 0
```
8. Specify the RPC program number.

```
[edit applications]
user@host# set application app-name term custom-options rpc-program-number
50
```
9. Specify the UUID value.

```
[edit applications]
user@host# set application app-name term custom-options uuid
1be617c0-31a5-11cf-a7d8-00805f48a135
```
10. Specify the inactivity timeout value.

```
[edit applications]
user@host# set application app-name term custom-options inactivity-timeout 60
```

Results

From configuration mode, confirm your configuration by entering the **show applications** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show applications
application app-name {
```

```
term custom-options alg dns protocol udp source-port 24000 icmp-type 5 icmp-code
  0 rpc-program-number 50 uuid 1be617c0-31a5-11cf-a7d8-00805f48a135
  inactivity-timeout 60;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the Configuration

Purpose Verify that the configuration is correct.

Action From operational mode, enter the **show applications** command.

```
user@host> show applications
application app-name {
term custom-options alg dns protocol udp source-port 24000 icmp-type 5 icmp-code
  0 rpc-program-number 50 uuid 1be617c0-31a5-11cf-a7d8-00805f48a135
  inactivity-timeout 60;
}
```

- [Example: Setting a Policy Application Timeout on page 1162](#)

Understanding Policy Application Timeout Configuration and Lookup

The application timeout value you set for an application determines the session timeout. You can set the timeout threshold for a predefined or custom application; you can use the application default timeout, specify a custom timeout, or use no timeout at all.

Application timeout values are stored in the root TCP and UDP port-based timeout table and in the protocol-based default timeout table. When you set an application timeout value, Junos OS updates these tables with the new value. There are also default timeout values in the applications entry database, which are taken from predefined applications. You can set a timeout, but you cannot alter a default value.

Each custom application can be configured with its own custom application timeout. If multiple custom applications are configured with custom timeouts, then each application will have its own custom application timeout.

If the application that is matched for the traffic has a timeout value, that timeout value is used. Otherwise, the lookup proceeds in the following order until an application timeout value is found:

1. The root TCP and UDP port-based timeout table is searched for a timeout value.
2. The protocol-based default timeout table is searched for a timeout value. See [Table 81](#).

Table 81: Protocol-Based Default Timeout

Protocol	Default Timeout (seconds)
TCP	1800
UDP	60
ICMP	60
OSPF	60

Table 81: Protocol-Based Default Timeout (*continued*)

Protocol	Default Timeout (seconds)
Other	1800

 - [Understanding Policy Application Timeouts Contingencies on page 1162](#)
 - [Custom Application Mappings on page 1155](#)
 - [Example: Adding and Modifying Custom Policy Applications on page 1156](#)

Understanding Policy Application Timeouts Contingencies

When setting timeouts, be aware of the following contingencies:

- If an application contains several application rule entries, all rule entries share the same timeout. You need to define the application timeout only once. For example, if you create an application with two rules, the following commands will set the timeout to 20 seconds for both rules:

```
user@host# set applications application test protocol tcp destination-port 1035-1035
inactivity-timeout 20
user@host# set applications application test term test protocol udp
user@host# set applications application test term test source-port 1-65535
user@host# set applications application test term test destination-port 1111-1111
```

- If multiple custom applications are configured with custom timeouts, then each application will have its own custom application timeout. For example:

```
user@host# set applications application ftp-1 protocol tcp source-port 0-65535 destination-port
2121-2121 inactivity-timeout 10
user@host# set applications application telnet-1 protocol tcp source-port 0-65535
destination-port 2300-2348 inactivity-timeout 20
```

With this configuration, Junos OS applies a 10-second timeout for destination port 2121 and a 20-second timeout for destination port 2300 in an application group.

- Related Documentation**
- [Understanding Custom Policy Applications on page 1155](#)
 - [Custom Application Mappings on page 1155](#)
 - [Understanding Policy Application Timeout Configuration and Lookup on page 1161](#)
 - [Example: Adding and Modifying Custom Policy Applications on page 1156](#)

Example: Setting a Policy Application Timeout

This example shows how to set a policy application timeout value.

- [Requirements on page 1163](#)
- [Overview on page 1163](#)

- [Configuration on page 1163](#)
- [Verification on page 1163](#)

Requirements

Before you begin, understand policy application timeouts. See "[Understanding Policy Application Timeout Configuration and Lookup](#)" on page 1161.

Overview

Application timeout values are stored in the application entry database and in the corresponding vsys TCP and UDP port-based timeout tables. In this example, you set the device for a policy application timeout to 75 minutes for the FTP predefined application.

When you set an application timeout value, Junos OS updates these tables with the new value.

Configuration

Step-by-Step Procedure

To set a policy application timeout:

1. Set the inactivity timeout value.

```
[edit applications application ftp]  
user@host# set inactivity-timeout 75
```
2. Commit the configuration if you are done configuring the device.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show applications** command.

Understanding Internet-Related Predefined Policy Applications

When you create a policy, you can specify predefined Internet-related applications for the policy.

[Table 82](#) lists Internet-related predefined applications. Depending on your network requirements, you can choose to permit or deny any or all of these applications. Each entry lists the application name, default receiving port, and application description.

Table 82: Predefined Applications

Application Name	Port(s)	Application Description
AOL	5190-5193	America Online Internet service provider (ISP) provides Internet, chat, and instant messaging applications.

Table 82: Predefined Applications (*continued*)

Application Name	Port(s)	Application Description
DHCP relay	67 (default)	Dynamic Host Configuration Protocol.
DHCP	68 client 67 server	Dynamic Host Configuration Protocol allocates network addresses and delivers configuration parameters from server to hosts.
DNS	53	Domain Name System translates domain names into IP addresses.
FTP	20 data	File Transfer Protocol (FTP) allows the sending and receiving of files between machines. You can choose to deny or permit ANY or to selectively permit or deny.
	21 control	We recommend denying FTP applications from untrusted sources (Internet).
Gopher	70	Gopher organizes and displays Internet servers' contents as a hierarchically structured list of files. We recommend denying Gopher access to avoid exposing your network structure.
HTTP	80	HyperText Transfer Protocol is the underlying protocol used by the World Wide Web (WWW). Denying HTTP application disables your users from viewing the Internet. Permitting HTTP application allows your trusted hosts to view the Internet.
HTTP-EXT	—	Hypertext Transfer Protocol with extended nonstandard ports
HTTPS	443	Hypertext Transfer Protocol with Secure Sockets Layer (SSL) is a protocol for transmitting private documents through the Internet. Denying HTTPS disables your users from shopping on the Internet and from accessing certain online resources that require secure password exchange. Permitting HTTPS allows your trusted hosts to participate in password exchange, shop online, and visit various protected online resources that require user login.
Internet Locator Service	—	Internet Locator Service includes LDAP, User Locator Service, and LDAP over TLS/SSL.
IRC	6665-6669	Internet Relay Chat (IRC) allows people connected to the Internet to join live discussions.
LDAP	389	Lightweight Directory Access Protocol is a set of protocols used to access information directories.
PC-Anywhere	—	PC-Anywhere is a remote control and file transfer software.
TFTP	69	Trivial File transfer Protocol (TFTP) is a protocol for simple file transfer.

Table 82: Predefined Applications (*continued*)

Application Name	Port(s)	Application Description
WAIS	—	Wide Area Information Server is a program that finds documents on the Internet.

Understanding Microsoft Predefined Policy Applications

When you create a policy, you can specify predefined Microsoft applications for the policy.

[Table 83](#) lists predefined Microsoft applications, parameters associated with each application, and a brief description of each application. Parameters include universal unique identifiers (UUIDs) and TCP/UDP source and destination ports. A UUID is a 128-bit unique number generated from a hardware address, a timestamp, and seed values.

Table 83: Predefined Microsoft Applications

Application	Parameter/UUID	Description
Junos MS-RPC-EPM	135 e1af8308-5d1f-11c9-91a4-08002b14a0fa	Microsoft remote procedure call (RPC) Endpoint Mapper (EPM) Protocol.
Junos MS-RPC	—	Any Microsoft remote procedure call (RPC) applications.
Junos MS-RPC-MSEXCHANGE	3 members	Microsoft Exchange application group includes: <ul style="list-style-type: none"> • Junos-MS-RPC-MSEXCHANGE-DATABASE • Junos-MS-RPC-MSEXCHANGE-DIRECTORY • Junos-MS-RPC-MSEXCHANGE-INFO-STORE
Junos-MS-RPC-MSEXCHANGE-DATABASE	1a190310-bb9c-11cd-90f8-00aa00466520	Microsoft Exchange Database application.
Junos-MS-RPC-MSEXCHANGE-DIRECTORY	f5cc5a18-4264-101a-8c59-08002b2f8426 f5cc5a7c-4264-101a-8c59-08002b2f8426 f5cc59b4-4264-101a-8c59-08002b2f8426	Microsoft Exchange Directory application.
Junos-MS-RPC-MSEXCHANGE-INFO-STORE	0e4a0156-dd5d-11d2-8c2f-00c04fb6bcde 1453c42c-0fa6-11d2-a910-00c04f990f3b 10f24e8e-0fa6-11d2-a910-00c04f990f3b 1544f5e0-613c-11d1-93df-00c04fd7bd09	Microsoft Exchange Information Store application.

Table 83: Predefined Microsoft Applications (*continued*)

Application	Parameter/UUID	Description
Junos-MS-RPC-TCP	—	Microsoft Transmission Control Protocol (TCP) application.
Junos-MS-RPC-UDP	—	Microsoft User Datagram Protocol (UDP) application.
Junos-MS-SQL	—	Microsoft Structured Query Language (SQL).
Junos-MSN	—	Microsoft Network Messenger application.

Understanding Dynamic Routing Protocols in Predefined Policy Applications

When you create a policy, you can specify predefined dynamic routing protocol applications for the policy.

Depending on your network requirements, you can choose to permit or deny messages generated from these dynamic routing protocols and packets of these dynamic routing protocols. [Table 84](#) lists each supported dynamic routing protocol by name, port, and description.

Table 84: Dynamic Routing Protocols

Dynamic Routing Protocol	Port	Description
RIP	520	RIP is a common distance-vector routing protocol.
OSPF	89	OSPF is a common link-state routing protocol.
BGP	179	BGP is an exterior/interdomain routing protocol.

- Related Documentation**
- [Example: Configuring Applications and Application Sets on page 1152](#)

Understanding Streaming Video Predefined Policy Applications

When you create a policy, you can specify predefined streaming video applications for the policy.

[Table 85](#) lists each supported streaming video application by name and includes the default port and description. Depending on your network requirements, you can choose to permit or deny any or all of these applications.

Table 85: Supported Streaming Video Applications

Application	Port	Description
H.323	TCP source 1-65535; TCP destination 1720, 1503, 389, 522, 1731 UDP source 1-65535; UDP source 1719	H.323 is a standard approved by the International Telecommunication Union (ITU) that defines how audiovisual conference data is transmitted across networks.
NetMeeting	TCP source 1-65535; TCP destination 1720, 1503, 389, 522 UDP source 1719	Microsoft NetMeeting uses TCP to provide teleconferencing (video and audio) applications over the Internet.
Real media	TCP source 1-65535; TCP destination 7070	Real Media is streaming video and audio technology.
RTSP	554	Real-Time Streaming Protocol (RTSP) is for streaming media applications
SIP	5056	Session Initiation Protocol (SIP) is an Application-Layer control protocol for creating, modifying, and terminating sessions.
VDO Live	TCP source 1-65535; TCP destination 7000-7010	VDOLive is a scalable, video streaming technology.

Understanding Security and Tunnel Predefined Policy Applications

When you create a policy, you can specify predefined security and tunnel applications for the policy.

[Table 87](#) lists each supported application and gives the default port(s) and a description of each entry.

Table 87: Supported Applications

Application	Port	Description
IKE	UDP source 1-65535; UDP destination 500	Internet Key Exchange is the protocol that sets up a security association in the IPsec protocol suite. Internet Key protocol (IKE) is a protocol to obtain authenticated keying material for use with ISAKMP.
IKE-NAT	4500	IKE-Network Address Translation (NAT) performs Layer 3 NAT for S2C IKE traffic.
L2TP	1701	L2TP combines PPTP with Layer 2 Forwarding (L2F) for remote access.
PPTP	1723	Point-to-Point Tunneling Protocol allows corporations to extend their own private network through private <i>tunnels</i> over the public Internet.

Understanding IP-Related Predefined Policy Applications

When you create a policy, you can specify predefined IP-related applications for the policy.

[Table 88](#) lists the predefined IP-related applications. Each entry includes port numbers and a description of the application.

TCP-ANY means any application that is using TCP, so there is no default port for it. The same is true for UDP-ANY.

Table 88: Predefined IP-Related Applications

Application	Port	Description
Any	—	Any application
TCP-ANY	0-65,535	Any protocol using the TCP
UDP-ANY	0-65,535	Any protocol using the UDP

Understanding Instant Messaging Predefined Policy Applications

When you create a policy, you can specify predefined instant messaging applications for the policy.

[Table 89](#) lists predefined Internet-messaging applications. Each entry includes the name of the application, the default or assigned port, and a description of the application.

Table 89: Predefined Internet-Messaging Applications

Application	Port	Description
Gnutella	6346 (default)	Gnutella is a public domain file sharing protocol that operates over a distributed network. You can assign any port, but the default is 6346.
MSN	1863	Microsoft Network Messenger is a utility that allows you to send instant messages and talk online.
NNTP	119	Network News Transport Protocol is a protocol used to post, distribute, and retrieve USENET messages.
SMB	445	Server Message Block (SMB) over IP is a protocol that allows you to read and write files to a server on a network.

Table 89: Predefined Internet-Messaging Applications (*continued*)

Application	Port	Description
YMSG	5010	Yahoo! Messenger is a utility that allows you to check when others are online, send instant messages, and talk online.

Understanding Management Predefined Policy Applications

When you create a policy, you can specify predefined management applications for the policy.

[Table 90](#) lists the predefined management applications. Each entry includes the name of the application, the default or assigned port, and a description of the application.

Table 90: Predefined Management Applications

Application	Port	Description
NBNAME	137	NetBIOS Name application displays all NetBIOS name packets sent on UDP port 137.
NDBDS	138	NetBIOS Datagram application, published by IBM, provides connectionless (datagram) applications to PCs connected with a broadcast medium to locate resources, initiate sessions, and terminate sessions. It is unreliable and the packets are not sequenced.
NFS	—	Network File System uses UDP to allow network users to access shared files stored on computers of different types. SUN RPC is a building block of NFS.
NS Global	—	NS-Global is the central management protocol for Juniper Networks Firewall/VPN devices.
NS Global PRO	—	NS Global-PRO is the scalable monitoring system for the Juniper Networks Firewall/VPN device family.
NSM	—	Network and Security Manager
NTP	123	Network Time Protocol provides a way for computers to synchronize to a time reference.
RLOGIN	513	RLOGIN starts a terminal session on a remote host.
RSH	514	RSH executes a shell command on a remote host.
SNMP	161	Simple Network Management Protocol is a set of protocols for managing complex networks.

Table 90: Predefined Management Applications (*continued*)

Application	Port	Description
SQL*Net V1	66	SQL*Net Version 1 is a database language that allows for the creation, access, modification, and protection of data.
SQL*Net V2	66	SQL*Net Version 2 is a database language that allows for the creation, access, modification, and protection of data.
MSSQL	1433 (default instance)	Microsoft SQL is a proprietary database server tool that allows for the creation, access, modification, and protection of data.
SSH	22	SSH is a program to log into another computer over a network through strong authentication and secure communications on an unsecure channel.
SYSLOG	514	Syslog is a UNIX program that sends messages to the system logger.
Talk	517-518	Talk is a visual communication program that copies lines from your terminal to that of another user.
Telnet	23	Telnet is a UNIX program that provides a standard method of interfacing terminal devices and terminal-oriented processes to each other.
WinFrame	—	WinFrame is a technology that allows users on non-Windows machines to run Windows applications.
X-Windows	—	X-Windows is the windowing and graphics system that Motif and OpenLook are based on.

Understanding Miscellaneous Predefined Policy Applications

When you create a policy, you can specify miscellaneous predefined applications for the policy.

[Table 93](#) lists predefined miscellaneous applications. Each entry includes the application name, default or assigned port, and a description of the application.

Table 93: Predefined Miscellaneous Applications

Application	Port	Description
CHARGEN	19	Character Generator Protocol is a UDP- or TCP-based debugging and measurement tool.
DISCARD	9	Discard protocol is an Application Layer protocol that describes a process for discarding TCP or UDP data sent to port 9.
IDENT	113	Identification protocol is a TCP/IP Application Layer protocol used for TCP client authentication.
LPR	515 listen; 721-731 source range (inclusive)	Line Printer Daemon protocol is a TCP-based protocol used for printing applications.
RADIUS	1812	Remote Authentication Dial-In User Service application is a server program used for authentication and accounting purposes.
RADIUS Accounting	1813	A RADIUS Accounting server receives statistical data about users logging in to or out of a LAN.

Table 93: Predefined Miscellaneous Applications (*continued*)

Application	Port	Description
SQLMON	1434 (SQL Monitor Port)	SQL monitor (Microsoft)
VNC	5800	Virtual Network Computing facilitates viewing and interacting with another computer or mobile Juniper Networks device connected to the Internet.
WHOIS	43	Network Directory Application Protocol is a way to look up domain names.
SCCP	2000	Cisco Station Call Control Protocol (SCCP) uses the signaling connection control port to provide high availability and flow control.

Understanding the ICMP Predefined Policy Application

When you create a policy, you can specify the ICMP predefined application for the policy.

Internet Control Message Protocol (ICMP) is a part of IP and provides a way to query a network (ICMP query messages) and to receive feedback from the network for error patterns (ICMP error messages). ICMP does not, however, guarantee error message delivery or report all lost datagrams; and it is not a reliable protocol. ICMP codes and type codes describe ICMP query messages and ICMP error messages.

You can choose to permit or deny any or specific types of ICMP messages to improve network security. Some types of ICMP messages can be exploited to gain information about your network that might compromise security. For example, ICMP, TCP, or UDP packets can be constructed to return ICMP error messages that contain information about a network, such as its topology, and access list filtering characteristics. [Table 94](#) lists ICMP message names, the corresponding code, type, and description.

Table 94: ICMP Messages

ICMP Message Name	Type	Code	Description
ICMP-ANY	all	all	ICMP-ANY affects any protocol using ICMP. Denying ICMP-ANY impairs any attempt to ping or monitor a network using ICMP. Permitting ICMP-ANY allows all ICMP messages.

Table 94: ICMP Messages (*continued*)

ICMP Message Name	Type	Code	Description
ICMP-ADDRESS-MASK	17	0	ICMP address mask query is used for systems that need the local subnet mask from a bootstrap server.
<ul style="list-style-type: none"> Request Reply 	18	0	<p>Denying ICMP address mask request messages can adversely affect diskless systems.</p> <p>Permitting ICMP address mask request messages might allow others to fingerprint the operating system of a host in your network.</p>
ICMP-DEST-UNREACH	3	0	<p>ICMP destination unreachable error message indicates that the destination host is configured to reject the packets.</p> <p>Codes 0, 1, 4, or 5 can be from a gateway. Codes 2 or 3 can be from a host (RFC 792).</p> <p>Denying ICMP destination unreachable error messages can remove the assumption that a host is up and running behind an SRX Series device.</p> <p>Permitting ICMP destination unreachable error messages can allow some assumptions, such as security filtering, to be made about the network.</p>
ICMP Fragment Needed	3	4	<p>ICMP fragmentation error message indicates that fragmentation is needed but the don't fragment flag is set.</p> <p>We recommend denying these messages from the Internet to an internal network.</p>
ICMP FragmentReassembly	11	1	<p>ICMP fragment reassembly time exceeded error indicates that a host reassembling a fragmented message ran out of time and dropped the packet. This message is sometimes sent.</p> <p>We recommend denying these messages from the Internet (external) to the trusted (internal) network.</p>
ICMP-HOST-UNREACH	3	1	<p>ICMP host unreachable error messages indicate that routing table entries do not list or list as infinity a particular host. Sometimes this error is sent by gateways that cannot fragment when a packet requiring fragmentation is received.</p> <p>We recommend denying these messages from the Internet to a trusted network.</p> <p>Permitting these messages allows others to be able to determine your internal host's IP addresses by a process of elimination or make assumptions about gateways and fragmentation.</p>

Table 94: ICMP Messages (*continued*)

ICMP Message Name	Type	Code	Description
ICMP-INFO	15	0	ICMP-INFO query messages allow diskless host systems to query the network and self-configure.
<ul style="list-style-type: none"> Request Reply 	16	0	<p>Denying ICMP address mask request messages can adversely affect diskless systems.</p> <p>Permitting ICMP address mask request messages might allow others to broadcast information queries to a network segment to determine computer type.</p>
ICMP-PARAMETER-PROBLEM	12	0	<p>ICMP parameter problem error messages notify you when incorrect header parameters are present and have caused a packet to be discarded.</p> <p>We recommend denying these messages from the Internet to a trusted network.</p> <p>Permitting ICMP parameter problem error messages allows others to make assumptions about your network.</p>
ICMP-PORT-UNREACH	3	3	<p>ICMP port unreachable error messages indicate that gateways processing datagrams requesting certain ports are unavailable or unsupported in the network.</p> <p>We recommend denying these messages from the Internet to a trusted network.</p> <p>Permitting ICMP port unreachable error messages can allow others to determine which ports you use for certain protocols.</p>
ICMP-PROTOCOL-UNREACH	3	2	<p>ICMP protocol unreachable error messages indicate that gateways processing datagrams requesting certain protocols are unavailable or unsupported in the network.</p> <p>We recommend denying these messages from the Internet to a trusted network.</p> <p>Permitting ICMP protocol unreachable error messages can allow others to determine what protocols your network is running.</p>
ICMP-REDIRECT	5	0	<p>ICMP redirect network error messages are sent by an SRX Series device.</p> <p>We recommend denying these messages from the Internet to a trusted network.</p>
ICMP-REDIRECT-HOST	5	1	ICMP redirect messages indicate datagrams destined for the specified host to be sent along another path.

Table 94: ICMP Messages (*continued*)

ICMP Message Name	Type	Code	Description
ICMP-REDIRECT-TOS-HOST	5	3	ICMP redirect type of service (TOS) and host error is a type of message.
ICMP-REDIRECT-TOS-NET	5	2	ICMP redirect TOS and network error is a type of message.
ICMP-SOURCE-QUENCH	4	0	<p>ICMP source quench error message indicates that a device does not have the buffer space available to accept, queue, and send the packets on to the next hop.</p> <p>Denying these messages will not help or impair internal network performance.</p> <p>Permitting these messages can allow others to know that a device is congested, making it a viable attack target.</p>
ICMP-SOURCE-ROUTE-FAIL	3	5	<p>ICMP source route failed error message</p> <p>We recommend denying these messages from the Internet (external).</p>
ICMP-TIME-EXCEEDED	11	0	<p>ICMP time-to-live (TTL) exceeded error message indicates that a packet's TTL setting reached zero before the packet reached its destination. This ensures that older packets are discarded before resent ones are processed.</p> <p>We recommend denying these messages from a trusted network out to the Internet.</p>
ICMP-TIMESTAMP • Request • Reply	13 14	0 0	ICMP-TIMESTAMP query messages provide the mechanism to synchronize time and coordinate time distribution in a large, diverse network.
Ping (ICMP ECHO)	8	0	<p>Ping is a utility to determine whether a specific host is accessible by its IP address.</p> <p>Denying ping functionality removes your ability to check to see if a host is active.</p> <p>Permitting ping can allow others to execute a denial-of-service (DoS) or Smurf attack.</p>
ICMP-ECHO-FRAGMENT-ASSEMBLY-EXPIRE	11	1	<p>ICMP fragment echo reassembly time expired error message indicates that the reassembly time was exceeded.</p> <p>We recommend denying these messages.</p>

Table 94: ICMP Messages (*continued*)

ICMP Message Name	Type	Code	Description
Traceroute	30	0	Traceroute is a utility to indicate the path to access a specific host.
• Forward	30	1	We recommend denying this utility from the Internet (external) to your trusted network (internal).
• Discard

Example: Defining a Custom ICMP Application

This example shows how to define a custom ICMP application.

- [Requirements on page 1180](#)
- [Overview on page 1180](#)
- [Configuration on page 1181](#)
- [Verification on page 1181](#)

Requirements

Before you begin:

- Understand custom policy application. See [“Understanding Custom Policy Applications” on page 1155](#).
- Understand the ICMP predefined policy application. See [“Understanding the ICMP Predefined Policy Application” on page 1175](#).

Overview

Junos OS supports ICMP—as well as several ICMP messages—as predefined or custom applications. When configuring a custom ICMP application, you define a type and code.

- There are different message types within ICMP. For example:
 - type 0 = Echo Request message
 - type 3 = Destination Unreachable message
- An ICMP message type can also have a message code. The code provides more specific information about the message, as shown in [Table 95](#).

Table 95: Message Descriptions

Message Type	Message Code
5 = Redirect	0 = Redirect datagram for the network (or subnet)
	1 = Redirect datagram for the host
	2 = Redirect datagram for the type of application and network
	3 = Redirect datagram for the type of application and host
11 = Time Exceeded Codes	0 = Time to live exceeded in transit
	1 = Fragment reassembly time exceeded

Junos OS supports any type or code within the range of **0** through **55**.

In this example, you define a custom application named host-unreachable using ICMP as the transport protocol. The type is 3 (for destination unreachable) and the code is 1 (for host unreachable). You set the timeout value at 4 minutes.

NOTE: For more information about ICMP types and codes, refer to RFC 792, *Internet Control Message Protocol*.

Configuration

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the CLI User guide.

To define a custom ICMP application:

1. Set the application type and code.

```
[edit applications application host-unreachable]  
user@host# set icmp-type 5 icmp-code 0
```

2. Set the inactivity timeout value.

```
[edit applications application host-unreachable]  
user@host# set inactivity-timeout 4
```

3. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show applications** command.

Related Documentation

- [Security Policies Overview on page 1065](#)

Default Behavior of ICMP Unreachable Errors

For different levels of security, the default behavior for ICMP unreachable errors is handled as follows:

- Sessions are closed for ICMP type-3, code-0, code-1, code-2, and code-3 messages only when the following conditions are met:
 - The ICMP unreachable message is received in the server-to-client direction.
 - No normal packet is received in the server-to-client direction.

Otherwise, sessions do not close.

- Sessions do not close for ICMP type-3, code-4 messages.

address (Security Address Book)

Syntax `address address-name {
 ip-prefix {
 description text;
 }
 description text;
 dns-name domain-name {
 ipv4-only;
 ipv6-only;
 }
 range-address lower-limit to upper-limit;
 wildcard-address ipv4-address/wildcard-mask;
 }`

Hierarchy Level `[edit security address-book book-name]`

Release Information Statement introduced in Junos OS Release 8.5. Support for IPv6 addresses added in Junos OS Release 10.2. Support for IPv6 addresses in active/active chassis cluster configurations (in addition to the existing support of active/passive chassis cluster configurations) added in Junos OS Release 10.4. Support for wildcard addresses added in Junos OS Release 11.1. Support for address range added in Junos OS Release 12.1. The **description** option added in Junos OS Release 12.1.

Description Add an entry containing an IP address or DNS hostname, or wildcard address to the address book. An address book contains entries for addressable entities in security zones, policies, and NAT rules. Address book entries can include any combination of IPv4 addresses, IPv6 addresses, and DNS names.

- Options**
- **address address-name**—Name of an address entry.
 - **description text**—Descriptive text about an address entry.
 - **dns-address domain-name**—DNS address name.
 - **ip-prefix**—IP address with prefix.
 - **range-address lower-limit to upper-limit**—Address range for an address book.
 - **wildcard-address ipv4-address/wildcard-mask**—IPv4 wildcard address in the form of A.B.C.D/wildcard-mask.

NOTE: IPv6 wildcard address configuration is not supported in this release.

Required Privilege Level security—To view this statement in the configuration.
 security-control—To add this statement to the configuration.

address-book

```
Syntax  address-book (book-name | global) {
        address address-name {
            ip-prefix {
                description text;
            }
            description text;
            dns-name domain-name {
                ipv4-only;
                ipv6-only;
            }
            range-address lower-limit to upper-limit;
            wildcard-address ipv4-address/wildcard-mask;
        }
        address-set address-set-name {
            address address-name;
            address-set address-set-name;
            description text;
        }
        attach {
            zone zone-name;
        }
        description text;
    }
```

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 8.5. Support for wildcard addresses added in Junos OS Release 11.1. Statement moved under the security hierarchy in Junos OS Release 11.2. Support for address range added in Junos OS Release 12.1. The **description** option added in Junos OS Release 12.1.

Description Define entries in the address book. Address book entries can include any combination of IPv4 addresses, IPv6 addresses, DNS names, wildcard addresses, and address range. You define addresses and address sets in an address book and then use them when configuring different features, such as security policies and NAT.

NOTE: IPv6 wildcard address configuration is not supported in this release.

- Options**
- **address-book *book-name***—Name of the address book.
 - **global**—An address book that is available by default. You can add any combination of IPv4 addresses, IPv6 addresses, wildcard addresses, DNS names, or address range to the global address book. You do not need to attach the global address book to a security zone; entries in the global address book are available to all security zones that are not attached to address books.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

address-set

Syntax `address-set address-set-name {
 address address-name;
 address-set address-set-name;
 description text;
}`

Hierarchy Level [edit security address-book *book-name*]

Release Information Statement introduced in Junos OS Release 8.5. Support for nested address sets introduced in Release 11.2 of Junos OS. The **description** option added in Junos OS Release 12.1.

Description Specify a collection of addresses, as defined in the **address (Address Book)** statement. Using address sets, you can organize addresses in logical groups and use them to easily configure other features, such as policies and NAT rules. Using this statement, you can also include a description for an address set.

You can also define address sets within address sets.

Options *address-set-name*—Name of the address set.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Hierarchy Level [edit applications]

Release Information Statement introduced in Junos OS Release 8.5.

Description Configure application properties at the [applications] hierarchy level.

- Options**
- **application-protocol *protocol-name***—Specify the name of the application protocol.
 - **description *text***—Describe the application.
 - **destination-port *port-identifier***—Specify a TCP or UDP destination port number.
 - **do-not-translate-A-query-to-AAAA-query**—Set the statement to control the translation of A query to AAAA query.
 - **do-not-translate-AAAA-query-to-A-query**—Set the statement to control the translation of AAAA query to A query.
 - **ether-type *value***—Specify the Ethernet packet type value.

- **icmp-code *value***—Specify the Internet Control Message Protocol (ICMP) code value.
Range: 0 through 255.
- **icmp-type *value***—Specify the ICMP packet type value.
Range: 0 through 255.
- **icmp6-code *value***—Specify the ICMP6 code value.
Range: 0 through 255.
- **icmp6-type *value***—Specify the ICMP6 packet type value.
Range: 0 through 255.
- **inactivity-timeout (*seconds* | *never*)**—Specify the amount of time the application is inactive before it times out in seconds.
Range: 4 through 129,600 seconds.
Default: For TCP, 1800 seconds; for UDP, 60 seconds.
- **protocol *value***—Specify the networking protocol name or number.
- **rpc-program-number *value***—Specify the remote procedure call (RPC) or Distributed Computing Equipment (DCE) value.
- **source-port *port-number***—Specify a TCP or UDP source port number.

- **term *term-name***—Specify the individual application protocol.
 - **alg *application***—Specify the name of the application protocol.
 - **destination-port *port-identifier***—Specify a TCP or UDP destination port number.
 - **icmp-code *value***—Specify the ICMP code value.
Range: 0 through 255.
 - **icmp-type *value***—Specify the ICMP packet type value.
Range: 0 through 255.
 - **icmp6-code *value***—Specify the ICMP6 code value.
Range: 0 through 255.
 - **icmp6-type *value***—Specify the ICMP6 packet type value.
Range: 0 through 255.
 - **inactivity-timeout (*seconds* | *never*)**—Specify the amount of time the application is inactive before it times out in seconds.
Range: 4 through 129,600 seconds.
Default: For TCP, 1800 seconds; for UDP, 60 seconds.
 - **protocol *number***—Specify the networking protocol name or number.
 - **rpc-program-number *number***—Specify the RPC or DCE value.
 - **source-port *port-number***—Specify a TCP or UDP source port number.
 - **uuid *hex-vale***—Specify the universal unique identifier (UUID) for objects.
- **uuid *hex-value***—Specify the UUID for objects.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

application (Security Alarms)

Syntax	<pre> application { duration <i>interval</i>; size <i>count</i>; threshold <i>value</i>; } </pre>
Hierarchy Level	[edit security alarms potential-violation policy]
Release Information	Statement introduced in Junos OS Release 11.2.
Description	Configure alarms for a number of policy violations to an application within a specified time period.
Options	<ul style="list-style-type: none"> • duration <i>interval</i>—Indicate the duration of counters. Range: 1 through 3600 seconds. Default: 1 second. • size <i>count</i>—Indicate the number of applications for which policy violation checks can be done concurrently. Range: 1 through 10240. Default: 1024. • threshold <i>value</i>—Indicate the maximum number of application matches required to raise an alarm. Range: 1 through 4294967295. Default: 1000.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Policies Overview on page 1065

application (Security Policies)

Syntax	<pre> application { [application]; any; } </pre>
Hierarchy Level	<p>[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> match]</p> <p>[edit security policies global policy <i>policy-name</i> match]</p>
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the IP or remote procedure call (RPC) application or set of applications to be used as match criteria.
Options	<p><i>application-name-or-set</i>—Name of the predefined or custom application or application set used as match criteria.</p> <p><i>any</i>—Any predefined or custom applications or application sets.</p>
<div>  <p>NOTE: A custom application that does not use a well-known destination port for the application will not be included in the <i>any</i> option, and must be named explicitly.</p> </div>	
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

application-tracking (Security Zones)

Syntax	application-tracking;
Hierarchy Level	[edit security zones security-zone <i>zone-name</i>]
Release Information	Statement introduced in Junos OS Release 10.2.
Description	Enable application tracking support for the zone.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • [edit security zones] Hierarchy Level on page 324

application-traffic-control (Application Services)

Syntax	application-traffic-control { rule-set <i>rule-set-name</i> ; }
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit application-services]
Release Information	Statement introduced in Junos OS Release 11.4.
Description	Enables AppQoS, application-aware quality of service, as specified in the rules of the specified rule set.
Options	<ul style="list-style-type: none"> • rule-set <i>rule-set-name</i>—Name of the rule set that contains application-aware traffic control specification rules.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Policies Overview on page 1065

attach

Syntax	<code>attach { zone <i>zone-name</i>; }</code>
Hierarchy Level	[edit security address-book <i>book-name</i>]
Release Information	Statement introduced in Release 11.2 of Junos OS.
Description	Attach a security zone to an address book. You do not need to attach a security zone to the global address book. The global address book is available by default.
Options	zone <i>zone-name</i> —Name of a security zone to be attached to the address book.
Required Privilege Level	security —To view this statement in the configuration. security-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Understanding Address Books on page 1049• Understanding Address Sets on page 1051

audible (Security Alarms)

Syntax	<code>audible { continuous; }</code>
Hierarchy Level	[edit security alarms]
Release Information	Statement modified in Junos OS Release 11.2.
Description	Configure alarm to beep when a new security alarm is enabled.
Options	continuous —Specify alarm to keep beeping until all security alarms are cleared.
Required Privilege Level	security —To view this statement in the configuration. security-control —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065

authentication (Security Alarms)

Syntax	authentication <i>failures</i> ;
Hierarchy Level	[edit security alarms potential-violation]
Release Information	Statement introduced in Junos OS Release 11.2.
Description	<p>Raise a security alarm when the device or switch detects a specified number of authentication failures (bad password attempts) before an alarm is raised.</p> <p>This value must be equal to or less than the tries-before-disconnect setting at the [edit system login retry-options] hierarchy level; otherwise, the login session ends before the user reaches the alarmable threshold.</p>
Default	Multiple authentication failures do not cause an alarm to be raised.
Options	<p><i>failures</i>—Number of authentication failures that causes an alarm to be raised.</p> <p>Range: 1 through 10.</p>
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065

authentication-source

Syntax	authentication-source { active-directory-authentication-table priority <i>priority</i> ; firewall-authentication priority <i>priority</i> ; local-authentication-table priority <i>priority</i> ; unified-access-control priority <i>priority</i> ; }
Hierarchy Level	[edit security user-identification]
Release Information	Statement introduced in Junos OS Release 12.1. Statement updated in Junos OS Release 12.1-X45-D10. Support for the active-directory-authentication-table priority command statement added in Junos OS Release 12.1X47-D10.
Description	Identifies one or more tables to be used as the source for user role information. Tables are searched in sequence based on lowest to highest priority.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• local-authentication-table on page 1244• firewall-authentication (User Identification) on page 1232• unified-access-control (Security) on page 1308• Understanding User Role Firewalls on page 1107• Understanding the User Identification Table on page 1110

captive-portal (Services UAC Policy)

Syntax	captive-portal <i>captive-portal-policy-name</i> ;
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit application-services uac-policy]
Release Information	Statement introduced in Junos OS Release 10.2.
Description	Create the captive portal policy in the UAC security policy. You use the captive portal policy to configure the captive portal feature on the Junos OS Enforcer. By configuring the captive portal feature, you can redirect traffic destined for protected resources to the IC Series device or to the URL you configure on the Junos OS Enforcer.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065

count (Security Policies)

Syntax	count;
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then]
Release Information	Statement introduced in Junos OS Release 8.5. Statement updated in Junos OS Release 12.1X47-D10.
Description	Enable a count, in bytes or kilobytes, of all network traffic the policy allows to pass through the device in both directions: the originating traffic from the client to the server (from the from-zone to the to-zone), and the return traffic from the server to the originating client.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • show security policies on page 780 • Security Policies Overview on page 1065

default-policy

Syntax	default-policy (deny-all permit-all);
Hierarchy Level	[edit security policies]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure the default security policy that defines the actions the device takes on a packet that does not match any user-defined policy.
Options	<p>deny-all—Deny all traffic. Packets are dropped. This is the default.</p> <p>permit-all—Permit all traffic that does not match a policy.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Policies Overview on page 1065 • [edit security policies] Hierarchy Level on page 320

deny (Security Policies)

Syntax	deny;
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Block the service at the firewall. The device drops the packets.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Policies Overview on page 1065

description (Applications)

Syntax	description text;
Hierarchy Level	[edit applications application <i>application-name</i>], [edit applications application-set <i>application-set-name</i>]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Specify descriptive text for an application or an application set.

NOTE: The descriptive text should not include characters, such as "<", ">", "&", or "\n".

Options	text —Descriptive text about an application or an application set. Range: 1 through 300 characters
----------------	---------------------------------------------------------------------------------------------------------------------

NOTE: The upper limit of the description text range is related to character encoding, and is therefore dynamic. However, if you configure the descriptive text length beyond 300 characters, the configuration might fail to take effect.

destination-address (Security Policies)

Syntax	<pre>destination-address { [address]; any; any-ipv4; any-ipv6; }</pre>
Hierarchy Level	<p>[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> match]</p> <p>[edit security policies global policy <i>policy-name</i> match]</p>
Release Information	Statement introduced in Junos OS Release 8.5. Support for IPv6 addresses added in Junos OS Release 10.2. Support for IPv6 addresses in active/active chassis cluster configurations (in addition to the existing support of active/passive chassis cluster configurations) added in Junos OS Release 10.4. Support for wildcard addresses added in Junos OS Release 11.1.
Description	Define the matching criteria. You can specify one or more IP addresses, address sets, or wildcard addresses. You can specify wildcards any , any-ipv4 , or any-ipv6 .
Options	address —IP address (any , any-ipv4 , any-ipv6), IP address set, or address book entry, or wildcard address (represented as A.B.C.D/wildcard-mask). You can configure multiple addresses or address prefixes separated by spaces and enclosed in square brackets.
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065• [edit security policies] Hierarchy Level on page 320

destination-address (Security Policies Flag)

Syntax	<pre>destination-address { drop-translated; drop-untranslated; }</pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit]
Release Information	Statement introduced in Junos OS Release 9.2.
Description	<p>Specify whether the traffic permitted by the security policy is limited to packets where the destination IP address has been translated by means of a destination NAT rule or to packets where the destination IP address has not been translated.</p> <p>On Juniper Networks security devices, destination NAT rules are processed before security policy lookup. Therefore, it is possible for a security policy to permit traffic from a source S to a destination D (where no destination NAT is performed) and also to permit traffic from the source S to the destination d (where d has been translated to D).</p>
Options	<ul style="list-style-type: none"> • drop-translated—Drop packets with translated destination IP addresses. Traffic permitted by the security policy is limited to packets where the destination IP address has not been translated. • drop-untranslated—Drop packets without translated destination IP addresses. Traffic permitted by the security policy is limited to packets where the destination IP address has been translated by means of a destination NAT rule.
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

Hierarchy Level	[edit system services]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Configure the device as a dynamic DNS server that maintains the list of the changed addresses and their associated domain names registered with it. The device updates these DDNS servers with this information periodically or whenever there is a change in IP addresses.
Options	<ul style="list-style-type: none"> • client—Specifies the hostname of the registered client. • agent—Specifies the name of the dynamic DNS agent. • interface—Specifies the interface whose IP address is mapped to the registered domain name. • password—Specifies the password. • server—Specifies the name of the dynamic DNS server that allows dynamic DNS clients to update the IP address changes associated with the registered hostname. • username—Specifies the dynamic DNS username.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

exclude (Schedulers)

Syntax	exclude;
Hierarchy Level	[edit schedulers scheduler <i>scheduler-name</i> daily], [edit schedulers scheduler <i>scheduler-name</i> friday], [edit schedulers scheduler <i>scheduler-name</i> monday], [edit schedulers scheduler <i>scheduler-name</i> saturday], [edit schedulers scheduler <i>scheduler-name</i> sunday], [edit schedulers scheduler <i>scheduler-name</i> tuesday], [edit schedulers scheduler <i>scheduler-name</i> thursday], [edit schedulers scheduler <i>scheduler-name</i> wednesday]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	<p>Exclude a specified day from the schedule.</p> <p>Use the exclude statement to exclude a day from a daily schedule created with the daily statement. You cannot use the exclude statement for a particular day unless it is in conjunction with the daily statement in a schedule.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Security Policy Schedulers Overview on page 1103

firewall-authentication (Security Policies)

Syntax	<pre> firewall-authentication { pass-through { access-profile <i>profile-name</i>; client-match <i>user-or-group-name</i>; ssl-termination-profile <i>profile-name</i>; web-redirect; web-redirect-to-https; } user-firewall { access-profile <i>profile-name</i>; domain <i>domain-name</i> ssl-termination-profile <i>profile-name</i>; } web-authentication { client-match <i>user-or-group-name</i>; } } </pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit]
Release Information	Statement introduced in Junos OS Release 8.5. Support for the ssl-termination-profile and web-redirect-to-https options added in Junos OS Release 12.1X44-D10. Support added for the user-firewall option in Junos OS Release 12.1X45-D10.
Description	Configure firewall authentication methods.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Understanding User Role Firewalls on page 1107

firewall-authentication (User Identification)

Syntax	firewall-authentication priority <i>priority</i> ;
Hierarchy Level	[edit security user-identification authentication-source]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10. Support for disable option dropped in Junos OS Release 12.1X47-D10.
Description	Enables the firewall authentication table as an authentication source. The priority of this table among other authentication tables establishes the search sequence used to identify user and role values.
Options	<p>priority <i>priority</i>—A unique value between 0 and 65535 that determines the sequence for searching multiple tables to retrieve a user role. Each table is given a unique priority value. The lower the value, the higher the priority. A table with priority 120 is searched before a table with priority 200. The default priority value of the firewall authentication table is 150.</p> <p>Setting the priority value of the firewall authentication table to 0 is equivalent to disabling the table and eliminating it from the search sequence.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• authentication-source on page 1214• Understanding User Role Firewalls on page 1107

forward-only (DNS)

Syntax	forward-only;
Hierarchy Level	[edit system services dns dns-proxy view <i>view-name</i> domain <i>domain-name</i>]
Release Information	Statement introduced in Junos OS Release 12.1X46-D10.
Description	Specify that the server to forward only DNS queries. This configuration prevents the device from acquiring public IP addresses, in case the IP address specified in forwarders option is not reachable, by terminating the DNS query.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

from-zone (Security Policies)

```

Syntax  from-zone zone-name to-zone zone-name {
        policy policy-name {
            description description;
            match {
                application {
                    [application];
                    any;
                }
                destination-address {
                    [address];
                    any;
                    any-ipv4;
                    any-ipv6;
                }
                source-address {
                    [address];
                    any;
                    any-ipv4;
                    any-ipv6;
                }
                source-identity {
                    [role-name];

initial-tcp-mss

Syntax	<code>initial-tcp-mss <i>mss-value</i>;</code>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit tcp-options]
Release Information	Statement introduced in Junos OS Release 12.3X48-D20.
Description	<p>Configure the TCP maximum segment size (MSS) for packets that arrive at the ingress interface (initial direction), match a specific policy, and for which a session is created. The value you configure overrides the TCP MSS value in the incoming packet when the value in the packet is higher than the one you specify.</p> <p>The initial-tcp-mss value per policy takes precedence over a global tcp-mss value (all-tcp, ipsec-vpn, gre-in, gre-out), if one is configured. However, when the syn-flood-protection-mode syn-proxy statement at the [edit security flow] hierarchy level is used to enable SYN proxy defenses against SYN attacks, the TCP MSS value is not overridden.</p> <p>Because each policy has two directions, you can configure a value for both directions or for just one direction. To configure a TCP MSS value for the reverse session, use the reverse-tcp-mss option.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • reverse-tcp-mss on page 1272

ipsec-group-vpn (Security Policies)

Syntax	<code>ipsec-group-vpn <i>group-vpn</i>;</code>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit tunnel]
Release Information	Statement introduced in Junos OS Release 10.2.
Description	Specify group VPN tunnel for the traffic configured by the scope policy on a group member.
Options	<i>group-vpn</i> —Name of the group VPN tunnel configured on the group member.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

                }
            }
        }
        screen screen-name;
    }
```

Hierarchy Level [edit security zones functional-zone]

Release Information Statement introduced in Junos OS Release 8.5. The **description** option added in Junos OS Release 12.1.

Description Specify the host for out-of-band management interfaces. You can set firewall options in this zone to protect the management interface from different types of attacks. Because this zone cannot be specified in policies, traffic entering from this zone can only be traffic originating from the device itself and cannot originate from any other zone.

Options The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

        [zone-name];
        any;
    }
}
```

Hierarchy Level [edit security policies global policy *policy-name*]

Release Information Statement modified in Junos OS Release 8.5. Statement updated with **source-identity** option in Junos OS Release 12.1. Statement updated with **to-zone** and **from-zone** options in Junos OS Release 12.1X47-D10.

Description Configure security global policy match criteria.

NOTE: We recommend that, for security reasons and to avoid spoofing traffic, when you create a multizone policy you use identical matching criteria (source address, destination address, application) and an identical action. For more information see “[Global Policy Overview](#)” on page 1095.

Options The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

no-policy-cold-synchronization

Syntax no-policy-cold-synchronization

Hierarchy Level [edit security idp sensor-configuration high-availability]

Release Information Statement introduced in Junos OS Release 11.1.

Description Disable policy cold synchronization functionality. This prevents the SRX Series devices from waiting for the IPS policy to be loaded on all service PICs, and there by forfeits IPS service protection during the ISSU (In-service software upgrade) operation/window.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

pair-policy

Syntax	<code>pair-policy <i>pair-policy</i> ;</code>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit tunnel]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	<p>Link the policy that you are configuring with another policy that references the same VPN tunnel so that both policies share one proxy ID and one security association (SA). Policy pairing is useful when you want to allow bidirectional traffic over a policy-based VPN that is using source or destination address translation with a dynamic IP address pool or destination address translation with a mapped IP (MIP) or dynamic IP (DIP) address pool.</p> <p>Without policy pairing, the device derives a different proxy ID from the outbound and inbound policies. Two proxy IDs causes a problem for the remote peer with a single proxy ID for the VPN tunnel.</p> <p>Pairing two policies solves the proxy ID problem for the remote peer and conserves SA resources. The single proxy ID is derived from the policy you configured last.</p>
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

pass-through

Syntax	<pre>pass-through { access-profile <i>profile-name</i>; client-match <i>user-or-group-name</i>; ssl-termination-profile <i>profile-name</i>; web-redirect; web-redirect-to-https; }</pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit firewall-authentication]
Release Information	Statement introduced in Junos OS Release 8.5. Support for ssl-termination-profile and web-redirect-to-https options added in Junos OS Release 12.1X44-D10.
Description	<p>Configure pass-through firewall user authentication. The user needs to use an FTP, Telnet, or HTTP client to access the IP address of the protected resource in another zone. Subsequent traffic from the user or host is allowed or denied based on the result of this authentication. Once authenticated, the firewall proxies the connection.</p>
Options	<ul style="list-style-type: none"> • access-profile <i>profile-name</i> —(Optional) Specify the name of the access profile. • client-match <i>user-or-group</i> —(Optional) Specify the name of the users or user groups in a profile who are allowed access by this policy. If you do not specify any users or user groups, any user who is successfully authenticated is allowed access. • ssl-termination-profile <i>profile-name</i> —(Optional) Specify the SSL termination profile used for SSL offloading. • web-redirect—(Optional) Enable redirecting an HTTP request to the device and redirecting the client system to a webpage for authentication. Including this statement allows users an easier authentication process because they need to know only the name or IP address of the resource they are trying to access. • web-redirect-to-https—(Optional) Redirect unauthenticated HTTP requests to the internal HTTPS Web server of the device.
<div style="display: flex; align-items: center;">  <div> <p>NOTE: If web-redirect-to-https is set, then you must specify the SSL termination profile used for SSL offloading.</p> </div> </div>	
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

Hierarchy Level [edit security policies from-zone *zone-name* to-zone *zone-name*]

Release Information Statement introduced in Junos OS Release 8.5. The **services-offload** option added in Junos OS Release 11.4. Statement updated with the **source-identity** option and the **description** option added in Junos OS Release 12.1. Support for the **user-firewall** option added in Junos OS Release 12.1X45-D10. Support for the **initial-tcp-mss** and **reverse-tcp-mss** options added in Junos OS Release 12.3X48-D20.

Description Define a security policy.

Options	<i>policy-name</i> —Name of the security policy. The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065• [edit security policies] Hierarchy Level on page 320

policy-match

Syntax	<pre>policy match { duration <i>interval</i>; size <i>count</i>; threshold <i>value</i>; }</pre>
Hierarchy Level	[edit security alarms potential-violation policy]
Release Information	Statement introduced in Junos OS Release 11.2.
Description	Configure alarms for a policy rule or a group of rule violations within a specified time period.
Options	<ul style="list-style-type: none">• <i>duration interval</i>—Indicate the duration of counters. Range: 1 through 3600 seconds. Default: 1 second.• <i>size count</i>—Indicate the number of policies for which policy violation checks can be done concurrently. Range: 1 through 10240. Default: 1024.• <i>threshold value</i>—Indicate the number of policies for which policy violation checks can be done concurrently. Range: 1 through 4294967295. Default: 1000.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065• [edit security policies] Hierarchy Level on page 320

policy-rematch

Syntax	<code>policy-rematch <extensive>;</code>
Hierarchy Level	[edit security policies]
Release Information	Statement introduced in Junos OS Release 8.5. Support for the extensive option added in Junos OS Release 15.1X49D20.
Description	<p>Enable the device to reevaluate an active session when its associated security policy is changed, renamed, deactivated, or deleted. The session remains open if it matches any policy that allows the session.</p> <p>The policy rematch feature is disabled by default, so that modified policies do not affect active sessions, and an active session is closed if its associated policy is renamed, deactivated, or deleted.</p>
Options	<p>extensive—When a security policy associated with an active session is changed, renamed, deactivated, or deleted, the session remains active if it matches another policy that allows the session. If a match occurs, the new policy is applied to the session, along with the new scheduler (if any), but the session retains the timeout value of the old policy. If policy-rematch is specified without extensive, a rematch is attempted only for changed policies, and a session is closed if it no longer matches the modified policy.</p>
<div style="display: flex; align-items: center;">  <div> <p>NOTE: The extensive option does not apply to ALG data sessions or to policies that specify a source-identity, application-services, destination-address (drop-untranslated or drop-translated), firewall-authentication, or a tunnel.</p> </div> </div>	
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

protocols (Security Zones Host Inbound Traffic)

Syntax	<pre>protocols { (protocol-name all <protocol-name except>); }</pre>
Hierarchy Level	[edit security zones security-zone <i>zone-name</i> host-inbound-traffic]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	<p>Specify the types of protocol traffic that can reach the device for all interfaces in a zone. You can do this in one of several ways:</p> <ul style="list-style-type: none"> • You can enable traffic from each protocol individually. • You can enable traffic from all protocols. • You can enable traffic from all but some protocols.
Options	<p><i>protocol-name</i>—Protocol for which traffic is allowed. The following protocols are supported:</p> <ul style="list-style-type: none"> • all—Enable traffic from all possible protocols available. Use the <i>except</i> option to disallow specific protocols. • bfd—Enable incoming Bidirectional Forwarding Detection (BFD) protocol traffic. • bgp—Enable incoming BGP traffic. • dvmrp—Enable incoming Distance Vector Multicast Routing Protocol (DVMRP) traffic. • igmp—Enable incoming Internet Group Management Protocol (IGMP) traffic. • ldp—Enable incoming Label Distribution Protocol (LDP) traffic (UDP and TCP port 646). • msdp—Enable incoming Multicast Source Discovery Protocol (MSDP) traffic. • nhrp—Enable incoming Next Hop Resolution Protocol (NHRP) traffic. • ospf—Enable incoming OSPF traffic. • ospf3—Enable incoming OSPF version 3 traffic. • pgm—Enable incoming Pragmatic General Multicast (PGM) protocol traffic (IP protocol number 113). • pim—Enable incoming Protocol Independent Multicast (PIM) traffic. • rip—Enable incoming RIP traffic. • ripng—Enable incoming RIP next generation traffic. • router-discovery—Enable incoming router discovery traffic. • rsvp—Enable incoming Resource Reservation Protocol (RSVP) traffic (IP protocol number 46).

- **sap**— Enable incoming Session Announcement Protocol (SAP) traffic. SAP always listens on **224.2.127.254:9875**. New addresses and ports can be added dynamically. This information must be propagated to the Packet Forwarding Engine (PFE).
- **vrrp**—Enable incoming Virtual Router Redundancy Protocol (VRRP) traffic.

except—(Optional) Disable specific incoming protocol traffic, but only when the *all* option has been defined . For example, to enable all but BGP and VRRP protocol traffic:

```
set security zones security-zone trust host-inbound-traffic protocols all
set security zones security-zone trust host-inbound-traffic protocols bgp except
set security zones security-zone trust host-inbound-traffic protocols vrrp except
```

Required Privilege	security—To view this statement in the configuration.
Level	security-control—To add this statement to the configuration.

reject (Security)

Syntax	reject;
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Block the service at the firewall. The device drops the packet and sends a TCP reset (RST) segment to the source host for TCP traffic and an ICMP “destination unreachable, port unreachable” message (type 3, code 3) for UDP traffic. For types of traffic other than TCP and UDP, the device drops the packet without notifying the source host, which is also what occurs when the action is deny .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065• [edit security policies] Hierarchy Level on page 320

reverse-tcp-mss

Syntax	reverse-tcp-mss <i>mss-value</i> ;
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit tcp-options]
Release Information	Statement introduced in Junos OS Release 12.3X48-D20.
Description	<p>Configure the TCP maximum segment size (MSS) for packets that match a specific policy and travel in the reverse direction of a session. The value you configure replaces the TCP MSS value when the value in the packet is higher than the one you specify.</p> <p>The reverse-tcp-mss value per policy takes precedence over a global tcp-mss value (all-tcp, ipsec-vpn, gre-in, gre-out), if one is configured. However, when the syn-flood-protection-mode syn-proxy statement at the [edit security flow] hierarchy level is used to enable SYN proxy defenses against SYN attacks, the TCP MSS value is not overridden.</p> <p>Because each policy has two directions, you can configure a value for both directions or for just one direction. To configure the TCP MSS value for the initial session, use the initial-tcp-mss option.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• initial-tcp-mss on page 1243

rpc-program-number (Applications)

Syntax	<code>rpc-program-number <i>number</i>;</code>
Hierarchy Level	[edit applications application <i>application-name</i>] [edit applications application <i>application-name</i> term <i>term-name</i>]
Release Information	Statement modified in Junos OS Release 8.5.
Description	Specify the remote procedure call (RPC) or Distributed Computing Environment (DCE) value.
Options	<i>number</i> —RPC or DCE program value. Range: 0 through 65,535
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

source-address-excluded

Syntax	source-address-excluded;
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> match]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Exclude the source address(es) from the policy.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Policies Overview on page 1065 • [edit security policies] Hierarchy Level on page 320

source-identity

Syntax	<pre>source-identity { [user-or-role-name]; any; authenticated-user; unauthenticated-user; unknown-user; }</pre>
Hierarchy Level	<p>[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> match]</p> <p>[edit security policies global policy <i>policy-name</i> match]</p>
Release Information	Statement introduced in Junos OS Release 12.1. Statement updated in Junos OS Release 12.1X44-D10.
Description	<p>Identifies users and roles to be used as match criteria for a policy. If a value other than any is specified as match criteria for a policy within a zone pair, the traffic is matched to table entries to retrieve associated user and roles before policy lookup occurs. Users and roles are retrieved from the local authentication table or from a user identification table (UIT) pushed to the SRX Series device from an access control service when a user is authenticated.</p> <p>The following entries specify the source identities that match a policy.</p> <p><i>user-or-role-name</i>—A list of specific users and roles.</p> <p>any—Any user or role, as well as the keywords authenticated-user, unauthenticated-user, and unknown-user.</p> <p>authenticated-user—All users and roles that have been authenticated.</p> <p>unauthenticated-user—Any user or role that does not have an IP-address mapped to authentication sources and the authentication source is up and running.</p> <p>unknown-user—Any user or role that does not have an IP address mapped to authentication sources, because the authentication source is disconnected from the SRX Series device. In this case, users are unable to be authenticated due to an authentication server disconnection, such as a power outage.</p> <p>Unknown-user must be configured for non-domain users to be able to authenticate and log in.</p>
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

system-services (Security Zones Host Inbound Traffic)

Syntax	<pre>system-services { (service-name all <service-name except>); }</pre>
Hierarchy Level	[edit security zones security-zone <i>zone-name</i> host-inbound-traffic]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	<p>Specify the types of incoming system service traffic that can reach the device for all interfaces in a zone. You can do this in one of several ways:</p> <ul style="list-style-type: none"> • You can enable traffic from each system service individually. • You can enable traffic from all system services. • You can enable traffic from all but some system services.
Options	<ul style="list-style-type: none"> • service-name—System-service for which traffic is allowed. The following system services are supported: <ul style="list-style-type: none"> • all—Enable traffic from the defined system services available on the Routing Engine (RE). Use the <i>except</i> option to disallow specific system services. • any-service—Enable all system services on entire port range including the system services that are not defined. • bootp—Enable traffic destined to BOOTP and DHCP relay agents. • dhcp—Enable incoming DHCP requests. • dhcipv6—Enable incoming DHCP requests for IPv6. • dns—Enable incoming DNS services. • finger—Enable incoming finger traffic. • ftp—Enable incoming FTP traffic. • http—Enable incoming J-Web or clear-text Web authentication traffic. • https—Enable incoming J-Web or Web authentication traffic over Secure Sockets Layer (SSL). • ident-reset—Enable the access that has been blocked by an unacknowledged identification request. • ike—Enable Internet Key Exchange traffic. • lsping—Enable label switched path ping service. • netconf—Enable incoming NETCONF service. • ntp—Enable incoming Network Time Protocol (NTP) traffic. • ping—Allow the device to respond to ICMP echo requests. • r2cp—Enable incoming Radio Router Control Protocol traffic.

- **reverse-ssh**—Reverse SSH traffic.
- **reverse-telnet**—Reverse Telnet traffic.
- **rlogin**—Enable incoming **rlogin** (remote login) traffic.
- **rpm**—Enable incoming Real-time performance monitoring (RPM) traffic.
- **rsh**—Enable incoming Remote Shell (**rsh**) traffic.
- **snmp**—Enable incoming SNMP traffic (UDP port 161).
- **snmp-trap**—Enable incoming SNMP traps (UDP port 162).
- **ssh**—Enable incoming SSH traffic.
- **telnet**—Enable incoming Telnet traffic.
- **tftp**—Enable TFTP services.
- **traceroute**—Enable incoming traceroute traffic (UDP port 33434).
- **xnm-clear-text**—Enable incoming Junos XML protocol traffic for all specified interfaces.
- **xnm-ssl**— Enable incoming Junos XML protocol-over-SSL traffic for all specified interfaces.
- **except**—(Optional) Enable specific incoming system service traffic but only when the *all* option has been defined . For example, to enable all but FTP and HTTP system service traffic:

```
set security zones security-zone trust host-inbound-traffic system-services all
set security zones security-zone trust host-inbound-traffic system-services ftp except
set security zones security-zone trust host-inbound-traffic system-services http except
```

Required Privilege Level security—To view this statement in the configuration.
 security-control—To add this statement to the configuration.

system-services (Security Zones Interfaces)

Syntax	<code>system-services <i>service-name</i> { except; }</code>
Hierarchy Level	[edit security zones security-zone <i>zone-name</i> interfaces <i>interface-name</i> host-inbound-traffic]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the types of traffic that can reach the device on a particular interface.
Options	<ul style="list-style-type: none"> • <i>service-name</i>—Service for which traffic is allowed. The following services are supported: <ul style="list-style-type: none"> • all—Enable all possible system services available on the Routing Engine (RE). • any-service—Enable services on entire port range. • bootp—Enable traffic destined to BOOTP and DHCP relay agents. • dhcp—Enable incoming DHCP requests. • dhcpv6—Enable incoming DHCP requests for IPv6. • dns—Enable incoming DNS services. • finger—Enable incoming finger traffic. • ftp—Enable incoming FTP traffic. • http—Enable incoming J-Web or clear-text Web authentication traffic. • https—Enable incoming J-Web or Web authentication traffic over Secure Sockets Layer (SSL). • ident-reset—Enable the access that has been blocked by an unacknowledged identification request. • ike—Enable Internet Key Exchange traffic. • netconf SSH—Enable incoming NetScreen Security Manager (NSM) traffic over SSH. • ntp—Enable incoming Network Time Protocol (NTP) traffic. • ping—Allow the device to respond to ICMP echo requests. • r2cp—Enable incoming Radio Router Control Protocol traffic. • reverse-ssh—Reverse SSH traffic. • reverse-telnet—Reverse Telnet traffic. • rlogin—Enable incoming rlogin (remote login) traffic. • rpm—Enable incoming real-time performance monitoring (RPM) traffic. • rsh—Enable incoming Remote Shell (rsh) traffic. • snmp—Enable incoming SNMP traffic (UDP port 161).

- **snmp-trap**—Enable incoming SNMP traps (UDP port 162).
- **ssh**—Enable incoming SSH traffic.
- **telnet**—Enable incoming Telnet traffic.
- **tftp**—Enable TFTP services.
- **traceroute**—Enable incoming traceroute traffic (UDP port 33434).
- **xnm-clear-text**—Enable incoming Junos XML protocol traffic for all specified interfaces.
- **xnm-ssl**— Enable incoming Junos XML protocol-over-SSL traffic for all specified interfaces.
- **except**—(Optional) except can only be used if all has been defined.

Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

Hierarchy Level [edit security policies from-zone *zone-name*]

Release Information Statement introduced in Junos OS Release 8.5. Support for the **services-offload** and **junos-host** options added in Junos OS Release 11.4. Support for the **source-identity** option added in Junos OS Release 12.1. Support for the **ssl-termination-profile** and **web-redirect-to-https** options added in Junos OS Release 12.1X44-D10.

Description Specify a destination zone to be associated with the security policy.

- Options**
- **zone-name**—Name of the destination zone object.
 - **junos-host**—Default security zone for self-traffic of the device.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

to-zone (Security Policies Global)

Syntax

```
to-zone {  
    [zone-name];  
    any;  
}
```

Hierarchy Level [edit security policies global policy *policy-name* match]

Release Information Statement introduced in Junos OS Release 12.1X47-D10.

Description Identify a single destination zone or multiple destination zones to be used as a match criteria for a policy. You must configure specific zones or default to any zone, but you cannot have both in a global policy.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Related Documentation

traceoptions (Security Policies)

Syntax	<pre> traceoptions { file { filename; files number; match regular-expression; size maximum-file-size; (world-readable no-world-readable); } flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit security policies]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure policy tracing options.
Options	<ul style="list-style-type: none"> file—Configure the trace file options. <ul style="list-style-type: none"> filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <code>/var/log</code>. By default, the name of the file is the name of the process being traced. files number—Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed to trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten. <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> match regular-expression—Refine the output to include lines that contain the regular expression. size maximum-file-size—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named trace-file reaches this size, it is renamed trace-file.0. When the trace-file again reaches its maximum size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten. <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the files option and a filename.</p> <p>Syntax: x K to specify KB, x m to specify MB, or x g to specify GB</p> <p>Range: 10 KB through 1 GB</p>

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.
 - **all**—Trace with all flags enabled
 - **configuration**—Trace configuration events
 - **compilation**—Trace policy compilation events
 - **ipc**—Trace process inter communication events
 - **lookup**—Trace policy lookup events
 - **routing-socket**—Trace routing socket events
 - **rules**—Trace policy rules-related events
- **no-remote-trace**—Set remote tracing as disabled.

Required Privilege Level	trace—To view this statement in the configuration.
	trace-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Security Policies Overview on page 1065

traceoptions (Security User Identification)

```
Syntax  traceoptions {
        file {
            filename;
            files number;
            match regular-expression;
            size maximum-file-size;
            (world-readable | no-world-readable);
        }
        flag flag;
        no-remote-trace;
    }
```

Hierarchy Level [edit security user-identification]

Release Information Statement introduced in Release 12.1 of Junos OS.

Description Configure flow tracing options.

Options • **file**—Configure the trace file options.

- **filename**—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. By default, the name of the file is the name of the process being traced.
- **files number**—Maximum number of trace files. When a trace file named **trace-file** its maximum size, it is renamed to **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option and a filename.

Range: 2 through 1000 files

Default: 10 files

- **match regular-expression**—Refine the output to include lines that contain the regular expression.
- **size maximum-file-size**—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and a filename.

Syntax: **x K** to specify KB, **x m** to specify MB, or **x g** to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Trace operation to perform.
 - **all**—Trace with all flags enabled
 - **no-remote-trace**—Set remote tracing as disabled.

tracoptions (System Services DNS)

Syntax	<pre>tracoptions { category { category-type; } file; }</pre>
Hierarchy Level	[edit system services dns]
Release Information	Statement introduced in Junos OS Release 10.2.
Description	Defines tracing options for DNS services.
Options	<p>category—Specifies the logging category. See Table 15 for the different logging categories and their descriptions.</p> <p>file—Trace file information.</p>

Table 97: Category Names

Category Name	Description
client	Processing of client requests
config	Configuration file parsing and processing
database	Messages relating to the databases
default	Categories for which there is no specific configuration
delegation-only	Delegation only
dispatch	Dispatching of incoming packets to the server
dnssec	DNSSEC and TSIG protocol processing
edns-disabled	Log query using plain DNS
general	General information
lame-servers	Lame servers
network	Network options
notify	NOTIFY protocol
queries	DNS query resolver
resolver	DNS resolution security
security	Approval and denial of requests
unmatched	Unable to determine the class for messages named
update	Dynamic updates
update-security	Approval and denial of update requests
xfer-in	Zone transfers that the server is receiving xfer-out
xfer-out	Zone transfers that the server is sending

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation • *DNS Overview*

tunnel (Security Policies)

Syntax	<pre>tunnel { ipsec-group-vpn <i>group-vpn</i>; ipsec-vpn <i>vpn-name</i>; pair-policy <i>pair-policy</i>; }</pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit]
Release Information	Statement introduced in Junos OS Release 8.5. The ipsec-group-vpn option added in Junos OS Release 10.2.
Description	Encapsulate outgoing IP packets and decapsulate incoming IP packets.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Policies Overview on page 1065 • Understanding Security Policy Rules on page 1067 • Understanding Security Policy Elements on page 1071

uac-policy (Application Services)

Syntax	<pre>uac-policy { captive-portal <i>captive-portal</i>; }</pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit application-services]
Release Information	Statement modified in Junos OS Release 9.4.
Description	Enable Unified Access Control (UAC) for the security policy. This statement is required when you are configuring the SRX Series device to act as a Junos OS Enforcer in a UAC deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series UAC Appliance .
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Understanding User Role Firewalls on page 1107 • Example: Configuring a User Role Firewall on an SRX Series Device on page 1118

unified-access-control (Security)

Syntax	unified-access-control priority <i>priority</i> ;
Hierarchy Level	[edit security user-identification authentication-source]
Release Information	Statement introduced in Release 12.1 of Junos OS. Support for disable option dropped in Junos OS Release 12.1X47-D10.
Description	An authentication table pushed from a configured authentication device, such as the Junos Pulse Access Control Service.
Options	<p>priority <i>priority</i>—A unique value between 0 and 65535 that determines the sequence for searching multiple tables to retrieve a user role. Each authentication table is given a unique priority value. The lower the value, the higher the priority. A table with priority 120 is searched before a table with priority 200. The default priority value of the unified-access-control authentication table is 200.</p> <p>Setting the priority value of the unified-access-control authentication table to 0 is equivalent to disabling the table and eliminating it from the search sequence.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

user-firewall

Syntax	<pre> user-firewall { access-profile <i>profile-name</i>; domain <i>domain-name</i> ssl-termination-profile <i>profile-name</i>; } </pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit firewall-authentication]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10. Support for the domain keyword added in Junos OS Release 12.1X47-D10.
Description	Configure user role firewall authentication, and map the source IP address to the username and its associated roles (groups). The mapped data is written to the firewall authentication table for later retrieval by the user role firewall. The user role firewall uses the username and role information to determine whether to permit or deny a user's session or traffic.
Options	<p>access-profile <i>profile-name</i>—Specify the name of the access profile to be used for authentication.</p> <p>domain <i>domain-name</i>—Specify the name of the domain where firewall authentication occurs in the event that the Windows Management Instrumentation client (WMIC) is not available to get IP-to-user mapping for the integrated user firewall feature. The maximum length is 65 bytes.</p> <p>ssl-termination-profile <i>profile-name</i>—For HTTPS traffic, specify the name of the SSL termination profile used for SSL offloading.</p>
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

uuid (Applications)

Syntax	uuid <i>hex-value</i> ;
Hierarchy Level	[edit applications application <i>application-name</i> term <i>term-name</i>]
Release Information	Statement modified in Junos OS Release 8.5.
Description	<p>Specify the Universal Unique Identifier (UUID) for objects. DCE RPC services are mainly used by Microsoft applications. The ALG uses well-known TCP port 135 for port mapping services and uses the Universal Unique Identifier (UUID) instead of the program number to identify protocols. The main application-based DCE RPC is the Microsoft Exchange Protocol.</p> <p>Support for stateful firewall and NAT services requires that you configure the DCE RPC port map ALG on TCP port 135. The DCE RPC ALG uses the TCP protocol with application-specific UUIDs.</p>
Options	uuid <i>hex-value</i> —Specify the universal unique identifier (UUID) for objects.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	• Applications Configuration Statement Hierarchy on page 311

vrrp

Syntax	<pre>vrrp { command <i>binary-file-path</i>; disable; failover (alternate-media other-routing-engine); }</pre>
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the Virtual Router Redundancy Protocol (VRRP) process.
Options	<ul style="list-style-type: none"> • command <i>binary-file-path</i>—Path to the binary process. • disable—Disable the VRRP process. • failover—Configure the device to reboot if the software process fails four times within 30 seconds, and specify the software to use during the reboot. <ul style="list-style-type: none"> • alternate-media—Configure the device to switch to backup media that contains a version of the system if a software process fails repeatedly. • other-routing-engine—Instruct the secondary Routing Engine to take mastership if a software process fails. If this statement is configured for a process, and that process fails four times within 30 seconds, then the device reboots from the secondary Routing Engine.
<div>  <p>NOTE: On SRX100, SRX110, SRX210, and SRX220 devices, you cannot configure the same VRRP group ID on different interfaces of a single device</p> </div>	
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Security Configuration Statement Hierarchy on page 595

web-authentication

Syntax	<code>web-authentication { client-match <i>user-or-group-name</i>; }</code>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit firewall-authentication]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify that the policy allows access to users who have previously been authenticated by Web authentication. Web authentication must be enabled on one of the addresses on the interface to which the HTTP request is redirected.
Options	<code>client-match <i>user-or-group</i></code> —(Optional) Username or user group name.
Required Privilege Level	<code>security</code> —To view this statement in the configuration. <code>security-control</code> —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Understanding User Role Firewalls on page 1107

web-redirect

Syntax	<code>web-redirect;</code>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit firewall-authentication pass-through]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	<p>Optionally, redirect HTTP requests to the device's internal webserver by sending a redirect HTTP response to the client system to reconnect to the webserver for user authentication. The interface on which the client's request arrived is the interface to which the request is redirected.</p> <p>Using this feature allows for a richer user login experience. For example, instead of a popup prompt asking for username and password, users can get the login page in a browser. Enabling web-redirect has the same effect as users typing the Web authentication IP address in a client browser. Using web-redirect provides a more seamless authentication experience because users do not need to know the Web authentication IP address but only the IP address of the resource they are trying to access. After the user has been authenticated this way, traffic from user's IP address is authenticated to go through the web-redirect method.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 8.5. Support for wildcard addresses added in Junos OS Release 11.1. The **description** option added in Junos OS Release 12.1.

Description A zone is a collection of interfaces for security purposes. All interfaces in a zone are equivalent from a security point of view. Configure the following zones:

- Functional zone—Special-purpose zone, such as a management zone that can host dedicated management interfaces.
- Security zone—Most common type of zone that is used as a building block in policies.

Options The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Syntax clear security alarms
<all>
<alarm-id *id-number*>
<alarm-type [*types*]>
<newer-than YYYY-MM-DD.HH:MM:SS>
<older-than YYYY-MM-DD.HH:MM:SS>
<process *process*>
<severity *severity*>

Release Information Command introduced in Junos OS Release 11.2.

Description Clear (acknowledge) the alarms that are active on the device.

Options **all**—(Optional) Clear all active alarms.

alarm-id *id-number*—(Optional) Clear the specified alarm.

alarm-type [*types*]—(Optional) Clear the specified alarm type or a set of types.

You can specify one or more of the following alarm types:

- **authentication**
- **cryptographic-self-test**
- **decryption-failures**
- **encryption-failures**
- **ike-phase1-failures**
- **ike-phase2-failures**
- **key-generation-self-test**
- **non-cryptographic-self-test**
- **policy**
- **replay-attacks**

newer-than YYYY-MM-DD.HH:MM:SS—(Optional) Clear active alarms that were raised after the specified date and time.

older-than YYYY-MM-DD.HH:MM:SS—(Optional) Clear active alarms that were raised before the specified date and time.

process *process*—(Optional) Clear active alarms that were raised by the specified system process.

severity *severity*—(Optional) Clear active alarms of the specified severity.

You can specify the following severity levels:

- alert
- crit
- debug
- emerg
- err
- info
- notice
- warning

Required Privilege Level security—To view this statement in the configuration.

Output Fields This command produces no output, except a statement about the number of security alarms cleared.

Sample Output

[clear security alarms all](#)

```
[3 SECURITY ALARMS] user@router> clear security alarms all

3 security alarms cleared
```

[clear security alarms alarm-id <alarm-id>](#)

```
[3 SECURITY ALARMS] user@router> clear security alarms alarm-id 1

1 security alarm cleared
```

[clear security alarms alarm-type authentication](#)

```
[3 SECURITY ALARMS] user@router> clear security alarms alarm-type authentication

3 security alarms cleared
```

clear security alarms newer-than <time>

```
[3 SECURITY ALARMS] user@router> clear security alarms newer-than 2010-01-19.13:41:59  
1 security alarm cleared
```

show security alarms older-than <time>

```
[3 SECURITY ALARMS] user@router> clear security alarms older-than 2010-01-19.13:41:59  
2 security alarms cleared
```

show security alarms process <process>

```
[3 SECURITY ALARMS] user@router> clear security alarms process sshd  
3 security alarms cleared
```

show security alarms severity <severity>

```
[3 SECURITY ALARMS] user@router> clear security alarms severity notice  
3 security alarms cleared
```

clear security policies hit-count

Syntax	clear security policies hit-count <from-zone <i>zone-name</i> > <to-zone <i>zone-name</i> >
Release Information	Command introduced in Junos Release 12.1.
Description	Clear the hit-count values for security policies.
Options	<ul style="list-style-type: none">• from-zone <i>zone-name</i>—(Optional) Clear the number of hits for security policies associated with the named source zone.• to-zone <i>zone-name</i>—(Optional) Clear the number of hits for security policies associated with the named destination zone.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show security policies hit-count on page 1355• Monitoring Policy Statistics on page 1142
Output Fields	This command produces no output.

clear security policies statistics

Syntax	clear security policies statistics
Release Information	Command introduced in Junos OS Release 8.5. Support for systemwide policies statistics added in Junos OS Release 12.1X46-D10.
Description	Clear systemwide policies statistics and security policies statistics configured on the device.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show security policies on page 780• Monitoring Policy Statistics on page 1142

Output Fields	This command produces no output.

Sample Output

clear security policies statistics

```
user@host> clear security policies statistics
```

clear system services dns dns-proxy

Syntax	clear system services dns dns-proxy
Release Information	Command introduced in Junos OS Release 12.1X44-D10.
Description	Clear DNS proxy cache information.
Options	<ul style="list-style-type: none">• cache—Clear DNS proxy cache information.• statistics—Clear DNS proxy statistics.• none—Clear all DNS proxy cache information.• hostname—(Optional) Clear DNS proxy cache information from the specified host.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show system services dns dns-proxy on page 1372• show system services dynamic-dns on page 1375
List of Sample Output	clear system services dns dns-proxy on page 1325
Output Fields	When you enter this command no output is produced.

Sample Output

clear system services dns dns-proxy

```
user@host> clear system services dns dns-proxy cache
user@host> clear system services dns dns-proxy statistics
```

request security user-identification local-authorization-table add

Syntax	<code>request security user-identification local-authorization-table add user <i>user-name</i> ip-address <i>ip-address</i> roles [<i>role-name</i>]</code>
Release Information	Command introduced in Junos OS Release 12.1. Command updated in Junos OS Release 12.1X44-D10.
Description	<p>This command adds user and role information to the local authentication table. The table is used to retrieve user and role information for traffic from the specified IP address to enforce a user role firewall.</p> <p>To add an entry, specify the user name, IP address, and up to 40 roles to be associated with this user. Subsequent commands for the same user and IP address aggregates any new roles to the existing list. An authentication entry can contain up to 200 roles.</p>
	<p> NOTE: To change the user name of an entry or to remove or change entries in a role list, you must delete the existing entry and create a new one.</p>
	<p>An IP address can be associated with only one user. If a second request is made to add a different user using the same IP address, the second authentication entry overwrites the existing entry.</p>
Options	<p><code>user <i>user-name</i></code>—Specify the name of the user to be added to the table.</p> <p><code>ip-address <i>ip-address</i></code>—Specify the IP address of the user. Either IPv4 or IPv6 addresses are supported.</p> <p><code>roles [<i>role-name</i>]</code>—(Optional) Specify the role or list of roles to be associated with the specified user. If the specified user and IP address already exist, any roles specified in the command are added to the existing role list.</p>
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> • request security user-identification local-authentication-table delete on page 1328 • Understanding the User Identification Table on page 1110
List of Sample Output	request security user-identification local-authentication-table add on page 1327
Output Fields	When you enter this command, either an entry is added to the local authentication table, or the roles of an existing entry are aggregated with additional roles.

Sample Output

`request security user-identification local-authentication-table add`

```
user@host> request security user-identification local-authentication-table add user user1
ip-address 1.1.1.1 roles role1
user@host> request security user-identification local-authentication-table add user user2
ip-address 2.2.2.2 roles [role2 role3]
user@host> request security user-identification local-authentication-table add user user2
ip-address 2.2.2.2 roles role1
user@host> show security user-identification local-authentication-table all
Total entries: 2
Source IP      Username      Roles
1.1.1.1        user1         role1
2.2.2.2        user2         role2, role3, role1
```

request security user-identification local-authentication-table delete

Syntax	<code>request security user-identification local-authentication-table delete <i>ip-address</i> <i>user-name</i></code>
Release Information	Command introduced in Junos OS Release 12.1.
Description	This command removes an entry from the local authentication table. You can identify the entry by IP address or user-name. To change the user name of an entry or to remove or change entries in a role list, you must delete the existing entry and create a new one.
Options	<p><i>ip-address</i>—The IP address of the entry to be deleted.</p> <p><i>user-name</i>—The user name of the entry to be deleted. To change the user name of an entry, you must delete the old entry and create a new one.</p>
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> • request security user-identification local-authorization-table add on page 1326 • Understanding the User Identification Table on page 1110
Output Fields	The specified show command verifies the table content before and after an entry has been deleted from the local authentication table.

Sample Output

```

user@host> show security user-identification local-authentication-table all
Total entries: 2
  Ip-address: 1.1.1.1
  Username: user1
  Roles: role1

  Ip-address: 2.2.2.2
  Username: user2
  Roles: role2, role3, role1

user@host> request security user-identification local-authentication-table delete 2.2.2.2
user@host> show security user-identification local-authentication-table all
Total entries: 1
  Ip-address: 1.1.1.1
  Username: user1
  Roles: role1

```

show security alarms

Syntax show security alarms
 <detail>
 <alarm-id *id-number*>
 <alarm-type [*types*]>
 <newer-than YYYY-MM-DD.HH:MM:SS>
 <older-than YYYY-MM-DD.HH:MM:SS>
 <process *process*>
 <severity *severity*>

Release Information Command introduced in Junos OS Release 11.2.

Description Display the alarms that are active on the device. Run this command when the CLI prompt indicates that a security alarm has been raised, as shown here:

```
[1 SECURITY ALARM] user@host#
```

Options **none**—Display all active alarms.

detail—(Optional) Display detailed output.

alarm-id *id-number*—(Optional) Display the specified alarm.

alarm-type [*types*]—(Optional) Display the specified alarm type or a set of types.

You can specify one or more of the following alarm types:

- authentication
- cryptographic-self-test
- decryption-failures
- encryption-failures
- ike-phase1-failures
- ike-phase2-failures
- key-generation-self-test
- non-cryptographic-self-test
- policy
- replay-attacks

newer-than YYYY-MM-DD.HH:MM:SS—(Optional) Display active alarms that were raised after the specified date and time.

older-than YYYY-MM-DD.HH:MM:SS—(Optional) Display active alarms that were raised before the specified date and time.

process *process*—(Optional) Display active alarms that were raised by the specified system process.

severity *severity*—(Optional) Display active alarms of the specified severity.

You can specify the following severity levels:

- **alert**
- **crit**
- **debug**
- **emerg**
- **err**
- **info**
- **notice**
- **warning**

Required Privilege Level security—To view this statement in the configuration.

Output Fields	Table 99 lists the output fields for the show security firewall-authentication users address command. Output fields are listed in the approximate order in which they appear.

Table 99: show security firewall-authentication users address Output Fields

Field Name	Field Description
Username	User ID.
Source IP	IP address of the authentication source.
Authentication state	Status of authentication (success or failure).
Authentication method	Path chosen for authentication.
Access time remaining	Duration for which the connection exists.

Table 99: show security firewall-authentication users address Output Fields (*continued*)

Field Name	Field Description
Lsys	The logical system where the traffic was received.
Source zone	User traffic received from the zone.
Destination zone	User traffic destined to the zone.
Policy index	Identification number of the policy.
Policy name	Name of the policy.
Access profile	Name of profile used for authentication.
Interface Name	Name of the interface.
Bytes sent by this user	Number of bytes sent by the user.
Bytes received by this user	Number of bytes received by the user.
Client-groups	Name of the client group.

Sample Output

show security firewall-authentication users address 211.0.0.6

```

user@host>show security firewall-authentication users address 211.0.0.6
Username: hello
Source IP: 211.0.0.6
Authentication state: Success
Authentication method: Pass-through using Telnet
Access time remaining: 0
Source zone: z2
Destination zone: z1
Policy index: 5
Access profile: profile1
Interface Name: ge-0/0/2.0
Bytes sent by this user: 0
Bytes received by this user: 0
Client-groups: Sunnyvale Bangalore

```

Sample Output

show security firewall-authentication users address 100.0.0.1 node local

```

user@host> show security firewall-authentication users address 100.0.0.1 node local
node0:

Output Fields	Table 100 lists the output fields for the show security firewall-authentication users auth-type command. Output fields are listed in the approximate order in which they appear.

Table 100: show security firewall-authentication users auth-type Output Fields

Field Name	Field Description
Total users in table	Total number of users authenticated by this method.
Id	The ID assigned to the entry.
Source IP	The source IP address of the traffic.
Src zone	The source zone of the traffic.
Dst zone	The destination zone of the traffic.
Profile	The profile used to authenticate the used.
Age	The length of time since authentication.
Status	The status of the authentication.
User	The username associated with the traffic.

Sample Output

show security firewall-authentication users auth-type user-firewall

```
user@host> show security firewall-authentication users auth-type user-firewall
User-firewall authentication data:
Total users in table: 2
  Id Source Ip   Src zone Dst zone Profile  Age Status  User
  1 10.208.16.1  N/A     N/A     test    0 Success jasonliu
  2 10.208.16.6  N/A     N/A     test6   0 Failed  jason
```

show security firewall-authentication users auth-type pass-through

```
user@host> show security firewall-authentication users auth-type pass-through
Pass-through firewall authentication data:
Total users in table: 1
  Id Source Ip   Src zone Dst zone Profile  Age Status  User
  1 10.208.16.2  zone1   zone2   test2    0 Success jasonliu2
```

show security firewall-authentication users auth-type pass-through

```
user@host> show security firewall-authentication users auth-type web-authentication
Web firewall authentication data:
Total users in table: 1
  Id Source Ip   Src zone Dst zone Profile  Age Status  User
  1 10.208.16.3  N/A     N/A     test3    0 Success jasonliu3
```

show security flow session application

Syntax	show security flow session application <i>application-name</i> [brief extensive summary]
Release Information	Command introduced in Junos OS Release 8.5. Filter and view options added in Junos OS Release 10.2.
Description	Display information about each session of the specified application type.
Options	<ul style="list-style-type: none"> • <i>application-name</i>—Type of application about which to display sessions information. Possible values are: <ul style="list-style-type: none"> • dns—Domain Name System • ftp—File Transfer Protocol • ignore—Ignore application type • mgcp-ca—Media Gateway Control Protocol with Call Agent • mgcp-ua—MGCP with User Agent • pptp—Point-to-Point Tunneling Protocol • q931—ISDN connection control protocol • ras—Remote Access Server • realaudio—RealAudio • rsh—UNIX remote shell services • rtsp—Real-Time Streaming Protocol • sccp—Skinny Client Control Protocol • sip—Session Initiation Protocol • sqlnet-v2—Oracle SQLNET • talk—TALK program • tftp—Trivial File Transfer Protocol • brief extensive summary—Display the specified level of output.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • clear security flow session application on page 422
List of Sample Output	show security flow session application telnet on page 1340 show security flow session application telnet brief on page 1340 show security flow session application telnet extensive on page 1340 show security flow session application telnet summary on page 1341

Output Fields Table 27 lists the output fields for the **show security flow session application** command. Output fields are listed in the approximate order in which they appear.

Table 101: show security flow session application Output Fields

Field Name	Field Description
Session ID	Number that identifies the session. You can use this ID to get additional information about the session.
Policy name	Policy that permitted the traffic.
Timeout	Idle timeout after which the session expires.
In	Incoming flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).
Out	Reverse flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).
Total sessions	Total number of sessions.
Status	Session status.
Flag	Internal flag depicting the state of the session, used for debugging purposes.
Policy name	Name and ID of the policy that the first packet of the session matched.
Source NAT pool	The name of the source pool where NAT is used.
Application	Name of the application.
Maximum timeout	Maximum session timeout.
Current timeout	Remaining time for the session unless traffic exists in the session.
Session State	Session state.
Start time	Time when the session was created, offset from the system start time.
Unicast-sessions	Number of unicast sessions.
Multicast-sessions	Number of multicast sessions.
Failed-sessions	Number of failed sessions.

Table 101: show security flow session application Output Fields (*continued*)

Field Name	Field Description
Sessions-in-use	Number of sessions in use. <ul style="list-style-type: none"> Valid sessions Pending sessions Invalidated sessions Sessions in other states
Maximum-sessions	Number of maximum sessions.

show security match-policies

Syntax `show security match-policies`
`destination-ip ip-address`
`destination-port port-number`
`from-zone zone-name`
`protocol protocol-name | protocol-number`
`result-count number`
`source-identity role-name`
`source-ip ip-address`
`source-port port-number`
`to-zone zone-name`

Release Information Command introduced in Junos OS Release 10.3. Command updated in Junos OS Release 10.4. Command updated in Junos OS Release 12.1. Command updated to include optional from-zone and to-zone global match options in Junos OS Release 12.1X47-D10.

Description The **show security match-policies** command allows you to troubleshoot traffic problems using the match criteria: source port, destination port, source IP address, destination IP address, and protocol. For example, if your traffic is not passing because either an appropriate policy is not configured or the match criteria is incorrect, then the **show security match-policies** command allows you to work offline and identify where the problem actually exists. It uses the search engine to identify the problem and thus enables you to use the appropriate match policy for the traffic.

The **result-count** option specifies how many policies to display. The first enabled policy in the list is the policy that is applied to all matching traffic. Other policies below it are “shadowed” by the first and are never encountered by matching traffic.

NOTE: The **show security match-policies** command is applicable only to security policies; IDP policies are not supported.

- Options**
- **destination-ip *destination-ip***—Destination IP address of the traffic.
 - **destination-port *destination-port***—Destination port number of the traffic. Range is 1 through 65,535
 - **from-zone *from-zone***—Name or ID of the source zone of the traffic.
 - **protocol *protocol-name* | *protocol-number***—Protocol name or numeric value of the traffic.
 - **ah** or 51
 - **egp** or 8
 - **esp** or 50
 - **gre** or 47
 - **icmp** or 1
 - **igmp** or 2

- **igp** or 9
 - **ipip** or 94
 - **ipv6** or 41
 - **ospf** or 89
 - **pgm** or 113
 - **pim** or 103
 - **rdp** or 27
 - **rsvp** or 46
 - **sctp** or 132
 - **tcp** or 6
 - **udp** or 17
 - **vrrp** or 112
- **result-count** *number*—(Optional) The number of policy matches to display. Valid range is from 1 through 16. The default value is 1.
 - **source-identity** *role-name*—Source identity of the traffic determined by the user role.
 - **source-ip** *source-ip*—Source IP address of the traffic.
 - **source-port** *source-port*—Source port number of the traffic. Range is 1 through 65,535.
 - **to-zone** *to-zone*—Name or ID of the destination zone of the traffic.

Output Fields [Table 102](#) lists the output fields for the **show security match-policies** command. Output fields are listed in the approximate order in which they appear.

Table 102: show security match-policies Output Fields

Field Name	Field Description
Policy	Name of the applicable policy.

Table 102: show security match-policies Output Fields (*continued*)

Field Name	Field Description
Action or Action-type	<p>The action to be taken for traffic that matches the policy's match criteria. Actions include the following:</p> <ul style="list-style-type: none"> • permit • firewall-authentication • tunnel ipsec-vpn <i>vpn-name</i> • pair-policy <i>pair-policy-name</i> • source-nat pool <i>pool-name</i> • pool-set <i>pool-set-name</i> • interface • destination-nat <i>name</i> • deny • reject
State	<p>Status of the policy:</p> <ul style="list-style-type: none"> • enabled: The policy can be used in the policy lookup process, which determines access rights for a packet and the action taken in regard to it. • disabled: The policy cannot be used in the policy lookup process, and therefore it is not available for access control.
Index	An internal number associated with the policy.
Sequence number	Number of the policy within a given context. For example, three policies that are applicable in a from-zoneA-to-zoneB context might be ordered with sequence numbers 1, 2, and 3. Also, in a from-zoneC-to-zoneD context, four policies might have sequence numbers 1, 2, 3, and 4.
From zone	Name of the source zone.
To zone	Name of the destination zone.
Source addresses	The names and corresponding IP addresses of the source addresses for a policy. Address sets are resolved to their individual address name-IP address pairs.
Destination addresses	The names and corresponding IP addresses of the destination addresses (or address sets) for a policy as entered in the destination zone's address book. A packet's destination address must match one of these addresses for the policy to apply to it.
Application	Name of a preconfigured or custom application, or any if no application is specified.
IP protocol	Numeric value for the IP protocol used by the application, such as 6 for TCP or 1 for ICMP.
ALG	If an ALG is associated with the session, the name of the ALG. Otherwise, 0.
Inactivity timeout	Elapsed time without activity after which the application is terminated.
Source-port range	Range of matching source ports defined in the policy.

Table 102: show security match-policies Output Fields (*continued*)

Field Name	Field Description
Destination-port range	Range of matching destination ports defined in the policy.
Source identities	One or more user roles defined in the matching policy.

Sample Output

Example 1: show security match-policies

```

user@host> show security match-policies from-zone z1 to-zone z2 source-ip 10.10.10.1
destination-ip 30.30.30.1 source-port 1 destination-port 21 protocol tcp
Policy: p1, action-type: permit, State: enabled, Index: 4

Application: any
IP protocol: 1, ALG: 0, Inactivity timeout: 0
Source port range: [1000-1030]
Destination port range: [80-80]

Policy: p15, action-type: deny, State: enabled, Index: 18
Sequence number: 15
From zone: zone-A, To zone: zone-B
Source addresses:
  sa11: 10.10.10.1/32
Destination addresses:
  da15: 20.20.20.5/32
Application: any
IP protocol: 1, ALG: 0, Inactivity timeout: 0
Source port range: [1000-1030]
Destination port range: [80-80]

```

Example 3: show security match policies ... source-identity

```
user@host> show security match-policies from-zone untrust to-zone trust source-ip 10.10.10.1
destination-ip 20.20.20.5 destination_port 21 protocol 6 source-port 1234 source-identity role1
Policy: p1, action-type: permit, State: enabled, Index: 40
  Policy Type: Configured
  Sequence number: 1
  From zone: untrust, To zone: trust
  Source addresses:
    a1: 20.0.0.0/8
  Destination addresses:
    d1: 21.0.0.0/8
  Application: junos-ftp
    IP protocol: tcp, ALG: ftp, Inactivity timeout: 1800
    Source port range: [0-0]
    Destination port range: [21-21]
  Source identities: role1
  Per policy TCP Options: SYN check: No, SEQ check: No
```

show security policies

Syntax	<pre>show security policies <detail> <none> policy-name <i>policy-name</i> <detail> <global></pre>
Release Information	<p>Command modified in Junos OS Release 9.2. Support for IPv6 addresses added in Junos OS Release 10.2. Support for IPv6 addresses in active/active chassis cluster configurations in addition to the existing support of active/passive chassis cluster configurations added in Junos OS Release 10.4. Support for wildcard addresses added in Junos OS Release 11.1. Support for global policy added in Junos OS Release 11.4. Support for services offloading added in Junos OS Release 11.4. Support for source-identities added in Junos OS Release 12.1. The Description output field added in Junos OS Release 12.1. Support for negated address added in Junos OS Release 12.1X45-D10. The output fields for Policy Statistics expanded, and the output fields for the global and policy-name options expanded to include from-zone and to-zone global match criteria in Junos OS Release 12.1X47-D10. Support for the initial-tcp-mss and reverse-tcp-mss options added in Junos OS Release 12.3X48-D20.</p>
Description	<p>Display a summary of all security policies configured on the device. If a particular policy is specified, display information particular to that policy.</p>
Options	<ul style="list-style-type: none"> • none—Display basic information about all configured policies. • detail—(Optional) Display a detailed view of all of the policies configured on the device. • policy-name <i>policy-name</i>—(Optional) Display information about the specified policy. • global—Display information about global policies.

Output Fields Table 51 lists the output fields for the **show security policies** command. Output fields are listed in the approximate order in which they appear.

Table 103: show security policies Output Fields

Field Name	Field Description
From zone	Name of the source zone.
To zone	Name of the destination zone.
Policy	Name of the applicable policy.
Description	Description of the applicable policy.
State	Status of the policy: <ul style="list-style-type: none"> • enabled: The policy can be used in the policy lookup process, which determines access rights for a packet and the action taken in regard to it. • disabled: The policy cannot be used in the policy lookup process, and therefore it is not available for access control.
Index	Internal number associated with the policy.
Sequence number	Number of the policy within a given context. For example, three policies that are applicable in a from-zoneA-to-zoneB context might be ordered with sequence numbers 1, 2, 3. Also, in a from-zoneC-to-zoneD context, four policies might have sequence numbers 1, 2, 3, 4.
Source addresses	For standard display mode, the names of the source addresses for a policy. Address sets are resolved to their individual names. For detail display mode, the names and corresponding IP addresses of the source addresses for a policy. Address sets are resolved to their individual address name-IP address pairs.
Destination addresses	Name of the destination address (or address set) as it was entered in the destination zone's address book. A packet's destination address must match this value for the policy to apply to it.
Source addresses (excluded)	Name of the source address excluded from the policy.
Destination addresses (excluded)	Name of the destination address excluded from the policy.
Source identities	One or more user roles specified for a policy.

Table 103: show security policies Output Fields (*continued*)

Field Name	Field Description
Applications	<p>Name of a preconfigured or custom application whose type the packet matches, as specified at configuration time.</p> <ul style="list-style-type: none"> • IP protocol: The Internet protocol used by the application—for example, TCP, UDP, ICMP. • ALG: If an ALG is explicitly associated with the policy, the name of the ALG is displayed. If application-protocol ignore is configured, ignore is displayed. Otherwise, 0 is displayed. However, even if this command shows ALG: 0, ALGs might be triggered for packets destined to well-known ports on which ALGs are listening, unless ALGs are explicitly disabled or when application-protocol ignore is not configured for custom applications. • Inactivity timeout: Elapsed time without activity after which the application is terminated. • Source port range: The low-high source port range for the session application.
Destination Address Translation	<p>Status of the destination address translation traffic:</p> <ul style="list-style-type: none"> • drop translated—Drop the packets with translated destination addresses. • drop untranslated—Drop the packets without translated destination addresses.
Application Firewall	<p>An application firewall includes the following:</p> <ul style="list-style-type: none"> • Rule-set—Name of the rule set. • Rule—Name of the rule. <ul style="list-style-type: none"> • Dynamic applications—Name of the applications. • Dynamic application groups—Name of the application groups. • Action—The action taken with respect to a packet that matches the application firewall rule set. Actions include the following: <ul style="list-style-type: none"> • permit • deny • Default rule—The default rule applied when the identified application is not specified in any rules of the rule set.
Action or Action-type	<ul style="list-style-type: none"> • The action taken in regard to a packet that matches the policy's tuples. Actions include the following: <ul style="list-style-type: none"> • permit • firewall-authentication • tunnel ipsec-vpn <i>vpn-name</i> • pair-policy <i>pair-policy-name</i> • source-nat pool <i>pool-name</i> • pool-set <i>pool-set-name</i> • interface • destination-nat <i>name</i> • deny • reject • services-offload
Session log	<p>Session log entry that indicates whether the at-create and at-close flags were set at configuration time to log session information.</p>

Table 103: show security policies Output Fields (*continued*)

Field Name	Field Description
Scheduler name	Name of a preconfigured scheduler whose schedule determines when the policy is active and can be used as a possible match for traffic.
Policy statistics	<ul style="list-style-type: none"> • Input bytes—The total number of bytes presented for processing by the device. <ul style="list-style-type: none"> • Initial direction—The number of bytes presented for processing by the device from the initial direction. • Reply direction—The number of bytes presented for processing by the device from the reply direction. • Output bytes—The total number of bytes actually processed by the device. <ul style="list-style-type: none"> • Initial direction—The number of bytes from the initial direction actually processed by the device. • Reply direction—The number of bytes from the reply direction actually processed by the device. • Input packets—The total number of packets presented for processing by the device. <ul style="list-style-type: none"> • Initial direction—The number of packets presented for processing by the device from the initial direction. • Reply direction—The number of packets presented for processing by the device from the reply direction. • Output packets—The total number of packets actually processed by the device. <ul style="list-style-type: none"> • Initial direction—The number of packets actually processed by the device from the initial direction. • Reply direction—The number of packets actually processed by the device from the reply direction. • Session rate—The total number of active and deleted sessions. • Active sessions—The number of sessions currently present because of access control lookups that used this policy. • Session deletions—The number of sessions deleted since system startup. • Policy lookups—The number of times the policy was accessed to check for a match. <p>NOTE: Configure the Policy P1 with the count option to display policy statistics.</p>
Per policy TCP Options	Configured sync and sequence checks, and the configured TCP MSS value for the initial direction and /or the reverse direction.

show security policies hit-count

Syntax	<pre>show security policies hit-count <ascending descending> <from-zone zone-name> <greater-than count> <less-than count> <to-zone zone-name></pre>
Release Information	Command introduced in Junos OS Release 12.1.
Description	<p>Display the utility rate of security policies according to the number of hits they receive. The number of hits can be listed without an order or sorted in either ascending or descending order, and they can be restricted to the number of hits that fall above or below a specific count or within a range. Data is shown for all zones associated with the policies or named zones.</p> <p>Use this command without options to display the number of hits in random order for all security policies and for all zones.</p>
Options	<ul style="list-style-type: none"> • ascending descending—(Optional) Display the number of hits for security policies in ascending or descending order. • from-zone zone-name—(Optional) Display the number of hits for security policies associated with the named source zone. • greater-than count—(Optional) Display security policies for which the number of hits is greater than the specified number. Range: 0 through 4,294,967,295 • less-than count—(Optional) Display security policies for which the number of hits is less than the specified number. Range: 0 through 4,294,967,295 • to-zone zone-name—(Optional) Display the number of hits for security policies associated with the named destination zone.
Required Privilege Level	view

List of Sample Output	show security policies hit-count on page 1356 show security policies hit-count ascending on page 1356 show security policies hit-count descending greater-than 70 less-than 100 on page 1356 show security policies hit-count from-zone untrust to-zone trust on page 1356
Output Fields	Table 104 lists the output fields for the show security policies hit-count command. Output fields are listed in the approximate order in which they appear.

Table 104: show security policies hit-count Output Fields

Field Name	Field Description
from-zone	Name of the source zone.
to-zone	Name of the destination zone.
policy	Name of the security policy.
hit-count	Number of hits for each security policy.
Number of policy	Number of security policies for which hit counts are displayed.

Sample Output

show security policies hit-count

```

user@host> show security policies hit-count
from-zone  to-zone  policy  hit-count
untrust    vrtrust  u2t1    40
untrust    trust    u2t2    20
untrust    trust    u2t3    80

Number of policy: 3

```

Sample Output

show security policies hit-count ascending

```

user@host> show security policies hit-count ascending
from-zone  to-zone  policy  hit-count
untrust    trust    u2t2    20
untrust    vrtrust  u2t1    40
untrust    trust    u2t3    80

Number of policy: 3

```

Sample Output

show security policies hit-count descending greater-than 70 less-than 100

```

user@host> show security policies hit-count descending greater-than 70 less-than 100
from-zone  to-zone  policy  hit-count
untrust    trust    u2t2    100
untrust    vrtrust  u2t1    90
untrust    vrtrust  u2t3    80

Number of policy: 3

```

Sample Output

show security policies hit-count from-zone untrust to-zone trust

```

user@host> show security policies hit-count from-zone untrust to-zone trust
from-zone  to-zone  policy  hit-count
untrust    trust    u2t2    20

```

```
untrust    trust    u2t3    80
```

```
Number of policy: 2
```

show security policies unknown-source-identity

Syntax	show security policies unknown-source-identity
Release Information	Command introduced in Junos OS Release 12.1X45-D10.
Description	<p>Display a list of any user or role that is referenced in a policy as a source-identity, but is not yet included in the role provisioning table.</p> <p>The role provisioning table is created from the local authentication table, UAC authentication tables, and firewall authentication tables. The UAC and firewall authentication tables are dynamic and contain only those users currently authenticated. Because of this, a role can be listed as unknown because no user associated with the role has authenticated yet. There is no consequence if a role remains unknown.</p>
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> Security Policies Overview on page 1065
List of Sample Output	show security policies unknown-source-identity on page 1358
Output Fields	Table 105 lists the output fields for the show security policies unknown-source-identity command. Output fields are listed in the approximate order in which they appear.

Table 105: show security policies unknown-source-identity Output Fields

Field Name	Field Description
From zone	Part of the zone pair that identifies the source of the traffic to which a policy applies. Affected policies are grouped by their zone pair.
To zone	Part of the zone pair that identifies the destination of the traffic to which a policy applies. Affected policies are grouped by their zone pair.
Policy	The name of the policy that contains the unknown source identity.
Unknown source identities	A list of user names and roles specified in the source-identity field of the named policy that are unknown.

Sample Output

show security policies unknown-source-identity

In the following sample output, policy p1 which controls traffic from the untrust zone to the trust zone specifies two roles, r1 and r3, that are not yet provisioned. Similarly, policy p2 affecting traffic from the trust zone to the trust zone also contains two roles that are not provisioned, role1 and abc.

```
user@host> show security policies unknown-source-identity
```

```
From zone: untrust, To zone: trust
Policy: p1
Unknown source identities: r1, r3
From zone: trust, To zone: trust
Policy: p2
Unknown source identities: role1, abc
```

show security shadow-policies logical-system

Syntax	<code>show security shadow-policies logical-system <i>lsys-name</i> [from-zone <i>from-zone-name</i> to-zone <i>to-zone-name</i> policy <i>policy-name</i> reverse global policy <i>policy-name</i> reverse]</code>
Release Information	Command introduced in Junos OS Release 12.1X44-D10.
Description	Display the shadowing and shadowed policies in a policy list.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> show security policies on page 780
List of Sample Output	show security shadow-policies from-zone zone-a to-zone zone-b on page 1360 show security shadow-policies from-zone zone-a to-zone zone-b policy P1 on page 1360 show security shadow-policies from-zone zone-a to-zone zone-b policy P4 reverse on page 1360

show system services dns dns-proxy

Syntax	show system services dns dns-proxy
Release Information	Command introduced in Junos OS Release 12.1X44-D10.
Description	Display domain name system (DNS) proxy information.
Options	<ul style="list-style-type: none"> • none—Display DNS proxy statistics information. • cache—(Optional) Display the DNS proxy cache. • statistics—(Optional) Display the DNS proxy statistics.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • clear system services dns dns-proxy on page 1325 • dns-proxy on page 1228
List of Sample Output	show system services dns-proxy statistics on page 1373 show system services dns-proxy cache on page 1373 show system services dns-proxy cache <viewname V1> on page 1373
Output Fields	Table 113 lists the output fields for the show system services dns-proxy command. Output fields are listed in the approximate order in which they appear.

Table 113: show system services dns-proxy

Field Name	Field Description
DNS proxy statistics	Display information about the DNS proxy. <ul style="list-style-type: none"> • Status—State of the proxy server as Enabled or disabled. • Queries received—Number of DNS queries received by the DNS proxy. • Responses sent—Number of DNS responses sent by the DNS proxy. • Queries forwarded—Number of DNS queries forwarded by the DNS proxy. • Negative responses—Number of negative responses the DNS proxy sent to the DNS client. • Retry requests—Number of retries the DNS proxy received from the DNS client. • Pending requests—Number of pending queries the DNS proxy has yet to send the DNS client a response for. • Server failures—Number of DNS proxy server failures.
Hostname	Hostname of the host that has been cached.
IP address	IP address of the host.

Table 113: show system services dns-proxy (continued)

Field Name	Field Description
Time-to-live	Length of time before an entry is purged from the DNS cache.
Type	Type of DNS Resource Record. For example, A records refer to IPv4 host addresses.
Class	Class of DNS. A parameter used to define a DNS Resource Record. For example, IN class is used for Internet domain names.

Sample Output

show system services dns-proxy statistics

```

user@host> show system services dns-proxy statistics
DNS proxy statistics      :
  DNS proxy statistics    :
    Status                : enabled
    IPV4 Queries received : 30
    IPV6 Queries received : 0
    Responses sent        : 30
    Queries forwarded     : 13
    Negative responses     : 23
    Positive responses     : 23
    Retry requests        : 0

- [Understanding CoS Default Settings on page 1387](#)

Understanding Class of Service

When a network experiences congestion and delay, some packets must be dropped. Junos OS class of service (CoS) allows you to divide traffic into classes and offer various levels of throughput and packet loss when congestion occurs. This allows packet loss to happen according to the rules you configure.

For interfaces that carry IPv4, IPv6, or MPLS traffic, you can configure the Junos OS CoS features to provide multiple classes of service for different applications. On the device, you can configure multiple forwarding classes for transmitting packets, define which packets are placed into each output queue, schedule the transmission service level for each queue, and manage congestion using a random early detection (RED) algorithm.

Traffic shaping is the allocation of the appropriate amount of network bandwidth to every user and application on an interface. The appropriate amount of bandwidth is defined as cost-effective carrying capacity at a guaranteed CoS. You can use a Juniper Networks device to control traffic rate by applying classifiers and shapers.

The CoS features provide a set of mechanisms that you can use to provide differentiated services when best-effort delivery is insufficient.

Using Junos OS CoS features, you can assign service levels with different delay, jitter (delay variation), and packet loss characteristics to particular applications served by specific traffic flows. CoS is especially useful for networks supporting time-sensitive video and audio applications.

NOTE: Policing, scheduling, and shaping CoS services are not supported for pre-encryption and post-encryption packets going into and coming out of an IPsec VPN tunnel.

Junos OS supports the following RFCs for traffic classification and policing:

- RFC 2474, *Definition of the Differentiated Services Field in the IPv4 and IPv6*
- RFC 2475, *An Architecture for Differentiated Services*
- RFC 2597, *Assured Forwarding PHB Group*
- RFC 2598, *An Expedited Forwarding PHB*
- RFC 2697, *A Single Rate Three Color Marker*
- RFC 2698, *A Two Rate Three Color Marker*

Benefits of CoS

IP routers normally forward packets independently, without controlling throughput or delay. This type of packet forwarding, known as *best-effort service*, is as good as your network equipment and links allow. Best-effort service is sufficient for many traditional IP data delivery applications, such as e-mail or Web browsing. However, newer IP applications such as real-time video and audio (or voice) require lower delay, jitter, and packet loss than simple best-effort networks can provide.

CoS features allow a Juniper Networks device to improve its processing of critical packets while maintaining best-effort traffic flows, even during periods of congestion. Network throughput is determined by a combination of available bandwidth and delay. CoS dedicates a guaranteed minimum bandwidth to a particular service class by reducing forwarding queue delays. (The other two elements of overall network delay, serial transmission delays determined by link speeds and propagation delays determined by media type, are not affected by CoS settings.)

Normally, packets are queued for output in their order of arrival, regardless of service class. Queuing delays increase with network congestion and often result in lost packets when queue buffers overflow. CoS packet classification assigns packets to forwarding queues by service class.

Because CoS must be implemented consistently end-to-end through the network, the CoS features on the Juniper Networks device are based on IETF Differentiated Services (DiffServ) standards to interoperate with other vendors' CoS implementations.

Related Documentation • [Understanding Class of Service on page 1381](#)

CoS Across the Network

CoS works by examining traffic entering at the edge of your network. The edge devices classify traffic into defined service groups, which allow for the special treatment of traffic across the network. For example, voice traffic can be sent across certain links, and data traffic can use other links. In addition, the data traffic streams can be serviced differently along the network path to ensure that higher-paying customers receive better service. As the traffic leaves the network at the far edge, you can reclassify the traffic.

To support CoS, you must configure each device in the network. Generally, each device examines the packets that enter it to determine their CoS settings. These settings then dictate which packets are first transmitted to the next downstream device. In addition, the devices at the edges of your network might be required to alter the CoS settings of the packets transmitting to the neighboring network.

[Figure 70](#) shows an example of CoS operating across an Internet Service Provider (ISP) network.

Figure 70: CoS Across the Network

In the ISP network shown in [Figure 70](#), Device A is receiving traffic from your network. As each packet enters, Device A examines the packet's current CoS settings and classifies the traffic into one of the groupings defined by the ISP. This definition allows Device A to prioritize its resources for servicing the traffic streams it is receiving. In addition, Device A might alter the CoS settings (forwarding class and loss priority) of the packets to better match the ISP's traffic groups. When Device B receives the packets, it examines the CoS settings, determines the appropriate traffic group, and processes the packet according to those settings. Device B then transmits the packets to Device C, which performs the same actions. Device D also examines the packets and determines the appropriate group. Because it sits at the far end of the network, the ISP might decide once again to alter the CoS settings of the packets before Device D transmits them to the neighboring network.

Junos OS CoS Components

Junos OS supports CoS components on Juniper Networks devices as indicated in [Table 115](#).

Table 115: Supported Junos OS CoS Components

Junos OS CoS Component	Description	For More Information
Code-point aliases	A code-point alias assigns a name to a pattern of code-point bits. You can use this name, instead of the bit pattern, when you configure other CoS components such as classifiers, drop-profile maps, and rewrite rules.	“Code-Point Aliases Overview” on page 1521
Classifiers	Packet classification refers to the examination of an incoming packet. This function associates the packet with a particular CoS servicing level. Two general types of classifiers are supported—behavior aggregate (BA) classifiers and multifield (MF) classifiers. When both BA and MF classifications are performed on a packet, the MF classification has higher precedence.	“Classification Overview” on page 1391
Forwarding classes	Forwarding classes allow you to group packets for transmission. Based on forwarding classes, you assign packets to output queues. The forwarding class plus the loss priority define the per-hop behavior (PHB in DiffServ) of a packet. Juniper Networks routers and services gateways support eight queues (0 through 7).	“Forwarding Classes Overview” on page 1425
Loss priorities	Loss priorities allow you to set the priority of dropping a packet. You can use the loss priority setting to identify packets that have experienced congestion.	“Understanding Packet Loss Priorities” on page 1394
Forwarding policy options	CoS-based forwarding (CBF) enables you to control next-hop selection based on a packet's class of service and, in particular, the value of the IP packet's precedence bits. For example, you can specify a particular interface or next hop to carry high-priority traffic while all best-effort traffic takes some other path.	“Example: Assigning a Forwarding Class to an Interface” on page 1434
Transmission queues	After a packet is sent to the outgoing interface on a device, it is queued for transmission on the physical media. The amount of time a packet is queued on the device is determined by the availability of the outgoing physical media as well as the amount of traffic using the interface. Juniper Networks routers and services gateways support queues 0 through 7.	“Transmission Scheduling Overview” on page 1451
Schedulers	An individual device interface has multiple queues assigned to store packets temporarily before transmission. To determine the order to service the queues, the device uses a round-robin scheduling method based on priority and the queue's weighted round-robin (WRR) credits. Junos OS schedulers allow you to define the priority, bandwidth, delay buffer size, rate control status, and RED drop profiles to be applied to a particular queue for packet transmission.	“Schedulers Overview” on page 1445
Virtual channels	On Juniper Networks routers and services gateways, you can configure virtual channels to limit traffic sent from a corporate headquarters to branch offices. Virtual channels might be required when the headquarters site has an expected aggregate bandwidth higher than that of the individual branch offices. The router at the headquarters site must limit the traffic sent to each branch office router to avoid oversubscribing their links.	“Virtual Channels Overview” on page 1503
Policers for traffic classes	Policers allow you to limit traffic of a certain class to a specified bandwidth and burst size. Packets exceeding the policer limits can be discarded, or can be assigned to a different forwarding class, a different loss priority, or both. You define policers with firewall filters that can be associated with input or output interfaces.	“Simple Filters and Policers Overview” on page 1407

Table 115: Supported Junos OS CoS Components (*continued*)

Junos OS CoS Component	Description	For More Information
Rewrite rules	A rewrite rule modifies the appropriate CoS bits in an outgoing packet. Modification of CoS bits allows the next downstream device to classify the packet into the appropriate service group. Rewriting or marking outbound packets is useful when the device is at the border of a network and must alter the CoS values to meet the policies of the targeted peer.	“Rewrite Rules Overview” on page 1439

CoS Components Packet Flow

On Juniper Networks devices, you configure CoS functions using different components. These components are configured individually or in a combination to define particular CoS services. [Figure 71](#) displays the relationship of different CoS components to each other and illustrates the sequence in which they interact.

Figure 71: Packet Flow Through Juniper Networks Device

Each box in [Figure 71](#) represents a CoS component. The solid lines show the direction of packet flow in a device. The upper row indicates an incoming packet, and the lower row an outgoing packet. The dotted lines show the inputs and outputs of particular CoS components. For example, the forwarding class and loss priority are outputs of behavior aggregate classifiers and multifield classifiers and inputs for rewrite markers and schedulers.

Typically, only a combination of some components shown in [Figure 71](#) (not all) is used to define a CoS service offering. For example, if a packet's class is determined by a

behavior aggregate classifier, it is associated with a forwarding class and loss priority and does not need further classification by the multifield classifier.

This section contains the following topics:

- [CoS Process on Incoming Packets on page 1386](#)
- [CoS Process on Outgoing Packets on page 1386](#)

CoS Process on Incoming Packets

Classifiers and policers perform the following operations on incoming packets:

1. A classifier examines an incoming packet and assigns a forwarding class and loss priority to it.
2. Based on the forwarding class, the packet is assigned to an outbound transmission queue.
3. Input policers meter traffic to see if traffic flow exceeds its service level. Policers might discard, change the forwarding class and loss priority, or set the PLP bit of a packet. A packet for which the PLP bit is set has an increased probability of being dropped during congestion.

CoS Process on Outgoing Packets

The scheduler map and rewrite rules perform the following operations on outgoing packets:

1. Scheduler maps are applied to interfaces and associate the outgoing packets with a scheduler and a forwarding class.
2. The scheduler defines how the packet is treated in the output transmission queue based on the configured transmit rate, buffer size, priority, and drop profile.
 - The buffer size defines the period for which the packet is stored during congestion.
 - The scheduling priority and transmit rate determine the order in which the packet is transmitted.
 - The drop profile defines how aggressively to drop packets that are using a particular scheduler.
3. Output policers meter traffic and might change the forwarding class and loss priority of a packet if a traffic flow exceeds its service level.
4. The rewrite rule writes information to the packet (for example, EXP or DSCP bits) according to the forwarding class and loss priority of the packet.

- [Understanding CoS Default Settings on page 1387](#)
- [CoS Device Configuration Overview on page 1387](#)

CoS Device Configuration Overview

Before you begin configuring a Juniper Networks device for CoS, complete the following tasks:

- Determine whether the device needs to support different traffic streams, such as voice or video. If so, CoS helps to make sure this traffic receives more than basic best-effort packet delivery service.
- Determine whether the device is directly attached to any applications that send CoS-classified packets. If no sources are enabled for CoS, you must configure and apply rewrite rules on the interfaces facing the sources.
- Determine whether the device must support assured forwarding (AF) classes. Assured forwarding usually requires random early detection (RED) drop profiles to be configured and applied.
- Determine whether the device must support expedited forwarding (EF) classes with a policer. Policers require you to apply a burst size and bandwidth limit to the traffic flow, and set a consequence for packets that exceed these limits—usually a high loss priority, so that packets exceeding the policer limits are discarded first.

NOTE: When the T1/E1 mPIM is oversubscribed, we recommend that you configure its shaping rate for consistent CoS functionality. The shaping rate should be less than the total link speed.

Understanding CoS Default Settings

The Class of Service menu in J-Web allows you to configure most of the Junos OS CoS components for the IPv4 and MPLS traffic on a Juniper Networks device. You can configure forwarding classes for transmitting packets, define which packets are placed into each output queue, schedule the transmission service level for each queue, and manage congestion using a random early detection (RED) algorithm. After defining the CoS components, you must assign classifiers to the required physical and logical interfaces.

Even when you do not configure any CoS settings on your routing platform, the software performs some CoS functions to ensure that user traffic and protocol packets are forwarded with minimum delay when the network is experiencing congestion. Some default mappings are automatically applied to each logical interface that you configure. Other default mappings, such as explicit default classifiers and rewrite rules, are in operation only if you explicitly associate them with an interface.

You can display default CoS settings by running the **show class-of-service** operational mode command.

You configure CoS when you need to override the default packet forwarding behavior of a Juniper Networks device—especially in the three areas identified in [Table 116](#).

Table 116: Reasons to Configure Class of Service (CoS)

Default Behavior to Override with CoS	CoS Configuration Area
Packet classification—By default, the Juniper Networks device does not use behavior aggregate (BA) classifiers to classify packets. Packet classification applies to incoming traffic.	Classifiers
Scheduling queues—By default, the Juniper Networks device has only two queues enabled. Scheduling queues apply to outgoing traffic.	Schedulers
Packet headers—By default, the Juniper Networks device does not rewrite CoS bits in packet headers. Rewriting packet headers applies to outgoing traffic.	Rewrite rules

Classification Overview

Packet classification refers to the examination of an incoming packet, which associates the packet with a particular class-of-service (CoS) servicing level. Junos operating system (OS) supports these classifiers:

- Behavior aggregate (BA) classifiers
- Multifield (MF) classifiers
- Default IP precedence classifiers

NOTE: The total number of classifiers supported on a Services Processing Unit (SPU) is 79. Three classifiers are installed on the SPU as default classifiers in the Layer 3 mode, independent of any CoS configuration, which leaves 76 classifiers that can be configured using the CoS CLI commands. The default classifiers number can vary in future releases or in different modes.

Verify the number of default classifiers installed on the SPU to determine how many classifiers can be configured using the CoS CLI commands.

When both BA and MF classifications are performed on a packet, the MF classification has higher precedence.

In Junos OS, classifiers associate incoming packets with a forwarding class (FC) and packet loss priority (PLP), and, based on the associated FC, assign packets to output queues. A packet's FC and PLP specify the behavior of a hop, within the system, to process the packet. The per-hop behavior (PHB) comprises packet forwarding, policing, scheduling, shaping, and marking. For example, a hop can put a packet in one of the priority queues

according to its FC and then manage the queues by checking the packet's PLP. Junos OS supports up to eight FCs and four PLPs.

This topic includes the following sections:

- [Behavior Aggregate Classifiers on page 1392](#)
- [Multifield Classifiers on page 1392](#)
- [Default IP Precedence Classifier on page 1393](#)

Behavior Aggregate Classifiers

A BA classifier operates on a packet as it enters the device. Using BA classifiers, the device aggregates different types of traffic into a single FC so that all the types of traffic will receive the same forwarding treatment. The CoS value in the packet header is the single field that determines the CoS settings applied to the packet. BA classifiers allow you to set a packet's FC and PLP based on the Differentiated Services (DiffServ) code point (DSCP) value, DSCP IPv4 value, DSCP IPv6 value, IP precedence value, MPLS EXP bits, or IEEE 802.1p value. The default classifier is based on the IP precedence value. For more information, see [“Default IP Precedence Classifier” on page 1393](#).

Junos OS performs BA classification for a packet by examining its Layer 2, Layer 3, and related CoS parameters, as shown in [Table 117](#).

Table 117: BA Classification

Layer	CoS Parameter
Layer 2	IEEE 802.1p value: User Priority
Layer 3	IPv4 precedence IPv4 Differentiated Services code point (DSCP) value IPv6 DSCP value

NOTE: A BA classifier evaluates Layer 2 and Layer 3 parameters independently. The results from Layer 2 parameters override the results from the Layer 3 parameters.

Multifield Classifiers

An MF classifier is a second means of classifying traffic flows. Unlike the BA classifier, an MF classifier can examine multiple fields in the packet—for example, the source and destination address of the packet, or the source and destination port numbers of the packet. With MF classifiers, you set the FC and PLP based on firewall filter rules.

NOTE: For a specified interface, you can configure both an MF classifier and a BA classifier without conflicts. Because the classifiers are always applied in sequential order (the BA classifier followed by the MF classifier), any BA classification result is overridden by an MF classifier if they conflict.

Junos OS performs MF traffic classification by directly scrutinizing multiple fields of a packet to classify a packet. This avoids having to rely on the output of the previous BA traffic classification. Junos OS can simultaneously check a packet's data for Layers 2, 3, 4, and 7, as shown in [Table 118](#).

Table 118: MF Classification

Layer	CoS Parameter
Layer 2	IEEE 802.1Q: VLAN ID
	IEEE 802.1p: User priority
Layer 3	IP precedence value
	DSCP or DSCP IPv6 value
	Source IP address
	Destination IP address
	Protocol
	ICMP: Code and type
Layer 4	TCP/UDP: Source port
	TCP/UDP: Destination port
	TCP: Flags
	AH/ESP: SPI
Layer 7	Not supported for this release.

Using Junos OS, you configure an MF classifier with a firewall filter and its associated match conditions. This enables you to use any filter match criterion to locate packets that require classification.

Default IP Precedence Classifier

With Junos OS, all logical interface are automatically assigned a default IP precedence classifier when the logical interface is configured. This default traffic classifier maps IP precedence values to an FC and a PLP as shown in [Table 119](#). These mapping results are in effect for an ingress packet until the packet is further processed by another classification method.

Table 119: Default IP Precedence Classifier

IP Precedence CoS Values	Forwarding Class	Packet Loss Priority
000	best-effort	low
001	best-effort	high
010	best-effort	low
011	best-effort	high
100	best-effort	low
101	best-effort	high
110	network-control	low
111	network-control	high

- [Sample Behavior Aggregate Classification on page 1396](#)
- [Example: Configuring Behavior Aggregate Classifiers on page 1397](#)

Understanding Packet Loss Priorities

Packet loss priorities (PLPs) allow you to set the priority for dropping packets. You can use the PLP setting to identify packets that have experienced congestion. Typically, you mark packets exceeding some service level with a high loss priority—that is, a greater likelihood of being dropped. You set PLP by configuring a classifier or a policer. The PLP is used later in the work flow to select one of the drop profiles used by random early detection (RED).

You can configure the PLP bit as part of a congestion control strategy. The PLP bit can be configured on an interface or in a filter. A packet for which the PLP bit is set has an increased probability of being dropped during congestion.

Default Behavior Aggregate Classification

Table 120 shows the forwarding class (FC) and packet loss priority (PLP) that are assigned by default to each well-known Differentiated Services (DiffServ) code point (DSCP).

Although several DSCPs map to the expedited-forwarding (ef) and assured-forwarding (af) classes, by default no resources are assigned to these forwarding classes. All af classes other than af1x are mapped to best-effort, because RFC 2597, *Assured Forwarding PHB Group*, prohibits a node from aggregating classes. Assignment to the best-effort FC implies that the node does not support that class. You can modify the default settings through configuration.

Table 120: Default Behavior Aggregate Classification

DSCP and DSCP IPv6 Alias	Forwarding Class	Packet Loss Priority
ef	expedited-forwarding	low
af11	assured-forwarding	low
af12	assured-forwarding	high
af13	assured-forwarding	high
af21	best-effort	low
af22	best-effort	low
af23	best-effort	low
af31	best-effort	low
af32	best-effort	low

Sample Behavior Aggregate Classification

Table 121 shows the device forwarding classes (FCs) associated with each well-known Differentiated Services (DiffServ) code point (DSCP) and the resources assigned to the output queues for a sample DiffServ CoS implementation. This example assigns expedited forwarding to queue 1 and a subset of the assured FCs (afx) to queue 2, and distributes resources among all four forwarding classes. Other DiffServ-based implementations are possible.

Table 121: Sample Behavior Aggregate Classification Forwarding Classes and Queues

DSCP and DSCP IPv6 Alias	DSCP and DSCP IPv6 Bits	Forwarding Class	Packet Loss Priority	Queue
ef	101110	expedited-forwarding	low	1
af11	001010	assured-forwarding	low	2
af12	001100	assured-forwarding	high	2
af13	001110	assured-forwarding	high	2
af21	010010	best-effort	low	0
af22	010100	best-effort	low	0
af23	010110	best-effort	low	0
af31	011010	best-effort	low	0
af32	011100	best-effort	low	0
af33	011110	best-effort	low	0
af41	100010	best-effort	low	0

Table 121: Sample Behavior Aggregate Classification Forwarding Classes and Queues (*continued*)

DSCP and DSCP IPv6 Alias	DSCP and DSCP IPv6 Bits	Forwarding Class	Packet Loss Priority	Queue
af42	100100	best-effort	low	0

Example: Configuring Behavior Aggregate Classifiers

This example shows how to configure behavior aggregate classifiers for a device to determine forwarding treatment of packets.

- [Requirements on page 1397](#)
- [Overview on page 1398](#)
- [Configuration on page 1399](#)
- [Verification on page 1401](#)

Requirements

Before you begin, determine the forwarding class and PLP that are assigned by default to each well-known DSCP that you want to configure for the behavior aggregate classifier. See “[Default Behavior Aggregate Classification](#)” on page 1394.

Overview

You configure behavior aggregate classifiers to classify packets that contain valid DSCPs to appropriate queues. Once configured, you must apply the behavior aggregate classifier to the correct interfaces. You can override the default IP precedence classifier by defining a classifier and applying it to a logical interface. To define new classifiers for all code point types, include the **classifiers** statement at the **[edit class-of-service]** hierarchy level.

In this example, you set the DSCP behavior aggregate classifier to **ba-classifier** as the default DSCP map. You set a best-effort forwarding class as **be-class**, an expedited forwarding class as **ef-class**, an assured forwarding class as **af-class**, and a network control forwarding class as **nc-class**. Finally, you apply the behavior aggregate classifier to an interface called **ge-0/0/0**.

[Table 122](#) shows how the behavior aggregate classifier assigns loss priorities, to incoming packets in the four forwarding classes.

Table 122: Sample ba-classifier Loss Priority Assignments

mf-classifier Forwarding Class	For CoS Traffic Type	ba-classifier Assignments
be-class	Best-effort traffic	High-priority code point: 000001
ef-class	Expedited forwarding traffic	High-priority code point: 101111
af-class	Assured forwarding traffic	High-priority code point: 001100
nc-class	Network control traffic	High-priority code point: 110001

Topology

[Figure 72](#) shows the sample network.

Figure 72: Behavior Aggregate Classifier Scenario

[“CLI Quick Configuration” on page 1399](#) shows the configuration for all of the Juniper Networks devices in [Figure 72](#).

The section [“Step-by-Step Procedure” on page 1399](#) describes the steps on Device R2.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service classifiers dscp ba-classifier import default
set class-of-service classifiers dscp ba-classifier forwarding-class be-class loss-priority
  high code-points 000001
set class-of-service classifiers dscp ba-classifier forwarding-class ef-class loss-priority
  high code-points 101111
set class-of-service classifiers dscp ba-classifier forwarding-class af-class loss-priority
  high code-points 001100
set class-of-service classifiers dscp ba-classifier forwarding-class nc-class loss-priority
  high code-points 110001
set class-of-service interfaces ge-0/0/0 unit 0 classifiers dscp ba-classifier
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure behavior aggregate classifiers for a device:

1. Configure the class of service.

```
[edit]
user@host# edit class-of-service
```
2. Configure behavior aggregate classifiers for DiffServ CoS.

```
[edit class-of-service]
user@host# edit classifiers dscp ba-classifier
user@host# set import default
```
3. Configure a best-effort forwarding class classifier.

```
[edit class-of-service classifiers dscp ba-classifier]
user@host# set forwarding-class be-class loss-priority high code-points 000001
```
4. Configure an expedited forwarding class classifier.

```
[edit class-of-service classifiers dscp ba-classifier]
user@host# set forwarding-class ef-class loss-priority high code-points 101111
```
5. Configure an assured forwarding class classifier.

```
[edit class-of-service classifiers dscp ba-classifier]
user@host# set forwarding-class af-class loss-priority high code-points 001100
```
6. Configure a network control forwarding class classifier.

```
[edit class-of-service classifiers dscp ba-classifier]
user@host# set forwarding-class nc-class loss-priority high code-points 110001
```
7. Apply the behavior aggregate classifier to an interface.

```
[edit]
```

```
user@host# set class-of-service interfaces ge-0/0/0 unit 0 classifiers dscp
ba-classifier
```

NOTE: You can use interface wildcards for interface-name and logical-unit-number.

Results From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
classifiers {
  dscp ba-classifier {
    import default;
    forwarding-class be-class {
      loss-priority high code-points 000001;
    }
    forwarding-class ef-class {
      loss-priority high code-points 101111;
    }
    forwarding-class af-class {
      loss-priority high code-points 001100;
    }
    forwarding-class nc-class {
      loss-priority high code-points 110001;
    }
  }
}
forwarding-classes {
  class BE-data queue-num 0;
  class Premium-data queue-num 1;
  class Voice queue-num 2;
  class NC queue-num 3;
}
interfaces {
  ge-0/0/0 {
    unit 0 {
      classifiers {
        dscp ba-classifier;
      }
    }
  }
  ge-1/0/9 {
    unit 0 {
      classifiers {
        dscp v4-ba-classifier;
      }
    }
  }
  ge-1/0/9 {
    unit 0 {
      classifiers {
        dscp v4-ba-classifier;
      }
    }
  }
}
```

```

ge-1/0/9 {
  unit 0 {
    classifiers {
      dscp v4-ba-classifier;
    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Code-Point Aliases on page 1401](#)
- [Verifying the DSCP Classifier on page 1402](#)
- [Verifying the Forwarding Classes and Output Queues on page 1403](#)
- [Verifying That the Classifier Is Applied to the Interfaces on page 1404](#)
- [Verifying Behavior Aggregate Classifiers on page 1404](#)

Verifying the Code-Point Aliases

Purpose Make sure that the code-point aliases are configured as expected.

Action On Device R2, run the **show class-of-service code-point-aliases dscp** command.

```
user@R2> show class-of-service code-point-aliases dscp
```

```

Code point type: dscp
Alias      Bit pattern
af11      001010
af12      001100
af13      001110
af21      010010
af22      010100
af23      010110
af31      011010
af32      011100
af33      011110
af41      100010
af42      100100
af43      100110
be        000000
be1      000001
cs1       001000
cs2       010000
cs3       011000
cs4       100000
cs5       101000
cs6       110000
cs7       111000
ef        101110
ef1      101111
nc1       110000

```

nc2 111000

Meaning The code-point aliases are configured as expected. Notice that the custom aliases that you configure are added to the default code-point aliases.

Verifying the DSCP Classifier

Purpose Make sure that the DSCP classifier is configured as expected.

Action On Device R2, run the **show class-of-service classifiers name v4-ba-classifier** command.

```
user@R2> show class-of-service classifiers name v4-ba-classifier
```

```
Classifier: v4-ba-classifier, Code point type: dscp, Index: 10755
Code point      Forwarding class      Loss priority
000000          BE-data              high
000001          BE-data              low
000010          BE-data              low
000011          BE-data              low
000100          BE-data              low
000101          BE-data              low
000110          BE-data              low
000111          BE-data              low
001000          BE-data              low
001001          BE-data              low
001010          Voice                low
001011          BE-data              low
001100          Voice                high
001101          BE-data              low
001110          Voice                high
001111          BE-data              low
010000          BE-data              low
010001          BE-data              low
010010          BE-data              low
010011          BE-data              low
010100          BE-data              low
010101          BE-data              low
010110          BE-data              low
010111          BE-data              low
011000          BE-data              low
011001          BE-data              low
011010          BE-data              low
011011          BE-data              low
011100          BE-data              low
011101          BE-data              low
011110          BE-data              low
011111          BE-data              low
100000          BE-data              low
100001          BE-data              low
100010          BE-data              low
100011          BE-data              low
100100          BE-data              low
100101          BE-data              low
100110          BE-data              low
100111          BE-data              low
101000          BE-data              low
101001          BE-data              low
```

101010	BE-data	low
101011	BE-data	low
101100	BE-data	low
101101	BE-data	low
101110	Premium-data	high
101111	Premium-data	low
110000	NC	low
110001	BE-data	low
110010	BE-data	low
110011	BE-data	low
110100	BE-data	low
110101	BE-data	low
110110	BE-data	low
110111	BE-data	low
111000	NC	low
111001	BE-data	low
111010	BE-data	low
111011	BE-data	low
111100	BE-data	low
111101	BE-data	low
111110	BE-data	low
111111	BE-data	low

Meaning Notice that the default classifier is incorporated into the customer classifier. If you were to remove the **import default** statement from the custom classifier, the custom classifier would look like this:

```
user@R2> show class-of-service classifier name v4-ba-classifier
Classifier: v4-ba-classifier, Code point type: dscp, Index: 10755
  Code point      Forwarding class      Loss priority
  000000          BE-data                  high
  000001          BE-data                  low
  101110          Premium-data            high
  101111          Premium-data            low
```

Verifying the Forwarding Classes and Output Queues

Purpose Make sure that the forwarding classes are configured as expected.

Action On Device R2, run the **show class-of-service forwarding-class** command.

```
user@R2> show class-of-service forwarding-class
```

Forwarding class	ID	Queue	Restricted queue	Fabric
priority Policing priority SPU priority				
BE-data	0	0	0	low
normal				
Premium-data	1	1	1	low
normal				
Voice	2	2	2	low
normal				
NC	3	3	3	low
normal				

Meaning The forwarding classes are configured as expected.

Verifying That the Classifier Is Applied to the Interfaces

Purpose Make sure that the classifier is applied to the correct interfaces.

Action On Device R2, run the **show class-of-service interface** command.

```
user@R2> show class-of-service interface ge-1/0/3
```

```
Physical interface: ge-1/0/3, Index: 144
Queues supported: 8, Queues in use: 4
  Scheduler map: <default>, Index: 2
Congestion-notification: Disabled
```

```
Logical interface: ge-1/0/3.0, Index: 333
```

Object	Name	Type	Index
Classifier	v4-ba-classifier	dscp	10755

```
user@R2> show class-of-service interface ge-1/0/9
```

```
Physical interface: ge-1/0/9, Index: 150
Queues supported: 8, Queues in use: 4
  Scheduler map: <default>, Index: 2
Congestion-notification: Disabled
```

```
Logical interface: ge-1/0/9.0, Index: 332
```

Object	Name	Type	Index
Classifier	v4-ba-classifier	dscp	10755

Meaning The interfaces are configured as expected.

Verifying Behavior Aggregate Classifiers

Purpose Verify that the behavior aggregate classifiers were configured properly on the device.

Action From configuration mode, enter the **show class-of-service** command.

When you are using **hping** to set the DSCP code points in the IPv4 packet header, the type-of-service (ToS) hex value (in this case, BC) is required in the **--tos** option of the **hping** command.

If your binary-to-hex or binary-to-decimal conversion skills are rusty, you can use an online calculator, such as

<http://www.mathsisfun.com/binary-decimal-hexadecimal-converter.html>.

NOTE: When you convert a binary DSCP code point value, be sure to add two extra zeros at the end. So instead of 101111, use 10111100. These 0 values (the 7th and 8th bits) are reserved and ignored, but if you do not include them in the conversion, your hex and decimal values will be incorrect.

Extended Ping Sent from Device R1

```
user@R1> ping 172.16.70.1 tos 188 rapid count 25
```

```

len=46 ip=172.16.70.1 ttl=61 DF id=0 sport=0 flags=RA seq=24 win=0 rtt=0.4 ms
```

On Device R2, Verify that Queue 2 is Incrementing.

Code point 101111 is associated with Premium-data, which uses queue 1.

```
user@R2> show interfaces extensive ge-1/0/3 | find "queue counters"
```

Queue counters:	Queued packets	Transmitted packets	Dropped packets
0	0	0	0
1	50	50	0
2	0	0	0
3	42	42	0

Queue number:	Mapped forwarding classes
0	BE-data
1	Premium-data
2	Voice
3	NC

...

Meaning The output shows that queue 1 has incremented by 50 packets after sending 50 packets through the router.

Simple Filters and Policers Overview

You can configure simple filters and policers to handle oversubscribed traffic in SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices. In Junos OS, policers can be configured as part of the firewall filter hierarchy.

NOTE: For SRX5600 and SRX5800 devices, the simple filter or policing actions can be applied only to logical interfaces residing in an SRX5000 line Flex IOC (FIOC) because only an SRX5000 line FIOC supports the simple filter and policing features on the SRX5600 and SRX5800 devices.

The simple filter functionality consists of the following:

- Classifying packets according to configured policies
- Taking appropriate actions based on the results of classification

In Junos OS, ingress traffic policers can limit the rate of incoming traffic. Two main reasons to use traffic policing are:

- To enforce traffic rates to conform to the service-level agreement (SLA)
- To protect next hops, such as protecting the central point and the SPU from being overwhelmed by excess traffic like DOS attacks

Using the results of packet classification and traffic metering, a policer can take one of the following actions for a packet: forward a conforming (green) packet or drop a nonconforming (yellow) packet. Policers always discard a nonconforming red packet.

Traffic metering supports the algorithm of the two-rate tricolor marker (TCM). (See RFC 2698, *A Two Rate Three Color Marker*.)

- [Example: Configuring a Two-Rate Three-Color Policer on page 1409](#)
- [Example: Configuring and Applying a Firewall Filter for a Multifield Classifier on page 1417](#)

Two-Rate Three-Color Policer Overview

A two-rate three-color policer defines two bandwidth limits (one for guaranteed traffic and one for peak traffic) and two burst sizes (one for each of the bandwidth limits). A two-rate three-color policer is most useful when a service is structured according to arrival rates and not necessarily packet length.

Two-rate three-color policing meters a traffic stream based on the following configured traffic criteria:

- Committed information rate (CIR)—Bandwidth limit for guaranteed traffic.
- Committed burst size (CBS)—Maximum packet size permitted for bursts of data that exceed the CIR.
- Peak information rate (PIR)—Bandwidth limit for peak traffic.
- Peak burst size (PBS)—Maximum packet size permitted for bursts of data that exceed the PIR.

Two-rate tricolor marking (two-rate TCM) classifies traffic as belonging to one of three color categories and performs congestion-control actions on the packets based on the color marking:

- Green—Traffic that conforms to the bandwidth limit and burst size for guaranteed traffic (CIR and CBS). For a green traffic flow, two-rate TCM marks the packets with an implicit loss priority of **low** and transmits the packets.
- Yellow—Traffic that exceeds the bandwidth limit or burst size for guaranteed traffic (CIR or CBS) but not the bandwidth limit and burst size for peak traffic (PIR and PBS). For a yellow traffic flow, two-rate TCM marks packets with an implicit loss priority of **medium-high** and transmits the packets.
- Red—Traffic that exceeds the bandwidth limit and burst size for peak traffic (PIR and PBS). For a red traffic flow, two-rate TCM marks packets with an implicit loss priority of **high** and, optionally, discards the packets.

If congestion occurs downstream, the packets with higher loss priority are more likely to be discarded.

NOTE: For both single-rate and two-rate three-color policers, the only *configurable* action is to discard packets in a red traffic flow.

For a tricolor marking policer referenced by a firewall filter term, the **discard** policing action is supported on the following routing platforms:

- EX Series switches
- M7i and M10i routers with the Enhanced CFEB (CFEB-E)
- M120 and M320 routers with Enhanced-III FPCs
- MX Series routers with Trio MPCs

To apply a tricolor marking policer on these routing platforms, it is not necessary to include the **logical-interface-policer** statement.

Documentation**

- [Example: Configuring a Two-Rate Three-Color Policer on page 1409](#)

Example: Configuring a Two-Rate Three-Color Policer

This example shows how to configure a two-rate three-color policer.

- [Requirements on page 1409](#)
- [Overview on page 1409](#)
- [Configuration on page 1410](#)
- [Verification on page 1413](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

A two-rate three-color policer meters a traffic flow against a bandwidth limit and burst-size limit for guaranteed traffic, plus a bandwidth limit and burst-size limit for peak traffic. Traffic that conforms to the limits for guaranteed traffic is categorized as green, and nonconforming traffic falls into one of two categories:

- Nonconforming traffic that does not exceed peak traffic limits is categorized as yellow.
- Nonconforming traffic that exceeds peak traffic limits is categorized as red.

Each category is associated with an action. For green traffic, packets are implicitly set with a loss-priority value of **low** and then transmitted. For yellow traffic, packets are implicitly set with a loss-priority value of **medium-high** and then transmitted. For red traffic, packets are implicitly set with a loss-priority value of **high** and then transmitted. If the policer configuration includes the optional **action** statement (**action loss-priority high then discard**), then packets in a red flow are discarded instead.

You can apply a three-color policer to Layer 3 traffic as a firewall filter policer only. You reference the policer from a stateless firewall filter term, and then you apply the filter to the input or output of a logical interface at the protocol level.

Topology

In this example, you apply a color-aware, two-rate three-color policer to the input IPv4 traffic at logical interface **fe-0/1/1.0**. The IPv4 firewall filter term that references the policer does not apply any packet-filtering. The filter is used only to apply the three-color policer to the interface.

You configure the policer to rate-limit traffic to a bandwidth limit of 40 Mbps and a burst-size limit of 100 KB for green traffic, and you configure the policer to also allow a peak bandwidth limit of 60 Mbps and a peak burst-size limit of 200 KB for yellow traffic. Only nonconforming traffic that exceeds the peak traffic limits is categorized as red. In this example, you configure the three-color policer action **loss-priority high then discard**, which overrides the implicit marking of red traffic to a **high** loss priority.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure this example, perform the following tasks:

- [Configuring a Two-Rate Three-Color Policer on page 1410](#)
- [Configuring an IPv4 Stateless Firewall Filter That References the Policer on page 1412](#)
- [Applying the Filter to a Logical Interface at the Protocol Family Level on page 1412](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall three-color-policer trTCM1-ca two-rate color-aware
set firewall three-color-policer trTCM1-ca two-rate committed-information-rate 40m
set firewall three-color-policer trTCM1-ca two-rate committed-burst-size 100k
set firewall three-color-policer trTCM1-ca two-rate peak-information-rate 60m
set firewall three-color-policer trTCM1-ca two-rate peak-burst-size 200k
set firewall three-color-policer trTCM1-ca action loss-priority high then discard
set firewall family inet filter filter-trtcm1ca-all term 1 then three-color-policer two-rate
trTCM1-ca
set interfaces ge-2/0/5 unit 0 family inet address 10.10.10.1/30
set interfaces ge-2/0/5 unit 0 family inet filter input filter-trtcm1ca-all
set class-of-service interfaces ge-2/0/5 forwarding-class af
```

Configuring a Two-Rate Three-Color Policer

Step-by-Step Procedure

To configure a two-rate three-color policer:

1. Enable configuration of a three-color policer.

```
[edit]
user@host# set firewall three-color-policer trTCM1-ca
```

2. Configure the color mode of the two-rate three-color policer.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set two-rate color-aware
```

3. Configure the two-rate guaranteed traffic limits.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set two-rate committed-information-rate 40m
user@host# set two-rate committed-burst-size 100k
```

Traffic that does not exceed both of these limits is categorized as green. Packets in a green flow are implicitly set to **low** loss priority and then transmitted.

4. Configure the two-rate peak traffic limits.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set two-rate peak-information-rate 60m
user@host# set two-rate peak-burst-size 200k
```

Nonconforming traffic that does not exceed both of these limits is categorized as yellow. Packets in a yellow flow are implicitly set to **medium-high** loss priority and then transmitted. Nonconforming traffic that exceeds both of these limits is categorized as red. Packets in a red flow are implicitly set to **high** loss priority.

5. (Optional) Configure the policer action for red traffic.

```
[edit firewall three-color-policer trTCM1-ca]
user@host# set action loss-priority high then discard
```

For three-color policers, the only configurable action is to discard red packets. Red packets are packets that have been assigned high loss priority because they exceeded the peak information rate (PIR) and the peak burst size (PBS).

Results Confirm the configuration of the policer by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
three-color-policer trTCM1-ca {
  action {
    loss-priority high then discard;
  }
  two-rate {
    color-aware;
    committed-information-rate 40m;
    committed-burst-size 100k;
    peak-information-rate 60m;
    peak-burst-size 200k;
  }
}
```

Configuring an IPv4 Stateless Firewall Filter That References the Policer

Step-by-Step Procedure

To configure an IPv4 stateless firewall filter that references the policer:

1. Enable configuration of an IPv4 standard stateless firewall filter.

```
[edit]
user@host# set firewall family inet filter filter-trtcm1ca-all
```

2. Specify the filter term that references the policer.

```
[edit firewall family inet filter filter-trtcm1ca-all]
user@host# set term 1 then three-color-policer two-rate trTCM1-ca
```

Note that the term does not specify any match conditions. The firewall filter passes all packets to the policer.

Results

Confirm the configuration of the firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter filter-trtcm1ca-all {
    term 1 {
      then {
        three-color-policer {
          two-rate trTCM1-ca;
        }
      }
    }
  }
}
three-color-policer trTCM1-ca {
  action {
    loss-priority high then discard;
  }
  two-rate {
    color-aware;
    committed-information-rate 40m;
    committed-burst-size 100k;
    peak-information-rate 60m;
    peak-burst-size 200k;
  }
}
```

Applying the Filter to a Logical Interface at the Protocol Family Level

Step-by-Step Procedure

To apply the filter to the logical interface at the protocol family level:

1. Enable configuration of an IPv4 firewall filter.

```
[edit]
user@host# edit interfaces ge-2/0/5 unit 0 family inet
```

2. Apply the policer to the logical interface at the protocol family level.

```
[edit interfaces ge-2/0/5 unit 0 family inet]
user@host# set address 10.10.10.1/30
user@host# set filter input filter-trtcm1ca-all
```

3. (MX Series routers and EX Series switches only) (Optional) For input policers, you can configure a fixed classifier. A fixed classifier reclassifies all incoming packets, regardless of any preexisting classification.

```
[edit]
user@host# set class-of-service interfaces ge-2/0/5 forwarding-class af
```

The classifier name can be a configured classifier or one of the default classifiers.

Results Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
ge-2/0/5 {
  unit 0 {
    family inet {
      address 10.10.10.1/30;
      filter {
        input filter-trtcm1ca-all;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Displaying the Firewall Filters Applied to the Logical Interface on page 1413](#)

Displaying the Firewall Filters Applied to the Logical Interface

Purpose Verify that the firewall filter is applied to IPv4 input traffic at the logical interface.

Action Use the **show interfaces** operational mode command for the logical interface **ge-2/0/5.0**, and specify **detail** mode. The **Protocol inet** section of the command output displays IPv4 information for the logical interface. Within that section, the **Input Filters** field displays the name of IPv4 firewall filters associated with the logical interface.

```
user@host> show interfaces ge-2/0/5.0 detail
Logical interface ge-2/0/5.0 (Index 105) (SNMP ifIndex 556) (Generation 170)
Flags: Device-Down SNMP-Traps 0x4004000 Encapsulation: ENET2
Traffic statistics:
  Input bytes : 0
  Output bytes : 0
  Input packets: 0
```

```

Output packets:                0
Local statistics:
Input bytes :                  0
Output bytes :                  0
Input packets:                 0
Output packets:                0
Transit statistics:
Input bytes :                  0          0 bps
Output bytes :                  0          0 bps
Input packets:                 0          0 pps
Output packets:                0          0 pps

Guidelines for Configuring Simple Filters

This topic covers the following information:

- [Statement Hierarchy for Configuring Simple Filters on page 1414](#)
- [Simple Filter Protocol Families on page 1415](#)
- [Simple Filter Names on page 1415](#)
- [Simple Filter Terms on page 1415](#)
- [Simple Filter Match Conditions on page 1416](#)
- [Simple Filter Terminating Actions on page 1417](#)
- [Simple Filter Nonterminating Actions on page 1417](#)

Statement Hierarchy for Configuring Simple Filters

To configure a simple filter, include the **simple-filter** *simple-filter-name* statement at the **[edit firewall family inet]** hierarchy level.

```

[edit]
firewall {
  family inet {
    simple-filter simple-filter-name {
      term term-name {
        from {
          match-conditions;
        }
        then {
          actions;
        }
      }
    }
  }
}

```

```
}
}
```

Individual statements supported under the **simple-filter *simple-filter-name*** statement are described separately in this topic and are illustrated in the example of configuring and applying a simple filter.

Simple Filter Protocol Families

You can configure simple filters to filter IPv4 traffic (**family inet**) only. No other protocol family is supported for simple filters.

NOTE: You can apply simple filters to the family inet only, and only in the input direction. Because of hardware limitations on the SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices, a maximum of 400 logical input interfaces and 2000 terms (in one Broadcom packet processor) can be applied with simple filters.

Simple Filter Names

Under the **family inet** statement, you can include **simple-filter *simple-filter-name*** statements to create and name simple filters. The filter name can contain letters, numbers, and hyphens (-) and be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").

Simple Filter Terms

Under the **simple-filter *simple-filter-name*** statement, you can include **term *term-name*** statements to create and name filter terms.

- You must configure at least one term in a firewall filter.
- You must specify a unique name for each term within a firewall filter. The term name can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" ").
- The order in which you specify terms within a firewall filter configuration is important. Firewall filter terms are evaluated in the order in which they are configured. By default, new terms are always added to the end of the existing filter. You can use the **insert** configuration mode command to reorder the terms of a firewall filter.

Simple filters do *not* support the **next term** action.

NOTE: In one Broadcom packet processor, a maximum of 2000 terms can be applied with simple filters on the SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices.

Simple Filter Match Conditions

Simple filter terms support only a subset of the IPv4 match conditions that are supported for standard stateless firewall filters.

Unlike standard stateless firewall filters, the following restrictions apply to simple filters:

- On MX Series routers with the Enhanced Queuing DPC, simple filters do *not* support the **forwarding-class** match condition.
- Simple filters support only one **source-address** and one **destination-address** prefix for each filter term. If you configure multiple prefixes, only the last one is used.
- Simple filters do *not* support multiple source addresses and destination addresses in a single term. If you configure multiple addresses, only the last one is used.
- Simple filters do *not* support negated match conditions, such as the **protocol-except** match condition or the **exception** keyword.
- Simple filters support a range of values for **source-port** and **destination-port** match conditions only. For example, you can configure **source-port 400-500** or **destination-port 600-700**.
- Simple filters do *not* support noncontiguous mask values.

Table 123 lists the simple filter match conditions.

Table 123: Simple Filter Match Conditions

Match Condition	Description
destination-address <i>destination-address</i>	Match IP destination address.
destination-port <i>number</i>	<p>TCP or UDP destination port field.</p> <p>If you configure this match condition, we recommend that you also configure the protocol match statement to determine which protocol is being used on the port.</p> <p>In place of the numeric value, you can specify one of the following text aliases (the port numbers are also listed): afs (1483), bgp (179), biff (512), bootpc (68), bootps (67), cmd (514), cvspserver (2401), dhcp (67), domain (53), eklogin (2105), ekshell (2106), exec (512), finger (79), ftp (21), ftp-data (20), http (80), https (443), ident (113), imap (143), kerberos-sec (88), klogin (543), kpasswd (761), krb-prop (754), krbupdate (760), kshell (544), ldap (389), login (513), mobileip-agent (434), mobilip-mn (435), msdp (639), netbios-dgm (138), netbios-ns (137), netbios-ssn (139), nfsd (2049), nnntp (119), ntalk (518), ntp (123), pop3 (110), pptp (1723), printer (515), radacct (1813), radius (1812), rip (520), rkinit (2108), smtp (25), snmp (161), snmptrap (162), snpp (444), socks (1080), ssh (22), sunrpc (111), syslog (514), tacacs-ds (65), talk (517), telnet (23), tftp (69), timed (525), who (513), or xdmcp (177).</p>
forwarding-class <i>class</i>	<p>Match the forwarding class of the packet.</p> <p>Specify assured-forwarding, best-effort, expedited-forwarding, or network-control.</p>

Table 123: Simple Filter Match Conditions (*continued*)

Match Condition	Description
protocol number	IP protocol field. In place of the numeric value, you can specify one of the following text aliases (the field values are also listed): ah (51), dstopts (60), egp (8), esp (50), fragment (44), gre (47), hop-by-hop (0), icmp (1), icmp6 (58), icmpv6 (58), igmp (2), ipip (4), ipv6 (41), ospf (89), pim (103), rsvp (46), sctp (132), tcp (6), udp (17), or vrrp (112).
source-address <i>ip-source-address</i>	Match the IP source address.
source-port number	Match the UDP or TCP source port field. If you configure this match condition, we recommend that you also configure the protocol match statement to determine which protocol is being used on the port. In place of the numeric field, you can specify one of the text aliases listed for destination-port .

Simple Filter Terminating Actions

Simple filters do *not* support explicitly configurable terminating actions, such as **accept**, **reject**, and **discard**. Terms configured in a simple filter always accept packets.

Simple filters do *not* support the **next** action.

Simple Filter Nonterminating Actions

Simple filters support only the following nonterminating actions:

- **forwarding-class** (*forwarding-class* | **assured-forwarding** | **best-effort** | **expedited-forwarding** | **network-control**)

NOTE: On the MX Series routers with the Enhanced Queuing DPC, the forwarding class is not supported as a from match condition.

- **loss-priority** (**high** | **low** | **medium-high** | **medium-low**)

Simple filters do not support actions that perform other functions on a packet (such as incrementing a counter, logging information about the packet header, sampling the packet data, or sending information to a remote host using the system log functionality).

Example: Configuring and Applying a Firewall Filter for a Multifield Classifier

This example shows how to configure a firewall filter to classify traffic using a multifield classifier. The classifier detects packets of interest to CoS as they arrive on an interface.

- [Requirements on page 1418](#)
- [Overview on page 1418](#)

- [Configuration on page 1419](#)
- [Verification on page 1422](#)

Requirements

To verify this procedure, this example uses a traffic generator. The traffic generator can be hardware-based or it can be software running on a server or host machine.

The functionality in this procedure is widely supported on devices that run Junos OS. The example shown here was tested and verified on MX Series routers running Junos OS Release 10.4.

Overview

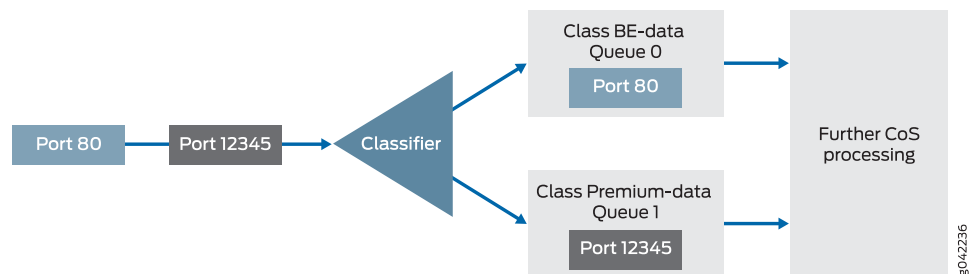

A classifier is a software operation that inspects a packet as it enters the router or switch. The packet header contents are examined, and this examination determines how the packet is treated when the network becomes too busy to handle all of the packets and you want your devices to drop packets intelligently, instead of dropping packets indiscriminately. One common way to detect packets of interest is by source port number. The TCP port numbers 80 and 12345 are used in this example, but many other matching criteria for packet detection are available to multifield classifiers, using firewall filter match conditions. The configuration in this example specifies that TCP packets with source port 80 are classified into the BE-data forwarding class and queue number 0. TCP packets with source port 12345 are classified into the Premium-data forwarding class and queue number 1.

Multifield classifiers are typically used at the network edge as packets enter an autonomous system (AS).

In this example, you configure the firewall filter `mf-classifier` and specify some custom forwarding classes on Device R1. In specifying the custom forwarding classes, you also associate each class with a queue.

The classifier operation is shown in [Figure 73](#).

Figure 73: Multifield Classifier Based on TCP Source Ports

You apply the multifield classifier's firewall filter as an input filter on each customer-facing or host-facing interface that needs the filter. The incoming interface is `ge-1/0/0` on Device R1. The classification and queue assignment is verified on the outgoing interface. The outgoing interface is Device R1's `ge-1/0/2` interface.

Topology

Figure 74 shows the sample network.

Figure 74: Multifield Classifier Scenario

“CLI Quick Configuration” on page 1419 shows the configuration for all of the Juniper Networks devices in Figure 74.

The section “Step-by-Step Procedure” on page 1420 describes the steps on Device R1.

Configuration

CLI Quick Configuration	To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter commit from the configuration mode.
Device R1	<pre> set interfaces ge-1/0/0 description to-host set interfaces ge-1/0/0 unit 0 family inet filter input mf-classifier set interfaces ge-1/0/0 unit 0 family inet address 172.16.50.2/30 set interfaces ge-1/0/2 description to-R2 set interfaces ge-1/0/2 unit 0 family inet address 10.30.0.1/30 set class-of-service forwarding-classes class BE-data queue-num 0 set class-of-service forwarding-classes class Premium-data queue-num 1 set class-of-service forwarding-classes class Voice queue-num 2 set class-of-service forwarding-classes class NC queue-num 3 set firewall family inet filter mf-classifier term BE-data from protocol tcp set firewall family inet filter mf-classifier term BE-data from port 80 set firewall family inet filter mf-classifier term BE-data then forwarding-class BE-data set firewall family inet filter mf-classifier term Premium-data from protocol tcp set firewall family inet filter mf-classifier term Premium-data from port 12345 set firewall family inet filter mf-classifier term Premium-data then forwarding-class Premium-data set firewall family inet filter mf-classifier term accept-all-else then accept </pre>

Step-by-Step Procedure The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R1:

1. Configure the device interfaces.

```
[edit interfaces]
user@R1# set ge-1/0/0 description to-host
user@R1# set ge-1/0/0 unit 0 family inet address 172.16.50.2/30
```

```
user@R1# set ge-1/0/2 description to-R2
user@R1# set ge-1/0/2 unit 0 family inet address 10.30.0.1/30
```

2. Configure the custom forwarding classes and associated queue numbers.

```
[edit class-of-service forwarding-classes]
user@R1# set BE-data queue-num 0
user@R1# set Premium-data queue-num 1
user@R1# set Voice queue-num 2
user@R1# set NC queue-num 3
```

3. Configure the firewall filter term that places TCP traffic with a source port of 80 (HTTP traffic) into the BE-data forwarding class, associated with queue 0.

```
[edit firewall family inet filter mf-classifier]
user@R1# set term BE-data from protocol tcp
user@R1# set term BE-data from port 80
user@R1# set term BE-data then forwarding-class BE-data
```

4. Configure the firewall filter term that places TCP traffic with a source port of 12345 into the Premium-data forwarding class, associated with queue 1.

```
[edit firewall family inet filter mf-classifier]
user@R1# set term Premium-data from protocol tcp
user@R1# set term Premium-data from port 12345
user@R1# set term Premium-data then forwarding-class Premium-data
```

5. At the end of your firewall filter, configure a default term that accepts all other traffic.

Otherwise, all traffic that arrives on the interface and is not explicitly accepted by the firewall filter is discarded.

```
[edit firewall family inet filter mf-classifier]
user@R1# set term accept-all-else then accept
```

6. Apply the firewall filter to the ge-1/0/0 interface as an input filter.

```
[edit interfaces]
user@R1# set ge-1/0/0 unit 0 family inet filter input mf-classifier
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show class-of-service**, **show firewall** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
```

```

ge-1/0/0 {
  description to-host;
  unit 0 {
    family inet {
      filter {
        input mf-classifier;
      }
      address 172.16.50.2/30;
    }
  }
}
ge-1/0/2 {
  description to-R2;
  unit 0 {
    family inet {
      address 10.30.0.1/30;
    }
  }
}

user@R1# show class-of-service
forwarding-classes {
  class BE-data queue-num 0;
  class Premium-data queue-num 1;
  class Voice queue-num 2;
  class NC queue-num 3;
}

user@R1# show firewall
family inet {
  filter mf-classifier {
    term BE-data {
      from {
        protocol tcp;
        port 80;
      }
      then forwarding-class BE-data;
    }
    term Premium-data {
      from {
        protocol tcp;
        port 12345;
      }
      then forwarding-class Premium-data;
    }
    term accept-all-else {
      then accept;
    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Checking the CoS Settings on page 1422](#)
- [Sending TCP Traffic into the Network and Monitoring the Queue Placement on page 1422](#)

Checking the CoS Settings

Purpose Confirm that the forwarding classes are configured correctly.

Action From Device R1, run the **show class-of-service forwarding-classes** command.

```
user@R1> show class-of-service forwarding-class
```

Forwarding class	ID	Queue	Restricted queue	Fabric
priority Policing priority SPU priority				
BE-data	0	0	0	low
normal	low			
Premium-data	1	1	1	low
normal	low			
Voice	2	2	2	low
normal	low			
NC	3	3	3	low
normal	low			

Meaning The output shows the configured custom classifier settings.

Sending TCP Traffic into the Network and Monitoring the Queue Placement

Purpose Make sure that the traffic of interest is sent out the expected queue.

Action 1. Clear the interface statistics on Device R1's outgoing interface.

```
user@R1> clear interfaces statistics ge-1/0/2
```

2. Use a traffic generator to send 50 TCP port 80 packets to Device R2 or to some other downstream device.

3. On Device R1, check the queue counters.

Notice that you check the queue counters on the downstream output interface, not on the incoming interface.

```
user@R1> show interfaces extensive ge-1/0/2 | find "Queue counters"
```

Queue counters:	Queued packets	Transmitted packets	Dropped packets
0	50	50	
0			
1	0	57	
0			
2	0	0	
0			
3	0	0	
0			

4. Use a traffic generator to send 50 TCP port 12345 packets to Device R2 or to some other downstream device.

```
[root@host]# hping 172.16.60.1 -c 50 -s 12345 -k
```

5. On Device R1, check the queue counters.

```
user@R1> show interfaces extensive ge-1/0/2 | find "Queue counters"
```

Queue counters:	Queued packets	Transmitted packets	Dropped packets
0	50	50	
0			
1	50	57	
0			
2	0	0	
0			
3	0	0	
0			

Meaning The output shows that the packets are classified correctly. When port 80 is used in the TCP packets, queue 0 is incremented. When port 12345 is used, queue 1 is incremented.

Forwarding Classes Overview

Forwarding classes (FCs) allow you to group packets for transmission and to assign packets to output queues. The forwarding class and the loss priority define the per-hop behavior (PHB in DiffServ) of a packet.

Juniper Networks devices support eight queues (0 through 7). For a classifier to assign an output queue (default queues 0 through 3) to each packet, it must associate the packet with one of the following forwarding classes:

- Expedited forwarding (EF)—Provides a low-loss, low-latency, low-jitter, assured-bandwidth, end-to-end service.
- Assured forwarding (AF)—Provides a group of values you can define and includes four subclasses—AF1, AF2, AF3, and AF4—each with three drop probabilities (low, medium, and high).
- Best effort (BE)—Provides no service profile. For the BE forwarding class, loss priority is typically not carried in a class-of-service (CoS) value, and random early detection (RED) drop profiles are more aggressive.
- Network Control (NC)—This class is typically high priority because it supports protocol control.

In addition to behavior aggregate (BA) and multifold (MF) classification, the forwarding class (FC) of a packet can be directly determined by the logical interface that receives the packet. The packet FC can be configured using CLI commands, and if configured, this

FC overrides the FC from any BA classification that was previously configured on the logical interface.

The following CLI command can assign an FC directly to packets received at a logical interface:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
forwarding-class class-name;
```

This section contains the following topics:

- [Forwarding Class Queue Assignments on page 1426](#)
- [Forwarding Policy Options on page 1427](#)

Forwarding Class Queue Assignments

Juniper Networks devices have eight queues built into the hardware. By default, four queues are assigned to four FCs. [Table 124](#) shows the four default FCs and queues that Juniper Networks classifiers assign to packets, based on the class-of-service (CoS) values in the arriving packet headers.

NOTE: Queues 4 through 7 have no default assignments to FCs and are not mapped. To use queues 4 through 7, you must create custom FC names and map them to the queues.

By default, all incoming packets, except the IP control packets, are assigned to the FC associated with queue 0. All IP control packets are assigned to the FC associated with queue 3.

Table 124: Default Forwarding Class Queue Assignments

Forwarding Queue	Forwarding Class	Forwarding Class Description
Queue 0	best-effort (BE)	The Juniper Networks device does not apply any special CoS handling to packets with 000000 in the DiffServ field, a backward compatibility feature. These packets are usually dropped under congested network conditions.
Queue 1	expedited-forwarding (EF)	<p>The Juniper Networks device delivers assured bandwidth, low loss, low delay, and low delay variation (jitter) end-to-end for packets in this service class.</p> <p>Devices accept excess traffic in this class, but in contrast to assured forwarding, out-of-profile expedited-forwarding packets can be forwarded out of sequence or dropped.</p>

Table 124: Default Forwarding Class Queue Assignments (*continued*)

Forwarding Queue	Forwarding Class	Forwarding Class Description
Queue 2	assured-forwarding (AF)	<p>The Juniper Networks device offers a high level of assurance that the packets are delivered as long as the packet flow from the customer stays within a certain service profile that you define.</p> <p>The device accepts excess traffic, but applies a random early detection (RED) drop profile to determine whether the excess packets are dropped and not forwarded.</p> <p>Three drop probabilities (low, medium, and high) are defined for this service class.</p>
Queue 3	network-control (NC)	<p>The Juniper Networks device delivers packets in this service class with a low priority. (These packets are not delay sensitive.)</p> <p>Typically, these packets represent routing protocol hello or keepalive messages. Because loss of these packets jeopardizes proper network operation, delay is preferable to discard.</p>

Forwarding Policy Options

CoS-based forwarding (CBF) enables you to control next-hop selection based on a packet's CoS and, in particular, the value of the IP packet's precedence bits. For example, you can specify a particular interface or next hop to carry high-priority traffic while all best-effort traffic takes some other path. CBF allows path selection based on FC. When a routing protocol discovers equal-cost paths, it can either pick a path at random or load-balance the packets across the paths, through either hash selection or round-robin selection.

A forwarding policy also allows you to create CoS classification overrides. You can override the incoming CoS classification and assign the packets to an FC based on the packets' input interfaces, input precedence bits, or destination addresses. When you override the classification of incoming packets, any mappings you configured for associated precedence bits or incoming interfaces to output transmission queues are ignored.

Related Documentation

- [Example: Assigning Forwarding Classes to Output Queues on page 1432](#)
- [Example: Assigning a Forwarding Class to an Interface on page 1434](#)

Example: Configuring Forwarding Classes

By default on all platforms, four output queues are mapped to four FCs as shown in [“Forwarding Classes Overview” on page 1425](#). On Juniper Networks devices, you can configure up to eight FCs and eight queues.

To configure up to eight FCs, include the **queue** statement at the **[edit class-of-service forwarding-classes]** hierarchy level:

```
[edit class-of-service forwarding-classes]
queue queue-number class-name;
```

The output queue number can be from 0 through 7, and you must map the forwarding classes one-to-one with the output queues. The default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent, respectively.

For example, to configure a one-to-one mapping between eight FCs and eight queues, you would use the following configuration:

Defining Eight Classifiers

```
[edit class-of-service]
forwarding-classes {
  queue 0 be;
  queue 1 ef;
  queue 2 af;
  queue 3 nc;
  queue 4 ef1;
  queue 5 ef2;
  queue 6 af1;
  queue 7 nc1;
}

[edit class-of-service]
classifiers {
  dscp dscp-table {
    forwarding-class ef {
      loss-priority low code-points [101000, 101001];
      loss-priority high code-points [101010, 101011];
    }
    forwarding-class af {
      loss-priority low code-points [010000, 010001];
      loss-priority high code-points [010010, 010011];
    }
    forwarding-class be {
      loss-priority low code-points [000000];
    }
    forwarding-class nc {
      loss-priority low code-points [111000];
    }
    forwarding-class ef1 {
      loss-priority low code-points [101100, 101101];
      loss-priority high code-points [101110];
    }
    forwarding-class af1 {
      loss-priority high code-points [101110];
    }
    forwarding-class ef2 {
      loss-priority low code-points [101111];
    }
    forwarding-class nc1 {
      loss-priority low code-points [111001];
    }
  }
}
```

Adding Eight Schedulers to a Scheduler Map

Configure a custom scheduler map that applies globally to all interfaces, except those that are restricted to four queues:

```
[edit class-of-service]
scheduler-maps {
  sched {
    forwarding-class be scheduler Q0;
    forwarding-class ef scheduler Q1;
    forwarding-class af scheduler Q2;
    forwarding-class nc scheduler Q3;
    forwarding-class ef1 scheduler Q4;
    forwarding-class ef2 scheduler Q5;
    forwarding-class af1 scheduler Q6;
    forwarding-class nc1 scheduler Q7;
  }
}
schedulers {
  Q0 {
    transmit-rate percent 25;
    buffer-size percent 25;
    priority low;
    drop-profile-map loss-priority any protocol both drop-default;
  }
  Q1 {
    buffer-size temporal 2000;
    priority strict-high;
    drop-profile-map loss-priority any protocol both drop-ef;
  }
  Q2 {
    transmit-rate percent 35;
    buffer-size percent 35;
    priority low;
    drop-profile-map loss-priority any protocol both drop-default;
  }
  Q3 {
    transmit-rate percent 5;
    buffer-size percent 5;
    drop-profile-map loss-priority any protocol both drop-default;
  }
  Q4 {
    transmit-rate percent 5;
    priority high;
    drop-profile-map loss-priority any protocol both drop-ef;
  }
  Q5 {
    transmit-rate percent 10;
    priority high;
    drop-profile-map loss-priority any protocol both drop-ef;
  }
  Q6 {
    transmit-rate remainder;
    priority low;
    drop-profile-map loss-priority any protocol both drop-default;
  }
  Q7 {
    transmit-rate percent 5;
```

Configuring an IP Precedence Classifier and Rewrite Tables

```

        priority high;
        drop-profile-map loss-priority any protocol both drop-default;
    }
}

[edit class-of-service]
classifiers {
    inet-precedence inet-classifier {
        forwarding-class be {
            loss-priority low code-points 000;
        }
        forwarding-class af11 {
            loss-priority high code-points 001;
        }
        forwarding-class ef {
            loss-priority low code-points 010;
        }
        forwarding-class nc1 {
            loss-priority high code-points 011;
        }
        forwarding-class {
            loss-priority low code-points 100;
        }
        forwarding-class af12 {
            loss-priority high code-points 101;
        }
        forwarding-class ef1 {
            loss-priority low code-points 110;
        }
        forwarding-class nc2 {
            loss-priority high code-points 111;
        }
    }
}

    }
    forwarding-class af12 {
        loss-priority high code-point 101;
    }
    forwarding-class ef1 {
        loss-priority low code-point 110;
    }
}

```

```

forwarding-class nc2 {
    loss-priority low code-point 111;
}
}
inet-precedence inet-rw-table {
    forwarding-class be {
        loss-priority low code-point 000;
    }
    forwarding-class af11 {
        loss-priority high code-point 001;
    }
    forwarding-class ef1 {
        loss-priority low code-point 010;
    }
    forwarding-class nc1 {
        loss-priority low code-point 111;
    }
    forwarding-class be1 {
        loss-priority low code-point 100;
    }
    forwarding-class af12 {
        loss-priority high code-point 101;
    }
    forwarding-class ef1 {
        loss-priority low code-point 111;
    }
    forwarding-class nc2 {
        loss-priority low code-point 110;
    }
}
}

```

Configuring an IDP Policy with a Forwarding Class

Configure an IDP policy with a forwarding class as an action to rewrite DSCP values of IP packets:

```

[edit class-of-service]
security idp idp-policy policy_name rulebase-ips rule rule_name {
    then {
        action {
            class-of-service {
                forwarding-class forwarding-class-name;
                dscp-code-point value;
            }
        }
    }
}

```

Example: Assigning Forwarding Classes to Output Queues

This example shows how to assign forwarding classes to output queues.

- [Requirements on page 1432](#)
- [Overview on page 1432](#)
- [Configuration on page 1432](#)
- [Verification on page 1433](#)

Requirements

Before you begin, determine the MF classifier. See [“Example: Configuring and Applying a Firewall Filter for a Multifield Classifier” on page 1417](#).

Overview

In this example, you configure class of service and assign best-effort traffic to queue 0 as be-class, expedited forwarding traffic to queue 1 as ef-class, assured forwarding traffic to queue 2 as af-class, and network control traffic to queue 3 as nc-class.

You must assign the forwarding classes established by the MF classifier to output queues. [Table 125](#) shows how this example assigns output queues.

Table 125: Sample Output Queue Assignments for mf-classifier Forwarding Queues

mf-classifier Forwarding Class	For Traffic Type	Output Queue
be-class	Best-effort traffic	Queue 0
ef-class	Expedited forwarding traffic	Queue 1
af-class	Assured forwarding traffic	Queue 2
nc-class	Network control traffic	Queue 3

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service forwarding-classes queue 0 be-class
set class-of-service forwarding-classes queue 1 ef-class
set class-of-service forwarding-classes queue 2 af-class
set class-of-service forwarding-classes queue 3 nc-class
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To assign forwarding classes to output queues:

1. Configure class of service.

```
[edit]
user@host# edit class-of-service forwarding-classes
```
2. Assign best-effort traffic to queue 0.

```
[edit class-of-service forwarding-classes]
user@host# set queue 0 be-class
```
3. Assign expedited forwarding traffic to queue 1.

```
[edit class-of-service forwarding-classes]
user@host# set queue 1 ef-class
```
4. Assign assured forwarding traffic to queue 2.

```
[edit class-of-service forwarding-classes]
user@host# set queue 2 af-class
```
5. Assign network control traffic to queue 3.

```
[edit class-of-service forwarding-classes]
user@host# set queue 3 nc-class
```

Results From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
forwarding-classes {
  queue 0 be-class;
  queue 1 ef-class;
  queue 2 af-class;
  queue 3 nc-class;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: You cannot commit a configuration that assigns the same forwarding class to two different queues.

Verification

Confirm that the configuration is working properly.

- [Verifying Forwarding Classes Are Assigned to Output Queues on page 1434](#)

Verifying Forwarding Classes Are Assigned to Output Queues

Purpose	Verify that the forwarding classes are properly assigned to output queues.
Action	From configuration mode, enter the show class-of-service command.
Related Documentation	<ul style="list-style-type: none">• Forwarding Classes Overview on page 1425• Example: Assigning a Forwarding Class to an Interface on page 1434• Example: Configuring Forwarding Classes on page 1427

Example: Assigning a Forwarding Class to an Interface

This example shows how to assign a forwarding class to an interface.

- [Requirements on page 1434](#)
- [Overview on page 1434](#)
- [Configuration on page 1434](#)
- [Verification on page 1435](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

On a device, you can configure fixed classification on a logical interface by specifying a forwarding class to be applied to all packets received by the logical interface, regardless of the packet contents.

In this example, you configure class of service, create interface ge-3/0/0 unit 0 and then set the forwarding class to assured-forwarding.

All packets coming into the device from the ge-3/0/0 unit 0 interface are assigned to the assured-forwarding forwarding class.

Configuration

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To assign a forwarding class to an interface:

1. Configure class of service and assign the interface.

```
[edit]  
user@host# edit class-of-service interfaces ge-3/0/0 unit 0
```
2. Specify the forwarding class.

```
[edit class-of-service interfaces ge-3/0/0 unit 0]
user@host# set forwarding-class assured-forwarding
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show class-of-service** command.

Understanding the SPC High-Priority Queue

The Services Processing Card (SPC) on SRX1400, SRX3000 line, and SRX5000 line devices provides processing power to run integrated services such as firewall, IPsec, and IDP. All traffic traversing the SRX Series device is passed to an SPC to have service processing applied. Junos OS provides a configuration option to enable packets with specific Differentiated Services (DiffServ) code points (DSCP) precedence bits to enter a high-priority queue on the SPC. The Services Processing Unit (SPU) draws packets from the high-priority queue and only draws packets from a low-priority queue when the high-priority queue is empty. This feature can reduce overall latency for real-time traffic, such as voice traffic.

To designate packets for the high-priority or low-priority queues, use the **spu-priority** configuration statement at the **[edit class-of-service forwarding-classes class]** hierarchy level. A value of **high** places packets into the high-priority queue, and a value of **low** places packets into the low-priority queue.

Related Documentation

- [Example: Configuring the SPC High-Priority Queue on page 1435](#)
- [Forwarding Classes Overview on page 1425](#)

Example: Configuring the SPC High-Priority Queue

This example shows how to configure a forwarding class for the high-priority queue on the SPC.

- [Requirements on page 1436](#)
- [Overview on page 1436](#)
- [Configuration on page 1436](#)
- [Verification on page 1437](#)

Requirements

This example uses the following hardware and software components:

- SRX1400, SRX3000 line, or SRX5000 line device
- Junos OS Release 11.4R2 or later

Overview

This example defines the following forwarding classes and assigns a queue number to each class:

Forwarding Class	Queue Number
best-effort	0
assured-forwarding	1
network-control	3
expedited-forwarding	2

The expedited-forwarding class is configured for the high-priority queue on the SPC.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service forwarding-classes class best-effort queue-num 0
set class-of-service forwarding-classes class assured-forwarding queue-num 1
set class-of-service forwarding-classes class network-control queue-num 3
set class-of-service forwarding-classes class expedited-forwarding queue-num 2
spu-priority high
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the high-priority queue on the SPC:

1. Define forwarding classes and assign queue numbers.

```
[edit class-of-service forwarding-classes]
user@host# set class best-effort queue-num 0
user@host# set class assured-forwarding queue-num 1
user@host# set class network-control queue-num 3
user@host# set class expedited-forwarding queue-num 2
```
2. Configure the SPC high-priority queue.

```
[edit class-of-service forwarding-classes]
user@host# set class expedited-forwarding spu-priority high
```

Results From configuration mode, confirm your configuration by entering the **show class-of-service forwarding-classes** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service forwarding-classes
class best-effort queue-num 0;
class assured-forwarding queue-num 1;
class network-control queue-num 3;
class expedited-forwarding queue-num 2 spu-priority high;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying SPU High-Priority Queue Mapping

Purpose Verify that the forwarding class is mapped to the SPU high-priority queue.

Action From operational mode, enter the **show class-of-service forwarding-class** command.

```
user@host> show class-of-service forwarding-class
```

Forwarding class	ID	Queue	Restricted queue	Fabric
priority Policing priority	SPU priority			
best-effort normal	low	0	0	low
expedited-forwarding normal	high	1	1	low
assured-forwarding normal	low	2	2	low
network-control normal	low	3	3	low

Altering Outgoing Packets Headers with Rewrite Rules

- [Rewrite Rules Overview on page 1439](#)
- [Rewriting Frame Relay Headers on page 1439](#)
- [Example: Configuring and Applying Rewrite Rules on page 1441](#)

Rewrite Rules Overview

A rewrite rule modifies the appropriate class-of-service (CoS) bits in an outgoing packet. Modification of CoS bits allows the next downstream device to classify the packet into the appropriate service group. Rewriting or marking outbound packets is useful when the device is at the border of a network and must alter the CoS values to meet the policies of the targeted peer. A rewrite rule examines the forwarding class and loss priority of a packet and sets its bits to a corresponding value specified in the rule.

Typically, a device rewrites CoS values in outgoing packets on the outbound interfaces of an edge device, to meet the policies of the targeted peer. After reading the current forwarding class and loss priority information associated with the packet, the transmitting device locates the chosen CoS value from a table, and writes this CoS value into the packet header.

NOTE: You can configure up to 32 IEEE 802.1p rewriters on each SRX5K-MPC on the SRX5600 and SRX5800 devices.

Rewriting Frame Relay Headers

This section contains the following topics:

- [Assigning the Default Frame Relay Rewrite Rule to an Interface on page 1440](#)
- [Defining a Custom Frame Relay Rewrite Rule on page 1440](#)

Assigning the Default Frame Relay Rewrite Rule to an Interface

For Juniper Networks device interfaces with Frame Relay encapsulation, you can rewrite the discard eligibility (DE) bit based on the loss priority of Frame Relay traffic. For each outgoing frame with the loss priority set to low, medium-low, medium-high, or high, you can set the DE bit CoS value to 0 or 1. You can combine a Frame Relay rewrite rule with other rewrite rules on the same interface. For example, you can rewrite both the DE bit and MPLS EXP bit.

The default Frame Relay rewrite rule contains the following settings:

```
loss-priority low code-point 0;
loss-priority medium-low code-point 0;
loss-priority medium-high code-point 1;
loss-priority high code-point 1;
```

This default rule sets the DE CoS value to 0 for each outgoing frame with the loss priority set to low or medium-low. This default rule sets the DE CoS value to 1 for each outgoing frame with the loss priority set to medium-high or high.

To assign the default rule to an interface, include the **frame-relay-de default** statement at the **[edit class-of-service interfaces interface *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
frame-relay-de default;
```

Defining a Custom Frame Relay Rewrite Rule

To define a custom Frame Relay rewrite rule, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
rewrite-rules {
  frame-relay-de rewrite-name {
    import (rewrite-name | default);
    forwarding-class class-name {
      loss-priority level code-point (0 | 1);
    }
  }
}
```

A custom rewrite rule sets the DE bit to the 0 or 1 CoS value based on the assigned loss priority of low, medium-low, medium-high, or high for each outgoing frame.

The rule does not take effect until you apply it to a logical interface. To apply a rule to a logical interface, include the **frame-relay-de *map-name*** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
frame-relay-de map-name;
```

Example: Configuring and Applying Rewrite Rules

This example shows how to configure and apply rewrite rules for a device.

- [Requirements on page 1441](#)
- [Overview on page 1441](#)
- [Configuration on page 1442](#)
- [Verification on page 1444](#)

Requirements

Before you begin, create and configure the forwarding classes.

Overview

You can configure rewrite rules to replace DSCPs on packets received from the customer or host with the values expected by other devices. You do not have to configure rewrite rules if the received packets already contain valid DSCPs. Rewrite rules apply the forwarding class information and packet loss priority used internally by the device to establish the DSCP on outbound packets. After you configure the rewrite rules, you must apply them to the correct interfaces.

NOTE: You can configure up to 32 IEEE 802.1p rewriters on each SRX5K-MPC on the SRX5600 and SRX5800 devices.

In this example, you configure the rewrite rules for DiffServ CoS as rewrite-dscps. You specify the best-effort forwarding class as be-class, expedited forwarding class as ef-class, an assured forwarding class as af-class, and a network control class as nc-class. Finally, you apply rewrite rules to an interface called ge-0/0/0.

[Table 126](#) shows how the rewrite rules replace the DSCPs on packets in the four forwarding classes.

Table 126: Sample rewrite-dscps Rewrite Rules to Replace DSCPs

mf-classifier Forwarding Class	For CoS Traffic Type	rewrite-dscps Rewrite Rules
be-class	Best-effort traffic—Provides no special CoS handling of packets. Typically, RED drop profile is aggressive and no loss priority is defined.	Low-priority code point: 000000 High-priority code point: 000001
ef-class	Expedited forwarding traffic—Provides low loss, low delay, low jitter, assured bandwidth, and end-to-end service. Packets can be forwarded out of sequence or dropped.	Low-priority code point: 101110 High-priority code point: 101111

Table 126: Sample rewrite-dscps Rewrite Rules to Replace DSCPs (*continued*)

mf-classifier Forwarding Class	For CoS Traffic Type	rewrite-dscps Rewrite Rules
af-class	Assured forwarding traffic—Provides high assurance for packets within the specified service profile. Excess packets are dropped.	Low-priority code point: 001010 High-priority code point: 001100
nc-class	Network control traffic—Packets can be delayed but not dropped.	Low-priority code point: 110000 High-priority code point: 110001

NOTE: Forwarding classes can be configured in a DSCP rewriter and also as an action of an IDP policy to rewrite DSCP code points. To ensure that the forwarding class is used as an action in an IDP policy, it is important that you do not configure an IDP policy and interface-based rewrite rules with the same forwarding class.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class be-class
  loss-priority low code-point 000000
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class be-class
  loss-priority high code-point 000001
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class ef-class loss-priority
  low code-point 101110
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class ef-class loss-priority
  high code-point 101111
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class af-class loss-priority
  low code-point 001010
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class af-class loss-priority
  high code-point 001100
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class nc-class loss-priority
  low code-point 110000
set class-of-service rewrite-rules dscp rewrite-dscps forwarding-class nc-class loss-priority
  high code-point 110001
set class-of-service interfaces ge-0/0/0 unit 0 rewrite-rules dscp rewrite-dscps
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure and apply rewrite rules for a device:

1. Configure rewrite rules for DiffServ CoS.

- ```
[edit]
user@host# edit class-of-service
user@host# edit rewrite-rules dscp rewrite-dscps
```
2. Configure best-effort forwarding class rewrite rules.
 

```
[edit class-of-service rewrite-rules dscp rewrite-dscps]
user@host# set forwarding-class be-class loss-priority low code-point 000000
user@host# set forwarding-class be-class loss-priority high code-point 000001
```
  3. Configure expedited forwarding class rewrite rules.
 

```
[edit class-of-service rewrite-rules dscp rewrite-dscps]
user@host# set forwarding-class ef-class loss-priority low code-point 101110
user@host# set forwarding-class ef-class loss-priority high code-point 101111
```
  4. Configure an assured forwarding class rewrite rules.
 

```
[edit class-of-service rewrite-rules dscp rewrite-dscps]
user@host# set forwarding-class af-class loss-priority low code-point 001010
user@host# set forwarding-class af-class loss-priority high code-point 001100
```
  5. Configure a network control class rewrite rules.
 

```
[edit class-of-service rewrite-rules dscp rewrite-dscps]
user@host# set forwarding-class nc-class loss-priority low code-point 110000
user@host# set forwarding-class nc-class loss-priority high code-point 110001
```
  6. Apply rewrite rules to an interface.
 

```
[edit class-of-service]
user@host# set interfaces ge-0/0/0 unit 0 rewrite-rules dscp rewrite-dscps
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
interfaces {
 interfaces {
 unit 0 {
 rewrite-rules {
 dscp rewrite-dscps;
 }
 }
 }
}
rewrite-rules {
 dscp rewrite-dscps {
 forwarding-class be-class {
 loss-priority low code-point 000000;
 loss-priority high code-point 000001;
 }
 forwarding-class ef-class {
 loss-priority low code-point 101110;
 loss-priority high code-point 101111;
 }
 }
 forwarding-class af-class {
```

```
 loss-priority low code-point 001010;
 loss-priority high code-point 001100;
 }
 forwarding-class nc-class {
 loss-priority low code-point 110000;
 loss-priority high code-point 110001;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Rewrite Rules Configuration on page 1444](#)

---

### Verifying Rewrite Rules Configuration

**Purpose** Verify that rewrite rules are configured properly.

**Action** From configuration mode, enter the **show class-of-service** command.

## Schedulers Overview

---

You use *schedulers* to define the properties of output queues. These properties include the amount of interface bandwidth assigned to the queue, the size of the memory buffer allocated for storing packets, the priority of the queue, and the random early detection (RED) drop profiles associated with the queue.

You associate the schedulers with forwarding classes by means of *scheduler maps*. You can then associate each scheduler map with an interface, thereby configuring the hardware queues, packet schedulers, and RED processes that operate according to this mapping.

An individual device interface has multiple queues assigned to store packets temporarily before transmission. To determine the order to service the queues, the device uses a round-robin scheduling method based on priority and the queue's weighted round-robin (WRR) credits. Junos OS schedulers allow you to define the priority, bandwidth, delay

buffer size, rate control status, and RED drop profiles to be applied to a particular queue for packet transmission.

You can configure *per-unit scheduling* (also called *logical interface scheduling*) to allow multiple output queues on a logical interface and to associate an output scheduler with each queue.

**NOTE:** For Juniper Network devices, when configuring the “protocol parameter” in the **drop-profile-map** statement, TCP and non-TCP values are not supported; only the value “any” is supported.

This section contains the following topics:

- [Transmit Rate on page 1446](#)
- [Delay Buffer Size on page 1447](#)
- [Scheduling Priority on page 1448](#)
- [Shaping Rate on page 1449](#)

## Transmit Rate

The transmission rate determines the traffic transmission bandwidth for each forwarding class you configure. The rate is specified in bits per second (bps). Each queue is allocated some portion of the bandwidth of the outgoing interface.

This bandwidth amount can be a fixed value, such as 1 megabit per second (Mbps), a percentage of the total available bandwidth, or the rest of the available bandwidth. You can limit the transmission bandwidth to the exact value you configure, or allow it to exceed the configured rate if additional bandwidth is available from other queues (SRX Series high-end devices do not support an exact value transmit rate). This property helps ensure that each queue receives the amount of bandwidth appropriate to its level of service.

The minimum transmit rate supported on high-speed interfaces is one-ten thousandth of the speed of that interface. For example, on a Gigabit Ethernet interface with a speed of 1,000 Mbps, the minimum transmit rate is 100 Kbps (1,000 Mbps x 1/10,000). You can configure transmit rates in the range 3,200 bps through 160,000,000,000 bps. When the configured rate is less than the minimum transmit rate, the minimum transmit rate is used instead.

**NOTE:** Interfaces with slower interface speeds, like T1, E1, or channelized T1/E1/ISDN PRI, cannot support minimum transmit rates because the minimum transmit rate supported on a services router is 3,200 bps.

Transmit rate assigns the weighted round-robin (WRR) priority values within a given priority level and not between priorities.

The transmit rate defines the transmission rate of a scheduler. The transmit rate determines the traffic bandwidth from each forwarding class you configure.

By default, queues 0 through 7 have the following percentage of transmission capacity:

- Queue 0—95 percent
- Queue 1—0 percent
- Queue 2—0 percent
- Queue 3—0 percent
- Queue 4—0 percent
- Queue 6—0 percent
- Queue 7—5 percent

To define a transmit rate, select the appropriate option:

- To specify a transmit rate, select **rate** and type an integer from 3200 to 160,000,000,000 bits per second.
- To enforce an exact transmit rate, select **rate**.
- To specify the remaining transmission capacity, select **remainder**.
- To specify a percentage of transmission capacity, select **percent** and type an integer from 1 through 100.

Optionally, you can specify the percentage of the remainder to be used for allocating the transmit rate of the scheduler on a prorated basis. If there are still points left even after allocating the remainder percentage with the transmit rate and there are no queues, then the points are allocated point by point to each queue in a round-robin method. If the remainder percentage is not specified, the remainder value will be shared equally.

## Delay Buffer Size

You can configure the delay buffer size to control congestion at the output stage. A delay buffer provides packet buffer space to absorb burst traffic up to a specified duration of delay. When the buffer is full, all packets are dropped.

On Juniper Networks devices, you can configure larger delay buffers on channelized T1/E1 interfaces. Larger delay buffers help these slower interfaces to avoid congestion and packet dropping when they receive large bursts of traffic.

By default, all branch SRX Series device interfaces support a delay buffer time of 100,000 microseconds.

To define a delay buffer size for a scheduler, select the appropriate option:

- To enforce exact buffer size, select **Exact**.
- To specify a buffer size as a temporal value (microseconds), select **Temporal**.

- To specify buffer size as a percentage of the total buffer, select **Percent** and type an integer from 1 through 100.
- To specify buffer size as the remaining available buffer, select **Remainder**.

Optionally, you can specify the percentage of the remainder to be used for allocating the buffer size of the scheduler on a prorated basis.

By default, sizes of the delay buffer queues 0 through 7 have the following percentage of the total available buffer space:

- Queue 0—95 percent
- Queue 1—0 percent
- Queue 2—0 percent
- Queue 3—0 percent
- Queue 4—0 percent
- Queue 5—0 percent
- Queue 6—0 percent
- Queue 7—5 percent

**NOTE:** A large buffer size value correlates with a greater possibility of packet delays. This might not be practical for sensitive traffic such as voice or video.

---

**NOTE:** For a Juniper Networks device, if the buffer size percentage is set to zero for T1 interfaces, traffic does not pass.

---

## Scheduling Priority

Scheduling priority determines the order in which an output interface transmits traffic from the queues, thus ensuring that queues containing important traffic are provided better access to the outgoing interface.

The queues for an interface are divided into sets based on their priority. Each set contains queues of the same priority. The device examines the sets in descending order of priority. If at least one queue in a set has a packet to transmit, the device selects that set. If multiple queues in the set have packets to transmit, the device selects a queue from the set according to the weighted round-robin (WRR) algorithm that operates within the set.

The packets in a queue are transmitted based on the configured scheduling priority, the transmit rate, and the available bandwidth.

The scheduling priority of the scheduler determines the order in which an output interface transmits traffic from the queues. You can set scheduling priority at different levels in an

order of increasing priority from low to high. A high-priority queue with a high transmission rate might lock out lower-priority traffic.

To specify a scheduling priority, select one of the following levels:

- **high**—Packets in this queue have high priority.
- **low**—Packets in this queue are transmitted last.
- **medium—low**—Packets in this queue have medium-low priority.
- **medium—high**—Packets in this queue have medium-high priority.
- **strict—high**—Packets in this queue are transmitted first.

## Shaping Rate

Shaping rates control the maximum rate of traffic transmitted on an interface. You can configure the shaping rate so that the interface transmits less traffic than it is physically capable of carrying.

You can configure shaping rates on logical interfaces. By default, output scheduling is not enabled on logical interfaces. Logical interface scheduling (also called per-unit scheduling) allows you to enable multiple output queues on a logical interface and associate an output scheduler and shaping rate with the queues.

By default, the logical interface bandwidth is the average of unused bandwidth for the number of logical interfaces that require default bandwidth treatment. You can specify a peak bandwidth rate in bits per second (bps), either as a complete decimal number or as a decimal number followed by the abbreviation *k* (1,000), *m* (1,000,000), or *g* (1,000,000,000). The range is from 1,000 through 32,000,000,000 bps.

For low-speed interfaces, the queue-limit values might become lower than the interface MTU so that traffic with large packets can no longer pass through some of the queues. If you want larger-sized packets to flow through, set the buffer-size configuration in the scheduler to a larger value. For more accuracy, the 100-ms queue-limit values are calculated based on shaper rates and not on interface rates.

The shaping rate defines the minimum bandwidth allocated to a queue. The default shaping rate is 100 percent, which is the same as no shaping at all. To define a shaping rate, select the appropriate option:

- To specify shaping rate as an absolute number of bits per second, select **rate** and type an integer from 3,200 to 160,000,000,000 bits per second.
- To specify shaping rate as a percentage, select **percent** and type an integer from 0 through 100.

- [Transmission Scheduling Overview on page 1451](#)

## Default Scheduler Settings

---

Each forwarding class has an associated scheduler priority. Only two forwarding classes, best-effort and network-control (queue 0 and queue 3), are used in the Junos OS default scheduler configuration.

By default, the best-effort forwarding class (queue 0) receives 95 percent, and the network-control (queue 3) receives 5 percent of the bandwidth and buffer space for the output link. The default drop profile causes the buffer to fill and then discard all packets until it again has space.

The expedited-forwarding and assured-forwarding classes have no schedulers, because by default no resources are assigned to queue 1 and queue 2. However, you can manually configure resources for the expedited-forwarding and the assured-forwarding classes.

By default, each queue can exceed the assigned bandwidth if additional bandwidth is available from other queues. When a forwarding class does not fully use the allocated transmission bandwidth, the remaining bandwidth can be used by other forwarding classes if they receive a larger amount of offered load than the bandwidth allocated. If you do not want a queue to use any leftover bandwidth, you must configure it for strict allocation.

The device uses the following default scheduler settings. You can configure these settings.

```
[edit class-of-service]
schedulers {
 network-control {
 transmit-rate percent 5;
 buffer-size percent 5;
 priority low;
 drop-profile-map loss-priority any protocol any drop-profile terminal;
 }
 best-effort {
 transmit-rate percent 95;
 buffer-size percent 95;
 priority low;
 drop-profile-map loss-priority any protocol any drop-profile terminal;
 }
}
drop-profiles {
 terminal {
 fill-level 100 drop-probability 100;
 }
}
```

- [Scheduler Buffer Size Overview on page 1461](#)
- [Example: Configuring a Large Delay Buffer on a Channelized T1 Interface on page 1465](#)
- [Example: Configuring and Applying Scheduler Maps on page 1472](#)
- [Transmission Scheduling Overview on page 1451](#)

## Transmission Scheduling Overview

The packets in a queue are transmitted based on their transmission priority, transmit rate, and the available bandwidth.

By default, each queue can exceed the assigned bandwidth if additional bandwidth is available from other queues. When a forwarding class does not fully use the allocated transmission bandwidth, the remaining bandwidth can be used by other forwarding classes if they receive a larger amount of offered load than the bandwidth allocated. A queue receiving traffic within its bandwidth configuration is considered to have positive bandwidth credit, and a queue receiving traffic in excess of its bandwidth allocation is considered to have negative bandwidth credit.

**NOTE:** The queues in a logical interface do not use the available buffer from other queues for packet transmission. Instead, the packets transmitted to a queue consider only the buffer size available in its own queue.

A queue with positive credit does not need to use leftover bandwidth, because it can use its own allocation. For such queues, packets are transmitted based on the priority of the queue, with packets from higher-priority queues transmitting first. The transmit rate is not considered during transmission. In contrast, a queue with negative credit needs a share of the available leftover bandwidth.

The leftover bandwidth is allocated to queues with negative credit in proportion to the configured transmit rate of the queues within a given priority set. The queues for an interface are divided into sets based on their priority. If no transmit rate is configured, each queue in the set receives an equal percentage of the leftover bandwidth. However, if a transmit rate is configured, each queue in the set receives the configured percentage of the leftover bandwidth.

[Table 127](#) shows a sample configuration of priority and transmit rate on six queues. The total available bandwidth on the interface is 100 Mbps.

**Table 127: Sample Transmission Scheduling**

| Queue | Scheduling Priority | Transmit Rate | Incoming Traffic |
|-------|---------------------|---------------|------------------|
| 0     | Low                 | 10%           | 20 Mbps          |
| 1     | High                | 20%           | 20 Mbps          |
| 2     | High                | 30%           | 20 Mbps          |

Table 127: Sample Transmission Scheduling (*continued*)

| Queue | Scheduling Priority | Transmit Rate               | Incoming Traffic |
|-------|---------------------|-----------------------------|------------------|
| 3     | Low                 | 30%                         | 20 Mbps          |
| 4     | Medium-high         | No transmit rate configured | 10 Mbps          |
| 5     | Medium-high         | No transmit rate configured | 20 Mbps          |

In this example, queues are divided into three sets based on their priority:

- High priority set—Consists of queue 1 and queue 2. Packets use 40 Mbps (20+20) of the available bandwidth (100 Mbps) and are transmitted first. Because of positive credit, the configured transmit rate is not considered.
- Medium-high priority set—Consists of queue 4 and queue 5. Packets use 30 Mbps (10+20) of the remaining 60 Mbps bandwidth. Because of positive credit, the transmit rate is not considered. If the queues had negative credit, they would receive an equal share of the leftover bandwidth because no transmit rate is configured.
- Low priority set—Consists of queue 0 and queue 3. Packets share the 20 Mbps of leftover bandwidth based on the configured transmit rate. The distribution of bandwidth is in proportion to the assigned percentages. Because the total assigned percentage is 40 (10 + 30), each queue receives a share of bandwidth accordingly. Thus queue 0 receives 5 Mbps (10/40 x 20), and queue 3 receives 15 Mbps (30/40 x 20).

## Excess Bandwidth Sharing and Minimum Logical Interface Shaping

The default excess bandwidth sharing proportional rate is 32.65 Mbps (128 Kbps x 255). In order to have better weighed fair queuing (WFQ) accuracy among queues, the shaping rate configured should be larger than the excess bandwidth sharing proportional rate. Some examples are shown in [Table 128](#).

Table 128: Shaping Rates and WFQ Weights

| Shaping Rate | Configured Queue Transmit Rate | WFQ Weight        | Total Weights |
|--------------|--------------------------------|-------------------|---------------|
| 10 Mbps      | (30, 40, 25, 5)                | (22, 30, 20, 4)   | 76            |
| 33 Mbps      | (30, 40, 25, 5)                | (76, 104, 64, 13) | 257           |

Table 128: Shaping Rates and WFQ Weights (*continued*)

| Shaping Rate | Configured Queue Transmit Rate | WFQ Weight       | Total Weights |
|--------------|--------------------------------|------------------|---------------|
| 40 Mbps      | (30, 40, 25, 5)                | (76, 104.64, 13) | 257           |

With a 10-Mbps shaping rate, the total weights are 76. This is divided among the four queues according to the configured transmit rate. Note that when the shaping rate is larger than the excess bandwidth sharing proportional rate of 32.65 Mbps, the total weight on the logical interface is 257 and the WFQ accuracy will be the same.

When using the IOC (40x1GE IOC or 4x10GE IOC) on a Juniper Networks device, there are circumstances when you should configure excess bandwidth sharing and minimum logical interface shaping.

## Excess Bandwidth Sharing Proportional Rates

To determine a good excess bandwidth-sharing proportional rate to configure, choose the largest CIR (guaranteed rate) among all the logical interfaces (units). If the logical units have PIRs (shaping rates) only, then choose the largest PIR rate. However, this is not ideal if a single logical interface has a large WRR rate. This method can skew the distribution of traffic across the queues of the other logical interfaces. To avoid this issue, set the excess bandwidth-sharing proportional rate to a lower value on the logical interfaces where the WRR rates are concentrated. This improves the bandwidth sharing accuracy among the queues on the same logical interface. However, the excess bandwidth sharing for the logical interface with the larger WRR rate is no longer proportional.

As an example, consider five logical interfaces on the same physical port, each with four queues, all with only PIRs configured and no CIRs. The WRR rate is the same as the PIR for the logical interface. The excess bandwidth is shared proportionally with a rate of 40 Mbps. The traffic control profiles for the logical interfaces are shown in [Table 129](#).

Table 129: Example Shaping Rates and WFQ Weights

| Shaping Rate     | Configured Queue Transmit Rate | WFQ Weight        | Total Weights |
|------------------|--------------------------------|-------------------|---------------|
| (Unit 0) 10 Mbps | (95, 0, 0, 5)                  | (60, 0, 0, 3)     | 63            |
| (Unit 1) 20 Mbps | (25, 25, 25, 25)               | (32, 32, 32, 32)  | 128           |
| (Unit 2) 40 Mbps | (40, 30, 20, 10)               | (102, 77, 51, 26) | 255           |

Table 129: Example Shaping Rates and WFQ Weights (*continued*)

| Shaping Rate      | Configured Queue Transmit Rate | WFQ Weight        | Total Weights |
|-------------------|--------------------------------|-------------------|---------------|
| (Unit 3) 200 Mbps | (70, 10, 10, 10)               | (179, 26, 26, 26) | 255           |
| (Unit 4) 2 Mbps   | (25, 25, 25, 25)               | (5, 5, 5, 5)      | 20            |

Even though the maximum transmit rate for the queue on logical interface unit 3 is 200 Mbps, the excess bandwidth-sharing proportional rate is kept at a much lower value. Within a logical interface, this method provides a more accurate distribution of weights across queues. However, the excess bandwidth is now shared equally between unit 2 and unit 3 (total weights = 255).

## Calculated Weights Mapped to Hardware Weights

The calculated weight in a traffic control profile is mapped to hardware weight, but the hardware only supports a limited WFQ profile. The weights are rounded to the nearest hardware weight according to the values in [Table 130](#).

Table 130: Rounding Configured Weights to Hardware Weights

| Traffic Control Profile Number | Number of Traffic Control Profiles | Weights                  | Maximum Error |
|--------------------------------|------------------------------------|--------------------------|---------------|
| 1–16                           | 16                                 | 1–16 (interval of 1)     | 50.00%        |
| 17–29                          | 13                                 | 18–42 (interval of 2)    | 6.25%         |
| 30–35                          | 6                                  | 45–60 (interval of 3)    | 1.35%         |
| 36–43                          | 8                                  | 64–92 (interval of 4)    | 2.25%         |
| 44–49                          | 6                                  | 98–128 (interval of 6)   | 3.06%         |
| 50–56                          | 7                                  | 136–184 (interval of 8)  | 3.13%         |
| 57–62                          | 6                                  | 194–244 (interval of 10) | 2.71%         |
| 63–63                          | 1                                  | 255–255 (interval of 11) | 2.05%         |

As shown in [Table 130](#), the calculated weight of 18.9 is mapped to a hardware weight of 18, because 18 is closer to 18.9 than 20 (an interval of 2 applies in the range of 18 to 42).

## Weight Allocation with Only Shaping Rates or Unshaped Logical Interfaces

Logical interfaces with only shaping rates (PIRs) or unshaped logical interfaces (units) are given a weight of 10. A logical interface with a small guaranteed rate (CIR) might get an overall weight less than 10. To allocate a higher share of the excess bandwidth to logical interfaces with a small guaranteed rate in comparison to the logical interfaces with only shaping rates configured, a minimum weight of 20 is given to the logical interfaces with guaranteed rates configured.

For example, a logical interface configuration with five units is shown in [Table 131](#).

**Table 131: Allocating Weights with PIR and CIR on Logical Interfaces**

| Logical Interface (Unit) | Traffic Control Profile  | WRR Percentages | Weights         |
|--------------------------|--------------------------|-----------------|-----------------|
| Unit 1                   | PIR 100 Mbps             | 95, 0, 0, 5     | 10, 1, 1, 1     |
| Unit 2                   | CIR 20 Mbps              | 25, 25, 25, 25  | 64, 64, 64, 64  |
| Unit 3                   | PIR 40 Mbps, CIR 20 Mbps | 50, 30, 15, 5   | 128, 76, 38, 13 |
| Unit 4                   | Unshaped                 | 95, 0, 0, 5     | 10, 1, 1, 1     |
| Unit 5                   | CIR 1 Mbps               | 95, 0, 0, 5     | 10, 1, 1, 1     |

The weights for these units are calculated as follows:

- The excess bandwidth-sharing proportional rate is the maximum CIR among all the logical interfaces which is 20 Mbps (unit 2).
- Unit 1 has a PIR and unit 4 is unshaped. The weight for these units is 10.
- The weight for unit 1 queue 0 is 9.5 (10 x 95%), which translates to a hardware weight of 10.
- The weight for unit 1 queue 1 is 0 (0 x 0%) but though the weight is zero, a weight of 1 is assigned to give minimal bandwidth to queues with zero WRR.
- Unit 5 has a very small CIR (1 Mbps), and a weight of 20 is assigned to units with a small CIR.

- The weight for unit 5 queue 0 is 19 (20 x 95%), which translates to a hardware weight of 18.
- Unit 3 has a CIR of 20 Mbps, which is the same as the excess bandwidth-sharing proportional rate, so it has a total weight of 255.
- The weight of unit 3 queue 0 is 127.5 (255 x 50%), which translates to a hardware weight of 128.

## Shared Bandwidth Among Logical Interfaces

As a simple example showing how bandwidth is shared among the logical interfaces, assume that all traffic is sent on queue 0. Assume also that there is a 40-Mbps load on all of the logical interfaces. Configuration details are shown in [Table 132](#).

**Table 132: Example of Shared Bandwidth Among Logical Interfaces**

| Logical Interface (Unit) | Traffic Control Profile  | WRR Percentages | Weights         |
|--------------------------|--------------------------|-----------------|-----------------|
| Unit 1                   | PIR 100 Mbps             | 95, 0, 0, 5     | 10, 1, 1, 1     |
| Unit 2                   | CIR 20 Mbps              | 25, 25, 25, 25  | 64, 64, 64, 64  |
| Unit 3                   | PIR 40 Mbps, CIR 20 Mbps | 50, 30, 15, 5   | 128, 76, 38, 13 |
| Unit 4                   | Unshaped                 | 95, 0, 0, 5     | 10, 1, 1, 1     |

When the port is shaped at 40 Mbps, because units 2 and 3 have a guaranteed rate (CIR) configured, both units 2 and 3 get 20 Mbps of shared bandwidth.

When the port is shaped at 100 Mbps, because units 2 and 3 have a guaranteed rate (CIR) configured, each of them can transmit 20 Mbps. On units 1, 2, 3, and 4, the 60 Mbps of excess bandwidth is shaped according to the values shown in [Table 133](#).

**Table 133: First Example of Bandwidth Sharing**

| Logical Interface (Unit) | Calculation                                         | Bandwidth  |
|--------------------------|-----------------------------------------------------|------------|
| 1                        | $10 / (10 + 64 + 128 + 10) \times 60 \text{ Mbps}$  | 2.83 Mbps  |
| 2                        | $64 / (10 + 64 + 128 + 10) \times 60 \text{ Mbps}$  | 18.11 Mbps |
| 3                        | $128 / (10 + 64 + 128 + 10) \times 60 \text{ Mbps}$ | 36.22 Mbps |

Table 133: First Example of Bandwidth Sharing (*continued*)

| Logical Interface (Unit) | Calculation                                | Bandwidth |
|--------------------------|--------------------------------------------|-----------|
| 4                        | $10 (10+64+128+10) \times 60 \text{ Mbps}$ | 2.83 Mbps |

However, unit 3 only has 20 Mbps extra (PIR and CIR) configured. This means that the leftover bandwidth of 16.22 Mbps (36.22 Mbps – 20 Mbps) is shared among units 1, 2, and 4. This is shown in [Table 134](#).

Table 134: Second Example of Bandwidth Sharing

| Logical Interface (Unit) | Calculation                                     | Bandwidth  |
|--------------------------|-------------------------------------------------|------------|
| 1                        | $10 / (10+64+128+10) \times 16.22 \text{ Mbps}$ | 1.93 Mbps  |
| 2                        | $64 / (10+64+128+10) \times 16.22 \text{ Mbps}$ | 12.36 Mbps |
| 4                        | $10 (10+64+128+10) \times 16.22 \text{ Mbps}$   | 1.93 Mbps  |

Finally, [Table 135](#) shows the resulting allocation of bandwidth among the logical interfaces when the port is configured with a 100-Mbps shaping rate.

Table 135: Final Example of Bandwidth Sharing

| Logical Interface (Unit) | Calculation                       | Bandwidth  |
|--------------------------|-----------------------------------|------------|
| 1                        | 2.83 Mbps + 1.93 Mbps             | 4.76 Mbps  |
| 2                        | 20 Mbps + 18.11 Mbps + 12.36 Mbps | 50.47 Mbps |
| 3                        | 20 Mbps + 20 Mbps                 | 40 Mbps    |
| 4                        | 2.83 Mbps + 1.93 Mbps             | 4.76 Mbps  |

## Example: Configuring Class-of-Service Schedulers

This example shows how to configure CoS schedulers on a device.

- [Requirements on page 1458](#)
- [Overview on page 1458](#)

- [Configuration on page 1459](#)
- [Verification on page 1461](#)

## Requirements

Before you begin, determine the buffer size allocation method to use. See [“Scheduler Buffer Size Overview” on page 1461](#).

## Overview

An individual device interface has multiple queues assigned to store packets temporarily before transmission. To determine the order in which to service the queues, the device uses a round-robin scheduling method based on priority and the queue's weighted round-robin (WRR) credits. Junos OS schedulers allow you to define the priority, bandwidth, delay buffer size, rate control status, and RED drop profiles to be applied to a particular queue for packet transmission.

You configure schedulers to assign resources, priorities, and drop profiles to output queues. By default, only queues 0 and 3 have resources assigned.

**NOTE:** Juniper Network devices support hierarchical schedulers, including per-unit schedulers.

In this example, you configure a best-effort scheduler called `be-scheduler`. You set the priority as low and the buffer size to 40. You set the `be-scheduler` transmit-rate remainder percentage to 40. You configure an expedited forwarding scheduler called `ef-scheduler` and set the priority as high and the buffer size to 10. You set the `ef-scheduler` transmit-rate remainder percentage to 50.

Then you configure an assured forwarding scheduler called `af-scheduler` and set the priority as high and buffer size to 45. You set an assured forwarding scheduler transmit rate to 45. You then configure a drop profile map for assured forwarding as low and high priority. (DiffServ can have a RED drop profile associated with assured forwarding.)

Finally, you configure a network control scheduler called `nc-scheduler` and set the priority as low and buffer size to 5. You set a network control scheduler transmit rate to 5.

[Table 136](#) shows the schedulers created in this example.

**Table 136: Sample Schedulers**

| Scheduler                 | For CoS Traffic Type         | Assigned Priority | Allocated Portion of Queue Buffer | Allocated Portion of Remainder (Transmit Rate) |
|---------------------------|------------------------------|-------------------|-----------------------------------|------------------------------------------------|
| <code>be-scheduler</code> | Best-effort traffic          | Low               | 40 percent                        | 40 percent                                     |
| <code>ef-scheduler</code> | Expedited forwarding traffic | High              | 10 percent                        | 50 percent                                     |

Table 136: Sample Schedulers (*continued*)

| Scheduler    | For CoS Traffic Type       | Assigned Priority | Allocated Portion of Queue Buffer | Allocated Portion of Remainder (Transmit Rate) |
|--------------|----------------------------|-------------------|-----------------------------------|------------------------------------------------|
| af-scheduler | Assured forwarding traffic | High              | 45 percent                        | —                                              |
| nc-scheduler | Network control traffic    | Low               | 5 percent                         | —                                              |

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service schedulers be-scheduler priority low buffer-size percent 40
set class-of-service schedulers be-scheduler transmit-rate remainder 40
set class-of-service schedulers ef-scheduler priority high buffer-size percent 10
set class-of-service schedulers ef-scheduler transmit-rate remainder 50
set class-of-service schedulers af-scheduler priority high buffer-size percent 45
set class-of-service schedulers af-scheduler transmit-rate percent 45
set class-of-service schedulers af-scheduler drop-profile-map loss-priority low protocol
 any drop-profile af-normal
set class-of-service schedulers af-scheduler drop-profile-map loss-priority high protocol
 any drop-profile af-with-PLP
set class-of-service schedulers nc-scheduler priority low buffer-size percent 5
set class-of-service schedulers nc-scheduler transmit-rate percent 5
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure CoS schedulers:

1. Configure a best-effort scheduler.  

```
[edit]
user@host# edit class-of-service schedulers be-scheduler
```
2. Specify a best-effort scheduler priority and buffer size.  

```
[edit class-of-service schedulers be-scheduler]
user@host# set priority low
user@host# set buffer-size percent 40
```
3. Configure a remainder option for a best-effort scheduler transmit rate.  

```
[edit class-of-service schedulers be-scheduler]
user@host# set transmit-rate remainder 40
```
4. Configure an expedited forwarding scheduler.  

```
[edit]
user@host# edit class-of-service schedulers ef-scheduler
```

5. Specify an expedited forwarding scheduler priority and buffer size.  

```
[edit class-of-service schedulers ef-scheduler]
user@host# set priority high
user@host# set buffer-size percent 10
```
6. Configure a remainder option for an expedited forwarding scheduler transmit rate.  

```
[edit class-of-service schedulers ef-scheduler]
user@host# set transmit-rate remainder 50
```
7. Configure an assured forwarding scheduler.  

```
[edit]
user@host# edit class-of-service schedulers af-scheduler
```
8. Specify an assured forwarding scheduler priority and buffer size.  

```
[edit class-of-service schedulers af-scheduler]
user@host# set priority high
user@host# set buffer-size percent 45
```
9. Configure an assured forwarding scheduler transmit rate.  

```
[edit class-of-service schedulers af-scheduler]
user@host# set transmit-rate percent 45
```
10. Configure a drop profile map for assured forwarding low and high priority.  

```
[edit class-of-service schedulers af-scheduler]
user@host# set drop-profile-map loss-priority low protocol any drop-profile
af-normal
user@host# set drop-profile-map loss-priority high protocol any drop-profile
af-with-PLP
```
11. Configure a network control scheduler.  

```
[edit]
user@host# edit class-of-service schedulers nc-scheduler
```
12. Specify a network control scheduler priority and buffer size.  

```
[edit class-of-service schedulers nc-scheduler]
user@host# set priority low
user@host# set buffer-size percent 5
```
13. Configure a network control scheduler transmit rate.  

```
[edit class-of-service schedulers nc-scheduler]
user@host# set transmit-rate percent 5
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
schedulers {
 be-scheduler {
 transmit-rate remainder 40;
 buffer-size percent 40;
```

```
priority low;
}
ef-scheduler {
 transmit-rate remainder 50;
 buffer-size percent 10;
priority high;
}
af-scheduler {
 transmit-rate percent 45;
 buffer-size percent 45;
 priority high;
 drop-profile-map loss-priority low protocol any drop-profile af-normal;
 drop-profile-map loss-priority high protocol any drop-profile af-with-PLP;
}
nc-scheduler {
 transmit-rate percent 5;
 buffer-size percent 5;
 priority low;
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Schedulers Configuration on page 1461](#)

---

### Verifying Schedulers Configuration

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>               | Verify that the schedulers are configured properly.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Action</b>                | From operational mode, enter the <b>show class-of-service</b> command.                                                                                                                                                                                                                                                                                                                                                                                 |

## Scheduler Buffer Size Overview

Large bursts of traffic from faster interfaces can cause congestion and dropped packets on slower interfaces that have small delay buffers. For example, a Juniper Networks device operating at the edge of the network can drop a portion of the burst traffic it receives on a channelized T1/E1 interface from a Fast Ethernet or Gigabit Ethernet interface on a router at the network core. On Juniper Networks devices, large delay buffers can be configured for both channelized T1/E1 and nonchannelized T1/E1 interfaces.

To ensure that traffic is queued and transmitted properly on slower interfaces, you can configure a buffer size larger than the default maximum.

This section contains the following topics:

- [Maximum Delay Buffer Sizes Available to Channelized T1/E1 Interfaces on page 1462](#)
- [Maximum Delay Buffer Size for vSRX Interfaces on page 1463](#)
- [Delay Buffer Size Allocation Methods on page 1463](#)
- [Delay Buffer Sizes for Queues on page 1464](#)

### Maximum Delay Buffer Sizes Available to Channelized T1/E1 Interfaces

When you enable the large delay buffer feature on interfaces, a larger buffer is available for allocation to scheduler queues. The maximum delay buffer size that is available for an interface depends on the maximum available delay buffer time and the speed of the interface as shown in [Table 137](#).

The default values are as follows:

- Clear-channel interface—The default delay buffer time is 500,000 microseconds (0.5 s).
- NxDS0 interface—The default delay buffer time is 1,200,000 microseconds (1.2 s).

**Table 137: Maximum Available Delay Buffer Time by Channelized Interface and Rate**

| Effective Line Rate | Maximum Available Delay Buffer Time |
|---------------------|-------------------------------------|
| < 4xDS0             | 4,000,000 microseconds (4 s)        |
| < 8xDS0             | 2,000,000 microseconds (2 s)        |
| < 16xDS0            | 1,000,000 microseconds (1 s)        |
| <= 32xDS0           | 500,000 microseconds (0.5 s)        |
| <= 10 mbps          | 400,000 microseconds (0.4 s)        |
| <= 20 mbps          | 300,000 microseconds (0.3 s)        |
| <= 30 mbps          | 200,000 microseconds (0.2 s)        |
| <= 40 mbps          | 150,000 microseconds (0.15 s)       |

You can calculate the maximum delay buffer size available for an interface, with the following formula:

$$\text{interface speed} \times \text{maximum delay buffer time} = \text{maximum available delay buffer size}$$

For example, the following maximum delay buffer sizes are available to 1xDS0 and 2xDS0 interfaces:

**1xDSO**—64 Kbps x 4 s = 256 Kb (32 KB)

**2xDSO**—128 Kbps x 4 s = 512 Kb (64 KB)

If you configure a delay buffer size larger than the maximum, the system allows you to commit the configuration but displays a system log warning message and uses the default buffer size setting instead of the configured maximum setting.

## Maximum Delay Buffer Size for vSRX Interfaces

For a vSRX virtual machine, 1 Gbps interfaces have a default delay buffer time of 1 second, a maximum buffer time of 32 seconds, and a maximum buffer size of 128 MB. Use the following CLI command to set the maximum delay buffer time for a scheduler:

```
set class-of-service schedulers be-scheduler buffer-size temporal 32m
```

On a logical vSRX interface, the delay buffer size for a queue that does not have a specific shaping rate acts as a guaranteed minimum buffer size, and the queue is allowed to grow without any packet drops if the queue size is less than the guaranteed buffer size.

The sum of the guaranteed delay buffer sizes for all the queues acts as a pool that can be shared among the queues that do not have a specific shaping rate.

**NOTE:** The delay buffers are used to control the size of the queues, but do not represent actual memory. The packet buffer pool contains the actual memory used to store packets.

Packets are tail-dropped (100% probability) from the queue if:

- The total buffer limit would be exceeded.
- The queue size would exceed the total free buffer size.
- The packet buffer pool is less than 25% free and the queue exceeds the guaranteed minimum buffer size.
- The packet buffer pool is only 5% free (or less).

Packets also can be dropped by a RED profile (RED-dropped) if the queue size exceeds the guaranteed buffer size. The queue size will be restricted to be less than or equal to the free shared buffers available.

## Delay Buffer Size Allocation Methods

You can specify delay buffer sizes for each queue using schedulers. The queue buffer can be specified as a period of time (microseconds) or as a percentage of the total buffer or as the remaining buffer. [Table 138](#) shows different methods that you can specify for buffer allocation in queues.

Table 138: Delay Buffer Size Allocation Methods

| Buffer Size Allocation Method | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Percentage                    | A percentage of the total buffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Temporal                      | <p>A period of time, value in microseconds. When you configure a temporal buffer, you must also configure a transmit rate. The system calculates the queue buffer size by multiplying the available bandwidth of the interface times the configured temporal value and transmit rate.</p> <p>When you specify a temporal method, the drop profile is assigned a static buffer and the system starts dropping packets once the queue buffer size is full. By default, the other buffer types are assigned dynamic buffers that use surplus transmission bandwidth to absorb bursts of traffic.</p>     |
| Remainder                     | <p>The remaining buffer available. The remainder is the percentage buffer that is not assigned to other queues. For example, if you assign 40 percent of the delay buffer to queue 0, allow queue 3 to keep the default allotment of 5 percent, and assign the remainder to queue 7, then queue 7 uses approximately 55 percent of the delay buffer.</p> <p>Optionally, you can specify the percentage of the remainder to be used for allocating the buffer size of the scheduler on a prorated basis. If the remainder percentage is not specified, the remainder value will be shared equally.</p> |

## Delay Buffer Sizes for Queues

You specify delay buffer sizes for queues using schedulers. The system calculates the buffer size of a queue based on the buffer allocation method you specify for it in the scheduler. See [Table 138](#) for different buffer allocation methods and [Table 139](#) for buffer size calculations.

Table 139: Delay Buffer Allocation Method and Queue Buffer

| Buffer Size Allocation Method | Queue Buffer Calculation                                                                                            | Example                                                                                                                                                                                                                                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Percentage                    | <i>available interface bandwidth x configured buffer size percentage x maximum delay buffer time = queue buffer</i> | <p>Suppose you configure a queue on a 1xDS0 interface to use 30 percent of the available delay buffer size. The system uses the maximum available delay buffer time (4 seconds) and allocates the queue 9600 bytes of delay buffer:</p> <p>64 Kbps x 0.3 x 4 s = 76,800 bits = 9,600 bytes</p> |

Table 139: Delay Buffer Allocation Method and Queue Buffer (*continued*)

| Buffer Size Allocation Method | Queue Buffer Calculation                                                                                                    | Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Temporal                      | <i>available interface bandwidth x configured transmit rate percentage x configured temporal buffer size = queue buffer</i> | <p>Suppose you configure a queue on a 1xDS0 interface to use 300,000,000 microseconds (3 seconds) of delay buffer, and you configure the transmission rate to be 20 percent. The queue receives 4800 bytes of delay buffer:</p> <p>64 Kbps x 0.2 x 3 s=38,400 bits=4,800 bytes</p> <p>If you configure a temporal value that exceeds the maximum available delay buffer time, the queue is allocated the buffer remaining after buffers are allocated for the other queues. Suppose you configure a temporal value of 6,000,000 microseconds on a 1xDS0 interface. Because this value exceeds the maximum allowed value of 4,000,000 microseconds, the queue is allocated the remaining delay buffer.</p> |

When you specify the buffer size as a percentage, the system ignores the transmit rate and calculates the buffer size based only on the buffer size percentage.

### Example: Configuring a Large Delay Buffer on a Channelized T1 Interface

This example shows how to configure a large delay buffer on a channelized T1 interface to help slower interfaces avoid congestion and packet dropping when they receive large bursts of traffic.

- [Requirements on page 1465](#)
- [Overview on page 1466](#)
- [Configuration on page 1466](#)
- [Verification on page 1467](#)

#### Requirements

Before you begin, enable the large buffer feature on the channelized T1/E1 PIM and then configure a buffer size for each queue in the CoS scheduler. See “[Scheduler Buffer Size Overview](#)” on page 1461.

## Overview

On devices, you can configure large delay buffers on channelized T1/E1 interfaces. Each channelized T1/E1 interface can be configured as a single clear channel, or for channelized (NxDSO) operation, where N denotes channels 1 to 24 for a T1 interface and channels 1 to 32 for an E1 interface.

In this example, you specify a queue buffer of 30 percent in scheduler **be-scheduler** and associate the scheduler to a defined forwarding class **be-class** using scheduler map **large-buf-sched-map**. Finally, you apply the scheduler map to channelized T1 interface **t1-3/0/0**.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set chassis fpc 3 pic 0 q-pic-large-buffer
set class-of-service schedulers be-scheduler buffer-size percent 30
set class-of-service scheduler-maps large-buf-sched-map forwarding-class be-class
scheduler be-scheduler
set class-of-service interfaces t1-3/0/0 unit 0 scheduler-map large-buf-sched-map
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a large delay buffer on a channelized T1 interface:

1. Enable the large buffer size feature on the channelized T1 interface.  

```
[edit]
user@host# edit chassis
user@host# set fpc 3 pic 0 q-pic-large-buffer
```
2. Create best-effort traffic and specify a buffer size.  

```
[edit]
user@host# edit class-of-service
user@host# set schedulers be-scheduler buffer-size percent 30
```
3. Configure the scheduler map to associate schedulers with defined forwarding classes.  

```
[edit class-of-service]
user@host# set scheduler-maps large-buf-sched-map forwarding-class be-class
scheduler be-scheduler
```
4. Apply the scheduler map to the channelized T1 interface.  

```
[edit class-of-service]
user@host# set interfaces t1-3/0/0 unit 0 scheduler-map large-buf-sched-map
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** and **show chassis** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
interfaces {
 t1-3/0/0 {
 unit 0 {
 scheduler-map large-buf-sched-map;
 }
 }
}
scheduler-maps {
 large-buf-sched-map {
 forwarding-class be-class scheduler be-scheduler;
 }
}
schedulers {
 be-scheduler {
 buffer-size percent 30;
 }
}
[edit]
user@host# show chassis
fpc 3 {
 pic 0 {
 q-pic-large-buffer;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Large Delay Buffers Configuration on page 1467](#)

### Verifying Large Delay Buffers Configuration

**Purpose** Verify that the large delay buffers are configured properly.

**Action** From configuration mode, enter the **show class-of-service** and **show chassis** commands.

- Related Documentation**
- [Schedulers Overview on page 1445](#)
  - [Default Scheduler Settings on page 1450](#)
  - [Example: Configuring Class-of-Service Schedulers on page 1457](#)
  - [Example: Configuring and Applying Scheduler Maps on page 1472](#)
  - [Transmission Scheduling Overview on page 1451](#)

## Configuring Large Delay Buffers in CoS

You can configure very large delay buffers using the **buffer-size-temporal** command combined with the **q-pic-large-buffer** command. The **buffer-size temporal** option in combination with **q-pic-large-buffer** can create extra-large delay buffer allocations for one or several queues on an interface.

**NOTE:** If the configured buffer size is too low, the buffer size for the forwarding class defaults to 9192 and the following log message is displayed: “fwdd\_cos\_set\_delay\_bandwidth:queue:16 delay buffer size (1414) too low, setting to default 9192.”

### Configuring Large Delay Buffers

The following configuration applies to the examples that follow:

1. Configure two VLANs (one ingress, one egress) on one interface. No interface shaping rate is initially defined for this configuration.

```
[edit]
set interfaces ge-0/0/3 per-unit-scheduler
set interfaces ge-0/0/3 vlan-tagging
set interfaces ge-0/0/3 unit 102 vlan-id 102
set interfaces ge-0/0/3 unit 102 family inet address 1.1.102.2/24
set interfaces ge-0/0/3 unit 201 vlan-id 201
set interfaces ge-0/0/3 unit 201 family inet address 2.2.201.2/24
set routing-options static route 33.33.1.1/32 next-hop 2.2.201.3
```

2. Enable the **q-pic-large-buffer** option on the same PIC, in addition to the **buffer-size temporal** option on the queue, to create a large buffer on the queue:

```
[edit]
set chassis fpc 0 pic 0 q-pic-large-buffer
```

**NOTE:** The CLI does not provide a warning when you use **buffer-size temporal** without **q-pic-large-buffer**. When you use **buffer-size temporal**, verify that the configuration also includes the **q-pic-large-buffer** command.

3. Define four forwarding-classes (queue names) for the four queues:

```
[edit]
set class-of-service forwarding-classes queue 0 be-Queue0
set class-of-service forwarding-classes queue 1 video-Queue1
set class-of-service forwarding-classes queue 2 voice-Queue2
set class-of-service forwarding-classes queue 3 nc-Queue3
```

4. Configure the forwarding classes (queue names) included in a scheduler map, applied to the egress VLAN:

```
[edit]
set class-of-service interfaces ge-0/0/3 unit 201 scheduler-map schedMapM
```

```

set class-of-service scheduler-maps schedMapM forwarding-class be-Queue0
 scheduler be-Scheduler0
set class-of-service scheduler-maps schedMapM forwarding-class video-Queue1
 scheduler video-Scheduler1
set class-of-service scheduler-maps schedMapM forwarding-class voice-Queue2
 scheduler voice-Scheduler2
set class-of-service scheduler-maps schedMapM forwarding-class nc-Queue3
 scheduler nc-Scheduler3

```

5. Set the queue priorities. Only queue priorities are initially defined, not transmit rates or buffer sizes.

```

[edit]
set class-of-service schedulers be-Scheduler0 priority low
set class-of-service schedulers video-Scheduler1 priority medium-low
set class-of-service schedulers voice-Scheduler2 priority medium-high
set class-of-service schedulers nc-Scheduler3 priority high

```

#### Example: Simple Configuration Using Four Queues

This configuration allocates 12,500,000 bytes of buffer for each of the four queues. To avoid exceeding the limits of the delay buffer calculation, this initial example has no interface shaping rate, scheduler transmit rate, or scheduler buffer size percent configuration.

1. Specify the maximum 4-second delay buffer on each of the four queues:

```

[edit]
set class-of-service schedulers be-Scheduler0 buffer-size temporal 4m
set class-of-service schedulers video-Scheduler1 buffer-size temporal 4m
set class-of-service schedulers voice-Scheduler2 buffer-size temporal 4m
set class-of-service schedulers nc-Scheduler3 buffer-size temporal 4m

```

Specifying **buffer-size temporal** on some or all queues uses implicit (default) or explicit transmit rate percentages as the buffer-size percentages of the temporal values for those queues. Because there are no explicitly specified transmit rate percentages, divide 100 percent by the number of configured queues (queues with schedulers configured in the scheduler map) to get the implicit (default) per-queue transmit rate percentages. Each queue gets an implicit (default) transmit rate of  $100\% / 4 = 25\%$ .

In this example, specifying the maximum 4-second delay on each queue, with no shaping rate on the interface and implicit (default) per-queue transmit rates of 25 percent, the total buffer for all temporal 4m queues on an interface = 4 seconds \* 100,000,000 maximum interface bps / 8 bits/byte = 4 seconds \* 12,500,000 bytes = 50,000,000 bytes. Each queue specifying temporal 4m gets  $25\% * 50,000,000 = 12,500,000$  bytes.

2. Add a shaping rate of 4 Mbps to the interface:

```

[edit]
set class-of-service interfaces ge-0/0/3 unit 201 shaping-rate 4m

```

The total buffer for all temporal 4m queues on an interface = 4 sec \* 4,000,000 bps shaping-rate / 8 bits/byte = 4 sec \* 500,000 bytes = 2,000,000 bytes. Therefore, each queue specifying temporal 4m receives  $25\% * 2,000,000 = 500,000$  bytes.

When using **buffer-size temporal** on any interface queues, if you also use the **transmit-rate percent** command, or the **buffer-size percent** command, or both commands, on any of the interface queues, the buffer size calculations become more complex and the limits of available queue depth might be reached. If the configuration attempts to exceed the available memory, then at commit time two system log messages appear in the `/var/log/messages` file, the interface class-of-service configuration is ignored, and the interface class-of-service configuration reverts to the two-queue defaults:

```
Mar 11 11:02:10.239 e1ma-n4 e1ma-n4 COSMAN_FWDD: queue mem underflow for ge-0/0/3
Mar 11 11:02:10.240 e1ma-n4 e1ma-n4 cosman_compute_install_sched_params: Failed
to compute scheduler params for ge-0/0/3.Hence retaining defaults
```

When configuring **buffer-size temporal** along with **transmit-rate percent** or **buffer-size percent**, or both, you must monitor the system log to see whether the available queue depth limit has been reached.

#### Example: Using **buffer-size temporal** with Explicit **transmit-rate percent** Commands

To add explicit transmit rates to all four queues:

```
[edit]
set class-of-service schedulers be-Scheduler0 transmit-rate percent 10
set class-of-service schedulers video-Scheduler1 transmit-rate percent 25
set class-of-service schedulers voice-Scheduler2 transmit-rate percent 25
set class-of-service schedulers nc-Scheduler3 transmit-rate percent 40
```

For example, if an interface is shaped to 4 Mbps, the transmit rate percentage of 10 for a queue means that the bandwidth share for the specific queue is 0.4 Mbps. The queues are allocated portions of the 2,000,000 bytes of total buffer available for temporal queues on this interface, proportionally to their transmit rates. The four queues get 200,000, 500,000, 500,000, and 800,000 bytes of delay buffer, respectively.

To avoid exceeding the queue depth limits and triggering system log messages and default configuration behavior, when configuring queues with **buffer-size temporal** and **transmit rate percent** and other (non-temporal) queues with **buffer-size percent**, the following configuration rule must be followed: When one or more queues on an interface are configured with **buffer-size temporal**, the sum of the temporal queues explicitly configured transmit rate percentages plus other non-temporal queues explicitly configured buffer size percentages must not exceed 100 percent.

If the total of the temporal queues transmit rate percentages and the non-temporal queues buffer-size percentages exceeds 100 percent, the **queue mem underflow** and **Failed to compute scheduler params** system log messages appear in the messages log, the explicitly configured CLI CoS configuration for the interface is ignored, and the interface reverts to a two-queue default CoS configuration.

When **buffer-size temporal** is specified on a queue, if **transmit-rate percent** is also configured on the same queue, the queue depth configured is based on the fractional bandwidth for the queue as obtained by the specified **transmit-rate percent**.

In addition to temporal delay times specified for one or more queues using buffer size temporal, there is another delay time automatically computed for the entire interface.

This interface delay time is distributed across all non-temporal queues, proportionally to their implicit (default) or explicit transmit-rate percentages. If **q-pic-large-buffer** is not enabled, the interface delay time defaults to 100 ms. As shown in Table 140, when **q-pic-large-buffer** is enabled, interface delay time is calculated according to configured shaping rate for the interface. Because the shaping-rate configured in the example above was 4 Mbps (> 2,048,000 bps), the interface delay time for the configuration is 100 msec.

**Table 140: Interface Delay Times Enabled By q-pic-large-buffer**

| Configured Shaping Rate (bps) | Interface Delay Time (msec) Used for Non-Temporal Queues with q-pic-large-buffer Enabled | Default Delay Time Used (msec) Without q-pic-large-buffer |
|-------------------------------|------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| 64,000-255,999                | 4000                                                                                     | 100                                                       |
| 256,000 - 511,999             | 2000                                                                                     | 100                                                       |
| 512,000 - 102,3999            | 1000                                                                                     | 100                                                       |
| 1,024,000 - 2,047,999         | 500                                                                                      | 100                                                       |
| >= 2,048,000                  | 100                                                                                      | 100                                                       |

This example properly computes the delay buffer limits on both temporal and non-temporal queues:

1. Substitute **buffer-size percent** for **buffer-size temporal** on queues 0 and 1:

```
[edit]
delete class-of-service schedulers be-Scheduler0 buffer-size temporal 4m
delete class-of-service schedulers video-Scheduler1 buffer-size temporal 4m
set class-of-service schedulers be-Scheduler0 buffer-size percent 10
set class-of-service schedulers video-Scheduler1 buffer-size percent 25
```

This deletes the requirement for hard-specified 4 seconds of buffering and replaces it with a proportional limit of 10 percent (or 25 percent) of the total interface delay time for the non-temporal queues. In both cases, the queue depth is calculated based on the share of the interface bandwidth for the specific queues. Total Interface Non-Temporal Queue Memory = shaping-rate \* Interface delay time (Table 1) = 4 Mbps \* 0.1 seconds = 500,000 bytes per second \* 0.1 seconds = 50,000 bytes, therefore queues 0 and 1 get 10% \* 50,000 = 5000 bytes and 25% \* 50,000 = 12,500 bytes of delay buffer, respectively.

2. Configure **buffer-size temporal** on queues 2 and 3:

```
[edit]
set class-of-service schedulers voice-Scheduler2 buffer-size temporal 4m
set class-of-service schedulers voice-Scheduler2 transmit-rate percent 25
set class-of-service schedulers nc-Scheduler3 buffer-size temporal 4m
set class-of-service schedulers nc-Scheduler3 transmit-rate percent 40
```

Queues 2 and 3 still get 500,000 and 800,000 bytes of delay buffer, respectively, as previously calculated. This configuration obeys the rule that the sum of the temporal

queues transmit rate percentages (25% + 40% = 65%), plus the non-temporal queues buffer size percentages (10% + 25% = 35%) do not exceed 100% (65% + 35% <= 100%).

The following example exceeds the delay buffer limit, triggering the system log messages and the default, two-queue class-of-service behavior.

Increase the buffer-size percentage from 25 percent to 26 percent for non-temporal queue 1:

```
[edit]
set class-of-service schedulers video-Scheduler1 buffer-size percent 26
```

This violates the configuration rule that the sum of the non-temporal queues buffer-size percentages (10% + 26% = 36%), plus the temporal queues transmit rate percentages (25% + 40% = 65%) now exceed 100% (36% + 65% = 101%). Therefore, the following two system log messages appear in the `/var/log/messages` file:

```
Mar 23 18:08:23 e1ma-n4 e1ma-n4 COSMAN_FWDD: %PFE-3: queue mem underflow for
ge-0/0/3 q_num(3)
Mar 23 18:08:23 e1ma-n4 e1ma-n4 cosman_compute_install_sched_params: %PFE-3:
Failed to compute scheduler params for ge-0/0/3.Hence retaining defaults
```

When the delay buffer limits are exceeded, the CLI-configured class-of-service settings are not used and the default class-of-service configuration (the default scheduler-map) is assigned to the interface. This uses two queues: the forwarding-class best-effort (queue 0) has transmit rate percent 95 and buffer-size percent 95 and the forwarding-class network-control (queue 3) has the transmit rate percent 5 and buffer-size percent 5.

```
queue 0: 1,187,500 Bytes
queue 1: 9,192 Bytes
queue 2: 9,192 Bytes
queue 3: 62,500 Bytes
```

## Example: Configuring and Applying Scheduler Maps

This example shows how to configure and apply a scheduler map to a device's interface.

- [Requirements on page 1472](#)
- [Overview on page 1473](#)
- [Configuration on page 1473](#)
- [Verification on page 1475](#)

## Requirements

Before you begin:

- Create and configure the forwarding classes. See [“Example: Configuring Forwarding Classes” on page 1427](#).
- Create and configure the schedulers. See [“Example: Configuring Class-of-Service Schedulers” on page 1457](#).

## Overview

After you define a scheduler, you can include it in a scheduler map, which maps a specified forwarding class to a scheduler configuration. You configure a scheduler map to assign a forwarding class to a scheduler, and then apply the scheduler map to any interface that must enforce DiffServ CoS.

After they are applied to an interface, the scheduler maps affect the hardware queues, packet schedulers, and RED drop profiles.

In this example, you create the scheduler map `diffserv-cos-map` and apply it to the device's Ethernet interface `ge-0/0/0`. The map associates the `mf-classifier` forwarding classes to the schedulers as shown in [Table 141](#).

**Table 141: Sample `diffserv-cos-map` Scheduler Mapping**

| mf-classifier Forwarding Class | For CoS Traffic Type         | diffserv-cos-map Scheduler |
|--------------------------------|------------------------------|----------------------------|
| be-class                       | Best-effort traffic          | be-scheduler               |
| ef-class                       | Expedited forwarding traffic | ef-scheduler               |
| af-class                       | Assured forwarding traffic   | af-scheduler               |
| nc-class                       | Network control traffic      | nc-scheduler               |

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service scheduler-maps diffserv-cos-map forwarding-class be-class scheduler
 be-scheduler
set class-of-service scheduler-maps diffserv-cos-map forwarding-class ef-class scheduler
 ef-scheduler
set class-of-service scheduler-maps diffserv-cos-map forwarding-class af-class scheduler
 af-scheduler
set class-of-service scheduler-maps diffserv-cos-map forwarding-class nc-class scheduler
 nc-scheduler
set class-of-service interfaces ge-0/0/0 unit 0 scheduler-map diffserv-cos-map
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure and apply a scheduler map to a device's interface:

1. Configure a scheduler map for DiffServ CoS.  

```
[edit class-of-service]
user@host# edit scheduler-maps diffserv-cos-map
```
2. Configure a best-effort forwarding class and scheduler.  

```
[edit class-of-service scheduler-maps diffserv-cos-map]
user@host# set forwarding-class be-class scheduler be-scheduler
```
3. Configure an expedited forwarding class and scheduler.  

```
[edit class-of-service scheduler-maps diffserv-cos-map]
user@host# set forwarding-class ef-class scheduler ef-scheduler
```
4. Configure an assured forwarding class and scheduler.  

```
[edit class-of-service scheduler-maps diffserv-cos-map]
user@host# set forwarding-class af-class scheduler af-scheduler
```
5. Configure a network control class and scheduler.  

```
[edit class-of-service scheduler-maps diffserv-cos-map]
user@host# set forwarding-class nc-class scheduler nc-scheduler
```
6. Apply the scheduler map to an interface.  

```
[edit class-of-service]
user@host# set interfaces ge-0/0/0 unit 0 scheduler-map diffserv-cos-map
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
interfaces {
 ge-0/0/0 {
 unit 0 {
 scheduler-map diffserv-cos-map;
 }
 }
}
scheduler-maps {
 diffserv-cos-map {
 forwarding-class be-class scheduler be-scheduler;
 forwarding-class ef-class scheduler ef-scheduler;
 forwarding-class af-class scheduler af-scheduler;
 forwarding-class nc-class scheduler nc-scheduler;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Scheduler Map Configuration on page 1475](#)

### Verifying the Scheduler Map Configuration

---

**Purpose** Verify that scheduler maps are configured properly.

**Action** From operational mode, enter the **show class-of-service** command.

## CHAPTER 70

# Removing Delays with Strict-Priority Queues

- [Strict-Priority Queue Overview on page 1477](#)
- [Understanding Strict-Priority Queues on page 1478](#)
- [Example: Configuring Priority Scheduling on page 1478](#)
- [Example: Configuring Strict-Priority Queuing on page 1480](#)

### Strict-Priority Queue Overview

---

You can configure one queue per interface to have strict-priority, which causes delay-sensitive traffic, such as voice traffic, to be removed and forwarded with minimum delay. Packets that are queued in a strict-priority queue are removed before packets in other queues, including high-priority queues.

The strict-high-priority queuing feature allows you to configure traffic policing that prevents lower priority queues from being starved. The strict-priority queue does not cause starvation of other queues because the configured policer allows the queue to exceed the configured bandwidth only when other queues are not congested. If the interface is congested, the software directs strict-priority queues to the configured bandwidth.

To prevent queue starvation of other queues, you must configure an output (egress) policer that defines a limit for the amount of traffic that the queue can service. The software services all traffic in the strict-priority queue that is under the defined limit. When strict-priority traffic exceeds the limit, the policer marks the traffic in excess of the limit as out-of-profile. If the output port is congested, the software drops out-of-profile traffic.

You can also configure a second policer with an upper limit. When strict-priority traffic exceeds the upper limit, the software drops the traffic in excess of the upper limit, regardless of whether the output port is congested. This upper-limit policer is not a requirement for preventing starvation of the lower priority queues. The policer for the lower limit, which marks the packets as out-of-profile, is sufficient to prevent starvation of other queues.

#### Related Documentation

- [Understanding Strict-Priority Queues on page 1478](#)

- [Example: Configuring Priority Scheduling on page 1478](#)
- [Example: Configuring Strict-Priority Queuing on page 1480](#)

## Understanding Strict-Priority Queues

---

You use strict-priority queuing and policing as follows:

- Identify delay-sensitive traffic by configuring a behavior aggregate (BA) or multifield (MF) classifier.
- Minimize delay by assigning all delay-sensitive packets to the strict-priority queue.
- Prevent starvation on other queues by configuring a policer that checks the data stream entering the strict-priority queue. The policer defines a lower bound, marks the packets that exceed the lower bound as out-of-profile, and drops the out-of-profile packets if the physical interface is congested. If there is no congestion, the software forwards all packets, including the out-of-profile packets.
- Optionally, configure another policer that defines an upper bound and drops the packets that exceed the upper bound, regardless of congestion on the physical interface.

To configure strict-priority queuing and prevent starvation of other queues, include the **priority strict-high** statement at the **[edit class-of-service schedulers *scheduler-name*]** hierarchy level and the **if-exceeding** and **then out-of-profile** statements at the **[edit firewall policer *policer-name*]** hierarchy level:

```
[edit class-of-service schedulers scheduler-name]
priority strict-high;
```

```
[edit firewall policer policer-name]
if-exceeding {
 bandwidth-limit bps;
 bandwidth-percent number;
 burst-size-limit bytes;
}
then out-of-profile;
```

## Example: Configuring Priority Scheduling

---

This example shows how to configure priority scheduling so important traffic receives better access to the outgoing interface.

- [Requirements on page 1479](#)
- [Overview on page 1479](#)

- [Configuration on page 1479](#)
- [Verification on page 1480](#)

## Requirements

Before you begin, review how to assign forwarding classes. See “[Example: Assigning Forwarding Classes to Output Queues](#)” on page 1432.

## Overview

In this example, you configure CoS and a scheduler called be-sched with a medium-low priority. Then you configure scheduler map be-map to associate be-sched with the best-effort forwarding class. Finally, you apply be-map to interface ge-0/0/0.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service schedulers be-sched priority medium-low
set class-of-service scheduler-maps be-map forwarding-class best-effort scheduler
 be-sched
set class-of-service interfaces ge-0/0/0 scheduler-map be-map
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure priority scheduling:

1. Configure CoS and a scheduler.
 

```
[edit]
user@host# edit class-of-service
user@host# edit schedulers be-sched
```
2. Set a priority.
 

```
[edit class-of-service schedulers be-sched]
user@host# set priority medium-low
```
3. Configure a scheduler map.
 

```
[edit]
user@host# edit class-of-service
user@host# edit scheduler-maps be-map
```
4. Specify the best-effort forwarding class.
 

```
[edit class-of-service scheduler-maps be-map]
user@host# set forwarding-class best-effort scheduler be-sched
```
5. Apply best-effort map to an interface.
 

```
[edit]
user@host# edit class-of-service
```

```
user@host# set interfaces ge-0/0/0 scheduler-map be-map
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
interfaces {
 ge-0/0/0 {
 scheduler-map be-map;
 }
}
scheduler-maps {
 be-map {
 forwarding-class best-effort scheduler be-sched;
 }
}
schedulers {
 be-sched {
 priority medium-low;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Priority Scheduling on page 1480](#)

---

### Verifying Priority Scheduling

**Purpose** Verify that the priority scheduling is configured properly on a device.

**Action** From configuration mode, enter the **show class-of-service** command.

**Related Documentation**

## Example: Configuring Strict-Priority Queuing

This example shows how to configure strict-priority queuing and prevent starvation of other queues.

- [Requirements on page 1481](#)
- [Overview on page 1481](#)

- [Configuration on page 1481](#)
- [Verification on page 1488](#)

## Requirements

Before you begin, review how to create and configure forwarding classes. See “[Forwarding Classes Overview](#)” on page 1425.

## Overview

In this example, you create a BA classifier to classify traffic based on the IP precedence of the packet. The classifier defines IP precedence value 101 as voice traffic and 000 as data traffic. You assign forwarding-class priority queue 0 to voice traffic and queue 1 as data traffic. You then configure the scheduler map as corp-map and voice scheduler as voice-sched.

Then you set the priority for the voice traffic scheduler as strict-high and for the data traffic scheduler as strict-low. You apply the BA classifier to input interface ge-0/0/0 and apply the scheduler map to output interface e1-1/0/0. You then configure two policers called voice-drop and voice-excess. You set the burst size limit and bandwidth limit for voice-drop policer and for voice-excess policer. You then create a firewall filter that includes the new policers and add the policer to the term.

Finally, you apply the filter to output interface e1-1/0/1 and set the IP address as 11.1.1.1/24.

## Configuration

- [Applying a Filter to an Output Interface on page 1487](#)

### Configuring a BA Classifier

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service classifiers inet-precedence corp-traffic forwarding-class voice-class
 loss-priority low code-points 101
set class-of-service classifiers inet-precedence corp-traffic forwarding-class data-class
 loss-priority high code-points 000
```

**Step-by-Step  
Procedure**

To configure a BA classifier:

1. Create a BA classifier and set the IP precedence value for voice traffic.  

```
[edit]
user@host# edit class-of-service classifiers inet-precedence corp-traffic
forwarding-class voice-class loss-priority low
user@host# set code-points 101
```
2. Create a BA classifier and set the IP precedence value for data traffic.  

```
[edit]
user@host# edit class-of-service classifiers inet-precedence corp-traffic
forwarding-class data-class loss-priority high
user@host# set code-points 000
```

**Results**

From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
classifiers {
 inet-precedence corp-traffic {
 forwarding-class voice-class {
 loss-priority low code-points 101;
 }
 forwarding-class data-class {
 loss-priority high code-points 000;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Forwarding Classes

---

**CLI Quick  
Configuration**

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service forwarding-classes queue 0 voice-class
set class-of-service forwarding-classes queue 1 data-class
```

**Step-by-Step  
Procedure**

To configure forwarding classes:

1. Assign priority queuing to voice traffic.  

```
[edit]
user@host# set class-of-service forwarding-classes queue 0 voice-class
```
2. Assign priority queuing to data traffic.  

```
[edit]
user@host# set class-of-service forwarding-classes queue 1 data-class
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
forwarding-classes {
 queue 0 voice-class;
 queue 1 data-class;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring a Scheduler Map

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service scheduler-maps corp-map forwarding-class voice-class scheduler
voice-sched
set class-of-service scheduler-maps corp-map forwarding-class data-class scheduler
data-sched
```

**Step-by-Step Procedure** To configure a scheduler map:

1. Configure a scheduler map and voice scheduler.

```
[edit]
user@host# edit class-of-service scheduler-maps corp-map forwarding-class
voice-class
user@host# set scheduler voice-sched
```

2. Configure a scheduler map and data scheduler.

```
[edit]
user@host# edit class-of-service scheduler-maps corp-map forwarding-class
data-class
user@host# set scheduler data-sched
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
scheduler-maps {
 corp-map {
 forwarding-class voice-class scheduler voice-sched;
 forwarding-class data-class scheduler data-sched;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring a Scheduler

---

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service schedulers voice-sched priority strict-high
set class-of-service schedulers data-sched priority lowset xxx
```

**Step-by-Step Procedure** To configure schedulers:

1. Configure a voice traffic scheduler and set the priority.

```
[edit]
user@host# edit class-of-service schedulers voice-sched
user@host# set priority strict-high
```

2. Configure a data traffic scheduler and set the priority.

```
[edit]
user@host# edit class-of-service schedulers data-sched
user@host# set priority low
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
schedulers {
 voice-sched {
 priority strict-high;
 }
 data-sched {
 priority low;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Applying a BA Classifier to an Input Interface

---

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service interfaces ge-0/0/0 unit 0 classifiers inet-precedence corp-traffic
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To apply a BA classifier to an input interface:

1. Configure an interface.  

```
[edit]
user@host# edit class-of-service interfaces ge-0/0/0 unit 0
```
2. Apply a BA classifier to an input interface.  

```
[edit class-of-service interfaces ge-0/0/0 unit 0]
user@host# set classifiers inet-precedence corp-traffic
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service interfaces
ge-0/0/0 {
 unit 0 {
 classifiers {
 inet-precedence corp-traffic;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Applying a Scheduler Map to an Output Interface

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service interfaces e1-1/0/0 unit 0 scheduler-map corp-map
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To apply the scheduler map to an output interface:

1. Configure an interface.  

```
[edit]
user@host# edit class-of-service interfaces e1-1/0/0 unit 0
```
2. Apply a scheduler map to an output interface.  

```
[edit class-of-service interfaces e1-1/0/0 unit 0]
user@host# set scheduler-map corp-map
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
interfaces {
 e1-1/0/0 {
 unit 0 {
 scheduler-map corp-map;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Two Policers

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall policer voice-drop if-exceeding burst-size-limit 200000 bandwidth-limit
2000000
set firewall policer voice-drop then discard
set firewall policer voice-excess if-exceeding burst-size-limit 200000 bandwidth-limit
1000000
set firewall policer voice-excess then out-of-profile
set firewall filter voice-term term 01 from forwarding-class voice-class
set firewall filter voice-term term 01 then policer voice-drop next term
set firewall filter voice-term term 02 from forwarding-class voice-class
set firewall filter voice-term term 02 then policer voice-excess accept
```

**Step-by-Step Procedure** To configure two policers:

1. Configure a policer voice drop.

```
[edit]
user@host# edit firewall policer voice-drop
user@host# set if-exceeding burst-size-limit 200000 bandwidth-limit 2000000
user@host# set then discard
```

2. Configure a policer voice excess.

```
[edit]
user@host# edit firewall policer voice-excess
user@host# set if-exceeding burst-size-limit 200000 bandwidth-limit 1000000
user@host# set then out-of-profile
```

3. Create a firewall filter that includes the new policers.

```
[edit]
user@host# edit firewall filter voice-term term 01
user@host# set from forwarding-class voice-class
user@host# set then policer voice-drop next term
```

4. Add the policer to the term.

```
[edit]
user@host# edit firewall filter voice-term term 02
user@host# set from forwarding-class voice-class
user@host# set then policer voice-excess accept
```

**Results** From configuration mode, confirm your configuration by entering the **show firewall** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show firewall
policer voice-drop {
 if-exceeding {
 bandwidth-limit 2m;
 burst-size-limit 200k;
 }
 then discard;
}
policer voice-excess {
 if-exceeding {
 bandwidth-limit 1m;
 burst-size-limit 200k;
 }
 then out-of-profile;
}
filter voice-term {
 term 01 {
 from {
 forwarding-class voice-class;
 }
 then {
 policer voice-drop;
 }
 }
 term 02 {
 from {
 forwarding-class voice-class;
 }
 then {
 policer voice-excess;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Applying a Filter to an Output Interface

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your

network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces e1-1/0/1 unit 0 family inet filter output voice-term
set interfaces e1-1/0/1 unit 0 family inet address 11.1.1.1/24
```

**Step-by-Step Procedure**

To apply a filter to an output interface:

1. Apply a filter to an interface.

```
[edit]
user@host# edit interfaces e1-1/0/1 unit 0 family inet filter output
user@host# set voice-term
```

2. Set an IP address.

```
[edit]
user@host# set interfaces e1-1/0/1 unit 0 family inet address 11.1.1.1/24
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces
e1-1/0/1 {
 unit 0 {
 family inet {
 filter {
 output voice-term;
 }
 address 11.1.1.1/24;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Scheduler Map on page 1488](#)
- [Verifying the Interfaces on page 1489](#)
- [Verifying the Interface Queues on page 1489](#)

### Verifying the Scheduler Map

---

**Purpose** Verify that the scheduler map is configured properly.

**Action** From operational mode, enter the **show class-of-service scheduler-map corp-map** command.

### Verifying the Interfaces

---

**Purpose** Verify that the interfaces are configured properly.

**Action** From configuration mode, enter the **show interfaces** command.

### Verifying the Interface Queues

---

**Purpose** Verify that the interface queues are configured properly.

**Action** From configuration mode, enter the **show interfaces queue** command.

# Controlling Congestion with Drop Profiles

- [RED Drop Profiles Overview on page 1491](#)
- [RED Drop Profiles and Congestion Control on page 1492](#)
- [Configuring RED Drop Profiles on page 1494](#)
- [Example: Configuring RED Drop Profiles on page 1495](#)

## RED Drop Profiles Overview

---

A drop profile is a feature of the random early detection (RED) process that allows packets to be dropped before queues are full. Drop profiles are composed of two main values—the queue fullness and the drop probability. The queue fullness represents percentage of memory used to store packets in relation to the total amount that has been allocated for that queue. The drop probability is a percentage value that correlates to the likelihood that an individual packet is dropped from the network. These two variables are combined in a graph-like format.

A random number between 0 and 100 is calculated for each packet. This random number is plotted against the drop profile having the current queue fullness of that particular queue. When the random number falls above the graph line, the packet is transmitted onto the physical media. When the number falls below the graph line, the packet is dropped from the network.

Randomly dropped packets are counted as RED-dropped, while packets dropped for other reasons (100% probability) are counted as tail-dropped.

You specify drop probabilities in the drop profile section of the class-of-service (CoS) configuration hierarchy and reference them in each scheduler configuration. For each scheduler, you can configure multiple separate drop profiles, one for each combination of loss priority (low, medium-low, medium-high, or high) and IP transport protocol (TCP or non-TCP or any).

**NOTE:** For SRX210, SRX240, and SRX650 devices, TCP and non-TCP values are not supported; only the value “any” is supported.

---

You can configure a maximum of 32 different drop profiles.

To configure RED drop profiles, include the following statements at the **[edit class-of-service]** hierarchy level of the configuration:

```
[edit class-of-service]
drop-profiles {
 profile-name {
 fill-level percentage drop-probability percentage;
 interpolate {
 drop-probability [values];
 fill-level [values];
 }
 }
}
```

## Default Drop Profiles

By default, if you configure no drop profiles, RED is still in effect and functions as the primary mechanism for managing congestion. In the default RED drop profile, when the fill level is 0 percent, the drop probability is 0 percent. When the fill level is 100 percent, the drop probability is 100 percent.

**Related Documentation**

- [Example: Configuring RED Drop Profiles on page 1495](#)

## RED Drop Profiles and Congestion Control

If the device must support assured forwarding, you can control congestion by configuring random early detection (RED) drop profiles. RED drop profiles use drop probabilities for different levels of buffer fullness to determine which scheduling queue on the device is likely to drop assured forwarding packets under congested conditions. The device can drop packets when the queue buffer becomes filled to the configured percentage.

Assured forwarding traffic with the PLP (packet loss priority) bit set is more likely to be discarded than traffic without the PLP bit set. This example shows how to configure a drop probability and a queue fill level for both PLP and non-PLP assured forwarding traffic. It is only one example of how to use RED drop profiles.

The example shows how to configure the RED drop profiles listed in [Table 142](#).

**Table 142: Sample RED Drop Profiles**

| Drop Profile                                                                        | Drop Probability                                           | Queue Fill Level           |
|-------------------------------------------------------------------------------------|------------------------------------------------------------|----------------------------|
| <b>af-normal</b> —For non-PLP (normal) assured forwarding traffic                   | Between 0 (never dropped) and 100 percent (always dropped) | Between 95 and 100 percent |
| <b>af-with-plp</b> —For PLP (aggressive packet dropping) assured forwarding traffic | Between 95 and 100 percent (always dropped)                | Between 80 and 95 percent  |

To configure RED drop profiles for assured forwarding congestion control on the device:

1. Navigate to the top of the configuration hierarchy in either the J-Web or CLI configuration editor.
2. Perform the configuration tasks described in [Table 143](#).
3. If you are finished configuring the device, commit the configuration.
4. Go on to one of the following tasks:
  - To assign resources, priorities, and profiles to output queues, see [“Example: Configuring Class-of-Service Schedulers” on page 1457](#).
  - To use adaptive shapers to limit bandwidth for Frame Relay, see [“Example: Configuring and Applying an Adaptive Shaper” on page 1501](#).

**Table 143: Configuring RED Drop Profiles for Assured Forwarding Congestion Control**

| Task                                                                          | CLI Configuration Editor                                                                                                                                                                 |
|-------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Navigate to the <b>Class of service</b> level in the configuration hierarchy. | From the <b>[edit]</b> hierarchy level, enter<br><b>edit class-of-service</b>                                                                                                            |
| Configure the lower drop probability for normal, non-PLP traffic.             | Enter<br><b>edit drop-profiles af-normal interpolate</b><br><b>set drop-probability 0</b><br><b>set drop-probability 100</b>                                                             |
| Configure a queue fill level for the lower non-PLP drop probability.          | Enter<br><b>set fill-level 95</b><br><b>set fill-level 100</b>                                                                                                                           |
| Configure the higher drop probability for PLP traffic.                        | From the <b>[edit class of service]</b> hierarchy level, enter<br><b>edit drop-profiles af-with-PLP interpolate</b><br><b>set drop-probability 95</b><br><b>set drop-probability 100</b> |
| Configure a queue fill level for the higher PLP drop probability.             | Enter<br><b>set fill-level 80</b><br><b>set fill-level 95</b>                                                                                                                            |

**Related Documentation** • [Example: Configuring RED Drop Profiles on page 1495](#)

## Configuring RED Drop Profiles

Create a segmented configuration and an interpolated configuration that correspond to the graphs in [Figure 75](#). The values defined in the configuration are matched to represent the data points in the graph line. In this example, the drop probability is 25 percent when the queue is 50 percent full. The drop probability increases to 50 percent when the queue is 75 percent full.

**Figure 75: Segmented and Interpolated Drop Profiles**

1704

**Segmented**

```

class-of-service {
 drop-profiles {
 segmented-style-profile {
 fill-level 25 drop-probability 25;
 fill-level 50 drop-probability 50;
 fill-level 75 drop-probability 75;
 fill-level 95 drop-probability 100;
 }
 }
}

```

To create the profile's graph line, the software begins at the bottom-left corner, representing a 0 percent fill level and a 0 percent drop probability. This configuration draws a line directly to the right until it reaches the first defined fill level, 25 percent for this configuration. The software then continues the line vertically until the first drop probability is reached. This process is repeated for all of the defined levels and probabilities until the top-right corner of the graph is reached.

Create a smoother graph line by configuring the profile with the **interpolate** statement. This allows the software to automatically generate 64 data points on the graph beginning at (0, 0) and ending at (100, 100). Along the way, the graph line intersects specific data points, which you define as follows:

**Interpolated**

```

class-of-service {
 drop-profiles {
 interpolated-style-profile {
 interpolate {
 fill-level [50 75];
 drop-probability [25 50];
 }
 }
 }
}

```

```

 }
 }
}

```

  - [Understanding RED Drop Profiles](#)

## Example: Configuring RED Drop Profiles

This example shows how to configure RED drop profiles.

- [Requirements on page 1495](#)
- [Overview on page 1495](#)
- [Configuration on page 1496](#)
- [Verification on page 1497](#)

### Requirements

Before you begin, determine which type of profile you want to configure. See *Example: Configuring Segmented and Interpolated Style Profiles*.

### Overview

A drop profile is a feature of the RED process that allows packets to be dropped before queues are full. Drop profiles are composed of two main values the queue fullness and the drop probability.

You can control congestion by configuring RED drop profiles, if the device supports assured forwarding. RED drop profiles use drop probabilities for different levels of buffer fullness to determine which scheduling queue on the device is likely to drop assured forwarding packets under congested conditions. The device can drop packets when the queue buffer becomes filled to the configured percentage. Assured forwarding traffic with the PLP bit set is more likely to be discarded than traffic without the PLP bit set.

In this example, you configure a drop probability and a queue fill level for both PLP and non-PLP assured forwarding traffic.

[Table 144](#) shows how to configure the RED drop profiles listed.

**Table 144: Sample RED Drop Profiles**

| Drop Profile                                                                        | Drop Probability                                           | Queue Fill Level           |
|-------------------------------------------------------------------------------------|------------------------------------------------------------|----------------------------|
| <b>af-normal</b> —For non-PLP (normal) assured forwarding traffic                   | Between 0 (never dropped) and 100 percent (always dropped) | Between 95 and 100 percent |
| <b>af-with-plp</b> —For PLP (aggressive packet dropping) assured forwarding traffic | Between 95 and 100 percent (always dropped)                | Between 80 and 95 percent  |

## Configuration

**CLI Quick Configuration** To quickly configure RED drop profiles, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
[edit]
set class-of-service drop-profiles af-normal interpolate drop-probability 0
set class-of-service drop-profiles af-normal interpolate drop-probability 100
set class-of-service drop-profiles af-normal interpolate fill-level 95
set class-of-service drop-profiles af-normal interpolate fill-level 100
set class-of-service drop-profiles af-with-PLP interpolate drop-probability 95
set class-of-service drop-profiles af-with-PLP interpolate drop-probability 100
set class-of-service drop-profiles af-with-PLP interpolate fill-level 80
set class-of-service drop-profiles af-with-PLP interpolate fill-level 95
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure RED drop profiles:

1. Configure the lower drop probability for normal, non-PLP traffic.

```
[edit]
user@host# edit class-of-service
user@host# edit drop-profiles af-normal interpolate
user@host# set drop-probability 0
user@host# set drop-probability 100
```

2. Configure a queue fill level for the lower non-PLP drop probability.

```
[edit class-of-service drop-profiles af-normal interpolate]
user@host# set fill-level 95
user@host# set fill-level 100
```

3. Configure the higher drop probability for PLP traffic.

```
[edit]
user@host# edit class-of-service
user@host# edit drop-profiles af-with-PLP interpolate
user@host# set drop-probability 95
user@host# set drop-probability 100
```

4. Configure a queue fill level for the higher PLP drop probability.

```
[edit class-of-service drop-profiles af-with-PLP interpolate]
user@host# set fill-level 80
user@host# set fill-level 95
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show class-of-service
```

```
drop-profiles {
 af-normal {
 interpolate {
 fill-level [95 100];
 drop-probability [0 100];
 }
 }
 af-with-PLP {
 interpolate {
 fill-level [80 95];
 drop-probability [95 100];
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying RED Drop Profiles Configuration on page 1497](#)

---

### Verifying RED Drop Profiles Configuration

# Controlling Congestion with Adaptive Shapers

- [Adaptive Shaping Overview on page 1499](#)
- [Assigning the Default Frame Relay Loss Priority Map to an Interface on page 1500](#)
- [Defining a Custom Frame Relay Loss Priority Map on page 1500](#)
- [Example: Configuring and Applying an Adaptive Shaper on page 1501](#)

## Adaptive Shaping Overview

---

You can use adaptive shaping to limit the bandwidth of traffic flowing on a Frame Relay logical interface. If you configure and apply adaptive shaping, the device checks the backward explicit congestion notification (BECN) bit within the last inbound (ingress) packet received on the interface.

**NOTE:** Adaptive shaping is not available on SRX210, SRX240, SRX650, SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices.

To configure an adaptive shaper, include the **adaptive-shaper** statement at the [edit class-of-service] hierarchy level:

```
[edit class-of-service]
adaptive-shaper {
 adaptive-shaper-name {
 trigger type shaping-rate (percent percentage | rate);
 }
}
```

The trigger type can be **BECN** only. If the last ingress packet on the logical interface has its BECN bit set to 1, the output queues on the logical interface are shaped according to the associated shaping rate.

The associated shaping rate can be a percentage of the available interface bandwidth from 0 through 100 percent. Alternatively, you can configure the shaping rate to be an absolute peak rate, in bits per second (bps) from 3200 through 32,000,000,000 bps. You can specify the value either as a complete decimal number or as a decimal number followed by the abbreviation **K** (1000), **M** (1,000,000), or **G** (1,000,000,000).

- Related Documentation**
- [Assigning the Default Frame Relay Loss Priority Map to an Interface on page 1500](#)
  - [Defining a Custom Frame Relay Loss Priority Map on page 1500](#)
  - [Example: Configuring and Applying an Adaptive Shaper on page 1501](#)

---

## Assigning the Default Frame Relay Loss Priority Map to an Interface

For SRX210, SRX240, and SRX650 device interfaces with Frame Relay encapsulation, you can set the loss priority of Frame Relay traffic based on the discard eligibility (DE) bit. For each incoming frame with the DE bit containing the CoS value 0 or 1, you can configure a Frame Relay loss priority value of low, medium-low, medium-high, or high.

The default Frame Relay loss priority map contains the following settings:

```
loss-priority low code-point 0;
loss-priority high code-point 1;
```

This default map sets the loss priority to low for each incoming frame with the DE bit containing the 0 CoS value. The map sets the loss priority to high for each incoming frame with the DE bit containing the 1 CoS value.

To assign the default map to an interface, include the **frame-relay-de default** statement at the [edit class-of-service interfaces *interface-name* unit *logical-unit-number* loss-priority-maps] hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number loss-priority-maps]
frame-relay-de default;
```

- Related Documentation**
- [Defining a Custom Frame Relay Loss Priority Map on page 1500](#)

---

## Defining a Custom Frame Relay Loss Priority Map

You can apply a classifier to the same interface on which you configure a Frame Relay loss priority value. The Frame Relay loss priority map is applied first, followed by the classifier. The classifier can change the loss priority to a higher value only (for example, from low to high). If the classifier specifies a loss priority with a lower value than the current loss priority of a particular packet, the classifier does not change the loss priority of that packet.

To define a custom Frame Relay loss priority map, include the following statements at the [edit class-of-service] hierarchy level:

```
[edit class-of-service]
loss-priority-maps {
 frame-relay-de map-name {
 loss-priority (low | medium-low | medium-high | high) code-point (0 | 1);
 }
}
```

A custom loss priority map sets the loss priority to low, medium-low, medium-high, or high for each incoming frame with the DE bit containing the specified 0 or 1 CoS value.

The map does not take effect until you apply it to a logical interface. To apply a map to a logical interface, include the **frame-relay-de *map-name*** statement at the [edit class-of-service interfaces *interface-name* unit *logical-unit-number* loss-priority-maps] hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number loss-priority-maps]
frame-relay-de map-name;
```

## Example: Configuring and Applying an Adaptive Shaper

This example shows how to configure and apply an adaptive shaper to limit the bandwidth of traffic on a Frame Relay logical interface.

- [Requirements on page 1501](#)
- [Overview on page 1501](#)
- [Configuration on page 1501](#)
- [Verification on page 1502](#)

### Requirements

Before you begin, review how to create and apply scheduler maps. See [“Example: Configuring and Applying Scheduler Maps” on page 1472](#)

### Overview

In this example, you create adaptive shaper fr-shaper and apply it to T1 interface t1-0/0/2. The adapter shaper limits the transmit bandwidth on the interface to 64 Kbps.

### Configuration

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure and apply an adaptive shaper to a logical interface:

1. Specify the name and the maximum transmit rate of the adaptive shaper.
 

```
[edit]
user@host# edit class-of-service
user@host# set adaptive-shapers fr-shaper trigger becn shaping-rate 64k
```
2. Apply the adaptive shaper to the logical interface.
 

```
[edit class-of-service]
user@host# set interfaces t1-0/0/2 unit 0 adaptive-shaper fr-shaper
```
3. If you are done configuring the device, commit the configuration.
 

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show class-of-service** command.

## CHAPTER 73

# Limiting Traffic Using Virtual Channels

- [Virtual Channels Overview on page 1503](#)
- [Understanding Virtual Channels on page 1504](#)
- [Example: Configuring Virtual Channels on page 1505](#)

### Virtual Channels Overview

---

You can configure virtual channels to limit traffic sent from a corporate headquarters to branch its offices. Virtual channels might be required when the headquarters site has an expected aggregate bandwidth higher than that of the individual branch offices. The headquarters router must limit the traffic sent to each branch office router to avoid oversubscribing their links. For instance, if branch 1 has a 1.5 Mbps link and the headquarters router attempts to send 6 Mbps to branch 1, all of the traffic in excess of 1.5 Mbps is dropped in the ISP network.

You configure virtual channels on a logical interface. Each virtual channel has a set of eight queues with a scheduler and an optional shaper. You can use an output firewall filter to direct traffic to a particular virtual channel. For example, a filter can direct all traffic with a destination address for branch office 1 to virtual channel 1, and all traffic with a destination address for branch office 2 to virtual channel 2.

Although a virtual channel group is assigned to a logical interface, a virtual channel is not the same as a logical interface. The only features supported on a virtual channel are queuing, packet scheduling, and accounting. Rewrite rules and routing protocols apply to the entire logical interface.

When you configure virtual channels on an interface, the virtual channel group uses the same scheduler and shaper you configure at the [edit interfaces *interface-name* unit *logical-unit-number*] hierarchy level. In this way, virtual channels are an extension of regular scheduling and shaping and not an independent entity.

#### Related Documentation

- [Understanding Virtual Channels on page 1504](#)
- [Example: Configuring Virtual Channels on page 1505](#)

## Understanding Virtual Channels

---

You configure a virtual channel to set up queuing, packet scheduling, and accounting rules to be applied to one or more logical interfaces. You then must apply the virtual channel to a particular logical interface.

You also create a list of virtual channels that you can assign to a virtual channel group. To define a virtual channel group that you can assign to a logical interface, include the **virtual-channel-groups** statement at the [edit class-of-service] hierarchy level.

The *virtual-channel-group-name* can be any name that you want. The *virtual-channel-name* must be one of the names that you define at the [edit class-of-service virtual-channels] hierarchy level. You can include multiple virtual channel names in a group.

The scheduler map is required. The *map-name* must be one of the scheduler maps that you configure at the [edit class-of-service scheduler-maps] hierarchy level. For more information, see [“Example: Configuring Class-of-Service Schedulers” on page 1457](#).

The shaping rate is optional. If you configure the shaping rate as a percentage, when the virtual channel is applied to a logical interface, the shaping rate is set to the specified percentage of the interface bandwidth. If you configure a shaper on a virtual channel, the shaper limits the maximum bandwidth transmitted by that virtual channel. Virtual channels without a shaper can use the full logical interface bandwidth. If there are multiple unshaped virtual channels, they share the available logical interface bandwidth equally.

When you apply the virtual channel group to a logical interface, a set of eight queues is created for each of the virtual channels in the group. The **scheduler-map** statement applies a scheduler to these queues. If you include the **shaping-rate** statement, a shaper is applied to the entire virtual channel.

You must configure one of the virtual channels in the group to be the default channel. Therefore, the **default** statement is required in the configuration of one virtual channel per channel group. Any traffic not explicitly directed to a particular channel is transmitted by this default virtual channel.

For the corresponding physical interface, you must also include the **per-unit-scheduler** statement at the [edit interfaces *interface-name*] hierarchy level as follows:

```
[edit interfaces interface-name]
per-unit-scheduler;
```

The **per-unit-scheduler** statement enables one set of output queues for each logical interface configured under the physical interface.

When you apply a virtual channel group to a logical interface, the software creates a set of eight queues for each of the virtual channels in the group.

If you apply a virtual channel group to multiple logical interfaces, the software creates a set of eight queues on each logical interface. The virtual channel names listed in the group are used on all the logical interfaces. We recommend specifying the scheduler and shaping rates in the virtual channel configuration in terms of percentages, rather than

absolute rates. This allows you to apply the same virtual channel group to logical interfaces that have different bandwidths.

When you apply a virtual channel group to a logical interface, you cannot include the **scheduler-map** and **shaping-rate** statements at the [edit class-of-service interfaces *interface-name* unit *logical-unit-number*] hierarchy level. In other words, you can configure a scheduler map and a shaping rate on a logical interface, or you can configure virtual channels on the logical interface, but not both.

If you configure multiple logical interfaces on a single physical interface, each logical interface is guaranteed an equal fraction of the physical interface bandwidth as follows:

$$\text{logical-interface-bandwidth} = \frac{\text{physical-interface-bandwidth}}{\text{number-of-logical-interfaces}}$$

If one or more logical interfaces do not completely use their allocation, the other logical interfaces share the excess bandwidth equally.

If you configure multiple virtual channels on a logical interface, they are each guaranteed an equal fraction of the logical interface bandwidth as follows:

$$\text{virtual-channel-bandwidth} = \frac{\text{logical-interface-bandwidth}}{\text{number-of-virtual-channels}}$$

If you configure a shaper on a virtual channel, the shaper limits the maximum bandwidth transmitted by that virtual channel. Virtual channels without a shaper can use the full logical interface bandwidth. If there are multiple unshaped virtual channels, they share the available logical interface bandwidth equally.

## Example: Configuring Virtual Channels

This example shows how to create virtual channels between a headquarters and its branch office.

- [Requirements on page 1505](#)
- [Overview on page 1506](#)
- [Configuration on page 1506](#)
- [Verification on page 1509](#)

### Requirements

Before you begin, ensure that your headquarters and branch office have a network connection where the expected aggregate bandwidth is higher for your headquarters than for your branch office. The devices at your headquarters will then be set up to limit the traffic sent to the branch office to avoid oversubscribing the link.

## Overview

In this example, you create the virtual channels as branch1-vc, branch2-vc, branch3-vc, and default-vc. You then define the virtual channel group as wan-vc-group to include the four virtual channels and assign the scheduler map as bestscheduler to each virtual channel. Three of the virtual channels are shaped to 1.5 Mbps. The fourth virtual channel is default-vc, and it is not shaped so it can use the full interface bandwidth.

Then you apply them in the firewall filter as choose-vc to the Services Router's interface t3-1/0/0. The output filter on the interface sends all traffic with a destination address matching 192.168.10.0/24 to branch1-vc, and similar configurations are set for branch2-vc and branch3-vc. Traffic not matching any of the addresses goes to the default, unshaped virtual channel.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set class-of-service virtual-channels branch1-vc
set class-of-service virtual-channels branch2-vc
set class-of-service virtual-channels branch3-vc
set class-of-service virtual-channels default-vc
set class-of-service virtual-channel-groups wan-vc-group branch1-vc scheduler-map
 bestscheduler
set class-of-service virtual-channel-groups wan-vc-group branch2-vc scheduler-map
 bestscheduler
set class-of-service virtual-channel-groups wan-vc-group branch3-vc scheduler-map
 bestscheduler
set class-of-service virtual-channel-groups wan-vc-group default-vc scheduler-map
 bestscheduler
set class-of-service virtual-channel-groups wan-vc-group default-vc default
set class-of-service virtual-channel-groups wan-vc-group branch1-vc shaping-rate
 1500000
set class-of-service virtual-channel-groups wan-vc-group branch2-vc shaping-rate
 1500000
set class-of-service virtual-channel-groups wan-vc-group branch3-vc shaping-rate
 1500000
set class-of-service interfaces t3-1/0/0 unit 0 virtual-channel-group wan-vc-group
set firewall family inet filter choose-vc term branch1 from destination-address
 192.168.10.0/24
set firewall family inet filter choose-vc term branch1 then accept
set firewall family inet filter choose-vc term branch1 then virtual-channel branch1-vc
set firewall family inet filter choose-vc term branch1 then virtual-channel branch2-vc
set firewall family inet filter choose-vc term branch1 then virtual-channel branch3-vc
set interfaces t3-1/0/0 unit 0 family inet filter output choose-vc
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure virtual channels:

1. Define the virtual channels and the default virtual channel.

```
[edit]
user@host# edit class-of-service
user@host# set virtual-channels branch1-vc
user@host# set virtual-channels branch2-vc
user@host# set virtual-channels branch3-vc
user@host# set virtual-channels default-vc
```

2. Define the virtual channel group and assign each virtual channel a scheduler map.

```
[edit class-of-service]
user@host# set virtual-channel-groups wan-vc-group branch1-vc scheduler-map
bestscheduler
user@host# set virtual-channel-groups wan-vc-group branch2-vc scheduler-map
bestscheduler
user@host# set virtual-channel-groups wan-vc-group branch3-vc scheduler-map
bestscheduler
user@host# set virtual-channel-groups wan-vc-group default-vc scheduler-map
bestscheduler
user@host# set virtual-channel-groups wan-vc-group default-vc default
```

3. Specify a shaping rate.

```
[edit class-of-service]
user@host# set virtual-channel-groups wan-vc-group branch1-vc shaping-rate 1.5m
user@host# set virtual-channel-groups wan-vc-group branch2-vc shaping-rate
1.5m
user@host# set virtual-channel-groups wan-vc-group branch3-vc shaping-rate
1.5m
```

4. Apply the virtual channel group to the logical interface.

```
[edit class-of-service]
user@host# set interfaces t3-1/0/0 unit 0 virtual-channel-group wan-vc-group
```

5. Create the firewall filter to select the traffic.

```
[edit firewall]
user@host# set family inet filter choose-vc term branch1 from destination
192.168.10.0/24
user@host# set family inet filter choose-vc term branch1 then accept
user@host# set family inet filter choose-vc term branch1 then virtual-channel
branch1-vc
user@host# set family inet filter choose-vc term branch1 then virtual-channel
branch2-vc
user@host# set family inet filter choose-vc term branch1 then virtual-channel
branch3-vc
```

6. Apply the firewall filter to output traffic.

```
[edit interfaces]
user@host# set t3-1/0/0 unit 0 family inet filter output choose-vc
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service**, **show firewall**, and **show interfaces t3-1/0/0** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show class-of-service
virtual-channels {
 branch1-vc;
 branch2-vc;
 branch3-vc;
 default-vc;
}
virtual-channel-groups {
 wan-vc-group {
 branch1-vc {
 scheduler-map bestscheduler;
 shaping-rate 1500000;
 }
 branch2-vc {
 scheduler-map bestscheduler;
 shaping-rate 1500000;
 }
 branch3-vc {
 scheduler-map bestscheduler;
 shaping-rate 1500000;
 }
 default-vc {
 scheduler-map bestscheduler;
 default;
 }
 }
}
interfaces {
 t3-1/0/0 {
 unit 0 {
 virtual-channel-group wan-vc-group;
 }
 }
}
[edit]
user@host# show firewall
family inet {
 filter choose-vc {
 term branch1 {
 from {
 destination-address {
 192.168.10.0/24;
 }
 }
 then {
 virtual-channel branch3-vc;
 accept;
 }
 }
 }
}
```

```
}
[edit]
user@host# show interfaces t3-1/0/0
unit 0 {
 family inet {
 filter {
 output choose-vc;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

# Enabling Queuing for Tunnel Interfaces

- [CoS Queuing for Tunnels Overview on page 1511](#)
- [Understanding the ToS Value of a Tunnel Packet on page 1513](#)
- [Example: Configuring CoS Queuing for GRE or IP-IP Tunnels on page 1514](#)
- [Copying Outer IP Header DSCP and ECN to Inner IP Header on page 1518](#)

## CoS Queuing for Tunnels Overview

---

On an SRX Series device running Junos OS, a tunnel interface is an internal interface and supports many of the same CoS features as a physical interface. The tunnel interface creates a virtual point-to-point link between two SRX Series devices at remote points over an IP network.

For example, you can configure CoS features for generic routing encapsulation (GRE) and IP-IP tunnel interfaces. Tunneling protocols encapsulate packets inside a transport protocol.

GRE and IP-IP tunnels are used with services like IPsec and NAT to set up point-to-point VPNs. Junos OS allows you to enable CoS queuing, scheduling, and shaping for traffic exiting through these tunnel interfaces. For an example of configuring CoS Queuing for GRE tunnels, see [“Example: Configuring CoS Queuing for GRE or IP-IP Tunnels” on page 1514](#).

This topic includes the following sections:

- [Benefits of CoS Queuing for Tunnel Interfaces on page 1511](#)
- [How CoS Queuing Works on page 1512](#)
- [Limitations on CoS Shapers for Tunnel Interfaces on page 1513](#)

## Benefits of CoS Queuing for Tunnel Interfaces

CoS queuing enabled for tunnel interfaces has the following benefits:

- Segregates tunnel traffic.

Each tunnel can be shaped so that a tunnel with low-priority traffic cannot flood other tunnels that carry high-priority traffic.

Traffic for one tunnel does not impact traffic on other tunnels.

- Controls tunnel bandwidth.

Traffic through various tunnels is limited to not exceed a certain bandwidth.

For example, suppose you have three tunnels to three remote sites through a single WAN interface. You can select CoS parameters for each tunnel such that traffic to some sites gets more bandwidth than traffic to other sites.

- Customizes CoS policies.

You can apply different queuing, scheduling, and shaping policies to different tunnels based on user requirements. Each tunnel can be configured with different scheduler maps, different queue depths, and so on. Customization allows you to configure granular CoS policy providing for better control over tunnel traffic.

- Prioritizes traffic before it enters a tunnel.

For example, CoS queuing avoids having low-priority packets scheduled ahead of high-priority packets when the interface speed is higher than the tunnel traffic speed. This feature is most useful when combined with IPsec. Typically, IPsec processes packets in a FIFO manner. However, with CoS queuing each tunnel can prioritize high-priority packets over low-priority packets. Also, each tunnel can be shaped so that a tunnel with low-priority traffic does not flood tunnels carrying high-priority traffic.

## How CoS Queuing Works

Figure 76 shows CoS-related processing that occurs for traffic entering and exiting a tunnel. For information on flow-based packet processing, see the *Flow-Based and Packet-Based Processing Feature Guide for Security Devices*.

**Figure 76: CoS Processing for Tunnel Traffic**

Inbound traffic traversing through the tunnel:

Outbound traffic traversing through the tunnel:

g020124

## Limitations on CoS Shapers for Tunnel Interfaces

When defining a CoS shaping rate on a tunnel interface, be aware of the following restrictions:

- The shaping rate on the tunnel interface must be less than that of the physical egress interface.
- The shaping rate only measures the packet size that includes the Layer 3 packet with GRE or IP-IP encapsulation. The Layer 2 encapsulation added by the physical interface is not factored into the shaping rate measurement.
- The CoS behavior works as expected only when the physical interface carries the shaped GRE or IP-IP tunnel traffic alone. If the physical interface carries other traffic, thereby lowering the available bandwidth for tunnel interface traffic, the CoS features do not work as expected.
- You cannot configure a logical interface shaper and a virtual circuit shaper simultaneously on the router. If virtual circuit shaping is desired, do not define a logical interface shaper. Instead, define a shaping rate for all the virtual circuits.

## Understanding the ToS Value of a Tunnel Packet

To ensure that the tunneled packet continues to have the same CoS treatment even in the physical interface, you must preserve the type-of-service (ToS) value from the inner IP header to the outer IP header.

For transit traffic, Junos OS preserves the CoS value of the tunnel packet for both GRE and IP-IP tunnel interfaces. The inner IPv4 or IPv6 ToS bits are copied to the outer IPv4 ToS header for both types of tunnel interfaces.

For Routing Engine traffic, however, the router handles GRE tunnel interface traffic differently from IP-IP tunnel interface traffic. Unlike for IP-IP tunnels, the IPv4 ToS bits are not copied to the outer IPv4 header by default. You have a configuration option to copy the ToS value from the packet's inner IPv4 header to the outer IPv4 header.

To copy the inner ToS bits to the outer IP header (which is required for some tunneled routing protocols) on packets sent by the Routing Engine, include the **copy-tos-to-outer-ip-header** statement at the logical unit hierarchy level of a GRE interface.

**NOTE:** For IPv6 traffic, the inner ToS value is not copied to the outer IPv4 header for both GRE and IP-IP tunnel interfaces even if the **copy-tos-to-outer-ip-header** statement is specified.

This example copies the inner ToS bits to the outer IP header on a GRE tunnel:

```
[edit interfaces]
gr-0/0/0 {
 unit 0 {
 copy-tos-to-outer-ip-header;
```

```
 family inet;
 }
}
```

- [Example: Configuring CoS Queuing for GRE or IP-IP Tunnels on page 1514](#)

## Example: Configuring CoS Queuing for GRE or IP-IP Tunnels

---

This example shows how to configure CoS queuing for GRE or IP-IP tunnels.

- [Requirements on page 1514](#)
- [Overview on page 1514](#)
- [Configuration on page 1515](#)
- [Verification on page 1516](#)

### Requirements

Before you begin:

- Establish a main office and a branch office connected by a VPN using GRE or IP-IP tunneled interfaces.
- Configure forwarding classes and schedulers. See [“Example: Assigning Forwarding Classes to Output Queues” on page 1432](#) and [“Example: Configuring Class-of-Service Schedulers” on page 1457](#).
- Configure a scheduler map and apply the scheduler map to the tunnel interface. See [“Example: Configuring and Applying Scheduler Maps” on page 1472](#).
- Configure classifiers and apply them to the tunnel interface. See [“Example: Configuring Behavior Aggregate Classifiers” on page 1397](#).
- Create rewrite rules and apply them to the tunnel interface. See [“Example: Configuring and Applying Rewrite Rules” on page 1441](#).

### Overview

In this example, you enable tunnel queuing, define the GRE tunnel interface as `gr-0/0/0`, (Alternatively, you could define the IP-IP tunnel interface as `ip-0/0/0`.) and set the per unit scheduler. You then set the GRE tunnel's line rate as 100 Mbps by using the shaper definition.

In [Figure 77](#), Router A has a GRE tunnel established with Router B through interface `ge-1/0/0`. Router A also has an IP-IP tunnel established with Router C through interface `ge-1/0/1`. Router A is configured so that tunnel-queuing is enabled. Router B and Router C do not have tunnel-queuing configured.

Figure 77: Configuring CoS Queuing for GRE Tunnels

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
set chassis fpc 0 pic 0 tunnel-queuing
set interfaces gr-0/0/0 unit 0
set interfaces gr-0/0/0 per-unit-scheduler
set class-of-services interfaces gr-0/0/0 unit 0 shaping-rate 100m
```

**Step-by-Step Procedure** To configure CoS queuing for GRE tunnels:

1. Enable tunnel queuing on the device.  

```
[edit]
user@host# set chassis fpc 0 pic 0 tunnel-queuing
```
2. Define the GRE tunnel interface.  

```
[edit]
user@host# set interfaces gr-0/0/0 unit 0
```
3. Define the per-unit scheduler for the GRE tunnel interface.  

```
[edit]
user@host# set interfaces gr-0/0/0 per-unit-scheduler
```
4. Define the GRE tunnel's line rate by using the shaper definition.  

```
[edit]
user@host# set class-of-services interfaces gr-0/0/0 unit 0 shaping-rate 100m
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service interfaces gr-0/0/0**, **show interfaces gr-0/0/0**, and **show chassis** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
```

```

user@host# show class-of-service interfaces gr-0/0/0
unit 0 {
 shaping-rate 100m;
}
[edit]
user@host# show interfaces gr-0/0/0
 per-unit-scheduler;
unit 0;
[edit]
user@host# show chassis
 fpc 0 {
 pic 0 {
 tunnel-queuing;
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying a CoS Queuing for GRE Tunnel Configuration on page 1516](#)
- [Verifying a CoS Queuing for IP-IP Tunnel Configuration on page 1518](#)

### Verifying a CoS Queuing for GRE Tunnel Configuration

**Purpose** Verify that the device is configured properly for tunnel configuration.

**Action** From configuration mode, enter the **show interfaces queue gr-0/0/0.0** command.

**NOTE:** If you enter **gr-0/0/0.0** only, queue information for all tunnels is displayed. If you enter **gr-0/0/0.0**, queue information for the specific tunnel is displayed.

```

user@host> show interfaces queue gr-0/0/0.0
Logical interface gr-0/0/0.0 (Index 68) (SNMP ifIndex 112)

### Verifying a CoS Queuing for IP-IP Tunnel Configuration

**Purpose** Verify that the device is configured properly for tunnel configuration.

**Action** From configuration mode, enter the **show interfaces queue ip-0/0/0.0** command.

**NOTE:** If you enter **ip-0/0/0.0** only, queue information for all tunnels is displayed. If you enter **ip-0/0/0.0**, queue information for the specific tunnel is displayed.

### Copying Outer IP Header DSCP and ECN to Inner IP Header

This feature enables copying of Differentiated Services Code Point (DSCP) (outer DSCP+ECN) field from the outer IP header encrypted packet to the inner IP header plain text message on the decryption path.

The benefit in enabling this feature is that after IPsec decryption, clear text packets can follow the inner CoS (DSCP+ECN) rules.

This feature supports chassis cluster and also supports IPv6 and IPv4. The following are supported:

- Copying outer IPv4 DSCP and Explicit Congestion Notification (ECN) field to inner IPv4 DSCP and ECN field
- Copying outer IPv6 DSCP and ECN field to inner IPv6 DSCP and ECN field
- Copying outer IPv4 DSCP and ECN field to inner IPv6 DSCP and ECN field
- Copying outer IPv6 DSCP and ECN field to inner IPv4 DSCP and ECN field

By default this feature is disabled. When you enable this feature on a VPN object, the corresponding IPsec security Association (SA) is cleared and reestablished.

- To enable the feature:  
**set security ipsec vpn *vpn-name* copy-outer-dscp**
- To disable the feature:  
**delete security ipsec vpn *vpn-name* copy-outer-dscp**
- To verify whether the feature is enabled or not:  
**show security ipsec security-associations detail**

# Naming Components with Code-Point Aliases

- [Code-Point Aliases Overview on page 1521](#)
- [Default CoS Values and Aliases on page 1522](#)
- [Example: Defining Code-Point Aliases for Bits on page 1525](#)

## Code-Point Aliases Overview

---

A code-point alias assigns a name to a pattern of code-point bits. You can use this name instead of the bit pattern when you configure other class-of-service (CoS) components, such as classifiers, drop-profile maps, and rewrite rules.

When you configure classes and define classifiers, you can refer to the markers by alias names. You can configure user-defined classifiers in terms of alias names. If the value of an alias changes, it alters the behavior of any classifier that references it.

The following types of code points are supported by Junos operating system (OS):

- DSCP—Defines aliases for DiffServ code point (DSCP) IPv4 values.  
You can refer to these aliases when you configure classes and define classifiers.
- DSCP-IPv6—Defines aliases for DSCP IPv6 values.  
You can refer to these aliases when you configure classes and define classifiers.
- EXP—Defines aliases for MPLS EXP bits.  
You can map MPLS EXP bits to the device forwarding classes.
- inet-precedence—Defines aliases for IPv4 precedence values.

Precedence values are modified in the IPv4 type-of-service (ToS) field and mapped to values that correspond to levels of service.

### Example: Defining Code-Point Aliases for Bits

This example shows how to define code-point aliases for bits on a device.

- [Requirements on page 1526](#)
- [Overview on page 1526](#)
- [Configuration on page 1526](#)
- [Verification on page 1526](#)

## Requirements

Before you begin, determine which default mapping to use. See [“Default CoS Values and Aliases” on page 1522](#).

## Overview

In this example, you configure class of service and specify names and values for the CoS code-point aliases that you want to configure. Finally, you specify CoS value using the appropriate formats.

## Configuration

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To define code-point aliases for bits on a device:

1. Configure class of service.  

```
[edit]
user@host# edit class-of-service
```
2. Specify CoS values.  

```
[edit class-of-service]
user@host# set code-point-aliases dscp my1 110001
user@host# set code-point-aliases dscp my2 101110
user@host# set code-point-aliases dscp be 000001
user@host# set code-point-aliases dscp cs7 110000
```
3. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show class-of-service code-point-aliases dscp** command.

- [Example: Controlling Remaining Traffic on page 1547](#)

## Understanding Hierarchical Schedulers

Hierarchical schedules consist of nodes and queues. Queues terminate the CLI hierarchy. Nodes can be either root nodes, leaf nodes, or internal (non-leaf) nodes. Internal nodes are nodes that have other nodes as “children” in the hierarchy. For example, if an **interface-set** statement is configured with a logical interface (such as unit 0) and queue, then the **interface-set** is an internal node at level 2 of the hierarchy. However, if there are no traffic control profiles configured on logical interfaces, then the interface set is at level 3 of the hierarchy.

[Table 146](#) shows how the configuration of an interface set or logical interface affects the terminology of hierarchical scheduler nodes.

**Table 146: Hierarchical Scheduler Nodes**

| Root Node (Level 1) | Internal Node (Level 2) | Leaf Node (Level 3) | Queue (Level 4)    |
|---------------------|-------------------------|---------------------|--------------------|
| Physical interface  | Interface set           | Logical interfaces  | One or more queues |
| Physical interface  | –                       | Interface set       | One or more queues |
| Physical interface  | –                       | Logical interfaces  | One or more queues |

When used, the interface set level of the hierarchy falls between the physical interface level (level 1) and the logical interface (level 3). Queues are always level 4 of the hierarchy. The schedulers hold the information about the queues, the last level of the hierarchy. In

all cases, the properties for level 4 of the hierarchical schedulers are determined by the scheduler map.

Hierarchical schedulers add CoS parameters to the new interface set level of the configuration. They use traffic control profiles to set values for parameters such as shaping rate (the peak information rate [PIR]), guaranteed rate (the committed information rate [CIR] on these interfaces), and scheduler maps (the queues and resources assigned to traffic).

The following CoS configuration places the following parameters in traffic control profiles at various levels:

- Traffic control profile at the port level (**tcp-port-level1**):
  - A shaping rate (PIR) of 100 Mbps
  - A delay buffer rate of 100 Mbps
- Traffic control profile at the interface set level (**tcp-interface-level2**):
  - A shaping rate (PIR) of 60 Mbps
  - A guaranteed rate (CIR) of 40 Mbps
- Traffic control profile at the logical interface level (**tcp-unit-level3**):
  - A shaping rate (PIR) of 50 Mbps
  - A guaranteed rate (CIR) of 30 Mbps
  - A scheduler map called `smap1` to hold various queue properties (level 4)
  - A delay buffer rate of 40 Mbps

In this case, the traffic control profiles look like this:

```
[edit class-of-service traffic-control-profiles]
tcp-port-level1 { # This is the physical port level
 shaping-rate 100m;
 delay-buffer-rate 100m;
}
tcp-interface-level2 { # This is the interface set level
 shaping-rate 60m;
 guaranteed-rate 40m;
}
tcp-unit-level3 { # This is the logical interface level
 shaping-rate 50m;
 guaranteed-rate 30m;
 scheduler-map smap1;
 delay-buffer-rate 40m;
}
```

Once configured, the traffic control profiles must be applied to the proper places in the CoS interfaces hierarchy.

```
[edit class-of-service interfaces]
interface-set level-2 {
 output-traffic-control-profile tcp-interface-level-2;
```

```

}
ge-0/1/0 {
 output-traffic-control-profile tcp-port-level-1;
 unit 0 {
 output-traffic-control-profile tcp-unit-level-3;
 }
}

```

Interface sets can be defined as a list of logical interfaces, for example, unit 100, unit 200, and so on. Service providers can use these statements to group interfaces to apply scheduling parameters such as guaranteed rate and shaping rate to the traffic in the groups. Interface sets are currently only used by CoS, but they are applied at the **[edit interfaces]** hierarchy level so that they might be available to other services.

All traffic heading downstream must be gathered into an interface set with the **interface-set** statement at the [edit class-of-service interfaces] hierarchy level.

**NOTE:** Ranges are not supported; you must list each logical interface separately.

Although the interface set is applied at the [edit interfaces] hierarchy level, the CoS parameters for the interface set are defined at the [edit class-of-service interfaces] hierarchy level, usually with the **output-traffic-control-profile *profile-name*** statement.

You cannot specify an interface set mixing the logical interface, S-VLAN, or VLAN outer tag list forms of the **interface-set** statement. A logical interface can only belong to one interface set. If you try to add the same logical interface to different interface sets, the commit will fail.

This example will generate a commit error:

```

[edit interfaces]
interface-set set-one {
 ge-2/0/0 {
 unit 0;
 unit 2;
 }
}
interface-set set-two {
 ge-2/0/0 {
 unit 1;
 unit 3;
 unit 0; # COMMIT ERROR! Unit 0 already belongs to -set-one.
 }
}

```

Members of an interface set cannot span multiple physical interfaces. Only one physical interface is allowed to appear in an interface set.

This configuration is not supported:

```

[edit interfaces]
interface-set set-group {

```

```
ge-0/0/1 {
 unit 0;
 unit 1;
}
ge-0/0/2 { # This type of configuration is NOT supported in the same interface set!
 unit 0;
 unit 1;
}
}
```

You can configure many logical interfaces under an interface. However, only a subset of them might have a traffic control profile attached. For example, you can configure three logical interfaces (units) over the same service VLAN, but you can apply a traffic control profile specifying best-effort and voice queues to only one of the logical interface units. Traffic from the two remaining logical interfaces is considered remaining traffic.

The scheduler map configured at individual interfaces (Level 3), interface sets (Level 2), or physical ports (Level 1), defines packet scheduling behavior at different levels. You can group logical interfaces in an interface set and configure the interfaces with scheduler maps. Any egress packet arriving at the physical or logical interfaces will be handled by the interface specific scheduler. If the scheduler map is not configured at the interface level, the packet will be handled by the scheduler configured at the interface set level or the port level.

Documentation**

- [SRX1400, SRX3400, and SRX3600 Device Hardware Capabilities and Limitations on page 1533](#)
- [Example: Configuring a Four-Level Scheduler Hierarchy on page 1535](#)
- [Example: Controlling Remaining Traffic on page 1547](#)
- [Understanding Internal Scheduler Nodes on page 1532](#)

---

## Understanding Internal Scheduler Nodes

A node in the hierarchy is considered internal if either of the following conditions apply:

- One of its children nodes has a traffic control profile configured and applied.
- You configure the **internal-node** statement.

There are more resources available at the logical interface (unit) level than at the interface set level. It might be desirable to configure all resources at a single level, rather than spread over several levels. The **internal-node** statement provides this flexibility. This can be a helpful configuration device when interface-set queuing without logical interfaces is used exclusively on the interface.

You can use the **internal-node** statement to raise the interface set without children to the same level as the other configured interface sets with children, allowing them to compete for the same set of resources.

Using the **internal-node** statement allows statements to all be scheduled at the same level with or without children.

The following example makes the interface sets **if-set-1** and **if-set-2** internal:

```
[edit class-of-service interfaces]
interface-set {
 if-set-1 {
 internal-node;
 output-traffic-control-profile tcp-200m-no-smap;
 }
 if-set-2 {
 internal-node;
 output-traffic-control-profile tcp-100m-no-smap;
 }
}
```

If an interface set has logical interfaces configured with a traffic control profile, then the use of the **internal-node** statement has no effect.

Internal nodes can specify a **traffic-control-profile-remaining** statement.

## SRX1400, SRX3400, and SRX3600 Device Hardware Capabilities and Limitations

For SRX1400, SRX3400, and SRX3600 devices, each Input/Output Card (IOC), Flexible PIC Concentrator (FPC), or IOC slot has only one Physical Interface Card (PIC), which contains either two 10-Gigabit Ethernet ports or sixteen 1-Gigabit Ethernet ports. [Table 147](#) shows the maximum number of cards and ports allowed in SRX1400, SRX3400, and SRX3600 devices.

**NOTE:** The number of ports the Network Processing Unit (NPU) needs to handle might be different from the fixed 10:1 port to NPU ratio for 1-Gigabit IOC, or the 1:1 ratio for the 10-Gigabit IOC that is needed on the SRX5600 and SRX5800 devices, leading to oversubscription on the SRX1400, SRX3400, and SRX3600 devices.

**Table 147: Available NPCs and IO Ports for SRX1400, SRX3400, and SRX3600 Devices**

| System  | IOCs | IO Ports          | NPCs |
|---------|------|-------------------|------|
| SRX3600 | 7    | 108 (16 x 6 + 12) | 3    |
| SRX3400 | 5    | 76 (16 x 4 + 12)  | 2    |
| SRX1400 | 2    | 28 (16 x 1 + 12)  | 1    |

SRX3400 and SRX3600 devices allow you to install up to three Network Processing Cards (NPCs). In a single NPC configuration, the NPC has to process all of the packets to and from each IOC. However, when there is more than one NPC available, an IOC will only exchange packets with a preassigned NPC. You can use the **set chassis ioc-npc-connectivity** CLI statement to configure the IOC-to-NPC mapping. By default, the mapping is assigned so that the load is shared equally among all NPCs. When the mapping is changed, for example, an IOC or NPC is removed, or you have mapped a specific NPC to an IOC, then the device has to be restarted.

**NOTE:** SRX1400 devices support a single NPC or an NSPC combo card.

For SRX1400, SRX3400, and SRX3600 devices, the IOC supports the following hierarchical scheduler characteristics:

- Level 1- Shaping at the physical interface (ifd)
- Level 2- Shaping and scheduling at the logical interface level (ifl)
- Level 3- Scheduling at the queue level

**NOTE:** Interface set (iflset) is not supported for SRX1400, SRX3400, and SRX3600 devices.

In SRX5600 and SRX5800 devices, an NPC supports 32 port-level shaping profiles at level 1, such that each front port can have its own shaping profile.

In SRX1400, SRX3400, and SRX3600 devices, an NPC supports only 16 port-level shaping profiles in the hardware, including two profiles that are predefined for 10-GB and 1-GB shaping rates. The user can configure up to 14 different levels of shaping rates. If more levels are configured, then the closest match found in the 16 profiles will be used instead.

For example, assume that a system is already configured with the following rates for ifd:

10 Mbps, 20 Mbps, 40 Mbps, 60 Mbps, 80 Mbps, 100 Mbps, 200 Mbps, 300 Mbps, 400 Mbps, 500 Mbps, 600 Mbps, 700 Mbps, 800 Mbps, 900 Mbps, 1 GB (predefined), 10 GB (predefined)

Each of these 16 rates is programmed into one of the 16 profiles in the hardware; then consider the following two scenarios:

- Scenario 1: If the user changes one port's shaping rate from 1 GB to 100 Mbps, which is already programmed in one of the 16 profiles, the profile with a 100 Mbps shaping rate will be used by the port.
- Scenario 2: If the user changes another port's shaping rate from 1 GB to 50 Mbps, which is not in the shaping profiles, the closest matching profile with a 60 Mbps shaping rate will be used instead.

When scenario 2 occurs, not all of the user-configured rates can be supported by the hardware. Even if more than 14 different rates are specified, only 14 will be programmed in the hardware. Which 14 rates are programmed in the hardware depends on many factors. For this reason, we recommend that you plan carefully and use no more than 14 levels of port-level shaping rates.

Each device supports Weighed Random Early Discard (WRED) at the port level, and each NPU has 512 MB of frame memory. Also, 10-Gigabit Ethernet ports get more buffers than the 1-Gigabit Ethernet ports. Buffer availability depends on how much bandwidth (number of NPCs, ports, 1 GB or 10 GB, and so on) the device has to support. The more bandwidth that the device has to support, the less buffer is available. When two NPCs are available, the amount of frame buffer available is doubled.

## Example: Configuring a Four-Level Scheduler Hierarchy

---

This example shows how to configure a 4-level hierarchy of schedulers.

- [Requirements on page 1535](#)
- [Overview on page 1535](#)
- [Configuration on page 1536](#)
- [Verification on page 1546](#)

### Requirements

Before you begin:

- Review how to configure schedulers. See [“Example: Configuring Class-of-Service Schedulers” on page 1457](#).
- Review RED drop profiles. See *Understanding RED Drop Profiles*.
- Review how to configure and apply scheduler maps. See [“Example: Configuring and Applying Scheduler Maps” on page 1472](#).

### Overview

The configuration parameters for this example are shown in [Figure 78](#). The queues are shown at the top of the figure with the other three levels of the hierarchy below.

Figure 78: Building a Scheduler Hierarchy

Figure 78's PIR values will be configured as the shaping rates, and the CIRs will be configured as the guaranteed rate on the Ethernet interface **ge-1/0/0**. The PIR can be oversubscribed (that is, the sum of the children PIRs can exceed the parent's, as in **svlan 1**, where  $200 + 200 + 100$  exceeds the parent rate of 400). However, the sum of the children node level's CIRs must never exceed the parent node's CIR, as shown in all the service VLANs (otherwise, the guaranteed rate could never be provided in all cases).

**NOTE:** Although a shaping rate can be applied directly to the physical interface, hierarchical schedulers must use a traffic control profile to hold the shaping rate parameter.

The keyword to configure hierarchical schedulers is at the physical interface level, as are VLAN tagging and the VLAN IDs. In this example, the interface sets are defined by logical interfaces (units) and not outer VLAN tags. All VLAN tags in this example are customer VLAN tags.

The traffic control profiles in this example are for both the service VLAN level (logical interfaces) and the customer VLAN (VLAN tag) level.

This example shows all details of the CoS configuration for the **ge-1/0/0** interface in Figure 78.

## Configuration

This section contains the following topics:

- [Configuring the Drop Profiles on page 1542](#)

- [Configuring the Scheduler Maps on page 1543](#)
- [Applying Traffic Control Profiles on page 1545](#)

### Configuring the Logical Interfaces

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from the configuration mode.

```
edit interface ge-1/0/0
set hierarchical-scheduler vlan-tagging unit 1 vlan-id 101
set hierarchical-scheduler vlan-tagging unit 1 vlan-id 101
set hierarchical-scheduler vlan-tagging unit 2 vlan-id 102
set hierarchical-scheduler vlan-tagging unit 3 vlan-id 103
set hierarchical-scheduler vlan-tagging unit 4 vlan-id 104
```

**Step-by-Step Procedure** To configure the logical interfaces:

1. Create the logical interface.

```
[edit]
user@host# edit interface ge-1/0/0
```

2. Create the interface sets by defining the VLAN tagging and the VLAN IDs for each level.

```
[edit interface ge-1/0/0]
user@host# set hierarchical-scheduler vlan-tagging unit 0 vlan-id 100
user@host# set hierarchical-scheduler vlan-tagging unit 1 vlan-id 101
user@host# set hierarchical-scheduler vlan-tagging unit 2 vlan-id 102
user@host# set hierarchical-scheduler vlan-tagging unit 3 vlan-id 103
user@host# set hierarchical-scheduler vlan-tagging unit 4 vlan-id 104
```

**Results** From configuration mode, confirm your configuration by entering the **show interface ge-1/0/0** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interface ge-1/0/0
hierarchical-scheduler;
vlan-tagging;
unit 0 {
 vlan-id 100;
}
unit 1 {
 vlan-id 101;
}
unit 2 {
 vlan-id 102;
}
unit 3 {
 vlan-id 103;
}
unit 4 {
```

```

 vlan-id 104;
 }

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring the Interface Sets

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set class-of-service interfaces interface-set svlan-0 interface ge-1/0/0 unit 0
set class-of-service interfaces interface-set svlan-0 interface ge-1/0/0 unit 1
set class-of-service interfaces interface-set svlan-1 interface ge-1/0/0 unit 2
set class-of-service interfaces interface-set svlan-1 interface ge-1/0/0 unit 3
set class-of-service interfaces interface-set svlan-1 interface ge-1/0/0 unit 4

```

#### Step-by-Step Procedure

To configure the interface sets:

1. Create the first logical interface and its CoS parameters.

```

[edit class-of-service interfaces]
user@host# set interface-set svlan-0 interface ge-1/0/0 unit 0
user@host# set interface-set svlan-0 interface ge-1/0/0 unit 1

```

2. Create the second logical interface and its CoS parameters.

```

[edit class-of-service interfaces]
user@host# set interface-set svlan-1 interface ge-1/0/0 unit 2
user@host# set interface-set svlan-1 interface ge-1/0/0 unit 3
user@host# set interface-set svlan-1 interface ge-1/0/0 unit 4

```

#### Results

From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show interfaces
interface-set svlan-0 {
 interface ge-1/0/0 {
 unit 0;
 unit 1;
 }
}
interface-set svlan-1 {
 interface ge-1/0/0 {
 unit 2;
 unit 3;
 unit 4;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Applying an Interface Set

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service interfaces interface-set set-ge-0 output-traffic-control-profile tcp-set1
```

**Step-by-Step Procedure** To apply an interface set:

1. Create the Ethernet interface set.

```
[edit class-of-service interfaces]
user@host# set interface-set set-ge-0
```

2. Apply a traffic control parameter to the Ethernet interface set.

```
[edit class-of-service interfaces interface-set set-ge-0]
user@host# set output-traffic-control-profile tcp-set1
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces
interface-set set-ge-0 {
 output-traffic-control-profile tcp-set1;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring the Traffic Control Profiles

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service traffic-control-profiles tcp-500m-shaping-rate shaping-rate 500m
set class-of-service traffic-control-profiles tcp-svlan0 shaping-rate 200m guaranteed-rate
100m delay-buffer-rate 300m
set class-of-service traffic-control-profiles tcp-svlan1 shaping-rate 400m guaranteed-rate
30100m delay-buffer-rate 100m
set class-of-service traffic-control-profiles tcp-cvlan0 shaping-rate 100m guaranteed-rate
60m scheduler-map tcp-map-cvlan0
set class-of-service traffic-control-profiles tcp-cvlan1 shaping-rate 100m guaranteed-rate
40m scheduler-map tcp-map-cvlan1
set class-of-service traffic-control-profiles tcp-cvlan2 shaping-rate 200m guaranteed-rate
100m scheduler-map tcp-map-cvlanx
set class-of-service traffic-control-profiles tcp-cvlan3 shaping-rate 200m guaranteed-rate
150m scheduler-map tcp-map-cvlanx
```

```
set class-of-service traffic-control-profiles tcp-cvlan4 shaping-rate 100m guaranteed-rate
50m scheduler-map tcp-map-cvlanx
```

### Step-by-Step Procedure

To configure the traffic control profiles:

1. Create the traffic profile parameters.  

```
[edit class-of-service traffic-control-profiles]
user@host# tcp-500m-shaping-rate shaping-rate 500m
```
2. Create the traffic control profiles and parameters for the S-VLAN (logical interfaces) level.  

```
[edit class-of-service traffic-control-profiles]
user@host# set tcp-svlan0 shaping-rate 200m guaranteed-rate 100m
delay-buffer-rate 300m
user@host# set tcp-svlan1 shaping-rate 400m guaranteed-rate 30100m
delay-buffer-rate 100m
```
3. Create the traffic control profiles and parameters for the C-VLAN (VLAN tags) level.  

```
[edit class-of-service traffic-control-profiles]
user@host# set tcp-cvlan0 shaping-rate 100m guaranteed-rate 60m scheduler-map
tcp-map-cvlan0
user@host# set tcp-cvlan1 shaping-rate 100m guaranteed-rate 40m scheduler-map
tcp-map-cvlan1
user@host# set tcp-cvlan2 shaping-rate 200m guaranteed-rate 100m
scheduler-map tcp-map-cvlanx
user@host# set tcp-cvlan3 shaping-rate 200m guaranteed-rate 150m scheduler-map
tcp-map-cvlanx
user@host# set tcp-cvlan4 shaping-rate 100m guaranteed-rate 50m scheduler-map
tcp-map-cvlanx
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service traffic-control-profiles** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service traffic-control-profiles
tcp-500m-shaping-rate {
 shaping-rate 500m;
}
tcp-svlan0 {
 shaping-rate 200m;
 guaranteed-rate 100m;
 delay-buffer-rate 300m; # This parameter is not shown in the figure
}
tcp-svlan1 {
 shaping-rate 400m;
 guaranteed-rate 300m;
 delay-buffer-rate 100m; # This parameter is not shown in the figure
}
tcp-cvlan0 {
 shaping-rate 100m;
 guaranteed-rate 60m;
 scheduler-map tcp-map-cvlan0; # This example applies scheduler maps to customer
VLANs
```

```

}
tcp-cvlan1 {
 shaping-rate 100m;
 guaranteed-rate 40m;
 scheduler-map tcp-map-cvlan1; # This example applies scheduler maps to customer
 VLANs
}
tcp-cvlan2 {
 shaping-rate 200m;
 guaranteed-rate 100m;
 scheduler-map tcp-map-cvlanx; # This example applies scheduler maps to customer
 VLANs
}
tcp-cvlan3 {
 shaping-rate 200m;
 guaranteed-rate 150m;
 scheduler-map tcp-map-cvlanx; # This example applies scheduler maps to customer
 VLANs
}
tcp-cvlan4 {
 shaping-rate 100m;
 guaranteed-rate 50m;
 scheduler-map tcp-map-cvlanx; # This example applies scheduler maps to customer
 VLANs
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring the Schedulers

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set class-of-service schedulers sched-cvlan0-qx priority low transmit-rate 20m buffer-size
temporal 100ms drop-profile-map loss-priority low dp-low drop-profile-map loss-priority
high dp-high
set class-of-service schedulers sched-cvlan1-q0 priority high transmit-rate 20m buffer-size
percent 40 drop-profile-map loss-priority low dp-low drop-profile-map loss-priority
high dp-high
set class-of-service schedulers sched-cvlanx-qx transmit-rate percent 30 buffer-size
percent 30 drop-profile-map loss-priority low dp-low drop-profile-map loss-priority
high dp-high
set class-of-service schedulers sched-cvlan1-qx transmit-rate 10m buffer-size temporal
100ms drop-profile-map loss-priority low dp-low drop-profile-map loss-priority high
dp-high

```

#### Step-by-Step Procedure

To configure the schedulers:

1. Create the schedulers and their parameters.  
**[edit class-of-service schedulers]**

```

user@host# set sched-cvlan0-qx priority low transmit-rate 20m buffer-size temporal
100ms drop-profile-map loss-priority low dp-low drop-profile-map loss-priority
high dp-high
user@host# set sched-cvlan1-q0 priority high transmit-rate 20m buffer-size percent
40 drop-profile-map loss-priority low dp-low drop-profile-map loss-priority high
dp-high
user@host# set sched-cvlanx-qx transmit-rate percent 30 buffer-size percent 30
drop-profile-map loss-priority low dp-low drop-profile-map loss-priority high
dp-high
user@host# set sched-cvlan1-qx transmit-rate 10m buffer-size temporal 100ms
drop-profile-map loss-priority low dp-low drop-profile-map loss-priority high
dp-high

```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service schedulers** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show class-of-service schedulers
sched-cvlan0-qx {
 priority low;
 transmit-rate 20m;
 buffer-size temporal 100ms;
 drop-profile-map loss-priority low dp-low;
 drop-profile-map loss-priority high dp-high;
}
sched-cvlan1-q0 {
 priority high;
 transmit-rate 20m;
 buffer-size percent 40;
 drop-profile-map loss-priority low dp-low;
 drop-profile-map loss-priority high dp-high;
}
sched-cvlanx-qx {
 transmit-rate percent 30;
 buffer-size percent 30;
 drop-profile-map loss-priority low dp-low;
 drop-profile-map loss-priority high dp-high;
}
sched-cvlan1-qx {
 transmit-rate 10m;
 buffer-size temporal 100ms;
 drop-profile-map loss-priority low dp-low;
 drop-profile-map loss-priority high dp-high;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring the Drop Profiles

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set class-of-service drop-profiles dp-low interpolate fill-level 80 drop-probability 80
set class-of-service drop-profiles dp-low interpolate fill-level 100 drop-probability 100
set class-of-service drop-profiles dp-high interpolate fill-level 60 drop-probability 80
set class-of-service drop-profiles dp-high interpolate fill-level 80 drop-probability 100

```

#### Step-by-Step Procedure

To configure the drop profiles:

1. Create the low drop profile.

```

[edit class-of-service drop-profiles]
user@host# set dp-low interpolate fill-level 80 drop-probability 80
user@host# set dp-low interpolate fill-level 100 drop-probability 100

```

2. Create the high drop profile.

```

[edit class-of-service drop-profiles]
user@host# set dp-high interpolate fill-level 60 drop-probability 80
user@host# set dp-high interpolate fill-level 80 drop-probability 100

```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service drop-profiles** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show class-of-service drop-profiles
dp-low {
 interpolate fill-level 80 drop-probability 80;
 interpolate fill-level 100 drop-probability 100;
}
dp-high {
 interpolate fill-level 60 drop-probability 80;
 interpolate fill-level 80 drop-probability 100;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

#### Configuring the Scheduler Maps

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set class-of-service scheduler-maps tcp-map-cvlan0 forwarding-class voice scheduler
 sched-cvlan0-qx
set class-of-service scheduler-maps tcp-map-cvlan0 forwarding-class video scheduler
 sched-cvlan0-qx
set class-of-service scheduler-maps tcp-map-cvlan0 forwarding-class data scheduler
 sched-cvlan0-qx
set class-of-service scheduler-maps tcp-map-cvlan1 forwarding-class voice scheduler
 sched-cvlan1-q0
set class-of-service scheduler-maps tcp-map-cvlan1 forwarding-class video scheduler
 sched-cvlan1-qx
set class-of-service scheduler-maps tcp-map-cvlan1 forwarding-class data scheduler
 sched-cvlan1-qx

```

```

set class-of-service scheduler-maps tcp-map-cvlanx forwarding-class voice scheduler
 sched-cvlanx-qx
set class-of-service scheduler-maps tcp-map-cvlanx forwarding-class video scheduler
 sched-cvlanx-qx
set class-of-service scheduler-maps tcp-map-cvlanx forwarding-class data scheduler
 sched-cvlanx-qx

```

### Step-by-Step Procedure

To configure three scheduler maps:

1. Create the first scheduler map.

```

[edit class-of-service scheduler-maps]
user@host# set tcp-map-cvlan0 forwarding-class voice scheduler sched-cvlan0-qx
user@host# set tcp-map-cvlan0 forwarding-class video scheduler sched-cvlan0-qx
user@host# set tcp-map-cvlan0 forwarding-class data scheduler sched-cvlan0-qx

```

2. Create the second scheduler map.

```

[edit class-of-service scheduler-maps]
user@host# set tcp-map-cvlan1 forwarding-class voice scheduler sched-cvlan1-q0
user@host# set tcp-map-cvlan1 forwarding-class video scheduler sched-cvlan1-qx
user@host# set tcp-map-cvlan1 forwarding-class data scheduler sched-cvlan1-qx

```

3. Create the third scheduler map.

```

[edit class-of-service scheduler-maps]
user@host# set tcp-map-cvlanx forwarding-class voice scheduler sched-cvlanx-qx
user@host# set tcp-map-cvlanx forwarding-class video scheduler sched-cvlanx-qx
user@host# set tcp-map-cvlanx forwarding-class data scheduler sched-cvlanx-qx

```

### Results

From configuration mode, confirm your configuration by entering the **show class-of-service scheduler-maps** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show class-of-service scheduler-maps
tcp-map-cvlan0 {
 forwarding-class voice scheduler sched-cvlan0-qx;
 forwarding-class video scheduler sched-cvlan0-qx;
 forwarding-class data scheduler sched-cvlan0-qx;
}
tcp-map-cvlan1 {
 forwarding-class voice scheduler sched-cvlan1-q0;
 forwarding-class video scheduler sched-cvlan1-qx;
 forwarding-class data scheduler sched-cvlan1-qx;
}
tcp-map-cvlanx {
 forwarding-class voice scheduler sched-cvlanx-qx;
 forwarding-class video scheduler sched-cvlanx-qx;
 forwarding-class data scheduler sched-cvlanx-qx;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Applying Traffic Control Profiles

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile
 tcp-500m-shaping-rate unit 0 output-control-traffic-control-profile tcp-cvlan0
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile
 tcp-500m-shaping-rate unit 1 output-control-traffic-control-profile tcp-cvlan1
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile
 tcp-500m-shaping-rate unit 2 output-control-traffic-control-profile tcp-cvlan2
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile
 tcp-500m-shaping-rate unit 3 output-control-traffic-control-profile tcp-cvlan3
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile
 tcp-500m-shaping-rate unit 4 output-control-traffic-control-profile tcp-cvlan4
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile
 tcp-500m-shaping-rate interface-set-svlan0 output-control-traffic-control-profile
 tcp-svlan0
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile
 tcp-500m-shaping-rate interface-set-svlan1 output-control-traffic-control-profile
 tcp-svlan1
```

**Step-by-Step Procedure** To apply traffic control profiles:

1. Set the interface.  

```
[edit class-of-service]
user@host# set interfaces ge-1/0/0
```
2. Set the traffic control profiles for the C-VLANs.  

```
[edit class-of-service interfaces ge-1/0/0]
user@host# set output-traffic-control-profile tcp-500m-shaping-rate unit 0
 output-control-traffic-control-profile tcp-cvlan0
user@host# set output-traffic-control-profile tcp-500m-shaping-rate unit 1
 output-control-traffic-control-profile tcp-cvlan1
user@host# set output-traffic-control-profile tcp-500m-shaping-rate unit 2
 output-control-traffic-control-profile tcp-cvlan2
user@host# set output-traffic-control-profile tcp-500m-shaping-rate unit 3
 output-control-traffic-control-profile tcp-cvlan3
user@host# set output-traffic-control-profile tcp-500m-shaping-rate unit 4
 output-control-traffic-control-profile tcp-cvlan4
```
3. Set the traffic control profiles for the S-VLANs.  

```
[edit class-of-service interfaces ge-1/0/0]
user@host# set output-traffic-control-profile tcp-500m-shaping-rate
 interface-set-svlan0 output-control-traffic-control-profile tcp-svlan0
user@host# set output-traffic-control-profile tcp-500m-shaping-rate
 interface-set-svlan1 output-control-traffic-control-profile tcp-svlan1
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service interfaces
ge-1/0/0 {
 output-traffic-control-profile tcp-500m-shaping-rate;
 unit 0 {
 output-traffic-control-profile tcp-cvlan0;
 }
 unit 1 {
 output-traffic-control-profile tcp-cvlan1;
 }
 unit 2 {
 output-traffic-control-profile tcp-cvlan2;
 }
 unit 3 {
 output-traffic-control-profile tcp-cvlan3;
 }
 unit 4 {
 output-traffic-control-profile tcp-cvlan4;
 }
}
interface-set svlan0 {
 output-traffic-control-profile tcp-svlan0;
}
interface-set svlan1 {
 output-traffic-control-profile tcp-svlan1;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

---

### Verifying Scheduler Hierarchy Configuration

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Example: Controlling Remaining Traffic

---

This example shows how to control remaining traffic from the remaining logical interfaces.

- [Requirements on page 1547](#)
- [Overview on page 1547](#)
- [Configuration on page 1549](#)
- [Verification on page 1552](#)

### Requirements

Before you begin:

- Review how to configure schedulers. See [“Example: Configuring Class-of-Service Schedulers” on page 1457](#).
- Review how to configure and apply scheduler maps. See [“Example: Configuring and Applying Scheduler Maps” on page 1472](#).

### Overview

To configure transmit rate guarantees for the remaining traffic, you configure the **output-traffic-control-profile-remaining** statement specifying a guaranteed rate for the remaining traffic. Without this statement, the remaining traffic gets a default, minimal bandwidth. Similarly, you can specify the **shaping-rate** and **delay-buffer-rate** statements in the traffic control profile referenced with the **output-traffic-control-profile-remaining** statement to shape and provide buffering for remaining traffic.

In the interface shown in [Figure 79](#), customer VLANs 3 and 4 have no explicit traffic control profile. However, the service provider might want to establish a shaping and guaranteed transmit rate for aggregate traffic heading for those C-VLANs. The solution is to configure and apply a traffic control profile for all remaining traffic on the interface.

**Figure 79: Example 1 Handling Remaining Traffic with no Explicit Traffic Control Profile**

Example 1 considers the case where C-VLANs 3 and 4 have no explicit traffic control profile, yet need to establish a shaping and guaranteed transmit rate for traffic heading for those C-VLANs. The solution is to add a traffic control profile to the **svlan1** interface set. This example builds on the example used in [“Example: Configuring a Four-Level Scheduler Hierarchy” on page 1535](#) and does not repeat all configuration details, only those at the S-VLAN level.

Next, consider Example 2 shown in [Figure 80](#).

**Figure 80: Example 2 Handling Remaining Traffic with an Interface Set**

In Example 2, **ge-1/0/0** has five logical interfaces (C-VLAN 0, 1, 2, 3 and 4), and S-VLAN 0, which are covered by the interface set:

- Scheduling for the interface set **svlan0** is specified by referencing an **output-traffic-control-profile** statement, which specifies the **guaranteed-rate**, **shaping-rate**, and **delay-buffer-rate** statement values for the interface set. In this example, the output traffic control profile called **tcp-svlan0** guarantees 100 Mbps and shapes the interface set **svlan0** to 200 Mbps.
- Scheduling and queuing for remaining traffic of **svlan0** is specified by referencing an **output-traffic-control-profile-remaining** statement, which references a **scheduler-map**

statement that establishes queues for the remaining traffic. The specified traffic control profile can also configure guaranteed, shaping, and delay-buffer rates for the remaining traffic. In Example 2, **output-traffic-control-profile-remaining tcp-svlan0-rem** references **scheduler-map smap-svlan0-rem**, which calls for a best-effort queue for remaining traffic (that is, traffic on unit 3 and unit 4, which is not classified by the **svlan0** interface set). The example also specifies a **guaranteed-rate** of 200 Mbps and a **shaping-rate** of 300 Mbps for all remaining traffic.

- Scheduling and queuing for logical interface **ge-1/0/0 unit 1** is configured “traditionally” and uses an **output-traffic-control-profile** specified for that unit. In this example, **output-traffic-control-profile tcp-ift1** specifies scheduling and queuing for **ge-1/0/0 unit 1**.

## Configuration

This section contains the following topics:

- [Controlling Remaining Traffic With No Explicit Traffic Control Profile on page 1549](#)
- [Controlling Remaining Traffic With An Interface Set on page 1550](#)

### Controlling Remaining Traffic With No Explicit Traffic Control Profile

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service interfaces interface-set svlan0 output-traffic-control-profile
 tcp-svlan0
set class-of-service interfaces interface-set svlan1 output-traffic-control-profile tcp-svlan1
set class-of-service interfaces interface-set svlan1 output-traffic-control-profile-remaining
 tcp-svlan1-remaining
set class-of-service traffic-control-profiles tcp-svlan1 shaping-rate 400m guaranteed-rate
 300m
set class-of-service traffic-control-profiles tcp-svlan1-remaining shaping-rate 300m
 guaranteed-rate 200m scheduler-map smap-remainder
```

#### Step-by-Step Procedure

To control remaining traffic with no explicit traffic control profile:

1. Set the logical interfaces for the S-VLANs.
 

```
[edit class-of-service interfaces]
user@host# set interface-set svlan0 output-traffic-control-profile tcp-svlan0
user@host# set interface-set svlan1 output-traffic-control-profile tcp-svlan1
user@host# set interface-set svlan1 output-traffic-control-profile-remaining
 tcp-svlan1-remaining
```
2. Set the shaping and guaranteed transmit rates for traffic heading for those C-VLANs.
 

```
[edit class-of-service traffic-control-profiles]
user@host# set tcp-svlan1 shaping-rate 400m guaranteed-rate 300m
user@host# set tcp-svlan1-remaining shaping-rate 300m guaranteed-rate 200m
 scheduler-map smap-remainder
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service interfaces** and **show class-of-service traffic-control-profiles** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service interfaces
interface-set svlan0 {
 output-traffic-control-profile tcp-svlan0;
}
interface-set svlan1 {
 output-traffic-control-profile tcp-svlan1;
 output-traffic-control-profile-remaining tcp-svlan1-remaining; # For all remaining traffic
}
```

```
[edit]
user@host# show class-of-service traffic-control-profiles
tcp-svlan1 {
 shaping-rate 400m;
 guaranteed-rate 300m;
}
tcp-svlan1-remaining {
 shaping-rate 300m;
 guaranteed-rate 200m;
 scheduler-map smap-remainder; # this smap is not shown in detail
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Controlling Remaining Traffic With An Interface Set

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service interfaces interface-set svlan0 output-traffic-control-profile
 tcp-svlan0
set class-of-service interfaces ge-1/0/0 output-traffic-control-profile-remaining
 tcp-svlan0-rem unit 1 output-traffic-control-profile tcp-ifl1
set class-of-service traffic-control-profiles tcp-svlan0 shaping-rate 200m guaranteed-rate
 100m
set class-of-service traffic-control-profiles tcp-svlan0-rem shaping-rate 300m
 guaranteed-rate 200m scheduler-map smap-svlan0-rem
set class-of-service traffic-control-profiles tcp-ifl1 scheduler-map smap-ifl1
set class-of-service scheduler-maps smap-svlan0-rem forwarding-class best-effort
 scheduler-sched-foo
set class-of-service scheduler-maps smap-ifl1 forwarding-class best-effort
 scheduler-sched-bar
set class-of-service scheduler-maps smap-ifl1 forwarding-class assured-forwarding
 scheduler-sched-bar
```

**Step-by-Step Procedure** To control remaining traffic with an interface set:

1. Set the interface set for the S-VLAN.  

```
[edit class-of-service interfaces]
user@host# set interface-set svlan0 output-traffic-control-profile tcp-svlan0
user@host# set ge-1/0/0 output-traffic-control-profile-remaining tcp-svlan0-rem
unit 1 output-traffic-control-profile tcp-ifl1
```
2. Set the traffic control profiles.  

```
[edit class-of-service traffic-control-profiles]
user@host# set tcp-svlan0 shaping-rate 200m guaranteed-rate 100m
user@host# set tcp-svlan0-rem shaping-rate 300m guaranteed-rate 200m
scheduler-map smap-svlan0-rem
user@host# set tcp-ifl1 scheduler-map smap-ifl1
```
3. Set the scheduler map.  

```
[edit class-of-service scheduler-maps]
user@host# set smap-svlan0-rem forwarding-class best-effort scheduler-sched-foo
user@host# set smap-ifl1 forwarding-class best-effort scheduler-sched-bar
user@host# set smap-ifl1 forwarding-class assured-forwarding scheduler-sched-bar
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service interfaces**, **show class-of-service traffic-control-profiles**, and **show class-of-service scheduler-maps** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it. Example 2 does not include the **[edit interfaces]** configuration.

```
[edit]
user@host# show class-of-service interfaces
interface-set {
 svlan0 {
 output-traffic-control-profile tcp-svlan0; # Guarantee & shaper for svlan0
 }
}
ge-1/0/0 {
 output-traffic-control-profile-remaining tcp-svlan0-rem
 # Unit 3 and 4 are not explicitly configured, but captured by "remaining"
 unit 1 {
 output-traffic-control-profile tcp-ifl1; # Unit 1 be & ef queues
 }
}
```

```
[edit]
user@host# show class-of-service traffic-control-profiles
tcp-svlan0 {
 shaping-rate 200m;
 guaranteed-rate 100m;
}
tcp-svlan0-rem {
 shaping-rate 300m;
 guaranteed-rate 200m;
 scheduler-map smap-svlan0-rem; # This specifies queues for remaining traffic
}
```

```
tcp-ifl1 {
 scheduler-map smap-ifl1;
}
```

```
[edit]
user@host# show class-of-service scheduler-maps
smap-svlan0-rem {
 forwarding-class best-effort scheduler sched-foo;
}
smap-ifl1 {
 forwarding-class best-effort scheduler sched-bar;
 forwarding-class assured-forwarding scheduler sched-baz;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

The configuration for the referenced schedulers is not given for this example.

## Verification

### Verifying Remaining Traffic Control

---

**Purpose** Verify that the remaining traffic is controlled properly.

**Action** From operational mode, enter the following commands:

- **show class-of-service interfaces**
- **show class-of-service traffic-control-profiles**
- **show class-of-service scheduler-maps**

**Related Documentation**

- [Understanding DSCP IPv6 Rewrite Rules on page 1562](#)
- [Example: Configuring CoS with DSCP IPv6 Rewrite Rules on page 1562](#)

## CoS Functions for IPv6 Traffic Overview

Class-of-service (CoS) processing for IPv6 traffic uses the IPv6 DiffServ code point (DSCP) value. The IPv6 DSCP value is the first six bits in the 8-bit Traffic Class field of the IPv6 header. The DSCP value is used to determine the behavior aggregate (BA) classification for the packet entering the network device. You use classifier rules to map the DSCP code points to a forwarding class and packet loss priority. You use rewrite rules to map the forwarding class and packet loss priority back to DSCP values on packets exiting the device.

Figure 81 shows the components of the CoS features for Juniper Networks devices, illustrating the sequence in which they interact.

**Figure 81: Packet Flow Through an SRX Series Device**

**NOTE:** Not all CoS features are supported on all devices.

- CoS components perform the following operations:

BA classifier rules map DSCP code points to a forwarding class and loss priority. The forwarding class and loss priority determine the per-hop behavior of the packet throughout the system. The forwarding class associates a packet with an outbound transmission queue. Loss priority affects the scheduling of a packet without affecting the relative ordering of packets. BA classification is a simple way that “downstream” nodes can honor the CoS objectives that were encoded “upstream.”

See [“Example: Configuring CoS with DSCP IPv6 BA Classifiers” on page 1559.](#)

- Multifield classifier rules overwrite the initial forwarding class and loss priority determination read by the BA classifier rule. You typically use multifield classifier rules on nodes close to the content origin, where a packet might not have been encoded with the desired DSCP values in the headers. A multifield classifier rule assigns packets to a forwarding class and assigns a packet loss priority based on filters, such as source IP, destination IP, port, or application.

See [“Example: Configuring and Applying a Firewall Filter for a Multifield Classifier” on page 1417.](#)

- Input policers meter traffic to see if traffic flow exceeds its service level. Policers might discard, change the forwarding class and loss priority, or set the packet loss priority bit of a packet. A packet for which the packet loss priority bit is set has an increased probability of being dropped during congestion.
- Scheduler maps are applied to interfaces and associate the outgoing packets with a scheduler and a forwarding class.

The scheduler manages the output transmission queue, including:

- Buffer size—Defines the period for which a packet is stored during congestion.
- Scheduling priority and transmit rate—Determines the order in which a packet is transmitted.
- Drop profile—Defines how aggressively to drop a packet that is using a particular scheduler.

See [“Example: Configuring Class-of-Service Schedulers” on page 1457.](#)

- Output policers meter traffic and might change the forwarding class and loss priority of a packet if a traffic flow exceeds its service level.
- Rewrite rules map forwarding class and packet loss priority to DSCP values. You typically use rewrite rules in conjunction with multifield classifier rules close to the content origin, or when the device is at the border of a network and must alter the code points to meet the policies of the targeted peer.

See [“Example: Configuring CoS with DSCP IPv6 Rewrite Rules” on page 1562.](#)

Only BA classification rules and rewrite rules require special consideration to support CoS for IPv6 traffic. The program logic for the other CoS features is not sensitive to differences between IPv4 and IPv6 traffic.

## Understanding CoS with DSCP IPv6 BA Classifier

A behavior aggregate (BA) classifier rule maps DSCP code points to a forwarding class and loss priority. The forwarding class and loss priority determine the per-hop behavior of the packet throughout the system. The forwarding class associates a packet with an outbound transmission queue. Loss priority affects the scheduling of a packet without affecting the relative ordering of packets.

BA classification can be applied within one DiffServ domain or between two domains, where each domain honors the CoS results generated by the other domain. [Table 148](#) shows the mapping for the default DSCP IPv6 BA classifier.

**Table 148: Default IPv6 BA Classifier Mapping**

| Code Points | DSCP IPv6 Alias | Forwarding Class     | Packet Loss Priority |
|-------------|-----------------|----------------------|----------------------|
| 101110      | ef              | expedited-forwarding | low                  |
| 001010      | af11            | assured-forwarding   | low                  |
| 001100      | af12            | assured-forwarding   | high                 |
| 001110      | af13            | assured-forwarding   | high                 |
| 010010      | af21            | best-effort          | low                  |
| 010100      | af22            | best-effort          | low                  |
| 010110      | af23            | best-effort          | low                  |
| 011010      | af31            | best-effort          | low                  |
| 011100      | af32            | best-effort          | low                  |
| 011110      | af33            | best-effort          | low                  |
| 100010      | af41            | best-effort          | low                  |
| 100100      | af42            | best-effort          | low                  |

Table 148: Default IPv6 BA Classifier Mapping (*continued*)

| Code Points | DSCP IPv6 Alias | Forwarding Class | Packet Loss Priority |
|-------------|-----------------|------------------|----------------------|
| 100110      | af43            | best-effort      | low                  |
| 000000      | be              | best-effort      | low                  |
| 001000      | cs1             | best-effort      | low                  |
| 010000      | cs2             | best-effort      | low                  |
| 011000      | cs3             | best-effort      | low                  |
| 100000      | cs4             | best-effort      | low                  |
| 101000      | cs5             | best-effort      | low                  |
| 110000      | nc1/cs6         | network-control  | low                  |
| 111000      | nc2/cs7         | network-control  | low                  |

You can use the CLI **show** command to display the settings for the CoS classifiers. The following command shows the settings for the default DSCP IPv6 classifier:

```

user@host# show class-of-service classifier type dscp-ipv6
Classifier: dscp-ipv6-default, Code point type: dscp-ipv6, Index: 8
 Code point Forwarding class Loss priority
 000000 best-effort low
 000001 best-effort low
 000010 best-effort low
 000011 best-effort low
 000100 best-effort low
 000101 best-effort low
 011011 best-effort low
 ...
Classifier: dscp-ipv6-compatibility, Code point type: dscp-ipv6, Index: 9
 Code point Forwarding class Loss priority
 000000 best-effort low
 000001 best-effort low
 000010 best-effort low
 000011 best-effort low
 000100 best-effort low
 000101 best-effort low
 000110 best-effort low
 000111 best-effort low
 ...

```

**NOTE:** The predefined classifier named `dscp-ipv6-compatibility` maps all code point loss priorities to low. It maps 110000 and 111000 (typically seen in network control packets) to the network-control class and all other code points to the best-effort class. The `dscp-ipv6-compatibility` classifier is an implicit classifier similar to `ipprec-compatibility`, which is provided to map IP precedence bits in IPv4 traffic when no classifier has been configured.

## Example: Configuring CoS with DSCP IPv6 BA Classifiers

This example shows how to associate an interface with a default or user-defined DSCP IPv6 BA classifier.

- [Requirements on page 1559](#)
- [Overview on page 1559](#)
- [Configuration on page 1559](#)
- [Verification on page 1561](#)

### Requirements

Before you begin, configure the `ge-0/0/0` interface on the device for IPv6 and define your user-defined DSCP IPv6 classifier settings. See [“Understanding CoS with DSCP IPv6 BA Classifier” on page 1557](#).

### Overview

In this example, you configure CoS and define forwarding classes. You create the behavior aggregate classifier for DiffServ CoS as `dscp-ipv6-example` and import the default DSCP IPv6 classifier.

You then specify the best-effort forwarding class as `be-class`, the expedited forwarding class as `ef-class`, the assured forwarding class as `af-class`, and the network control forwarding class as `nc-class`. Finally, you apply your user-defined classifier to interface `ge-0/0/0`.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service forwarding-classes queue 0 be-class
```

```

set class-of-service forwarding-classes queue 1 ef-class
set class-of-service forwarding-classes queue 2 af-class
set class-of-service forwarding-classes queue 3 nc-class
set class-of-service classifiers dscp-ipv6 dscp-ipv6-example import default
set class-of-service classifiers dscp-ipv6 dscp-ipv6-example forwarding-class be-class
 loss-priority high code-points 000001
set class-of-service classifiers dscp-ipv6 dscp-ipv6-example forwarding-class ef-class
 loss-priority high code-points 101111
set class-of-service classifiers dscp-ipv6 dscp-ipv6-example forwarding-class af-class
 loss-priority high code-points 001100
set class-of-service classifiers dscp-ipv6 dscp-ipv6-example forwarding-class nc-class
 loss-priority high code-points 110001
set class-of-service interfaces ge-0/0/0 unit 0 classifiers dscp-ipv6 dscp-ipv6-example

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure CoS with a user-defined DSCP IPv6 BA classifier:

1. Configure CoS.  

```

[edit]
user@host# edit class-of-service

```
2. Define forwarding classes.  

```

[edit class-of-service]
user@host# set forwarding-classes queue 0 be-class
user@host# set forwarding-classes queue 1 ef-class
user@host# set forwarding-classes queue 2 af-class
user@host# set forwarding-classes queue 3 nc-class

```
3. Create a behavior aggregate classifier for DiffServ CoS.  

```

[edit class-of-service]
user@host# edit classifiers dscp-ipv6 dscp-ipv6-example

```
4. Import a DSCP IPv6 classifier.  

```

[edit class-of-service classifiers dscp-ipv6 dscp-ipv6-example]
user@host# set import default

```
5. Specify a best-effort forwarding class classifier.  

```

[edit class-of-service classifiers dscp-ipv6 dscp-ipv6-example]
user@host# set forwarding-class be-class loss-priority high code-points 000001

```
6. Specify an expedited forwarding class classifier.  

```

[edit class-of-service classifiers dscp-ipv6 dscp-ipv6-example]
user@host# set forwarding-class ef-class loss-priority high code-points 101111

```
7. Specify an assured forwarding class classifier.  

```

[edit class-of-service classifiers dscp-ipv6 dscp-ipv6-example]
user@host# set forwarding-class af-class loss-priority high code-points 001100

```
8. Specify a network control forwarding class classifier.  

```

[edit class-of-service classifiers dscp-ipv6 dscp-ipv6-example]

```

```
user@host# set forwarding-class nc-class loss-priority high code-points 110001
```

9. Associate a user-defined classifier with an interface.

```
[edit class-of-service]
```

```
user@host# set interfaces ge-0/0/0 unit 0 classifiers dscp-ipv6 dscp-ipv6-example
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
classifiers {
 dscp-ipv6 dscp-ipv6-example {
 import default;
 }
 forwarding-class be-class {
 loss-priority high code-points 000001;
 }
 forwarding-class ef-class {
 loss-priority high code-points 101111;
 }
 forwarding-class af-class {
 loss-priority high code-points 001100;
 }
 forwarding-class nc-class {
 loss-priority high code-points 110001;
 }
}
forwarding-classes {
 queue 0 be-class;
 queue 1 ef-class;
 queue 2 af-class;
 queue 3 nc-class;
}
interfaces {
 ge-0/0/0 {
 unit 0 {
 classifiers {
 dscp-ipv6 dscp-ipv6-example;
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the CoS with DSCP IPv6 BA Classifier Configuration on page 1562](#)

### Verifying the CoS with DSCP IPv6 BA Classifier Configuration

- Purpose** Verify that the user-defined DSCP IPv6 BA classifier is associated with an interface.
- Action** From configuration mode, enter the **show class-of-service** command.
- Related Documentation**
- [Understanding CoS with DSCP IPv6 BA Classifier on page 1557](#)

  - [Understanding DSCP IPv6 Rewrite Rules on page 1562](#)
  - [Example: Configuring CoS with DSCP IPv6 Rewrite Rules on page 1562](#)

### Understanding DSCP IPv6 Rewrite Rules

After Junos OS CoS processing, a rewrite rule maps the forwarding class and loss priority after Junos OS CoS processing to a corresponding DSCP value specified in the rule. Typically, you use rewrite rules to alter the CoS values in outgoing packets to meet the requirements of the targeted peer.

You can use the CLI show command to display the configuration for the CoS classifiers. The following command shows the configuration of the default DSCP IPv6 rewrite rule:

```
user@host# show class-of-service rewrite-rule type dscp-ipv6
Rewrite rule: dscp-ipv6-default, Code point type: dscp-ipv6, Index: 32
 Forwarding class Loss priority Code point
 best-effort low 000000
 best-effort high 000000
 expedited-forwarding low 101110
 expedited-forwarding high 101110
 assured-forwarding low 001010
 assured-forwarding high 001100
 network-control low 110000
 network-control high 111000
```

### Example: Configuring CoS with DSCP IPv6 Rewrite Rules

This example shows how to associate an interface with a default or user-defined DSCP IPv6 rewrite rule. Typically, you use rewrite rules to alter CoS values in outgoing packets to meet the requirements of the targeted peer.

- [Requirements on page 1563](#)
- [Overview on page 1563](#)

- [Configuration on page 1563](#)
- [Verification on page 1565](#)

## Requirements

Before you begin, configure the ge-0/0/0 interface on the device for IPv6 and define your user-defined DSCP IPv6 rewrite rules.

## Overview

In this example, you configure CoS and create a user-defined rewrite rule called `rewrite-ipv6-dscps`. You then specify rewrite rules for the best-effort forwarding class as `be-class`, the expedited forwarding class as `ef-class`, the assured forwarding class as `af-class`, and the network control forwarding class as `nc-class`. Finally, you associate interface `ge-0/0/0` with the user-defined rule.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class be-class
 loss-priority low code-point 000000
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class be-class
 loss-priority high code-point 000001
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class ef-class
 loss-priority low code-point 101110
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class ef-class
 loss-priority high code-point 101111
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class af-class
 loss-priority low code-point 001010
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class af-class
 loss-priority high code-point 001100
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class nc-class
 loss-priority low code-point 110000
set class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps forwarding-class nc-class
 loss-priority high code-point 110001
set class-of-service interfaces ge-0/0/0 unit 0 rewrite-rules dscp rewrite-dscps
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a CoS with a user-defined DSCP IPv6 rewrite rule:

1. Configure CoS.  

```
[edit]
user@host# edit class-of-service
```
2. Create a user-defined rewrite rule.

```
[edit class-of-service]
user@host# edit rewrite-rules dscp-ipv6 rewrite-ipv6-dscps
```

- Specify rewrite rules for the best-effort forwarding class.

```
[edit class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps]
user@host# set forwarding-class be-class loss-priority low code-point 000000
user@host# set forwarding-class be-class loss-priority high code-point 000001
```

- Specify rewrite rules for the expedited-forwarding forwarding class.

```
[edit class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps]
user@host# set forwarding-class ef-class loss-priority low code-point 101110
user@host# set forwarding-class ef-class loss-priority high code-point 101111
```

- Specify rewrite rules for the assured-forwarding forwarding class.

```
[edit class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps]
user@host# set forwarding-class af-class loss-priority low code-point 001010
user@host# set forwarding-class af-class loss-priority high code-point 001100
```

- Specify rewrite rules for the network-control forwarding class.

```
[edit class-of-service rewrite-rules dscp-ipv6 rewrite-ipv6-dscps]
user@host# set forwarding-class nc-class loss-priority low code-point 110000
user@host# set forwarding-class nc-class loss-priority high code-point 110001
```

- Associate an interface with a user-defined rule.

```
[edit class-of-service]
user@host# set interfaces ge-0/0/0 unit 0 rewrite-rules dscp rewrite-dscps
```

**Results** From configuration mode, confirm your configuration by entering the **show class-of-service** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show class-of-service
interfaces {
 ge-0/0/0 {
 unit 0 {
 rewrite-rules {
 dscp rewrite-dscps;
 }
 }
 }
}
rewrite-rules {
 dscp-ipv6 rewrite-ipv6-dscps {
 forwarding-class be-class {
 loss-priority low code-point 000000;
 loss-priority high code-point 000001;
 }
 forwarding-class ef-class {
 loss-priority low code-point 101110;
 loss-priority high code-point 101111;
 }
 forwarding-class af-class {
 loss-priority low code-point 001010;
 }
 }
}
```

```

 loss-priority high code-point 001100;
 }
 forwarding-class nc-class {
 loss-priority low code-point 110000;
 loss-priority high code-point 110001;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the CoS with DSCP IPv6 Rewrite Rule Configuration on page 1565](#)

### Verifying the CoS with DSCP IPv6 Rewrite Rule Configuration

**Purpose** Verify that the user-defined CoS with DSCP IPv6 rewrite rule is associated with an interface.

**Action** From configuration mode, enter the **show class-of-service** command.

## PIR-Only and CIR Mode Overview

The actual behavior of many CoS parameters, especially the shaping rate and guaranteed rate, depends on whether the physical interface is operating in one of the following modes:

- [PIR-only Mode on page 1569](#)
- [CIR Mode on page 1570](#)

### PIR-only Mode

In PIR-only (peak information rate) mode, one or more nodes perform shaping. The physical interface is in PIR-only mode if no child (or grandchild) node under the port has a guaranteed rate configured. The mode of the port is important because in PIR-only mode, the scheduling across the child nodes is in proportion to their shaping rates (PIRs) and not the guaranteed rates (CIRs). This can be important if the observed behavior is not what is anticipated.

In PIR-only mode, nodes cannot send if they are above the configured shaping rate. [Table 149](#) shows the mapping between the configured priority and the hardware priority for PIR-only.

**Table 149: Internal Node Queue Priority for PIR-Only Mode**

| Configured Priority | Hardware Priority |
|---------------------|-------------------|
| Strict-high         | 0                 |

**Table 149: Internal Node Queue Priority for PIR-Only Mode (*continued*)**

| Configured Priority | Hardware Priority |
|---------------------|-------------------|
| High                | 0                 |
| Medium-high         | 1                 |
| Medium-low          | 1                 |
| Low                 | 2                 |

## CIR Mode

In CIR (committed information rate) mode, one or more nodes applies a guaranteed rate and might perform shaping. A physical interface is in CIR mode if at least one child (or grandchild) node has a guaranteed rate configured. In addition, any child or grandchild node under the physical interface can have a shaping rate configured. Only the guaranteed rate matters. In CIR mode, nodes that do not have a guaranteed rate configured are assumed to have a very small guaranteed rate (queuing weight).

In CIR mode, the priority for each internal node depends on whether the highest active child node is above or below the guaranteed rate. [Table 150](#) shows the mapping between the highest active child's priority and the hardware priority below and above the guaranteed rate.

**Table 150: Internal Node Queue Priority for CIR Mode**

| Configured Priority of Highest Active Child Node | Hardware Priority Below Guaranteed Rate | Hardware Priority Above Guaranteed Rate |
|--------------------------------------------------|-----------------------------------------|-----------------------------------------|
| Strict-high                                      | 0                                       | 0                                       |
| High                                             | 0                                       | 3                                       |
| Medium-high                                      | 1                                       | 3                                       |
| Medium-low                                       | 1                                       | 3                                       |
| Low                                              | 2                                       | 3                                       |

## Understanding Priority Propagation

SRX5600 and SRX5800 devices with input/output cards (IOCs) perform priority propagation. Priority propagation is useful for mixed traffic environments when, for example, you want to make [“Understanding IOC Map Queues” on page 1574](#) sure that the voice traffic of one customer does not suffer from the data traffic of another customer. Nodes and queues are always serviced in the order of their priority. The priority of a queue is decided by configuration (the default priority is low) in the scheduler. However, not all elements of hierarchical schedulers have direct priorities configured. Internal nodes, for example, must determine their priority in other ways.

The priority of any internal node is decided as follows:

- By the highest priority of an active child (interface sets only take the highest priority of their active children)
- Whether the node is above its configured guaranteed rate (CIR) or not (this is relevant only if the physical interface is in CIR mode)

Each queue has a configured priority and a hardware priority. [Table 151](#) shows the usual mapping between the configured priority and the hardware priority.

**Table 151: Queue Priority**

| Configured Priority | Hardware Priority |
|---------------------|-------------------|
| Strict-high         | 0                 |
| High                | 0                 |
| Medium-high         | 1                 |
| Medium-low          | 1                 |
| Low                 | 2                 |

[Figure 82](#) shows a physical interface with hierarchical schedulers configured. The configured priorities are shown for each queue at the top of the figure. The hardware priorities for each node are shown in parentheses. Each node also shows any configured shaping rate (PIR) or guaranteed rate (CIR) and whether or not the queues are above or below the CIR. The nodes are shown in one of the following three states:

- Above the CIR (clear)
- Below the CIR (dark)
- Condition where the CIR does not matter (gray)

**Figure 82: Hierarchical Schedulers and Priorities**

In Figure 82, the strict high queue for C-VLAN 0 (cvlan 0) receives service first, even though the C-VLAN is above the configured CIR. Once that queue has been drained, and the priority of the node has become 3 instead of 0 (because of the lack of strict-high traffic), the system moves on to the medium queues (cvlan 1 and cvlan 3), draining them in a round-robin fashion where empty queues lose their hardware priority. The low queue on cvlan 4 (priority 2) is sent next because that mode is below the CIR. Then, the high queues on cvlan 0 and cvlan 2 (both now with priority 3) are drained in a round-robin fashion, and finally the low queue on cvlan 0 is drained (because svlan 0 has a priority of 3).

## Understanding IOC Hardware Properties

On SRX5600 and SRX5800 devices, two IOCs (40x1GE IOC and 4x10GE IOC) are supported on which you can configure schedulers and queues. You can configure 15 VLAN sets per Gigabit Ethernet (40x1GE IOC) port and 255 VLAN sets per 10-Gigabit Ethernet (4x10GE IOC) port. The IOC performs priority propagation from one hierarchy level to another, and drop statistics are available on the IOC per color per queue instead of just per queue.

SRX5600 and SRX5800 devices with IOCs have Packet Forwarding Engines that can support up to 512 MB of frame memory, and packets are stored in 512-byte frames. [Table 152](#) compares the major properties of the Packet Forwarding Engine within the IOC.

Table 152: Packet Forwarding Engine Properties within 40x1GE IOC and 4x10GE IOC

| Feature                             | PFE Within 40x1GE IOC and 4x10GE IOC                   |
|-------------------------------------|--------------------------------------------------------|
| Number of usable queues             | 16,000                                                 |
| Number of shaped logical interfaces | 2,000 with 8 queues each, or 4,000 with 4 queues each. |
| Number of hardware priorities       | 4                                                      |
| Priority propagation                | Yes                                                    |
| Dynamic mapping                     | Yes: schedulers per port are not fixed.                |
| Drop statistics                     | Per queue per color (PLP high, low)                    |

Additionally, the IOC features also support hierarchical weighted random early detection (WRED).

The IOC supports the following hierarchical scheduler characteristics:

- Shaping at the physical interface level
- Shaping and scheduling at the service VLAN interface set level
- Shaping and scheduling at the customer VLAN logical interface level
- Scheduling at the queue level

The IOC supports the following features for scalability:

- 16,000 queues per PFE
- 4 PFEs per IOC
  - 4000 schedulers at logical interface level (level 3) with 4 queues each
  - 2000 schedulers at logical interface level (level 3) with 8 queues each
- 255 schedulers at the interface set level (level 2) per 1-port PFE on a 10-Gigabit Ethernet IOC (4x10GE IOC )
- 15 schedulers at the interface set level (level 2) per 10-port PFE on a 1-Gigabit Ethernet IOC (40x1GE IOC )
- About 400 milliseconds of buffer delay (this varies by packet size and if large buffers are enabled)
- 4 levels of priority (strict-high, high, medium, and low)

**NOTE:** The exact option for a transmit-rate (transmit-rate rate exact) is not supported on the IOCs on SRX Series devices.

## Understanding IOC Map Queues

The manner in which the IOC maps a queue to a scheduler depends on whether 8 queues or 4 queues are configured. By default, a scheduler at level 3 has 4 queues. Level 3 scheduler  $X$  controls queue  $X*4$  to  $X*4+3$ , so that scheduler 100 (for example) controls queues 400 to 403. However, when 8 queues per scheduler are enabled, the odd-numbered schedulers are disabled, allowing twice the number of queues per subscriber as before. With 8 queues, level 3 scheduler  $X$  controls queue  $X*4$  to  $X*4+7$ , so that scheduler 100 (for example) now controls queues 400 to 407.

You configure the **max-queues-per-interface** statement to set the number of queues at 4 or 8 at the FPC level of the hierarchy. Changing this statement will result in a restart of the FPC.

The IOC maps level 3 (customer VLAN) schedulers in groups to level 2 (service VLAN) schedulers. Sixteen contiguous level 3 schedulers are mapped to level 2 when 4 queues are enabled, and 8 contiguous level 3 schedulers are mapped to level 2 when 8 queues are enabled. All the schedulers in the group should use the same queue priority mapping. For example, if the queue priorities of one scheduler are high, medium, and low, all members of the group should have the same queue priority.

Groups at level 3 to level 2 can be mapped at any time. However, a group at level 3 can only be unmapped from a level 2 scheduler, and only if all the schedulers in the group are free. Once unmapped, a level 3 group can be remapped to any level 2 scheduler. There is no restriction on the number of level 3 groups that can be mapped to a particular level 2 scheduler. There can be 256 level 3 groups, but fragmentation of the scheduler space can reduce the number of schedulers available. In other words, there are scheduler allocation patterns that might fail even though there are free schedulers.

In contrast to level 3 to level 2 mapping, the IOC maps level 2 (service VLAN) schedulers in a fixed mode to level 1 (physical interface) schedulers. On 40-port Gigabit Ethernet IOCs, there are 16 level 1 schedulers, and 10 of these are used for the physical interfaces. There are 256 level 2 schedulers, or 16 per level 1 schedulers. A level 1 scheduler uses level schedulers  $X*16$  through  $X*16+15$ . Therefore level 1 scheduler 0 uses level 2 schedulers 0 through 15, level 1 scheduler 1 uses level 2 schedulers 16 through 31, and so on. On 4-port 10-Gigabit Ethernet PICs, there is one level 1 scheduler for the physical interface, and 256 level 2 schedulers are mapped to the single level 1 scheduler.

The maximum number of level 3 (customer VLAN) schedulers that can be used is 4076 (4 queues) or 2028 (8 queues) for the 10-port Gigabit Ethernet Packet Forwarding Engine

and 4094 (4 queues) or 2046 (8 queues) for the 10-Gigabit Ethernet Packet Forwarding Engine.

## WRED on the IOC Overview

Shaping to drop out-of-profile traffic is done on the IOC at all levels except the queue level. However, weighed random early discard (WRED) is done at the queue level with much the same result. With WRED, the decision to drop or send the packet is made before the packet is placed in the queue.

WRED shaping on the IOC involves two levels. The probabilistic drop region establishes a minimum and a maximum queue depth. Below the minimum queue depth, the drop probability is 0 (send). Above the maximum level, the drop probability is 100 (certainty).

There are four drop profiles associated with each queue. These correspond to each of four loss priorities (low, medium-low, medium-high, and high). Sixty-four sets of four drop profiles are available (32 for ingress and 32 for egress). In addition, there are eight WRED scaling profiles in each direction.

An example of an IOC drop profile for expedited forwarding traffic is as follows:

```
[edit class-of-service drop-profiles]
drop-ef {
 fill-level 20 drop-probability 0; # Minimum Q depth
 fill-level 100 drop-probability 100; # Maximum Q depth
}
```

**NOTE:** You can specify only two fill levels for the IOC.

You can configure the **interpolate** statement, but only two fill levels are used. The **delay-buffer-rate** statement in the traffic control profile determines the maximum queue size. This delay buffer rate is converted to packet delay buffers, where one buffer is equal to 512 bytes. For example, at 10 Mbps, the IOC will allocate 610 delay buffers when the delay buffer rate is set to 250 milliseconds. The WRED threshold values are specified in terms of absolute buffer values.

The WRED scaling factor multiplies all WRED thresholds (both minimum and maximum) by the value specified. There are eight values in all: 1, 2, 4, 8, 16, 32, 64, and 128. The WRED scaling factor is chosen to best match the user-configured drop profiles. This is done because the hardware supports only certain values of thresholds (all values must be a multiple of 16). So if the configured value of a threshold is 500 (for example), the multiple

of 16 is 256 and the scaling factor applied is 2, making the value 512, which allows the value of 500 to be used. If the configured value of a threshold is 1500, the multiple of 16 is 752 and the scaling factor applied is 2, making the value 1504, which allows the value of 1500 to be used.

Hierarchical RED is used to support the oversubscription of the delay buffers (WRED is configured only at the queue, physical interface, and PIC levels). Hierarchical RED works with WRED as follows:

- If any level accepts the packet (the queue depth is less than the minimum buffer levels), this level accepts the packet.
- If any level probabilistically drops the packet, then this level drops the packet.

However, these rules might lead to the accepting of packets under loaded conditions that might otherwise have been dropped. In other words, the logical interface will accept packets if the physical interface is not congested.

Because of the limits placed on shaping thresholds used in the hierarchy, there is a granularity associated with the IOCs. The shaper accuracies differ at various levels of the hierarchy:

- Level 3
- Level 2
- Level 1

Shapers at the logical interface level (level 3) are more accurate than shapers at the interface set level (level 2) or at the port level (level 1).

This section contains the following topics:

- [Shapers at the Logical Interface Level \(Level 3\) on page 1576](#)
- [Shapers at the Interface Set Level \(Level 2\) on page 1577](#)

## Shapers at the Logical Interface Level (Level 3)

Because of the limits placed on shaping thresholds used in the hierarchy, there is a granularity associated with the IOCs. The shaper accuracies differ at various levels of the hierarchy, with shapers at the logical interface level (level 3) being more accurate than shapers at the interface set level (level 2) or at the port level (level 1). [Table 153](#) shows the accuracy of the logical interface shaper at various speeds for Ethernet ports operating at 1 Gbps.

**Table 153: Shaper Accuracy of 1-Gbps Ethernet at the Logical Interface Level**

| Range of Logical Interface Shaper | Step Granularity |
|-----------------------------------|------------------|
| Up to 4.096 Mbps                  | 16 Kbps          |

**Table 153: Shaper Accuracy of 1-Gbps Ethernet at the Logical Interface Level (*continued*)**

| Range of Logical Interface Shaper | Step Granularity |
|-----------------------------------|------------------|
| 4.096 to 8.192 Mbps               | 32 Kbps          |
| 8.192 to 16.384 Mbps              | 64 Kbps          |
| 16.384 to 32.768 Mbps             | 128 Kbps         |
| 32.768 to 65.535 Mbps             | 256 Kbps         |
| 65.535 to 131.072 Mbps            | 512 Kbps         |
| 131.072 to 262.144 Mbps           | 1024 Kbps        |
| 262.144 to 1 Gbps                 | 4096 Kbps        |

Table 154 shows the accuracy of the logical interface shaper at various speeds for Ethernet ports operating at 10 Gbps.

**Table 154: Shaper Accuracy of 10-Gbps Ethernet at the Logical Interface Level**

| Range of Logical Interface Shaper | Step Granularity |
|-----------------------------------|------------------|
| Up to 10.24 Mbps                  | 40 Kbps          |
| 10.24 to 20.48 Mbps               | 80 Kbps          |
| 10.48 to 40.96 Mbps               | 160 Kbps         |
| 40.96 to 81.92 Mbps               | 320 Kbps         |
| 81.92 to 163.84 Mbps              | 640 Kbps         |
| 163.84 to 327.68 Mbps             | 1280 Kbps        |
| 327.68 to 655.36 Mbps             | 2560 Kbps        |
| 655.36 to 2611.2 Mbps             | 10240 Kbps       |
| 2611.2 to 5222.4 Mbps             | 20480 Kbps       |
| 5222.4 to 10 Gbps                 | 40960 Kbps       |

## Shapers at the Interface Set Level (Level 2)

Table 155 shows the accuracy of the interface set shaper at various speeds for Ethernet ports operating at 1 Gbps.

**Table 155: Shaper Accuracy of 1-Gbps Ethernet at the Interface Set Level**

| Range of Interface Set Shaper | Step Granularity |
|-------------------------------|------------------|
| Up to 20.48 Mbps              | 80 Kbps          |
| 20.48 Mbps to 81.92 Mbps      | 320 Kbps         |
| 81.92 Mbps to 327.68 Mbps     | 1.28 Mbps        |
| 327.68 Mbps to 1 Gbps         | 20.48 Mbps       |

Table 156 shows the accuracy of the interface set shaper at various speeds for Ethernet ports operating at 10 Gbps.

**Table 156: Shaper Accuracy of 10-Gbps Ethernet at the Interface Set Level**

| Range of Interface Set Shaper | Step Granularity |

- [MDRR on the IOC Overview on page 1579](#)

**MDRR on the IOC Overview**

The guaranteed rate CIR at the interface set level is implemented by using modified deficit round-robin (MDRR). The IOC hardware provides four levels of strict priority. There is no restriction on the number of queues for each priority. MDRR is used among queues of the same priority. Each queue has one priority when it is under the guaranteed rate and another priority when it is over the guaranteed rate but still under the shaping rate PIR. The IOC hardware implements the priorities with 256 service profiles. Each service profile assigns eight priorities for eight queues. One set is for logical interfaces under the guaranteed rate and another set is for logical interfaces over the guaranteed rate but under the shaping rate. Each service profile is associated with a group of 16 level 3 schedulers, so there is a unique service profile available for all 256 groups at level 3, giving 4,096 logical interfaces.

Junos OS provides three priorities for traffic under the guaranteed rate and one reserved priority for traffic over the guaranteed rate that is not configurable. Junos OS provides three priorities when there is no guaranteed rate configured on any logical interface.

[Table 159](#) shows the relationship between Junos OS priorities and the IOC hardware priorities below and above the guaranteed rate CIR.

**Table 159: Junos Priorities Mapped to IOC Hardware Priorities**

| Junos OS Priority | IOC Hardware Priority Below Guaranteed Rate | IOC Hardware Priority Above Guaranteed Rate |
|-------------------|---------------------------------------------|---------------------------------------------|
| Strict-high       | High                                        | High                                        |
| High              | High                                        | Low                                         |
| Medium-high       | Medium-high                                 | Low                                         |
| Medium-low        | Medium-high                                 | Low                                         |

Table 159: Junos Priorities Mapped to IOC Hardware Priorities (*continued*)

| Junos OS Priority | IOC Hardware Priority Below Guaranteed Rate | IOC Hardware Priority Above Guaranteed Rate |
|-------------------|---------------------------------------------|---------------------------------------------|
| Low               | Medium-low                                  | Low                                         |

The Junos OS parameters are set in the scheduler map:

```
[edit class-of-service schedulers]
best-effort-scheduler {
 transmit-rate percent 30; # if no shaping rate
 buffer-size percent 30;
 priority high;
}
expedited-forwarding-scheduler {
 transmit-rate percent 40; # if no shaping rate
 buffer-size percent 40;
 priority strict-high;
}
```

**NOTE:** The use of both a shaping rate and a guaranteed rate at the interface set level (level 2) is not supported.

MDRR is provided at three levels of the scheduler hierarchy of the IOC with a granularity of 1 through 255. There are 64 MDRR profiles at the queue level, 16 at the interface set level, and 32 at the physical interface level.

Queue transmit rates are used for queue-level MDRR profile weight calculation. The queue MDRR weight is calculated differently based on the mode set for sharing excess bandwidth. If you configure the **equal** option for excess bandwidth, then the queue MDRR weight is calculated as:

$$\text{Queue weight} = (255 * \text{Transmit-rate-percentage}) / 100$$

If you configure the **proportional** option for excess bandwidth, which is the default, then the queue MDRR weight is calculated as:

$$\text{Queue weight} = \text{Queue-transmit-rate} / \text{Queue-base-rate}, \text{ where}$$

$$\text{Queue-transmit-rate} = (\text{Logical-interface-rate} * \text{Transmit-rate-percentage}) / 100, \text{ and}$$

$$\text{Queue-base-rate} = \text{Excess-bandwidth-proportional-rate} / 255$$

To configure the way that the IOC should handle excess bandwidth, configure the **excess-bandwidth-share** statement at the [edit interface-set *interface-set-name*] hierarchy level. By default, the excess bandwidth is set to **proportional** with a default value of 32.64 Mbps. In this mode, the excess bandwidth is shared in the ratio of the logical interface shaping rates. If set to **equal**, the excess bandwidth is shared equally among the logical interfaces.

The following example sets the excess bandwidth sharing to proportional at a rate of 100 Mbps with a shaping rate of 80 Mbps:

```
[edit interface-set example-interface-set]
excess-bandwidth-share proportional 100m;
output-traffic-control-profile PIR-80Mbps;
```

Shaping rates established at the logical interface level are used to calculate the MDRR weights used at the interface set level. The 16 MDRR profiles are set to initial values, and the closest profile with rounded values is chosen. By default, the physical port MDRR weights are preset to the full bandwidth on the interface.

## CoS Support on the SRX5000 Module Port Concentrator Overview

The SRX5000 Module Port Concentrator (SRX5K-MPC) for the SRX5600 and SRX5800 uses the Trio chipset-based queuing model, which supports class of service (CoS) characteristics that are optimized compared to CoS characteristics supported by the standard queuing model. These CoS features enable SRX5600 and SRX5800 devices to achieve end-to-end quality of service and protect the network using various security functions.

CoS features on the SRX5600 and SRX5800 devices provide differentiated services to traffic in addition to the best-effort packet processing. The main CoS features include classification, CoS field rewriting, queuing, scheduling, and traffic shaping.

When a network experiences congestion and delay, you can use the CoS features to classify packets; assign them with different levels of packet loss priority, delay, and throughput; and mark their CoS-related fields defined in Layer 2 and Layer 3 headers.

The MPC supports the following CoS features:

- BA classifier based on IEEE 802.1p for packet classification (Layer 2 headers) for priority bits of ingress packets
- Rewrite rule based on IEEE 802.1p for priority bits of egress packets

**NOTE:** You can configure up to 32 IEEE 802.1p rewriters on each SRX5K-MPC on the SRX5600 and SRX5800 devices.

- Eight priority queues per port with configurable schedulers at the egress physical interface

By default, the MPC supports eight queues. You can use the following CLI statement to change that setting to four queues:

```
set chassis fpc fpc-number pic pic-number max-queues-per-interface 4
```

Changing to four-queue mode limits that number of configurable queues to four on the MPC. This does not have any effect on the performance.

The CoS features on the MPC have the following limitations:

- On the MPC, the per-unit-scheduler or the hierarchical-scheduler is not supported. For egress scheduling and queuing, only the default mode is supported.
- When an SPU is too busy to process every ingress packet from the MPC, some high-priority packets, such as voice packets, might be delayed or dropped by the SRX5600 or SRX5800.

**NOTE:** The total number of classifiers supported on a Services Processing Unit (SPU) is 79. Three classifiers are installed on the SPU as default classifiers in the Layer 3 mode, independent of any CoS configuration, which leaves 76 classifiers that can be configured using the CoS CLI commands. The default classifiers number might vary in future releases or in different modes. You can verify the number of default classifiers installed on the SPU to determine how many classifiers can be configured using the CoS CLI commands.

## Example: Configuring CoS on High-End SRX Series Devices with an MPC

---

This example shows how to configure CoS on an SRX5000 line device with an MPC.

- [Requirements on page 1582](#)
- [Overview on page 1583](#)
- [Configuration on page 1584](#)
- [Verification on page 1590](#)

### Requirements

This example uses the following hardware and software components:

- SRX5600 with an SRX5K-MPC
- Junos OS Release 12.1X46-D10 or later for SRX Series

Before you begin:

- Understand CoS. See [“Understanding Class of Service” on page 1381](#).

- Understand chassis cluster configuration. See *Example: Configuring an Active/Passive Chassis Cluster On a High-End SRX Series Services Gateway*.
- Understand chassis cluster redundant interface configuration. See *Example: Configuring Chassis Cluster Redundant Ethernet Interfaces for IPv4 and IPv6 Addresses*.

No special configuration beyond device initialization is required before configuring this feature.

## Overview

In this example, you create a BA classifier to classify traffic based on the IEEE 802.1p value of the packet and assign forwarding-class priority queue to the traffic. You then configure the scheduler map and set the priority for the traffic.

By default, the SRX5K-MPC supports eight queues. In this example, you are configuring eight queues.

You apply the BA classifier to input interface and apply the scheduler map to the output interface.

[Table 160](#) and [Table 161](#) show forwarding class details with priority, assigned queue numbers, and allocated queue buffers used in this example.

**Table 160: Forwarding Class Samples**

| Forwarding Class | Queue Number |
|------------------|--------------|
| BE               | 0            |
| SIG              | 1            |

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure forwarding classes:

1. Configure a classifier.

```

[edit class-of-service]
user@host# set classifiers ieee-802.1 c802 forwarding-class BE loss-priority low
 code-points 000
user@host# set classifiers ieee-802.1 c802 forwarding-class SIG loss-priority low
 code-points 001
user@host# set classifiers ieee-802.1 c802 forwarding-class AF loss-priority low
 code-points 010

```

```

user@host# set classifiers ieee-802.1 c802 forwarding-class Bronze-Class
loss-priority low code-points 011
user@host# set classifiers ieee-802.1 c802 forwarding-class Silver-Class loss-priority
low code-points 100
user@host# set classifiers ieee-802.1 c802 forwarding-class Gold-Class loss-priority
low code-points 101
user@host# set classifiers ieee-802.1 c802 forwarding-class Central loss-priority
low code-points 110
user@host# set classifiers ieee-802.1 c802 forwarding-class VOIP loss-priority low
code-points 111

```

2. Assign best-effort traffic to queue.

```

[edit class-of-service forwarding-classes class]
user@host# BE queue-num 0
user@host# SIG queue-num 1
user@host# AF queue-num 2
user@host# Bronze-Class queue-num 3
user@host# Silver-Class queue-num 4
user@host# Gold-Class queue-num 5
user@host# Control queue-num 6
user@host# VOIP queue-num 7

```

3. Define mapping of forwarding classes to packet schedulers.

```

[edit class-of-service]
user@host# set scheduler-maps test forwarding-class BE scheduler s-be
user@host# set scheduler-maps test forwarding-class SIG scheduler s-sig
user@host# set scheduler-maps test forwarding-class AF scheduler s-af
user@host# set scheduler-maps test forwarding-class Bronze-Class scheduler
s-bronze
user@host# set scheduler-maps test forwarding-class Silver-Class scheduler s-silver
user@host# set scheduler-maps test forwarding-class Gold-Class scheduler s-gold
user@host# set scheduler-maps test forwarding-class Control scheduler s-nc
user@host# set scheduler-maps test forwarding-class VOIP scheduler s-voip

```

4. Configure the CoS rewrite rules to map the forwarding class to the desired value for the 802.1p field.

```

[edit class-of-service]
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class BE loss-priority
low code-point 000
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class SIG loss-priority
low code-point 001
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class AF loss-priority
low code-point 010
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class Bronze-Class
loss-priority low code-point 011
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class Silver-Class
loss-priority low code-point 100
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class Gold-Class
loss-priority low code-point 101
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class Control loss-priority
low code-point 110
user@host# set rewrite-rules ieee-802.1 rw802 forwarding-class VOIP loss-priority
low code-point 111

```

5. Configure eight packet schedulers with scheduling priority and transmission rates.

```
[edit class-of-service]
user@host# set schedulers s-be transmit-rate percent 15
user@host# set schedulers s-be priority low
user@host# set schedulers s-sig transmit-rate percent 15
user@host# set schedulers s-sig priority low
user@host# set schedulers s-af transmit-rate percent 20
user@host# set schedulers s-af priority medium-low
user@host# set schedulers s-bronze transmit-rate percent 20
user@host# set schedulers s-bronze priority medium-low
user@host# set schedulers s-silver transmit-rate percent 10
user@host# set schedulers s-silver priority medium-high
user@host# set schedulers s-gold transmit-rate percent 10
user@host# set schedulers s-gold priority medium-high
user@host# set schedulers s-nc transmit-rate percent 5
user@host# set schedulers s-nc priority high
user@host# set schedulers s-voip transmit-rate percent 5
user@host# set schedulers s-voip priority high
```

6. Apply the classifier and rewrite rules to interfaces.

```
[edit class-of-service]
user@host# set interfaces reth0 unit 0 classifiers ieee-802.1 c802
user@host# set interfaces reth1 unit 0 rewrite-rules ieee-802.1 rw802
```

7. Apply the shaping rates to control the maximum rate of traffic transmitted on an interface.

```
[edit class-of-service]
user@host# set interfaces reth0 shaping-rate 1g
```

**Results** From configuration mode, confirm your configuration by entering the **show xxx** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
classifiers {
 ieee-802.1 c802 {
 forwarding-class BE {

 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Class-of-Service Configuration on page 1590](#)
- [Verifying the Number of Dedicated Queues Configured on MPC Interfaces on page 1590](#)

### Verifying Class-of-Service Configuration

**Purpose** Verify that CoS is configured.

**Action** From operational mode, enter the **show class-of-service classifier** command.

```
user@host> show class-of-service classifier type ieee-802.1
```

| Forwarding class<br>priority | SPU priority | ID | Queue | Restricted queue | Fabric priority | Policing |
|------------------------------|--------------|----|-------|------------------|-----------------|----------|
| BE                           |              | 0  | 0     | 0                | low             |          |
| normal                       | low          |    |       |                  |                 |          |

### Verifying the Number of Dedicated Queues Configured on MPC Interfaces

**Purpose** Display the number of dedicated queue resources that are configured for the interfaces on a port.

**Action** From operational mode, enter the **show class-of-service interface** command.

```
user@host> show class-of-service interface reth0
```

```
Physical interface: reth0, Index: 129
Queues supported: 8, Queues in use: 4
Scheduler map: <default>, Index: 2
Congestion-notification: Disabled
```

| Logical interface: reth0.0, Index: 71 |                         |           |       |
|---------------------------------------|-------------------------|-----------|-------|
| Object                                | Name                    | Type      | Index |
| Classifier                            | dscp-ipv6-compatibility | dscp-ipv6 | 9     |
| Classifier                            | ipprec-compatibility    | ip        | 13    |

Logical interface: reth1.32767, Index: 70

| <b>Release Information</b>      | Statement introduced in Junos OS Release 15.1X49-D30.                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Enable copying of Differentiated Services Code Point (DSCP) (outer DSCP+ECN) field from the outer IP header encrypted packet to the inner IP header plain text message on the decryption path. The benefit in enabling this feature is that after IPsec decryption, clear text packets can follow the inner CoS (DSCP+ECN) rules. |
| <b>Default</b>                  | By default, the copy outer dscp feature is disabled.                                                                                                                                                                                                                                                                              |
| <b>Required Privilege Level</b> | <p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>                                                                                                                                                                                                  |

## forwarding-classes (CoS)

|                            |                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <pre> forwarding-classes {   class <i>class-name</i> {     priority (high   low);     queue-num <i>number</i>;     spu-priority (high   low);   }   queue <i>queue-number</i> {     <i>class-name</i> {       priority (high   low);     }   } } </pre> |
| <b>Hierarchy Level</b>     | [edit class-of-service]                                                                                                                                                                                                                                 |
| <b>Release Information</b> | Statement introduced in Junos OS Release 8.5. Statement updated in Junos OS Release 11.4. The <b>spu-priority</b> option introduced in Junos OS Release 11.4R2.                                                                                         |
| <b>Description</b>         | Configure forwarding classes and assign queue numbers.                                                                                                                                                                                                  |
| <b>Options</b>             | <ul style="list-style-type: none"> <li><i>class-name</i>—Display the forwarding class name assigned to the internal queue number.</li> </ul>                                                                                                            |

**NOTE:** This option is supported only on high-end SRX Series devices, including the SRX1500, SRX5400, SRX5600, and SRX5800.

**NOTE:** AppQoS forwarding classes must be different from those defined for interface-based rewriters.

- **policing-priority**—Layer 2 policing. One forwarding class can be configured as **premium** and others are configured as **normal**.
- **priority**—Fabric priority value:
  - **high**—Forwarding class's fabric queuing has high priority.
  - **low**—Forwarding class's fabric queuing has low priority.
- *queue-number*—Specify the internal queue number to which a forwarding class is assigned.
- **spu-priority**—Services Processing Unit (SPU) priority queue, either **high** or **low**.

**NOTE:** The **spu-priority** option is only supported on SRX1500, SRX3000 line, and SRX5000 line devices.

**Required Privilege** interface—To view this statement in the configuration.  
**Level** interface-control—To add this statement to the configuration.

## frame-relay-de (CoS Interfaces)

---

**Syntax** frame-relay-de (*name* | default);

**Hierarchy Level** [edit class-of-service interfaces *interface-name* unit *logical-unit-number* loss-priority-maps],  
[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Assign the loss priority map or the rewrite rule to a logical interface.

**Options**

- **default**—Apply default loss priority map or default rewrite rule. The default loss priority map contains the following settings:

loss-priority low code-point 0;  
loss-priority high code-point 1;

- The default rewrite rule contains the following settings:

loss-priority low code-point 0;  
loss-priority medium-low code-point 0;  
loss-priority medium-high code-point 1;  
loss-priority high code-point 1;

- **name**—Name of loss priority map or rewrite rule to be applied.

**Required Privilege** interface—To view this statement in the configuration.  
**Level** interface-control—To add this statement to the configuration.

| <b>Description</b>         | <p>Add the configured number of bytes to the length of a packet entering the interface.</p> <p>Configure a policer overhead to control the rate of traffic received on an interface. Use this feature to help prevent denial-of-service (DoS) attacks or to enforce traffic rates to conform to the service-level agreement (SLA). When you configure a policer overhead, the configured policer overhead value (bytes) is added to the length of the final Ethernet frame. This calculated length of frame is used to determine the policer or the rate-limiting action.</p> <p>Traffic policing combines the configured policy bandwidth limits and the burst size to determine how to meter the incoming traffic. If you configure a policer overhead on an interface, Junos OS adds those bytes to the length of incoming Ethernet frames. This added overhead fills each frame closer to the burst size, allowing you to control the rate of traffic received on an interface.</p> <p>You can configure the policer overhead to rate-limit queues and Layer 2 and Layer 3 policers, for standalone (SA) and high-availability (HA) deployments. The policer overhead and the shaping overhead can be configured simultaneously on an interface.</p> |

**NOTE:** vSRX supports policer overhead on Layer 3 policers only.

The policer overhead applies to all interfaces on the PIC. In the following example, Junos OS adds 10 bytes of overhead to all incoming Ethernet frames on ports ge-0/0/0 through ge-0/0/4.

```
set chassis fpc 0 pic 0 ingress-policer-overhead 10
```

**NOTE:** vSRX only supports fpc 0 pic 0. When you commit the `ingress-policer-overhead` statement, the vSRX takes the PIC offline and then back online.

You need to craft the policer overhead size to match your network traffic. A value that is too low will have minimal impact on traffic bursts. A value that is too high will rate-limit too much of your incoming traffic.

In this example, the policer overhead of 255 bytes is configured for ge-0/0/0 through ge-0/0/4. The firewall policer is configured to discard traffic when the burst size is over

1500 bytes. This policer is applied to ge-0/0/0 and ge 0/0/1. Junos OS adds 255 bytes to every Ethernet frame that comes into the configured ports. If, during a burst of traffic, the combined length of incoming frames and the overhead bytes exceeds 1500 bytes, the policer starts to discard further incoming traffic.

```
set chassis fpc 0 pic 0 ingress-policer-overhead 255
set interfaces ge-0/0/0 unit 0 family inet policer input overhead_policer
set interfaces ge-0/0/0 unit 0 family inet address 10.9.1.2/24
set interfaces ge-0/0/1 unit 0 family inet policer input overhead_policer
set interfaces ge-0/0/1 unit 0 family inet address 10.9.2.2/24
set firewall policer overhead_policer if-exceeding bandwidth-limit 32k
set firewall policer overhead_policer if-exceeding burst-size-limit 1500
set firewall policer overhead_policer then discard
```

**Options** *bytes*—Number of bytes added to a frame entering an interface.

**Range:** 0–255 bytes

**Default:** 0

```
[edit chassis fpc 0 pic 0]
user@host# set ingress-policer-overhead 10;
```

| <b>Description</b>                                                                                                                                                                                     | Share the available bandwidth and burst size of a device's PICs by defining rate limiter profiles and applying them in AppQoS rules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                                                                                                                                                                                         | <ul style="list-style-type: none"> <li>• <b>rate-limiter-name</b>—Name of the rate limiter. It is applied in AppQoS rules to share device resources based on quality of service requirements.</li> </ul> <p>The combination of rate limiting parameters, namely bandwidth- limit and burst-size-limit rate limit, make up the rate limiter profile. A maximum of 16 profiles are allowed per device. The same profile can be used by multiple rate limiters. For example, a profile with a bandwidth-limit of 200 Kbps and a burst-limit of 130,000 bytes, could be used in several rate limiters.</p> <p>A maximum of 1000 rate limiters can be created. Rate limiters are defined for the device, and are assigned in rules in a rule set. A single rate limiter can be used multiple times within the same rule set. However, the rate limiter cannot be used in another rule set.</p> <ul style="list-style-type: none"> <li>• <b>bandwidth-limit <i>value-in-Kbps</i></b>—Maximum number of kilobits to be transmitted per second for this rate limiter. Up to 2 GB of bandwidth can be provisioned among multiple rate limiters to share the resource proportionally.</li> <li>• <b>burst-size-limit <i>value-in-bytes</i></b>—Maximum number of bytes to be transferred in a single burst or time-slice. This limit ensures that a high-priority transmission does not keep a lower priority transmission from transmitting.</li> </ul> |
| <div>  <p><b>NOTE:</b> The number of bandwidth-limit and burst-size-limit combinations cannot exceed 16.</p> </div> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | Associate a rewrite-rules configuration or default mapping with a specific interface.                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <ul style="list-style-type: none"><li>• <b>rewrite-name</b>—Name of a <b>rewrite-rules</b> mapping configured at the [edit class-of-service rewrite-rules] hierarchy level.</li><li>• <b>default</b>—The default mapping.</li></ul> <p>The remaining statements are explained separately. See <a href="#">CLI Explorer</a>.</p> |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration.                                                                                                                                                                                                         |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"><li>• <a href="#">rewrite-rules (CoS) on page 1617</a></li></ul>                                                                                                                                                                                                                              |

## rule-sets (CoS AppQoS)

```
Syntax rule-sets {
 rule-set-name {
 rule rule-name {
 match {
 application application-name;
 application-any;
 application-group application-group-name;
 application-known;
 application-unknown;
 }
 then {
 dscp-code-point dscp-value ;
 forwarding-class forwarding-class-name;
 log;
 loss-priority [high | medium-high | medium-low | low];
 rate-limit {
 loss-priority-high;
 client-to-server rate-limiter-name;
 server-to-client rate-limiter-name;
 }
 }
 }
 }
 }
```

**Hierarchy Level** [edit class-of-service application-traffic-control]

**Release Information** Statement introduced in Junos OS Release 11.4.

**Description** Defines AppQoS rule sets and the rules that establish priorities based on quality of service requirements for the associated applications. AppQoS rules can be included in policy statements to implement application-aware quality of service control.

- Options**
- **rule-set-name**—Name used to refer to a collection of AppQoS rules.
  - **rule rule-name**—Name applied to the match criteria and resulting actions that control the quality of service provided to any matching applications.
  - **application application-name**—Name of the application to be used as match criteria for the rule.
  - **application-any**—Any application encountering this rule. Note that when you use this specification, all application matching ends. Any application rule following this one will never be encountered.
  - **application-group application-group-name**—Group of applications to be used as match criteria for the rule. Both applications and application groups can be match criteria for a single rule.
  - **application-known**—Match criteria specifying any session that is identified, but its corresponding application is not specified.

- **application-unknown**—Match criteria specifying any session that is not identified.
- **forwarding-class *forwarding-class-name***—The AppQoS class with which matching applications will be marked. This field identifies the rewriter that has marked the DSCP value. Therefore, the AppQoS forwarding class must be different from those used by IDP or firewall filters. With this class specified, firewall filter class will not overwrite the existing DSCP value.
- **dscp-code-point**—DSCP alias or bit map with which matching applications will be marked to establish the output queue. This value can be marked by rewriters from IDP, AppQoS, or a firewall filter. The forwarding-class value identifies which rewriter has re-marked the packet with the current DSCP value. If a packet triggers all three rewriters, IDP takes precedence over AppQoS, which takes precedence over a firewall filter.
- **loss-priority**—Loss priority with which matching applications will be marked. This value is used to determine the likelihood that a packet would be dropped when encountering congestion. A high loss priority means that there is an 80% chance of packet loss in congestion. Possible values are high, medium-high, medium-low and low.
- **rate-limit**—Rate limiters to be associated with client-to-server and with server-to-client traffic for this application. The rate limiter profile defines maximum speed and volume limits for matching applications.
- **log**—AppQoS event logging.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

**Related Documentation** [• Example: Configuring AppQoS on page 581](#)

## **scheduler-map (CoS Virtual Channels)**

**Syntax** `scheduler-map map-name;`

**Hierarchy Level** [edit class-of-service virtual-channel-groups *group-name* *virtual-channel-name*]

**Release Information** Statement introduced in Junos OS Release 9.2.

**Description** Apply a scheduler map to this virtual channel.

**Options** *map-name*—Name of the scheduler map.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | <p>For logical interfaces on which you configure packet scheduling, configure traffic shaping by specifying the amount of bandwidth to be allocated to the logical interface.</p> <p>Logical and physical interface traffic shaping is mutually exclusive. This means you can include the <b>shaping-rate</b> statement at the [edit class-of-service interfaces <i>interface-name</i>] hierarchy level or the [edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i>] hierarchy level, but not both.</p> <p>Alternatively, you can configure a shaping rate for a logical interface and oversubscribe the physical interface by including the <b>shaping-rate</b> statement at the [edit class-of-service traffic-control-profiles] hierarchy level. With this configuration approach, you can independently control the delay-buffer rate.</p> |
| <b>Default</b>                  | <p>If you do not include this statement at the [edit class-of-service interfaces <i>interface-name</i> unit <i>logical-unit-number</i>] hierarchy level, the default logical interface bandwidth is the average of unused bandwidth for the number of logical interfaces that require default bandwidth treatment. If you do not include this statement at the [edit class-of-service interfaces <i>interface-name</i>] hierarchy level, the default physical interface bandwidth is the average of unused bandwidth for the number of physical interfaces that require default bandwidth treatment.</p>                                                                                                                                                                                                                                                                          |
| <b>Options</b>                  | <p><b>rate</b>—Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> For logical interfaces, 1000 through 32,000,000,000 bps.</p> <p>For physical interfaces, 1000 through 160,000,000,000 bps.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Required Privilege Level</b> | <p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Associate a virtual channel with a scheduler map and a shaping rate. Virtual channels and virtual channel groups enable you to direct traffic into a virtual channel and apply bandwidth limits to the channel.                                                                                                                                                                           |
| <b>Options</b>                  | <p><i>group-name</i>—Name of the virtual channel group.</p> <p>The remaining statements are explained separately. See <a href="#">CLI Explorer</a>.</p>                                                                                                                                                                                                                                   |
| <b>Required Privilege Level</b> | <p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                        |

## CHAPTER 80

# Operational Commands

- `show class-of-service application-traffic-control counter`
- `show class-of-service application-traffic-control statistics rate-limiter`
- `show class-of-service application-traffic-control statistics rule`
- `show class-of-service forwarding-class`
- `show interfaces queue`

## show class-of-service application-traffic-control counter

|                                 |                                                                                                                                                                                                            |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | show class-of-service application-traffic-control counter                                                                                                                                                  |
| <b>Release Information</b>      | Command introduced in Junos OS Release 11.4.                                                                                                                                                               |
| <b>Description</b>              | Display AppQoS DSCP marking and honoring statistics based on Layer 7 application classifiers.                                                                                                              |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                       |

| <b>Output Fields</b>            | <a href="#">Table 41</a> lists the output fields for the <b>show class-of-service application-traffic-control counter</b> command. Output fields are listed in the approximate order in which they appear. |

**Table 162: show class-of-service application-traffic-control counter Output Fields**

| Field Name                          | Field Description                                                                                                                    |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| pic                                 | PIC number of the accumulated statistics.<br><br><b>NOTE:</b> The PIC number is always displayed as 0 for branch SRX Series devices. |
| Sessions processed                  | The number of sessions where the class of service was checked.                                                                       |
| Sessions marked                     | The number of sessions marked based on application-aware DSCP marking.                                                               |
| Sessions honored                    | The number of sessions honored based on application-aware traffic honoring.                                                          |
| Sessions rate limited               | The number of sessions that have been rate limited.                                                                                  |
| Client-to-server flows rate limited | The number of client-to-server flows that have been rate limited.                                                                    |
| Server-to-client flows rate limited | The number of server-to-client flows that have been rate limited.                                                                    |

## Sample Output

### show class-of-service application-traffic-control counter

```

user@host> show class-of-service application-traffic-control counter
pic: 2/1
Counter type Value
Sessions processed 300
Sessions marked 200
Sessions honored 0
Sessions rate limited 100
Client-to-server flows rate limited 100
Server-to-client flows rate limited 70

```

```
pic: 2/0
Counter type Value
Sessions processed 400
Sessions marked 300
Sessions honored 0
Sessions rate limited 200
Client-to-server flows rate limited 200
Server-to-client flows rate limited 100
```

## show class-of-service application-traffic-control statistics rate-limiter

|                                 |                                                                                                                                                                                                                            |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Output Fields</b>            | <a href="#">Table 166</a> lists the output fields for the <b>show interfaces queue</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 166: show interfaces queue Output Fields**

| Field Name         | Field Description                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------|
| Physical interface | Name of the physical interface.                                                                      |
| Enabled            | State of the interface.                                                                              |
| Interface index    | Index number of the physical interface. The number reflects the interface's initialization sequence. |
| SNMP ifIndex       | SNMP index number for the interface.                                                                 |

## Sample Output

### show interfaces queue (vSRX)

The following truncated example shows the CoS queue sizes for queues 0, 1, and 3. Queue 1 has a queue buffer size (guaranteed allocated memory) of 9192 bytes.

```

user@host> show interfaces queue
Physical interface: ge-0/0/0, Enabled, Physical link is Up
 Interface index: 134, SNMP ifIndex: 509
 Forwarding classes: 8 supported, 8 in use
 Egress queues: 8 supported, 8 in use
Queue: 0, Forwarding classes: class0
 Queued:
 Packets : 0 0 pps
 Bytes : 0 0 bps
 Transmitted:
 Packets : 0 0 pps
 Bytes : 0 0 bps
 Tail-dropped packets : 0 0 pps
 RL-dropped packets : 0 0 pps
 RL-dropped bytes : 0 0 bps
 RED-dropped packets : 0 0 pps
 Low : 0 0 pps
 Medium-low : 0 0 pps
 Medium-high : 0 0 pps
 High : 0 0 pps
 RED-dropped bytes : 0 0 bps
 Low : 0 0 bps
 Medium-low : 0 0 bps
 Medium-high : 0 0 bps
 High : 0 0 bps

## Juniper Networks Devices Processing Overview

---

Junos OS for security devices integrates the world-class network security and routing capabilities of Juniper Networks. Junos OS includes a wide range of packet-based filtering, class-of-service (CoS) classifiers, and traffic-shaping features as well as a rich, extensive set of flow-based security features including policies, screens, network address translation (NAT), and other flow-based services.

Traffic that enters and exits a security device is processed according to features you configure, such as packet filters, security policies, and screens. For example, the software can determine:

- Whether the packet is allowed into the device
- Which firewall screens to apply to the packet
- The route the packet takes to reach its destination
- Which CoS to apply to the packet, if any
- Whether to apply NAT to translate the packet's IP address
- Whether the packet requires an Application Layer Gateway (ALG)

Packets that enter and exit a device undergo both packet-based and flow-based processing:

- Flow-based packet processing treats related packets, or a stream of packets, in the same way. Packet treatment depends on characteristics that were established for the first packet of the packet stream, which is referred to as a flow.

For the distributed processing architecture of the services gateway, all flow-based processing occurs on the SPU and sampling is multi-thread aware. Packet sequencing is maintained for the sampled packets.

- Packet-based, or stateless, packet processing treats packets discretely. Each packet is assessed individually for treatment.

For the distributed processing architecture of the services gateway, some packet-based processing, such as traffic shaping, occurs on the NPU. Some packet-based processing, such as application of classifiers to a packet, occurs on the SPU.

This topic includes the following sections:

- [Understanding Flow-Based Processing on page 1642](#)
- [Understanding Packet-Based Processing on page 1643](#)

## Understanding Flow-Based Processing

A packet undergoes flow-based processing after packet-based filters and some screens have been applied to it. All flow-based processing for a single flow occurs on a single System Processing Unit (SPU). An SPU processes the packets of a flow according to the security features and other services configured for the session.

Figure 83 shows a conceptual view of how flow-based traffic processing occurs on services gateway.

**Figure 83: Traffic Flow for Flow-Based Processing**

A flow is a stream of related packets that meet the same matching criteria and share the same characteristics. Junos OS treats packets belonging to the same flow in the same manner.

Configuration settings that determine the fate of a packet—such as the security policy that applies to it, if it requires an Application Layer Gateway (ALG), if NAT is applied to

translate the packet's source and/or destination IP address—are assessed for the first packet of a flow.

To determine if a flow exists for a packet, the NPU attempts to match the packet's information to that of an existing session based on the following match criteria:

- Source address
- Destination address
- Source port
- Destination port
- Protocol
- Unique session token number for a given zone and virtual router

### Zones and Policies

---

The security policy to be used for the first packet of a flow is cached in a flow table for use with the same flow and closely related flows. Security policies are associated with zones. A zone is a collection of interfaces that define a security boundary. A packet's incoming zone, as determined by the interface through which it arrived, and its outgoing zone, as determined by the forwarding lookup, together determine which policy is used for packets of the flow.

### Flows and Sessions

---

Flow-based packet processing, which is stateful, requires the creation of sessions. A session is created for the first packet of a flow for the following purposes:

- To store most of the security measures to be applied to the packets of the flow.
- To cache information about the state of the flow.

For example, logging and counting information for a flow is cached in its session. (Some stateful firewall screens rely on threshold values that pertain to individual sessions or across all sessions.)

- To allocate required resources for the flow for features such as NAT.
- To provide a framework for features such as ALGs and firewall features.

Most packet processing occurs in the context of a flow, including:

- Management of policies, NAT, zones, and most screens.
- Management of ALGs and authentication.

## Understanding Packet-Based Processing

A packet undergoes packet-based processing when it is removed from the queue from its input interface and before it is added to the queue on its output interface.

Packet-based processing applies stateless firewall filters, CoS features, and some screens to discrete packets.

- When a packet arrives at an interface, sanity checks, packet-based filters, some CoS features, and some screens are applied to it.
- Before a packet leaves the device, any packet-based filters, some CoS features, and some screens associated with the interface are applied to the packet.

Filters and CoS features are typically associated with one or more interfaces to influence which packets are allowed to transit the system and to apply special actions to packets as necessary.

The following topics describe the kinds of packet-based features that you can configure and apply to transit traffic.

### Configuring Packet-Based Processing

---

On SRX Series devices, the default mode for processing traffic is flow mode. To configure an SRX Series device as a border router, you must change the mode from flow-based processing to packet-based processing. Use the **set security forwarding-options family mpls mode packet-based** statement to configure the SRX device to packet mode. You must reboot the device for the configuration to take effect.

**NOTE:** Packet-based processing is supported only on the following SRX Series devices: SRX550, and SRX1500.

---

### Stateless Firewall Filters

---

Also referred to as access control lists (ACLs), stateless firewall filters control access and limit traffic rates. They statically evaluate the contents of packets transiting the device from a source to a destination, or packets originating from or destined for the Routing Engine. A stateless firewall filter evaluates every packet, including fragmented packets.

You can apply a stateless firewall filter to an input or output interface, or to both. A filter contains one or more terms, and each term consists of two components—match conditions and actions. By default, a packet that does not match a firewall filter is discarded.

You can plan and design stateless firewall filters to be used for various purposes—for example, to limit traffic to certain protocols, IP source or destination addresses, or data rates. Stateless firewall filters are executed on the SPU.

### Class-of-Service Features

---

CoS features allow you to classify and shape traffic. CoS features are executed on the SPU.

- Behavior aggregate (BA) classifiers—These classifiers operate on packets as they enter the device. Using behavior aggregate classifiers, the device aggregates different types of traffic into a single forwarding class to receive the same forwarding treatment. BA classifiers allow you to set the forwarding class and loss priority of a packet based on the Differentiated Service (DiffServ) value.

- Traffic shaping—You can shape traffic by assigning service levels with different delay, jitter, and packet loss characteristics to particular applications served by specific traffic flows. Traffic shaping is especially useful for real-time applications, such as voice and video transmission.

### Screens

Some screens, such as denial-of-service (DoS) screens, are applied to a packet outside the flow process. They are executed on the Network Processing Unit (NPU).

For details on specific stateless CoS features, see [Class of Service Feature Guide for Security Devices](#).

## Understanding SRX Series Services Gateways Central Point Architecture

The central point in the architecture has two basic flow functionalities: load balancing and traffic identification (global session matching). The central point forwards a packet to its Services Processing Unit (SPU) upon session matching, or distributes traffic to an SPU for security processing if the packet does not match any existing session.

On some SRX Series devices, an entire SPU cannot be dedicated for central point functionality, but a certain percentage of the SPU is automatically allocated for central point functionality and the rest is allocated for normal flow processing. When an SPU performs the function of central point as well as normal flow processing, it is said to be in combination, or *combo*, mode.

The percentage of SPU dedicated to the central point functionality depends on the number of SPUs in the device. Based on the number of SPUs, there are three modes available on the SRX Series devices— small central point, medium central point, and large central point.

In small central point mode, a small percentage of an SPU is dedicated to central point functionality and the rest is dedicated to the normal flow processing. In medium central point mode, an SPU is almost equally shared for central point functionality and normal flow processing. In large central point mode, an entire SPU is dedicated to central point functionality. In combo mode, the central point and SPU share the same load-balancing thread (LBT) and packet-ordering thread (POT) infrastructure.

This topic includes the following sections:

- [Load Distribution in Combo Mode on page 1646](#)
- [Sharing Processing Power and Memory in Combo Mode on page 1646](#)

## Load Distribution in Combo Mode

The central point maintains SPU mapping table (for load distribution) that lists live SPUs with the logic SPU IDs mapped to the physical Trivial Network Protocol (TNP) addresses mapping. In combo mode, the SPU that hosts the central point is included in the table. The load distribution algorithm is adjusted based on session capacity and processing power to avoid overloading of sessions.

## Sharing Processing Power and Memory in Combo Mode

The CPU processing power in a combo-mode SPU is shared based on the platform and the number of SPUs in the system. Similarly, the CPU memory is also shared between the central point and SPU.

An SPU has multiple cores (CPUs) for networking processing. In "small" SPU combo mode, CPU functionality takes a small portion of the cores, whereas "medium" SPU combo mode requires a larger portion of cores. The processing power for central point functionalities and flow processing is shared, based on the number of Services Processing Cards (SPC), as shown in [Table 167](#).

**Table 167: Combo Mode Processing**

| SRX Series device                                   | Central point mode with 1 SPC | Central point mode with 2 or More than 2 SPCs |
|-----------------------------------------------------|-------------------------------|-----------------------------------------------|
| SRX1400                                             | Small                         | Medium                                        |
| SRX3400                                             | Small                         | Medium                                        |
| SRX3600                                             | Small                         | Medium                                        |
| SRX3400 (expanded performance and capacity license) | Small                         | Large                                         |
| SRX3600 (expanded performance and capacity license) | Small                         | Large                                         |
| SRX5600                                             | Medium                        | Large                                         |
| SRX5800                                             | Medium                        | Large                                         |

**NOTE:** The combo mode processing only exists with SPC1 on SRX1400, SRX3400, SRX3600, and SRX5000 line devices.

## Understanding Enhancements to Central Point Architecture for the SRX5000 Line

Previously, for the SRX5000 line of services gateways, the central point was a bottleneck in device performance and scaling. When more Services Processing Cards (SPCs) were integrated into the system, the overall processing power increased linearly, but the system connections per second (cps) remained constant and could not be improved because of the single centralized point in the system. This severely impacted the overall system utilizations in both capacity and cps.

Beginning with Junos OS Release 15.1X49-D30, on SRX5000 line devices, the central point architecture is enhanced to handle higher connections per second (cps). The new central point architecture prevents data packets from going through the central point by offloading session management functionalities to the Services Processing Unit (SPU). Therefore, data packets are directly forwarded from the network processing unit to the SPU instead of going through the central point.

The central point architecture is divided into two modules, the application central point and the distributed central point. The application central point is responsible for global resource management and load balancing, while the distributed central point is responsible for traffic identification (global session matching). The application central point functionality runs on the dedicated central point SPU, while the distributed central point functionality is distributed to the rest of the SPUs. Now the central point sessions are no longer on the dedicated central point SPU, but with distributed central point on other flow SPUs.

**NOTE:** The central point for SRX5000 line refers to the application central point, or the distributed central point or both, with respect to global resource management and load balancing, it refers to the application central point, whereas with respect to traffic identification and session management, it refers to the distributed central point (sometimes referred to the SPU as well).

**NOTE:** The SNMP log and SNMP trap were generated by the central point with rate limit. Now, the SNMP log and SNMP trap are generated by the SPU or central point. As there is more than one SPU, the number of SNMP log and traps generated are more. To verify the number of connections per second (CPS) on the device run `SNMP MIB walk nxJsNodeSessionCreationPerSecond` command. The SNMP polling mechanism calculates the CPS value based on the average number of CPS in the past 96 seconds. So, if the CPS is not constant, the number of CPS reported is inaccurate.

## SRX5000 Line Devices Processing Overview

---

Junos OS is a distributed, parallel processing, high-throughput and high-performance system. The distributed parallel processing architecture of the SRX5000 line of services gateways includes multiple processors to manage sessions and run security and other services processing. This architecture provides greater flexibility and allows for high throughput and fast performance.

The SRX5000 line devices include I/O cards (IOCs) and Services Processing Cards (SPCs) that each contain processing units that process a packet as it traverses the device. A Network Processing Unit (NPU) runs on an IOC. An IOC has one or more NPUs. One or more Services Processing Units (SPUs) run on an SPC.

These processing units have different responsibilities. All flow-based services for a packet are executed on a single SPU. Otherwise, however, the responsibilities of these NPUs are not clearly delineated in regard to the other kind of services that run on them. (For details on flow-based processing, see [“Juniper Networks Devices Processing Overview” on page 1641.](#))

For example:

- An NPU processes packets discretely. It performs sanity checks and applies some screens that are configured for the interface, such as denial-of-service (DoS) screens, to the packet.
- An SPU manages the session for the packet flow and applies security features and other services to the packet. It also applies packet-based stateless firewall filters, classifiers, and traffic shapers to the packet.
- An NPU forwards a packet to the SPU using the hash algorithm. However, for some applications, like ALG, the system will need to query the application central point to determine on which SPU the packet should be processed.

These discrete, cooperating parts of the system, including the central point, each store the information identifying whether a session exists for a stream of packets and the information against which a packet is matched to determine if it belongs to an existing session.

This architecture allows the device to distribute processing of all sessions across multiple SPUs. It also allows an NPU to determine if a session exists for a packet, to check the packet, and to apply screens to the packet. How a packet is handled depends on whether it is the first packet in a flow.

The following sections describe the processing architecture using SRX5600 and SRX5800 devices as an example:

- [Understanding First-Packet Processing on page 1649](#)
- [Understanding Fast-Path Processing on page 1650](#)
- [Understanding the Data Path for Unicast Sessions on page 1651](#)
- [Understanding Services Processing Units on page 1657](#)

- [Understanding Scheduler Characteristics on page 1657](#)
- [Understanding Network Processor Bundling on page 1657](#)

## Understanding First-Packet Processing

If the packet matches an existing flow, processing for the packet is assessed in the context of its flow state. The SPU maintains the state for each session, and the settings are then applied to the rest of the packets in the flow. If the packet does not match an existing flow, it is used to create a flow state and a session is allocated for it.

[Figure 84](#) illustrates the path the first packet in a flow takes as it enters the device—the NPU determines that no session exists for the packet, and the NPU sends the packet to the distributed central point to set up a distributed central point session. The distributed central point then sends a message to the application central point to select the SPU to set up a session for the packet and to process the packet. The distributed central point then sends the packet to that SPU. The SPU processes the packet and sends it to the NPU for transmission from the device. (This high-level description does not address application of features to a packet.)

**Figure 84: First-Packet Processing**

For details on session creation for the first packet in a flow, see “[Understanding Session Creation: First-Packet Processing](#)” on page 1651.

After the first packet in a flow has traversed the system and a session has been established for it, it undergoes fast-path processing.

Subsequent packets in the flow also undergo fast-path processing; in this case, after each packet enters the session and the NPU finds a match for it in its session table, the NPU forwards the packet to the SPU that manages its session.

[Figure 85](#) illustrates fast-path processing. This is the path a packet takes when a flow has already been established for its related packets. (It is also the path that the first packet in a flow takes after the session for the flow that the packet initiated has been set up.) After the packet enters the device, the NPU finds a match for the packet in its session table, and it forwards the packet to the SPU that manages the packet’s session. Note that the packet bypasses interaction with the central point.

Figure 85: Fast-Path Processing

The following section explains how a session is created and the process a packet undergoes as it transits the device.

### Understanding Fast-Path Processing

Here is an overview of the main components involved in setting up a session for a packet and processing packets both discretely and as part of a flow as they transit the SRX5600 and SRX5800 devices:

- Network Processing Units (NPUs)—NPUs reside on IOCs. They handle packet sanity checking and application of some screens. NPUs maintain session tables that they use to determine if a session exists for an incoming packet or for reverse traffic.

The NPU session table contains an entry for a session if the session is established on an SPU for a packet that had previously entered the device via the interface and was processed by this NPU. The SPU installs the session in the NPU table when it creates the session.

An NPU determines if a session exists for a packet by checking the packet information against its session table. If the packet matches an existing session, the NPU sends the packet and the metadata for it to the SPU. If there is no session, the NPUs sends the packet to one SPU which is calculated using the hash algorithm.

- Services Processing Units (SPUs)—The main processors of the SRX5600 and SRX5800 devices reside on SPCs. SPUs establish and manage traffic flows and perform most of the packet processing on a packet as it transits the device. Each SPU maintains a hash table for fast session lookup. The SPU applies stateless firewall filters, classifiers, and traffic shapers to traffic. An SPU performs all flow-based processing for a packet and most packet-based processing. Each multicore SPU processes packets independently with minimum interaction among SPUs on the same or different SPC. All packets that belong to the same flow are processed by the same SPU.

The SPU maintains a session table with entries for all sessions that it established and whose packets it processes. When an SPU receives a packet from an NPU, it checks its session table to ensure that the packet belongs to it. It also checks its session table when it receives a packet from the distributed central point and sends a message to establish a session for that packet to verify that there is not an existing session for the packet.

- Central point—The central point architecture is divided into two modules, the application central point and the distributed central point. The application central point is responsible for global resource management and loading balancing, while the distributed central point is responsible for traffic identification (global session

matching). The application central point functionality runs on the dedicated central point SPU, while the distributed central point functionality is distributed to the rest of the SPUs. Now the central point sessions are no longer on the dedicated central point SPU, but with the distributed central point on other flow SPUs.

- Routing Engine—The Routing Engine runs the control plane.

## Understanding the Data Path for Unicast Sessions

This section describes the process of establishing a session for packets belonging to a flow that transits the device.

To illustrate session establishment and the packet “walk” including the points at which services are applied to the packets in a flow, this example uses the simple case of a unicast session.

This packet “walk” brings together the packet-based processing and flow-based processing that Junos OS performs on the packet.

### Session Lookup and Packet-Match Criteria

---

To determine if a packet belongs to an existing flow, the device attempts to match the packet’s information to that of an existing session based on the following six match criteria:

- Source address
- Destination address
- Source port
- Destination port
- Protocol
- Unique token from a given zone and virtual router

### Understanding Session Creation: First-Packet Processing

---

This section explains how a session is set up to process the packets composing a flow. To illustrate the process, this section uses an example with a source “a” and a destination “b”. The direction from source to destination for the packets of the flow is referred to as (a -> b). The direction from destination to source is referred to as (b -> a).

#### ***Step 1. A Packet Arrives at an Interface on the Device And the NPU Processes It.***

This section describes how a packet is handled when it arrives at an SRX Series device ingress IOC.

1. The packet arrives at the device’s IOC and is processed by the NPU on the IOC.
2. The NPU performs basic sanity checks on the packet and applies some screens configured for the interface to the packet.
3. The NPU checks its session table for an existing session for the packet. (It checks the packet’s tuple against those of packets for existing sessions in its session table.)

- a. If no existing session is found, the NPU forwards the packet to the hash SPU.
- b. If a session match is found, the session has already been created on an SPU that was assigned to it, so the NPU forwards the packet to the SPU for processing along with the session ID. (See [“Understanding Fast-Path Processing” on page 1654.](#))

**Example:** Packet (a ->b) arrives at NPU1. NPU1 performs sanity checks and applies DoS screens to the packet. NPU1 checks its session table for a tuple match, and no existing session is found. NPU1 forwards the packet to an SPU.

***Step 2. The Distributed Central Point Creates a Session with a "Pending" State.***

When an NPU receives a packet, the NPU send it to the distributed central point, based on the hash algorithm. The distributed central point then looks up the distributed central point session table and creates an entry if needed.

This process entails the following parts:

1. The distributed central point checks its session table to determine if a session exists for the packet received from the NPU. (An NPU forwards a packet to the distributed central point because it cannot find an existing session for the packet)
2. If there is no entry that matches the packet in the distributed central point session table, the distributed central point creates a pending wing for the session. The distributed central point then sends a query message to the application central point to select an SPU to be used for the session.
3. On receiving the query message, the application central point checks its gate table to determine if a gate exists for the packet. If a gate is matched or some other session distribution algorithm is triggered, the application central point selects another SPU to process the packet; otherwise, the SPU (that is, the distributed central point SPU) is selected. Finally, the application central point sends a query response to the distributed central point.
4. On receiving the query response, the distributed central point forwards the first packet in flow to the selected SPU in a message directing the SPU to set up a session locally to be used for the packet flow. For example, the distributed central point creates a pending wing (a ->b) for the session. The application central point selects SPU1 to be used for it. The distributed central point sends SPU1 the (a->b) packet along with a message to create a session for the distributed central point.

**Example:** The distributed central point creates a pending wing (a ->b) for the session. It selects SPU1 to be used for it. It sends SPU1 the (a->b) packet along with a message to create a session for it.

***Step 3. The SPU Sets Up the Session.***

Each SPU, too, has a session table, which contains information about its sessions. When the SPU receives a message from the distributed central point to set up a session, it checks its session table to ensure that a session does not already exist for the packet.

1. If there is no existing session for the packet, the SPU sets up the session locally.

2. The SPU sends a message to the distributed central point directing it to install the session.

**NOTE:** During first-packet processing, if NAT is enabled, the SPU allocates IP address resources for NAT. In this case, the first-packet processing for the session is suspended until the NAT allocation process is completed.

The SPU adds to the queue any additional packets for the flow that it might receive until the session has been installed.

**Example:** SPU1 creates the session for (a->b) and sends a message back to the distributed central point directing it to install the pending session.

#### ***Step 4. The Distributed Central Point Installs the Session.***

The distributed central point receives the install message from the SPU.

1. The distributed central point sets the state for the session's pending wing to active.
2. The distributed central point installs the reverse wing for the session as an active wing.

**NOTE:** For some cases, such as NAT, the reverse wing may be installed on a different distributed central point from the init wing distributed central point.

3. It sends an acknowledge (ACK) message to the SPU, indicating that the session is installed.

**Example:** The distributed central point receives a message from SPU1 to install the session for the (a->b) wing. It sets the session state for the (a->b) wing to active. It installs the reverse wing (b->a) for the session and makes it active; this allows for delivery of packets from the reverse direction of the flow: destination (b) to be delivered to the source (a).

#### ***Step 5. The SPU Sets Up the Session on the Ingress and Egress NPUs.***

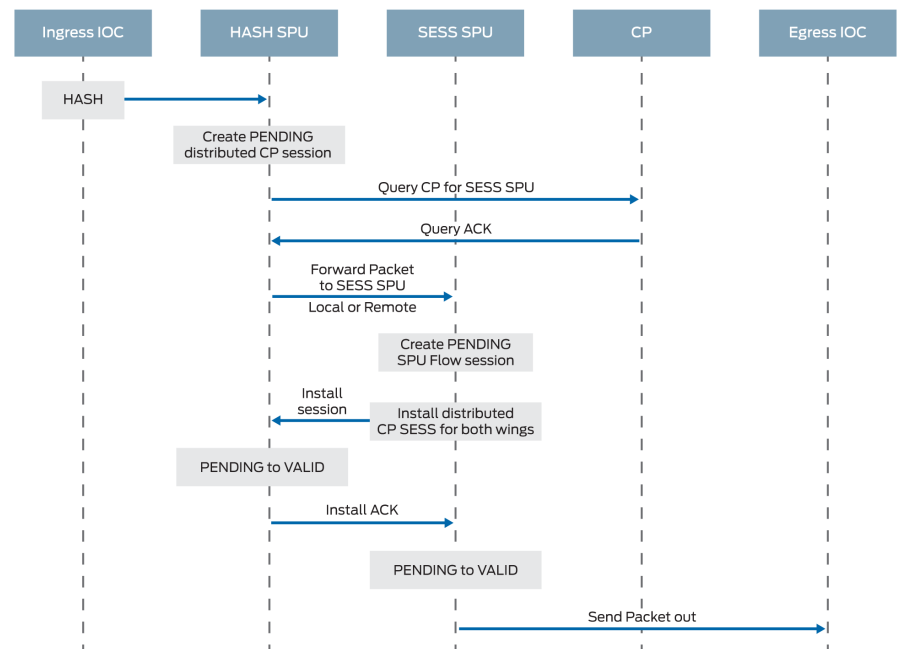

NPUs maintain information about a session for packet forwarding and delivery. Session information is set up on the egress and ingress NPUs (which sometimes are the same) so that packets can be sent directly to the SPU that manages their flows and not to the distributed central point for redirection.

#### ***Step 6. Fast-Path Processing Takes Place.***

For the remainder of the steps entailed in packet processing, proceed to Step 1 in [“Understanding Fast-Path Processing” on page 1654](#).

**Figure 86** illustrates the first part of the process that the first packet in a flow undergoes after it reaches the device. At this point a session is set up to process the packet and the rest of the packets belonging to its flow. Subsequently, it and the rest of the packets in the flow undergo fast-path processing.

Figure 86: Session Creation: First-Packet Processing

### Understanding Fast-Path Processing

All packets undergo fast-path processing. However, if a session exists for a packet, the packet undergoes fast-path processing and bypasses the first-packet process. When there is already a session for the packet's flow, the packet does not transit the central point.

Here is how fast-path processing works: NPUs at the egress and ingress interfaces contain session tables that include the identification of the SPU that manages a packet's flow. Because the NPUs have this session information, all traffic for the flow, including reverse traffic, is sent directly to that SPU for processing.

To illustrate the fast-path process, this section uses an example with a source "a" and a destination "b". The direction from source to destination for the packets of the flow is referred to as (a->b). The direction from destination to source is referred to as (b->a).

#### Step 1. A Packet Arrives at the Device and the NPU Processes It.

This section describes how a packet is handled when it arrives at a services gateway's IOC.

1. The packet arrives at the device's IOC and is processed by the NPU on the card.  
The NPU performs sanity checks and applies some screens, such as denial-of-service (DoS) screens, to the packet.
2. The NPU identifies an entry for an existing session in its session table that the packet matches.

3. The NPU forwards the packet along with metadata from its session table, including the session ID and packet tuple information, to the SPU that manages the session for the flow, applies stateless firewall filters and CoS features to its packets, and handles the packet's flow processing and application of security and other features.

**Example:** Packet (a ->b) arrives at NPU1. NPU1 performs sanity checks on the packet, applies DoS screens to it, and checks its session table for a tuple match. It finds a match and that a session exists for the packet on SPU1. NPU1 forwards the packet to SPU1 for processing.

***Step 2. The SPU for the Session Processes the Packet.***

Most of a packet's processing occurs on the SPU to which its session is assigned. The packet is processed for packet-based features such as stateless firewall filters, traffic shapers, and classifiers, if applicable. Configured flow-based security and related services such as firewall features, NAT, ALGs, and so on, are applied to the packet. (For information on how security services are determined for a session, see "[Juniper Networks Devices Processing Overview](#)" on page 1641.)

1. Before it processes the packet, the SPU checks its session table to verify that the packet belongs to one of its sessions.
2. The SPU processes the packet for applicable features and services.

**Example:** SPU1 receives packet (a->b) from NPU1. SPU1 checks its session table to verify that the packet belongs to one of its sessions. Then it processes packet (a->b) according to input filters and CoS features that apply to its input interface. The SPU applies the security features and services that are configured for the packet's flow to it, based on its zone and policies. If any are configured, it applies output filters, traffic shapers and additional screens to the packet.

***Step 3. The SPU Forwards the Packet to the NPU.***

1. The SPU forwards the packet to the NPU.
2. The NPU applies any applicable screens associated with the interface to the packet.

**Example:** SPU1 forwards packet (a ->b) to NPU2, and NPU2 applies DoS screens.

***Step 4. The Interface Transmits the Packet from the Device.***

**Example:** The interface transmits packet (a->b) from the device.

***Step 5. A Reverse Traffic Packet Arrives at the Egress Interface and the NPU Processes It.***

This step mirrors Step 1 exactly in reverse. See Step 1 in this section for details.

**Example:** Packet (b->a) arrives at NPU2. NPU2 checks its session table for a tuple match. It finds a match and that a session exists for the packet on SPU1. NPU2 forwards the packet to SPU1 for processing.

***Step 6. The SPU for the Session Processes the Reverse Traffic Packet.***

This step is the same as Step 2 except that it applies to reverse traffic. See Step 2 in this section for details.

**Example:** SPU1 receives packet (b->a) from NPU2. It checks its session table to verify that the packet belongs to the session identified by NPU2. Then it applies packet-based features configured for the NPU1's interface to the packet. It processes packet (b->a) according to the security features and other services that are configured for its flow, based on its zone and policies. (See [“Juniper Networks Devices Processing Overview”](#) on page 1641.)

#### ***Step 7. The SPU Forwards the Reverse Traffic Packet to the NPU.***

This step is the same as Step 3 except that it applies to reverse traffic. See Step 3 in this section for details.

**Example:** SPU1 forwards packet (b->a) to NPU1. NPU1 processes any screens configured for the interface.

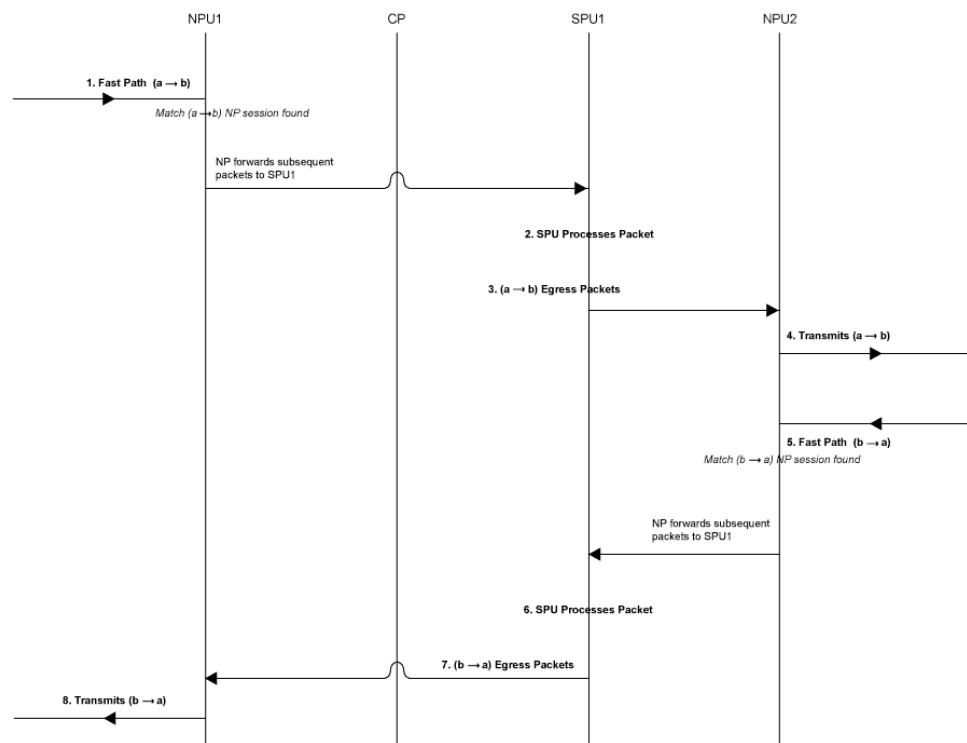

#### ***8. The Interface Transmits the Packet from the Device.***

This step is the same as Step 4 except that it applies to reverse traffic. See Step 4 in this section for details.

Example: The interface transmits packet (b->a) from the device.

Figure 87 illustrates the process a packet undergoes when it reaches the device and a session exists for the flow that the packet belongs to.

**Figure 87: Packet Walk for Fast-Path Processing**

## Understanding Services Processing Units

For a given physical interface, the SPU receives ingress packets from all network processors in the network processor bundle associated with the physical interface. The SPU extracts network processor bundle information from the physical interface and uses the same 5-tuple hash algorithm to map a flow to a network processor index. To determine the network processor, the SPU does a lookup on the network processor index in the network processor bundle. The SPU sends egress packets to the physical interface's local Physical Interface Module (PIM) for the outward traffic.

**NOTE:** The network processor and the SPU use the same 5-tuple hash algorithm to get the hash values for the packets.

## Understanding Scheduler Characteristics

For SRX5600 and SRX5800 devices, the IOC supports the following hierarchical scheduler characteristics:

- IFL – The configuration of the network processor bundle is stored in the physical interface data structure. For example, SRX5600 and SRX5800 devices have a maximum of 48 PIMs. The physical interface can use a 48-bit bit-mask to indicate the PIM, or the network processor traffic from this physical interface is distributed in addition to the physical interface's primary network processor.

On SRX5000 line devices, the iflset functionality is not supported for aggregated interfaces like *reth*.

- IFD – The logical interface associated with the physical interface of a network processor bundle is passed to all the IOCs that have a PIM in the network processor bundle.

## Understanding Network Processor Bundling

The network processor bundling feature is available on SRX5000 line devices. This feature enables distribution of data traffic from one interface to multiple network processors for packet processing. A primary network processor is assigned for an interface that receives the ingress traffic and distributes the packets to several other secondary network processors. A single network processor can act as a primary network processor or as a secondary network processor to multiple interfaces. A single network processor can join only one network processor bundle.

### Network Processor Bundling Limitations

Network processor bundling functionality has the following limitations:

- Network processor bundling allows a total of 16 PIMs per bundle and 8 different network processor bundle systems.
- You need to reboot the device to apply the configuration changes on the bundle.

- Network processor bundling is below the reth interface in the overall architecture. You can choose one or both interfaces from the network processor bundle to form the reth interface.
- If the IOC is removed from a network processor bundle, the packets forwarded to the PIM on that IOC are lost.
- When the network processor bundle is enabled, the ICMP, UDP, and TCP sync flooding thresholds no longer apply to an interface. Packets are distributed to multiple network processors for processing. These thresholds apply to each network processor in the network processor bundle.
- Network processor bundling is not supported in Layer 2 mode.
- Because of memory constraints on the network processor, the number of network processor bundled ports that are supported per PIM is limited. Within the network processor bundle, each port needs to have a global port index. The global port index is calculated using the following formula:  
$$\text{Global\_port\_index} = (\text{global\_pic} * 16) + \text{port\_offset}$$
- Link aggregation groups (LAGs) and redundant Ethernet interface LAGs in chassis cluster implementations can coexist with network processor bundling. However, neither LAGs nor redundant Ethernet interface LAGs can overlap with or share physical links with a network processor bundle.

---

## SRX3000 Line and SRX1400 Devices Processing Overview

---

Junos OS for the SRX1400, SRX3400 and SRX3600 Services Gateways integrates the world-class network security and routing capabilities of Juniper networks. Junos OS for these service gateways includes the wide range of security services including policies, screens, network address translation, class-of-service classifiers, and the rich, extensive set of flow-based services that are also supported on the other devices in the services gateways

The distributed parallel processing architecture of the SRX1400, SRX3400 and SRX3600 devices includes multiple processors to manage sessions and run security and other services processing. This architecture provides greater flexibility and allows for high throughput and fast performance.

The following sections describe the processing architecture using SRX3400 and SRX3600 devices as an example:

This topic includes the following information:

- [Components Involved in Setting Up a Session on page 1659](#)
- [Understanding the Data Path for Unicast Sessions on page 1659](#)
- [Session Lookup and Packet Match Criteria on page 1660](#)
- [Understanding Session Creation: First Packet Processing on page 1660](#)
- [Understanding Fast-Path Processing on page 1662](#)

## Components Involved in Setting Up a Session

Here is an overview of the main components involved in setting up a session for a packet and processing the packets as they transit the SRX3400 and SRX3600 devices:

- **Services Processing Units (SPUs)**—The main processors of the SRX3400 and SRX3600 devices reside on Services Processing Cards (SPCs). They establish and manage traffic flows and perform most of the packet processing on a packet as it transits the device. Each SPU maintains a hash table for fast session lookup. The SPU performs all flow-based processing for a packet, including application of security services, classifiers, and traffic shapers. All packets that belong to the same flow are processed by the same SPU.

The SPU maintains a session table with entries for all sessions that it established and whose packets it processes. When an SPU receives a packet from an NPU, it checks its session table to ensure that the packet belongs to it.

For SRX3400 and SRX3600 devices, one SPU acts in concert performing its regular session management and flow processing functions and acting as a central point in which it arbitrates sessions and allocates resources. When an SPU performs in this manner it is said to be in combo mode.

- **Central Point**—The central point is used to allocate session management to SPUs based on load balancing criteria. It distributes sessions in an intelligent way to avoid occurrences in which multiple SPUs might wrongly handle the same flow. The central point follows load balancing criteria in allocating sessions to SPUs. If the session exists, the central point forwards packets for that flow to the SPU hosting it. It also redirects packets to the correct SPU in the event that the NPU fails to do so.

For the SRX3400 and SRX3600 devices, one SPU always runs in what is referred to as combo mode in which it implements both the functionality of the central point and the flow and session management functionality. In combo mode, the SPU and the central point share the same load-balancing thread (LBT) and packet-ordering thread (POT) infrastructure. For more information, see [“Understanding SRX Series Services Gateways Central Point Architecture” on page 1645](#).

- **Routing Engine (RE)**—The Routing Engine runs the control plane and manages the Control Plane Processor (CPP).

## Understanding the Data Path for Unicast Sessions

Junos OS for the SRX3400 and SRX3600 Services Gateways is a distributed parallel processing high throughput and high performance system. This topic describes the process of establishing a session for packets belonging to a flow that transits the device.

To illustrate session establishment and the packet “walk” including the points at which services are applied to the packets of a flow, the following example uses the simple case of a unicast session. This packet “walk” brings together the packet-based processing and flow-based processing that the Junos OS performs on the packet.

## Session Lookup and Packet Match Criteria

To determine if a packet belongs to an existing flow, the device attempts to match the packet's information to that of an existing session based on the following six match criteria:

- Source address
- Destination address
- Source port
- Destination port
- Protocol
- Unique token from a given zone and virtual router

## Understanding Session Creation: First Packet Processing

This topic explains how a session is set up to process the packets composing a flow. To illustrate the process, this topic uses an example with a source "a" and a destination "b". The direction from source to destination for the packets of the flow is referred to as (a -> b). The direction from destination to source is referred to as (b -> a).

1. A packet arrives at an interface on the device and the IOC processes it.

The IOC dequeues the packet and sends it to the NPU with which it communicates.

2. The NPU receives the packet from the IOC and processes it.
  - The NPU performs basic sanity checks on the packet and applies some screens configured for the interface to the packet.
  - If a session match is found, the session has already been created on an SPU that was assigned to it, so the NPU forwards the packet to the SPU for processing along with the session ID.

Example: Packet (a ->b) arrives at NPU1 from IOC1. NPU1 performs sanity checks and applies DoS screens to the packet. NPU1 checks its session table for a tuple match and no existing session is found. NPU1 forwards the packet to the central point on SPU1 for assignment to an SPU.

3. The central point creates a session with a "Pending" state.

The central point maintains a global session table that includes entries for all sessions that exist across all SPUs on the device. It participates in session creation and delegates and arbitrates session resources allocation.

This process entails the following parts:

- a. The central point checks its session table and gate table to determine if a session or a gate exists for the packet it receives from the NPU. (An NPU has forwarded a packet to the central point because its table indicates there is no session for it. The central point verifies this information before allocating an SPU for the session.)

- b. If there is no entry that matches the packet in either table, the central point creates a pending wing for the session and selects an SPU to be used for the session, based on its load-balancing algorithm.

- c. The central point forwards the first packet of the flow to the selected SPU in a message telling it to set up a session locally to be used for the packet flow.

Example: The central point creates pending wing (a ->b) for the session. It selects SPU1 to be used for the session. It sends SPU1 the (a->b) packet along with a message to create a session for it. (It happens to be the case that SPU1 is the SPU that runs in combo mode. Therefore, its session-management and flow-processing services are used for the session.

4. The SPU sets up the session.

Each SPU, too, has a session table, which contains information about its sessions. When the SPU receives a message from the central point to set up a session, it checks its session table to ensure that a session does not already exist for the packet.

- a. If there is no existing session for the packet, the SPU sets up the session locally.
- b. The SPU sends a message to the central point, telling it to install the session.

During first-packet processing, if NAT is enabled, the SPU allocates IP address resources for NAT. In this case, the first-packet processing for the session is suspended until the NAT allocation process is completed.

The SPU adds to the queue any additional packets for the flow that it might receive until the session has been installed.

Example: SPU1 creates the session for (a ->b) and sends a message back to the central point (implemented on the same SPU) telling it to install the pending session.

5. The central point installs the session.

- It sets the state for the session's pending wing to active.
- It installs the reverse wing for the session as an active wing.
- It sends an ACK (acknowledge) message to the SPU, indicating that the session is installed.

Example: The central point receives a message from SPU1 to install the session for (a->b). It sets the session state for (a->b) wing to active. It installs the reverse wing (b->a) for the session and makes it active; this allows for delivery of packets from the reverse direction of the flow: destination (b) to be delivered to the source (a).

6. The SPU sets up the session on the ingress and egress NPUs.

NPUs maintain information about a session for packet forwarding and delivery. Session information is set up on the egress and ingress NPUs (which sometimes are the same) so that packets can be sent directly to the SPU that manages their flows and not to the central point for redirection.

7. Fast-path processing takes place.

For the remainder of the steps entailed in packet processing, proceed to Step 1 in "Understanding Fast-Path Processing".

## Understanding Fast-Path Processing

All packets undergo fast-path processing. However, if a session exists for a packet, the packet undergoes fast-path processing and bypasses the first-packet process. When there is already a session for the packet's flow, the packet does not transit the central point.

Here is how fast-path processing works: NPUs at the egress and ingress interfaces contain session tables that include the identification of the SPU that manages a packet's flow. Because the NPUs have this session information, all traffic for the flow, including reverse traffic, is sent directly to that SPU for processing.

On SRX1400, SRX3400, and SRX3600 devices, the `iflset` functionality is not supported for aggregated interfaces like *reth*.

## SRX210 Services Gateway Processing Overview

This topic describes the process that the SRX210 Services Gateway undertakes in establishing a session for packets belonging to a flow that transits the device. The flow services of the SRX210 device are single-threaded and non-distributed. Although it differs from the other SRX Series devices in this respect, the same flow model is followed and the same command line interface (CLI) is implemented.

To illustrate session establishment and the packet “walk” including the points at which services are applied to the packets of a flow, the example described in the following sections uses the simple case of a unicast session:

- [Understanding Flow Processing and Session Management on page 1662](#)
- [Understanding First-Packet Processing on page 1663](#)
- [Understanding Session Creation on page 1663](#)
- [Understanding Fast-Path Processing on page 1663](#)

## Understanding Flow Processing and Session Management

This topic explains how a session is set up to process the packets composing a flow. In the following topic, the SPU refers to the data plane thread of the SRX210 Services Gateway.

At the outset, the data plane thread fetches the packet and performs basic sanity checks on it. Then it processes the packet for stateless filters and CoS classifiers and applies some screens.

## Understanding First-Packet Processing

To determine if a packet belongs to an existing flow, the device attempts to match the packet's information to that of an existing session based on the following six match criteria:

- Source address
- Destination address
- Source port
- Destination port
- Protocol
- Unique token from a given zone and virtual router

The SPU checks its session table for an existing session for the packet. If no existent session is found, the SPU sets up a session for the flow. If a session match is found, the session has already been created, so the SPU performs fast-path processing on the packet.

## Understanding Session Creation

In setting up the session, the SPU executes the following services for the packet:

- Screens
- Route lookup
- Policy lookup
- Service lookup
- NAT, if required

After a session is set up, it is used for all packets belonging to the flow. Packets of a flow are processed according to the parameters of its session. For the remainder of the steps entailed in packet processing, proceed to Step 1 in “Fast-Path Processing”. All packets undergo fast-path processing.

## Understanding Fast-Path Processing

If a packet matches a session, Junos OS performs fast-path processing as described in the following steps. After a session has been set up for the first packet in a flow, also undergoes fast-path processing. All packets undergo fast-path processing.

1. The SPU applies flow-based security features to the packet.
  - Configured screens are applied.
  - TCP checks are performed.
  - Flow services, such as NAT, ALG, and IPsec are applied, if required.
2. The SPU prepares the packet for forwarding and transmits it.

- Routing packet filters are applied.
- Traffic shaping is applied.
- Traffic prioritizing is applied.
- Traffic scheduling is applied.
- The packet is transmitted.

## Understanding Session Characteristics for SRX Series Services Gateways

---

Sessions are created, based on routing and other classification information, to store information and allocate resources for a flow. Sessions have characteristics, some of which you can change, such as when they are terminated. For example, you might want to ensure that a session table is never entirely full to protect against an attacker's attempt to flood the table and thereby prevent legitimate users from starting sessions.

Depending on the protocol and service, a session is programmed with a timeout value. For example, the default timeout for TCP is 1800 seconds. The default timeout for UDP is 60 seconds. When a flow is terminated, it is marked as invalid, and its timeout is reduced to 2 to 4 seconds.

If no traffic uses the session before the service timeout, the session is aged out and freed to a common resource pool for reuse. You can affect the life of a session in the following ways:

- You can specify circumstances for terminating sessions by using any of the following methods:
  - Age out sessions based on how full the session table is
  - Set an explicit timeout for aging out TCP sessions
  - Configure a TCP session to be invalidated when it receives a TCP RST (reset) message

- You can configure sessions to accommodate other systems as follows:
  - Disable TCP packet security checks
  - Change the maximum segment size

---

## Understanding Aggressive Session Aging

---

The session table is a limited resource for SRX Series devices. If the session table is full, any new sessions will be rejected by the device.

The aggressive session-aging mechanism accelerates the session timeout process when the number of sessions in the session table exceeds the specified high-watermark threshold. This mechanism minimizes the likelihood that the SRX Series devices will reject new sessions when the session table becomes full.

Configure the following parameters to perform aggressive session aging:

- *high-watermark*—The device performs aggressive session aging when the number of sessions in the session table exceeds the *high-watermark* threshold.
- *low-watermark*—The device exits aggressive session aging and returns to normal when the number of sessions in the session table dips below the *low-watermark* threshold.
- *early-ageout*—During aggressive session aging, the sessions with an age-out time lower than the *early-ageout* threshold are marked as invalid.

On SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices, the SPU checks the session table, locates the sessions for which the timeout value is lower than the early-ageout time value, and then marks them as invalid.

---

## Example: Controlling Session Termination for SRX Series Services Gateways

---

This example shows how to terminate sessions for SRX Series devices based on aging out after a certain period of time, or when the number of sessions in the session table is

full or reaches a specified percentage. You specify a timeout value or the number of sessions in the session table.

- [Requirements on page 1669](#)
- [Overview on page 1669](#)
- [Configuration on page 1669](#)
- [Verification on page 1670](#)

## Requirements

Before you begin, understand the circumstances for terminating sessions. See [“Understanding Session Characteristics for SRX Series Services Gateways” on page 1667](#).

## Overview

You can control session termination in certain situations—for example, after receiving a TCP FIN Close or receiving an RST message, when encountering ICMP errors for UDP, and when no matching traffic is received before the service timeout. When sessions are terminated, their resources are freed up for use by other sessions.

In this example, you configure the following circumstances to terminate the session:

- A timeout value of 20 seconds.

**NOTE:** The minimum value you can configure for TCP session initialization is 4 seconds. The default value is 20 seconds; if required you can set the TCP session initialization value to less than 20 seconds.

- An explicit timeout value of 280 seconds, which changes the TCP session timeout during the three-way handshake.

The command sets the initial TCP session timeout to 280 in the session table during the TCP three-way handshake. The timer is initiated when the first SYN packet is received, and reset with each packet during the three-way handshake. Once the three-way handshake is completed, the session timeout is reset to the timeout defined by the specific application. If the timer expires before the three-way handshake is complete, the session is removed from the session table.

- Any session that receives a TCP RST (reset) message is invalidated.

## Configuration

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To control session termination for SRX Series devices:

1. Specify an age-out value for the session.

[edit security flow]

```
user@host# set aging early-ageout 20
```

2. Configure an aging out value.

```
[edit security flow]
```

```
user@host# set tcp-session tcp-initial-timeout 280
```

3. Invalidate any session that receives a TCP RST message.

```
[edit security flow]
```

```
user@host# set tcp-session rst-invalidate-session
```

4. If you are done configuring the device, commit the configuration.

```
[edit]
```

```
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security flow** command.

## Understanding TCP Session Checks per Policy

By default, the TCP SYN check and sequence check options are enabled on all TCP sessions. The Junos operating system (Junos OS) performs the following operations during TCP sessions:

- Checks for SYN flags in the first packet of a session and rejects any TCP segments with non-SYN flags that attempt to initiate a session.
- Validates the TCP sequence numbers during stateful inspection.

The TCP session check per-policy feature enables you to configure SYN and sequence checks for each policy. Currently, the TCP options flags, no-sequence-check and no-syn-check, are available at a global level to control the behavior of services gateways. To support per-policy TCP options, the following two options are available:

- **sequence-check-required:** The sequence-check-required value overrides the global value no-sequence-check.
- **syn-check-required:** The syn-check-required value overrides the global value no-syn-check.

To configure per-policy TCP options, you must turn off the respective global options; otherwise, the commit check will fail. If global TCP options are disabled and SYN flood protection permits the first packet, then the per-policy TCP options will control whether SYN and/or sequence checks are performed.

**NOTE:**

- The per-policy SYN check required option will not override the behavior of the `set security flow tcp-session no-syn-check-in-tunnel` CLI command.
- Disabling the global SYN check reduces the effectiveness of the device in defending against packet flooding.

Disabling the global SYN check and enforcing the SYN check after policy search will greatly impact the number of packets that the router can process. This in turn will result in intense CPU operations. When you disable global SYN check and enable per-policy SYN check enforcement, you should be aware of this performance impact.

## Example: Disabling TCP Packet Security Checks for SRX Series Services Gateways

This example shows how to disable TCP packet security checks in the device.

- [Requirements on page 1671](#)
- [Overview on page 1671](#)
- [Configuration on page 1672](#)
- [Verification on page 1672](#)

### Requirements

Before you begin, understand the circumstances for disabling TCP packet security checks. See [“Understanding Session Characteristics for SRX Series Services Gateways” on page 1667](#).

### Overview

Junos OS provides a mechanism for disabling security checks on TCP packets to ensure interoperability with hosts and devices with faulty TCP implementations. During no-SYN-check the Junos OS does not look for the TCP SYN packet for session creation. No-sequence check disables TCP sequence checking validation. Also, increases throughput. SYN check and sequence check are enabled by default. The `set security flow` command disables TCP SYN checks and TCP sequence checks on all TCP sessions thus reduces security. This may be required in scenarios with customers like big transfer files, or with applications that do not correctly work with standards.

## Configuration

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To disable TCP packet security checks:

1. Disable the checking of the TCP SYN bit before creating a session.

```
[edit security flow]
user@host# set tcp-session no-syn-check
```

2. Disable the checking of sequence numbers in TCP segments during stateful inspection.

```
[edit security flow]
user@host# set tcp-session no-sequence-check
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security flow** command.

**Related Documentation**

- [Example: Controlling Session Termination for SRX Series Services Gateways on page 1668](#)
- [Example: Setting the Maximum Segment Size for All TCP Sessions for SRX Series Services Gateways on page 1672](#)

---

## Example: Setting the Maximum Segment Size for All TCP Sessions for SRX Series Services Gateways

---

This example shows how to set the maximum segment size for all TCP sessions for SRX Series devices.

- [Requirements on page 1672](#)
- [Overview on page 1673](#)
- [Configuration on page 1673](#)
- [Verification on page 1674](#)

## Requirements

Before you begin, understand the circumstances for setting the maximum segment size. See “[Understanding Session Characteristics for SRX Series Services Gateways](#)” on [page 1667](#).

## Overview

You can terminate all TCP sessions by changing the TCP maximum segment size (TCP-MSS). To diminish the likelihood of fragmentation and to protect against packet loss, you can use the `tcp-mss` statement to specify a lower TCP MSS value. This statement applies to all TCP SYN packets traversing the router's ingress interfaces whose MSS value is higher than the one you specify.

If the DF bit is set, it will not fragment the packet and Junos OS will send ICMP error type 3 code 4 packet to the application server (Destination Unreachable; Fragmentation Needed and DF set). This ICMP error message contains the correct MTU (as defined in `tcp-mss`) to be used by the application server, which should receive this message and adjust the packet size accordingly. This is specifically required with VPNs, as IPsec has added packet overhead; thus `tcp-mss` must be lowered appropriately.

**NOTE:** When running SRX Series devices in packet mode, you use the `set system internet-options tcp-mss` statement to adjust the TCP-MSS value. All ports are affected by the TCP-MSS configuration; you cannot exclude a particular port. When running SRX Series devices in flow mode, although you can use the `set system internet-options tcp-mss` statement, we recommend using only the `set security flow tcp-mss` statement to adjust the TCP-MSS value. If both statements are configured, the lower of the two values will take effect.

## Configuration

### Step-by-Step Procedure

To configure the maximum segment size for all TCP sessions:

1. Set the TCP maximum segment size for all TCP sessions.

```
[edit security flow]
user@host# set tcp-mss all-tcp mss 1300
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

### Results

From configuration mode, confirm your configuration by entering the **show security flow** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show security flow
...
```

```
tcp-mss{
 all-tcp{
 mss 1300;
 }
}
...
```

## Verification

To verify the configuration is working properly, enter the **show configuration security flow** command from operational mode.

```
user@host> show configuration security flow
tcp-mss{
 all-tcp{
 mss 1300;
 }
}
```

## Example: Configuring TCP Packet Security Checks Per Policy

This example shows how to configure TCP packet security checks for each policy in the device.

- [Requirements on page 1674](#)
- [Overview on page 1674](#)
- [Configuration on page 1674](#)
- [Verification on page 1675](#)

## Requirements

Before you begin, you must disable the tcp options, **tcp-syn-check**, and **tcp-sequence-check** that are configured at global level. See [“Example: Disabling TCP Packet Security Checks for SRX Series Services Gateways” on page 1671](#).

## Overview

The SYN and sequence check options are enabled by default on all TCP sessions. In environments that need to support large file transfers, or that run nonstandard applications, it might be necessary to configure sequence and sync checks differently for each policy. In this example, you configure sequence and sync check for policy **pol1**.

## Configuration

### Step-by-Step Procedure

To configure TCP packet security checks at the policy level:

1. Configure the checking for the TCP SYN bit before creating a session.

```
[edit]
user@host# set security policies from-zone Zone-A to-zone Zone-B policy pol1 then
 permit tcp-options syn-check-required
```

2. Configure the checking for sequence numbers in TCP segments during stateful inspection.

```
[edit]
user@host# set security policies from-zone Zone-A to-zone Zone-B policy pol1 then
 permit tcp-options sequence-check-required
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify that the configuration is working properly, enter the **show security policies detail** command.

## Configuring the Timeout Value for Multicast Flow Sessions

You can configure the timeout value for multicast flow sessions by configuring a custom application and associating the application with a policy.

Multicast flow sessions have one template session and one or more leaf sessions. Because these sessions are linked together, they can have only one timeout value. The timeout value for multicast flow sessions is determined by considering the timeout values configured in the leaf session policies and the IP protocol timeout values. The highest of these timeout values is selected as the multicast flow session timeout.

If no leaf session timeout values are configured, the IP protocol timeout value is automatically used as the timeout value for the multicast flow session. The IP protocol timeout is the default and is not configurable.

Configuring leaf session timeouts can be especially helpful for multicast streams that have a longer packet interval than the default IP protocol timeout. For example, multicast streams with a packet interval of more than 60 seconds would experience premature aging-out of flow sessions and packet drops with the UDP timeout value, which is always 60 seconds. For such streams, you can configure a higher leaf session timeout value and prevent packet drop.

To set the leaf session timeout value, configure a custom application and associate the application with a policy:

1. Create a custom application, specify its properties, and specify bypassing the application type.

```
[edit]
user@host# edit applications application my-udp

[edit applications application my-udp]
user@host# set protocol udp
user@host# set destination-port 5000
user@host# set application-protocol ignore
```

2. Set the timeout value for the application protocol.

```
[edit applications application my-udp]
user@host# set inactivity-timeout 500
```

3. Create a policy.

```
[edit]
user@host# edit security policies from-zone vr-zone-1 to-zone junos-host policy
my-policy

[edit security policies from-zone vr-zone-1 to-zone junos-host policy my-policy]
user@host# set match source-address 18.1.1.2
user@host# set match destination-address any
```

4. Associate the custom application (with the configured timeout) to the policy.

```
[edit security policies from-zone vr-zone-1 to-zone junos-host policy my-policy]
user@host# set match application my-udp
user@host# set then permit
```

5. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

6. To verify the updated session timeout value, enter the **show security flow session** command.

```
user@host> show security flow session destination-prefix 224.1.1.1
```

```
Session ID: 2363, Policy name: N/A, Timeout: 498, Valid
 In: 18.1.1.2/17767-->224.1.1.1/5000;udp, If: ge-0/0/1.0, Pkts:0, Bytes:0
 Out: 255.255.255.255/5000-->255.255.255.255/17767;udp, If:.local..4, Pkts:0,
 Bytes:0
```

```
Session ID: 2364, Policy name: my-policy/4, Timeout: -1, Valid
 In: 18.1.1.2/17767-->224.1.1.1/5000;udp, If:ge-0/0/1.0, Pkts:1011,
 Bytes:258816
 Out: 224.1.1.1/5000-->18.1.1.2/17767;udp, If:ppe0.32769, Pkts:0, Bytes:0
Total sessions: 2
```

In this output, the session ID 2363 section displays a template session. A timeout value of 498 indicates that the template session timeout value is ticking down from the configured value of 500 seconds.

The session ID 2364 section displays a leaf session. The timeout value of -1 essentially indicates that the session will not age out unless the template session ages out.

In this example, the configured leaf session timeout value of 500 seconds is the highest timeout value and is accepted as the template session timeout value for the multicast flow session.

---

## Clearing Sessions for SRX Series Services Gateways

You can use the **clear** command to terminate sessions. You can clear all sessions, including sessions of a particular application type, sessions that use a specific destination port, sessions that use a specific interface or port, sessions that use a certain IP protocol, sessions that match a source prefix, and resource manager sessions.

- [Terminating Sessions for SRX Series Services Gateways on page 1677](#)
- [Terminating a Specific Session for SRX Series Services Gateways on page 1677](#)
- [Using Filters to Specify the Sessions to Be Terminated for SRX Series Services Gateways on page 1677](#)

### Terminating Sessions for SRX Series Services Gateways

You can use the following command to terminate all sessions except tunnel and resource manager sessions. The command output shows the number of sessions cleared. Be aware that this command terminates the management session through which the clear command is issued.

```
user@host> clear security flow session all
```

### Terminating a Specific Session for SRX Series Services Gateways

You can use the following command to terminate the session whose session ID you specify.

```
user@host> clear security flow session session-identifier 40000381
```

### Using Filters to Specify the Sessions to Be Terminated for SRX Series Services Gateways

You can terminate one or more sessions based on the filter parameter you specify for the **clear** command. The following example uses the protocol as a filter.

```
user@host> clear security flow session protocol 89
```

## PART 24

# Improving Flow-Based Performance

## Expanding Session Capacity by Device

To take advantage of the processing potential of a fully loaded SRX3400, SRX3600, or SRX5800 device, you can expand the maximum number of concurrent sessions for these devices.

[Table 168](#) shows the maximum number of concurrent sessions allowed on these devices by default and with expanded capacity.

**Table 168: Maximum Central Point Session Increases**

| SRX Series Devices | Maximum Concurrent Sessions on a Fully Loaded System |                         |
|--------------------|------------------------------------------------------|-------------------------|
|                    | Default                                              | With Expanded Capacity  |
| SRX3400            | 2.25 million                                         | 3 million               |
| SRX3600            | 2.25 million                                         | 6 million               |
| SRX5400            | 42 million                                           | Expansion not available |
| SRX5600            | 114 million                                          | Expansion not available |
| SRX5800            | 258 million                                          | Expansion not available |

The method used for expanding session capacity depends on the device:

- Central point session license installation and validation on an SRX3400 or SRX3600 device
- CLI optimization option on an SRX5800 device

## Expanding Session Capacity on an SRX3400 or SRX3600 Device

---

Expanding session capacity on an SRX3400 or SRX3600 device requires validation of a central point session license on the device.

1. Obtain the central point session license key and install the license on the device. For license installation details, see *Administration Guide for Security Devices*.
2. Reboot the device to implement the expanded session capacity.

### Related Documentation

- [Expanding Session Capacity by Device on page 1681](#)

## Reverting to Default Session Capacity on an SRX5800 Device

---

Reverting to the default session capacity on an SRX5800 device requires a CLI configuration change.

1. Enter the following command at the CLI configuration prompt to reestablish the default session capacity value:

```
user@host# set security gprs gtp enable
```

2. Reboot the device to implement the new value.

## Verifying the Current Session Capacity

---

**Purpose** The central point session summary includes the maximum sessions setting for the device. From this value you can determine if the session capacity has been modified as you expected.

**Action** To verify the current setting of the central point session capacity, enter the following CLI command.

```
user@host> show security flow cp-session summary
```

```
DCP Flow Sessions on FPC10 PIC0:
```

```
Valid sessions: 0
Pending sessions: 0
Invalidated sessions: 0
Sessions in other states: 0
Total sessions: 0
```

```
DCP Flow Sessions on FPC10 PIC1:
```

```
Valid sessions: 2
Pending sessions: 0
Invalidated sessions: 0
Sessions in other states: 0
Total sessions: 2
Maximum sessions: 7549747
Maximum inet6 sessions: 7549747
```

## DCP Flow Sessions on FPC10 PIC2:

Valid sessions: 2  
Pending sessions: 0  
Invalidated sessions: 0  
Sessions in other states: 0  
Total sessions: 2  
Maximum sessions: 7549747  
Maximum inet6 sessions: 7549747

## DCP Flow Sessions on FPC10 PIC3:

Valid sessions: 1  
Pending sessions: 0  
Invalidated sessions: 0  
Sessions in other states: 0  
Total sessions: 1  
Maximum sessions: 7549747  
Maximum inet6 sessions: 7549747

**Meaning** The **Maximum sessions** value reflects the current session capacity on your device. A value of 14000000 means that the SRX5800 device is configured for the expanded number of central point sessions.

# Managing Sessions and Flow Distribution

- [Understanding Load Distribution in High-End SRX Series Devices on page 1685](#)
- [Understanding Load Distribution on SRX5000 Line Devices Using the Packet-Ordering Function on page 1687](#)
- [Disabling Packet-Ordering Mode on SRX5000 Line Devices on page 1688](#)

## Understanding Load Distribution in High-End SRX Series Devices

---

The load distribution algorithm is adjusted based on session capacity and processing power.

Hash-based session distribution uses a hash table. The SPU session weight table is used to assign an SPU ID to each hash index in the session distribution hash table. This way, the number of sessions created on each SPU using hash-based distribution is proportional to the SPU's weight in the SPU session weight table. Each NPU also keeps an identical SPU session weight table and session distribution hash table that it uses to select an SPU to forward packets that do not match an NPU session.

In hash-based session distribution, weights are based on session capacity. We recommend the hash session distribution mode when high session capacity is required.

**NOTE:** Load distribution on SRX5000 line devices is always hash-based.

Insertion and removal of SPCs causes recalculation of the SPU session weight table at central point initialization time because the chassis must reboot after insertion.

### Hash-Based Forwarding on the SRX5K-MPC, SRX5K-MPC3-40G10G (IOC3), and the SRX5K-MPC3-100G10G (IOC3)

On a high-end SRX Series device, a packet goes through a series of events involving different components as it progresses from ingress to egress processing. With the datapath packet forwarding feature, you can obtain quick delivery of I/O traffic over the SRX 5000 line of devices.

The SRX5K-MPC, SRX5K-MPC3-40G10G (IOC3), and SRX5K-MPC3-100G10G (IOC3) are interface cards supported on the SRX5400, SRX5600, and SRX5800 devices. The

Modular Port Concentrator (MPC) provides load-balancing services for Services Processing Units (SPUs) by using the hash-based forwarding method.

In hash-based forwarding, the packet might be forwarded by the MPC to a selected SPU (DCP) instead of the central point. This approach enhances session scaling and prevents overloading of the central point.

Hash value calculation involves the following steps:

- For IPv4 packets, the hash-based forwarding module generates the hash value based on Layer 3 and Layer 4 information, depending on different Layer 4 protocol types.
- For Stream Control Transmission Protocol (SCTP), TCP, UDP, Authentication Header (AH), edge service provider (ESP), and Internet Control Message Protocol (ICMP) protocols, the hash module utilizes Layer 4 information to generate the hash value. For any other protocols, only Layer 3 information is used in hash generation.
- For IPv4 fragment packets, the hash value is calculated using only the Layer 3 information. This also applies to the first fragment of the packet.
- For non-IP packets, the hash-based forwarding module uses the Layer 2 information to calculate the hash value.

Once a hash value is calculated according to the packet's Layer 2, Layer 3, or Layer 4 information, an SPU ID is assigned to each hash index in the session distribution hash table.

**NOTE:** The SRX5K-MPC (IOC2), SRX5K-MPC3-40G10G (IOC3), and SRX5K-MPC3-100G10G (IOC3) can only be used on SRX5400, SRX5600, and SRX5800 devices that are configured for hash-based session distribution.

When the hash-based session distribution mode is enabled, the system changes its behavior to high-session-capacity-based mode when the SRX5K-MPC, SRX5K-MPC3-40G10G (IOC3), and SRX5K-MPC3-100G10G (IOC3) are installed on the device.

**NOTE:** On SRX5000 line devices with an SRX5K-MPC, SRX5K-MPC3-40G10G (IOC3), or SRX5K-MPC3-100G10G (IOC3) installed, during a system or an SPU reboot, when the hash-based session distribution mode is enabled, traffic will pass only when all SPUs are up after the reboot.

The MPCs on the IOC3 provide load-balancing services for SPUs by performing hash-based datapath packet forwarding to interconnect with all existing IOCs and SPCs.

The IOC3 processes ingress and egress packets. The IOC3 parses the ingress packet and sends it to the SPU for further security processing, including flow session lookup, zone and policy check, VPN, ALG, and so on.

The IOC3 manages packet data memory and fabric queuing for packet lookup and encapsulation functions.

**NOTE:** Starting with Junos OS Release 15.1X49-D10, hash-based session distribution is the default mode for the SRX5400, SRX5600, and SRX5800 devices. Selection of hash keys depends on application protocols.

The IOC3 sets up a security flow table (IPv4 and IPv6) including key, result table, and packet memory.

The following functions are provided with the flow table:

- Flow lookup
- Flow insertion and deletion
- Security flow aging out
- Security flow statistics

## Understanding Load Distribution on SRX5000 Line Devices Using the Packet-Ordering Function

The packet-ordering function improves the performance of the device by activating the built-in packet-ordering function of the Packet Ordering Engine on the XLP processor on the application central point. When you activate the packet-ordering function, the load-balancing thread (LBT) and the packet-ordering thread (POT) are removed and their core is freed to run the flow thread.

The flow thread receives the packets, processes them, and sends or drops them. For packets that require no ordering, the flow thread notifies the Network Acceleration Engine (NAE) egress to send or drop the packets. For packets that require ordering, the flow thread notifies the Packet Ordering Engine to dequeue the packets from the ordering list and to send or drop the packets in order.

The packet-ordering functionality using the Packet Ordering Engine is supported on SRX5400, SRX5800 and SRX5600 devices with next-generation SPCs.

## Disabling Packet-Ordering Mode on SRX5000 Line Devices

---

The packet-ordering functionality using the Packet Ordering Engine is supported on SRX5400, SRX5800 and SRX5600 devices with next-generation SPCs. By default, packet-ordering mode using the Packet Ordering Engine is enabled. To disable the packet-ordering functionality using the Packet Ordering Engine, you must update the packet-ordering mode on the device.

The following packet ordering modes are supported:

- **software**—Disables the packet-ordering mode using the Packet Ordering Engine.
- **hardware**—Enables the packet-ordering mode using the Packet Ordering Engine. This is the default option.

To disable the packet-ordering mode using the Packet Ordering Engine:

1. Enter the following command at the CLI configuration prompt to specify the packet-ordering mode.

```
[edit]
user@host# set security forwarding-process application-services
packet-ordering-mode software
```

2. Use the **show security forwarding-process** command to review your configuration.

```
[edit]
user@host# show security forwarding-process
application-services{
 packet-ordering-mode software;
}
```

3. Check your changes to the configuration before committing.

```
[edit]
user@host# commit check
```

```
warning: System packet ordering mode changed, reboot is required to take effect.
If you have deployed a cluster, be sure to reboot all nodes.
configuration check succeeds
```

4. Commit the configuration.

```
[edit]
user@host# commit
```

```
warning: System packet ordering mode changed, reboot is required to take effect.
If you have deployed a cluster, be sure to reboot all nodes.
commit complete
```

5. Reboot the device at an appropriate time.

6. Use the **show security flow status** command to verify the packet-ordering mode.

```
user@host> show security flow status

Flow forwarding mode:
 Inet forwarding mode: flow based
 Inet6 forwarding mode: drop
 MPLS forwarding mode: drop
```

ISO forwarding mode: drop  
Flow trace status  
Flow tracing status: off  
Flow session distribution  
Distribution mode: RR-based  
Flow packet ordering  
Ordering mode: Software (reboot needed to change to Software)

### Overview

The SRX5K-MPC (IOC2), SRX5K-MPC3-100G10G (IOC3), and SRX5K-MPC3-40G10G (IOC3) on SRX5400, SRX5600, and SRX5800 devices support session cache and selective installation of the session cache.

Session cache is used to cache a conversation between the network processor (NP) and the SPU on an IOC. A conversation could be a session, GTP-U tunnel traffic, IPsec VPN tunnel traffic, and so on. A conversation has two session cache entries, one for incoming traffic and the other for reverse traffic. Depending on where the traffic ingress and egress ports are, two entries might reside in the same network processor or in different network processors. IOCs support session cache for IPv6 sessions.

A session cache entry is also called a *session wing*.

Session cache on the IOC leverages Express Path (formerly known as *services offloading*) functionality and helps prevent issues such as high latency and IPsec performance drop.

A session cache entry records:

- To which SPU the traffic of the conversion should be forwarded
- To which egress port the traffic of the conversion should be forwarded in Express Path mode
- What processing to do for egress traffic, for example, NAT translation in Express Path mode

Prior to Junos OS Release 15.1X49-D10, on the IOC2, session cache was used for Express Path sessions only. Other traffic was hashed to SPUs based on their 5-tuple key information. VPN traffic employed the concept of the anchored SPU, which did not necessarily coincide with the functions of the flow SPU. The network processor could only forward the packets to the flow SPU based on the 5-tuple hash. The flow SPU then forwarded the packet to the anchored SPU. This created an extra hop for VPN traffic, which wasted the switch fabric bandwidth and reduced the VPN throughput roughly by half. This performance reduction occurred because the traffic still had to go back to the flow SPU after processing on the anchored SPU.

Starting with Junos OS Release 15.1X49-D10, the session cache of the sessions in the IOC helps solve these issues. The SPU can now instruct the IOC session cache to forward subsequent traffic to a specific anchor SPU.

The session cache table is extended on IOC to support the NP sessions. Express Path traffic and NP traffic share the same session cache table on IOCs. Express Path traffic is forwarded by the IOC itself either locally or to another IOC, because the traffic does not require any services from the SPU. NP traffic is forwarded to the SPU specified in the session cache for further processing. All the session cache entries are shared by both Express Path session traffic and NP traffic.

To enable session cache on the IOCs you need to run the **set chassis fpc <fpc-slot> np-cache** command.

**NOTE:** The IOC2 and the IOC3 utilize the delay sessions delete mechanism. The same sessions (sessions with the same five tuples) that are deleted and then reinstalled immediately are not cached on the IOCs.

## Selective Session Cache Installation

To avoid high latency, improve IPSec performance, and to better utilize the valuable resources, certain priority mechanisms are applied to both flow module and the IOC.

The IOCs maintain and monitor session cache usage threshold levels. The IOCs also communicate the session cache usage to the SPU, so that when a certain session cache usage threshold is reached, the SPU only sends session cache installation requests for selective high-priority traffic sessions.

The following three priority levels are used to determine which type of traffic can install session cache on the IOCs:

- **Priority 1 (P1)**—Express Path qualified traffic
- **Priority 2 (P2)**—IPsec tunneling, Fragmentation ordering, and NAT/SZ traffic
- **Priority 3 (P3)**—All other types of traffic

The IOCs maintain and monitor session cache usage threshold levels. Session cache usage less than 25 percent is defined as “green,” 26 to 50 percent is “yellow,” 51 to 99 percent is “orange,” and 99 percent and above is defined as “red.” The IOCs update current real-time session cache usage to the SPU. The SPU requests the IOC to install the session cache for selective high-priority traffic sessions. When the session cache usage is green, the session cache will be installed for all types of traffic. When the usage is yellow, session can be installed only for certain sessions including IPsec, Fragmentation, and NAT/SZ traffic sessions, and when the usage is orange, only Express Path qualified sessions will be installed. When the session cache usage is red, NP cache and the Express Path sessions are not allowed to install from SPU to the IOCs.

Table 169 shows the NP cache installation bars for different types of traffic.

**Table 169: Session Cache Installation Bars**

| Traffic Type                             | Green | Yellow | Orange | Red |
|------------------------------------------|-------|--------|--------|-----|
| Express Path traffic                     | Yes   | Yes    | Yes    | No  |
| IPsec, Fragmentation, and NAT/SZ traffic | Yes   | Yes    | No     | No  |
| Other traffic                            | Yes   | No     | No     | No  |

To conserve session entries on the IOC, the flow module selectively installs sessions on the IOC. To facilitate the session install selection, the IOC maintains corresponding thresholds to provide an indication to the flow module (on how full the session cache table is on the IOCs). Two bits in the meta header (see Table 170) are added to indicate the current cache table utilization status. All packets going to the SPU will carry these two status bits to inform the flow module of the utilization of the cache table on the IOC.

Table 170 shows the cache table utilization (CTU) bits and the respective session cache table utilization.

**Table 170: Session Cache Table Utilization Bits Status**

| Session Cache Table Utilization (CTU) Bits | IOC Session Cache/Express Path Table Utilization | Action                                                                                                                   |
|--------------------------------------------|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| 00                                         | 0% < utilization < 25%                           | Flowd installs any eligible session.                                                                                     |
| 01                                         | 25% < utilization < 75%                          | Flowd installs only high-priority sessions, such as Express Path, IPsec, IPsec clear-text, NAT, and fragmented sessions. |
| 10                                         | 75% < utilization < 100%                         | Flowd installs only Express Path sessions.                                                                               |
| 11                                         | NP cache/Express Path table is full              | Flowd stops installing sessions.                                                                                         |

## IPsec VPN Session Affinity Enhancement Using Session Cache

SRX Series devices are fully distributed systems, and an IPsec tunnel is allocated and anchored to a specific SPU. All the traffic that belongs to an IPsec tunnel is encrypted and decrypted on its tunnel-anchored SPU. In order to achieve better IPsec performance, IOC improves the flow module to create sessions for IPsec tunnel-based traffic (before encryption and after decryption) on its tunnel-anchored SPU, and installs session cache for the sessions so that the IOC can redirect the packets directly to the same SPU to minimize packet-forwarding overhead. Express Path traffic and NP traffic share the same session cache table on IOCs.

You need to enable session cache on the IOCs and set the security policy to determine whether a session is for Express Path (formerly known as *services offloading*) mode on the selected Flexible PIC Concentrator (FPC).

To enable IPsec VPN affinity use, the **set security flow load-distribution session-affinity ipsec** command.

## Fragmentation Packet Ordering Using NP Session Cache

A session might consist of both normal and fragmented packets. With hash-based distribution, 5-tuple and 3-tuple key can be used to distribute normal and fragmented packets to different SPUs, respectively. On SRX Series devices, all the packets of the session are forwarded to a processing SPU. Due to forwarding and processing latency, the processing SPU might not guarantee packet ordering of the session.

Session cache on the IOCs ensure ordering of packets of a session with fragmented packets. A session cache entry is allocated for normal packets of the session and a 3-tuple key is used to find the fragmented packets. On receipt of the first fragmented packet of the session, the flow module allows the IOC to update the session cache entry to

remember the fragmented packets for the SPU. Later, IOC forwards all subsequent packets of the session to the SPU to ensure ordering of packets of a session with fragmented packets.

## Express Path Overview

### Understanding Express Path Functionality

Express Path (formerly known as *services offloading*) is a mechanism for processing fast-path packets in the network processor instead of in the Services Processing Unit (SPU). This method reduces the packet-processing latency that arises when packets are forwarded from network processors to SPUs for processing and back to I/O cards (IOCs) for transmission.

Express Path considerably reduces packet-processing latency by 500–600 percent.

When the first packet arrives at the interface, the network processor forwards it to the SPU. If the SPU verifies that the traffic is qualified for Express Path, an Express Path session is created on the network processor. If the traffic does not qualify for Express Path, a normal session is created on the network processor. If an Express Path session is created, the subsequent fast-path packets are processed in the network processor itself.

---

**NOTE:** A normal session forwards packets from the network processor to the SPU for fast-path processing, whereas an Express Path session processes fast-path packets in the network processor and the packets exit out of the network processor itself.

---

When an Express Path session is created on the network processor, subsequent packets of the flow match the session on the network processors. The network processor then processes and forwards the packet. The network processor also handles additional processing such as TCP sequence check, time to live (TTL) processing, Network Address Translation (NAT), and Layer 2 header translation.

The network processor forwards packets to the SPU in the following cases:

- When the first packet arrives at the interface, the network processor forwards it to the central point (CP). The central point in turn forwards the packet to the SPU. The SPU then creates a session on the network processor.
- When an SPU session exists even if no network processor session exists, the network processor forwards a packet to the central point, which in turn forwards the packet to the SPU. The SPU then creates a session on the network processor.
- When a packet matches a normal session on the network processor, it is forwarded to the SPU.

**NOTE:** Prior to Junos OS Release 12.3X48-D10, Express Path was a licensed software feature. Starting with Junos OS Release 12.3X48-D10, the Express Path license is no longer required to enable this functionality. Your previously acquired Express Path license will not be effective anymore.

## Understanding Express Path Support on SRX Series Devices

Table 171 provides details about the Express Path support on different SRX Series cards.

**Table 171: Express Path Support on SRX Series Device Cards**

| SRX Series Device                                        | Card Name and Model Number                                                                                                                                                                               | Earliest Supported Release   |

**NOTE:** Different Express Path features are supported on different cards for different Junos OS releases. See the *Junos OS Release Notes* for details.

**NOTE:** On the SRX5600 and SRX5800 Services Gateways, the Express Path sessions for traffic that traverse between legacy IOC cards and the SRX5K-MPC or the SRX5K-MPC3 are not supported.

The Express Path sessions traversing only on legacy IOC cards or only on the SRX5K-MPC (IOC2), the SRX5K-MPC3-100G10G (IOC3), or the SRX5K-MPC3-40G10G (IOC3) are supported. However, the SRX5K-MPC (IOC2), the SRX5K-MPC3-100G10G (IOC3), the SRX5K-MPC3-40G10G (IOC3), and the legacy IOCs can still be present on the same chassis.

## Express Path Support on NP-IOC Card

The NP-IOC card integrates an existing I/O card (IOC) with a Network Processing Card (NPC) in one card with simplified Layer 2 functions in the hardware. This new hardware changes the way the interface is interpreted in the system. Currently, in the SRX3000 line all interfaces are assigned an internal global port number for interface configuration and management purposes. However, this method limits the slot positions in which an IOC card can be inserted (that is, an IOC can only be present in slot numbers 0–3). An NP-IOC can be present in any of the slots, meaning that there also can be an interface at any slot.

**NOTE:** Each interface in the NP-IOC card can only be attached to the network processor on the NP-IOC card. This fixed attachment setup requires the network processor to manage the interfaces as local or relative interfaces, instead of systemwide global interfaces.

Besides providing physical layer network connections, another function of the NP-IOC card is to distribute packets coming into the physical ports to the Services Processing Units (SPUs) and to forward packets out of the physical ports. For parallel security processing, flow sessions are assigned to multiple SPUs, based on a load balance algorithm. The network processor on the NP-IOC is responsible for directing traffic to the proper SPU based on the session table installed in its local memory.

In Express Path mode, the first packet is processed as is, meaning the packet is forwarded to the central point and the central point assigns an SPU and passes the packet to the SPU. For packets in fast-path, instead of forwarding all packets to the SPU, the network processor forwards the packets to an egress network processor, which can be different from or the same as the ingress network processor.

### Express Path Support on SRX5K Modular Port Concentrator

The SRX5K-MPC is a Modular Port Concentrator (MPC) that is supported on the SRX5400, SRX5600, and SRX5800.

The SRX5K-MPC is an interface card with two slots that accept MICs, which add Ethernet ports to your services gateway. An MPC with MICs installed functions in the same way as a regular I/O card (IOC) but allows you to add different types of Ethernet ports to your device.

Each MPC is equipped with Trio chipsets, which perform control functions tailored to the MPC's media type.

When a Trio chipset receives the first packet, the packet is forwarded to an SPU based on the hash value (which is determined by a hash function of the 5 tuples of the session).

If the SPU verifies that the traffic is qualified for Express Path (formerly known as *services loading*), an Express Path session is created on the Trio chipset. If the traffic does not qualify for Express Path, it is forwarded by default hash-based forwarding to SPUs. If an Express Path session is created, the subsequent fast-path packets are processed in the Trio chipset itself.

The Trio chipset performs all the necessary checks to forward the packet, including TTL checking and decreasing, TCP sequence check, NAT translation, and Layer 2 header encapsulation. In addition, the Trio chipset sends a session refresh message to the SPU every second. This message is used to refresh the SPU session, detect the current state of the Trio chip set and update SPU session statistics.

The session table on the SRX5K-MPC, managed by the SPU, provides the following functions:

- Flow insert or delete
- Flow lookup
- Flow aging
- Flow statistics

The SPU inserts and deletes flow entries in the session table based on policy matching results.

**NOTE:** Configuring the screen options on an SRX5K-MPC when operating in Express Path mode is the same as when the card is operating in normal mode.

### Express Path Support on SRX5K-MPC3-100G10G (IOC3) and SRX5K-MPC3-40G10G (IOC3)

Express Path (formerly known as *services loading*) on the IOC3 is based on processing fast-path packets through the Trio chipset instead of in the SPU to offload some basic firewall functions to the IOC3.

When the Express Path feature is enabled, the IOC3 provides much lower latency, and also supports higher throughput by removing the overload on the SPU. The IOC3 supports both intra-card traffic flow and inter-card traffic flow. To achieve the best latency results, both the ingress port and egress port of a traffic flow need to be on the same XM chip of the IOC3.

The flow table on the IOC3 is managed by the SPU of the flow module. The SPU inserts and deletes flow entries in the flow table based on policy matching results. In the data plane, the IOC3 parses packets, and looks them up in the flow table. If the IOC3 finds a match in the flow table, then it forwards packets based on the instructions given in the flow table. The IOC3 can perform NAT, encapsulate the Level 2 (L2) header, and forward the packets out of the egress interface. The egress interface can be located on the same IOC3 (intra-card case) or on another IOC3 (inter-card case).

**NOTE:** Flow table lookup in the IOC3 occurs only in ingress. Egress datapath packet handling is the same as supported in the previous release.

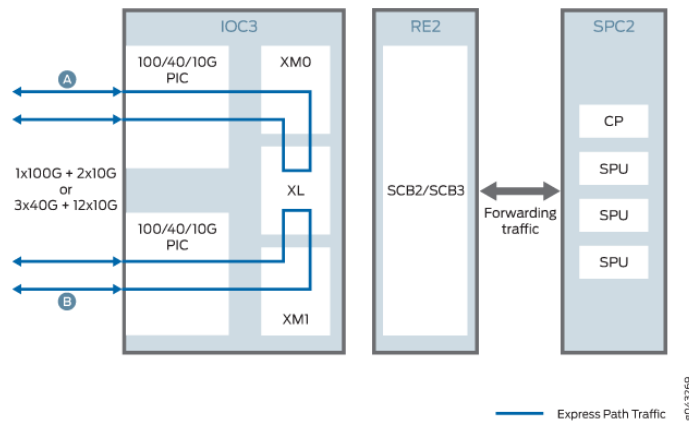

When the IOC3 receives the first packet, it does not match any existing fast-forward session. The default hash-based forwarding is performed to send the first packet to the SPU. The SPU then creates the security session. If the SPU finds that the traffic is qualified for fast forwarding, and the related IOC3 supports fast forwarding, it will install fast-forward session to the IOC3. If fast forwarding cannot be applied to the traffic, no session message is sent, and the IOC3 uses the default hash-based forwarding to forward the packets to the SPU.

In fast-forward IOC3 processing, if a fast-forward session is matched, the packet can be directly forwarded according to the session flow result. The IOC3 takes all the necessary actions, including forwarding the packet, TTL checking and decreasing, NAT translation, L2 header encapsulation and so on.

In addition, the XL chip sends one copy of the forwarding packet to the SPU at every predefined time. This copy is used to refresh the SPU session, detect the current XL chip state, and so on. The SPU consumes this packet and does not forward it, because the real packet has been processed and transmitted.

Express Path support on IOC3 is illustrated in [Figure 88](#), [Figure 89](#), and [Figure 90](#)

**Figure 88: IOC3 Intra-PFE Express Path**

**Figure 89: IOC3 Inter-PFE Express Path**

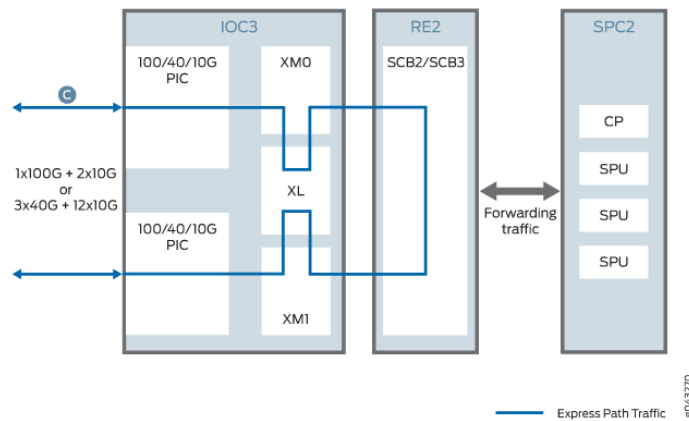

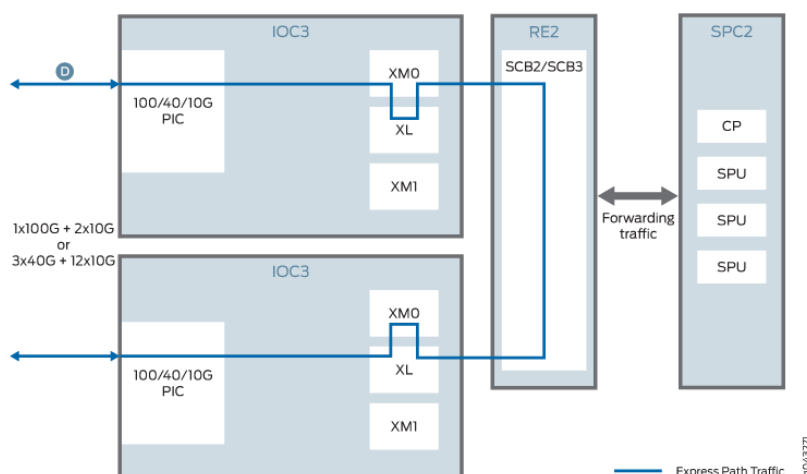

Figure 90: Inter-IOC3 Express Path

## Understanding Express Path Features

### Wing Statistics Counter

The network processor in Express Path mode provides the option for each flow entry to keep a per-wing bytes counter. The counter captures the number of bytes that the network processor sends out over the wing.

When the counter is enabled, for every ingress packet, the network processor searches its flow entry (a session wing). If the packet belongs to an established flow entry, the network processor increases the byte counter of the flow entry by byte count in the packet. The network processor periodically copies a packet (called a copy-packet) of each flow entry to its associated SPU, allowing the SPU to maintain the session. The network processor sends flow byte counter values in the header of copy-packet packets. The SPU accumulates and keeps per-wing statistics counters.

**NOTE:** The counter value carried to the SPU is always one packet short to allow the SPU to add the current packet's byte count to the counter to get the correct total. For example, if packet N's copy carries a counter value to the SPU, the counter value is the total bytes received in the flow up to packet N-1.

The counter value does not include packets that were sent before the session was set up on the network processor. Therefore, the SPU might need to account for the three-way handshake packet and other packets sent through the SPU. The actual session byte counter shown on the SPU might be short by the amount of bytes sent by the client during the copy interval. This discrepancy results because these bytes can be counted locally by the network processor, but have not yet been reported to the SPU.

**NOTE:** You cannot change the statistics configuration during the life cycle of a live session. Disabling or enabling the per-wing statistics configuration while a session is alive at the network processor invalidates the session statistics on the current session. The new sessions statistics can be valid only after the configuration changes are committed. Network processor per-wing counters cannot be cleared.

**NOTE:** Wing statistics counter configuration is not supported on the SRX5K-MPC.

### Sessions per Wing Statistics

The NP-IOC has a larger static RAM (SRAM) to accommodate session resources, thus hosting more sessions per PIC. [Table 172](#) displays the total number of session wings, including both Express Path and non-Express Path.

**Table 172: Total Number of Sessions per Wing in Network Processor Express Path Configuration Mode**

| Total Number of Wings                    |                                | Number of Express Path UDP Wings |                 | Number of Express Path TCP Wings |                 |
|------------------------------------------|--------------------------------|----------------------------------|-----------------|----------------------------------|-----------------|
| Cards and SRX Series Device              | Non-Express Path Mode Sessions | Without Statistics               | With Statistics | Without Statistics               | With Statistics |
| IOC                                      | 1.3 million                    | 1.3 million                      | 900,000         | 600,000                          | 400,000         |

### Cross-Network Traffic

Express Path provides additional cross-network-processor support; therefore, it is no longer restricted to the ports of the same network processor. If network processors for both the ingress and egress ports are in Express Path mode, then Express Path packets

are directly forwarded from the ingress network processor to the egress network processor in the fast-flow path. Packets cross switch fabric when they are forwarded from one network processor to another, thus increasing the latency of the packet. In Express Path mode, the latency of cross-network-processor packets is higher than the packets that are forwarded within an individual network processor.

**NOTE:** The SRX5K-MPC receives session messages from the SPU. The session messages carry the information to support inter- and intra-Packet Forwarding Engine Express Path for IPv4.

### LAG Support in Express Path Mode

Ethernet link aggregation groups (LAGs) combine links and provide increased bandwidth and link availability. Express Path reduces packet latency by processing and forwarding packets in the network processor instead of in the Services Processing Unit (SPU). Supporting LAG in the Express Path mode combines the benefits of both these features and provides enhanced throughput, link redundancy, and reduced packet latency.

#### *Qualifying for Express Path Mode*

You can use the links in a LAG as ingress or egress interfaces in Express Path mode. The LAG links can include links from different network processors (in case of legacy cards such as IOCs or Flex IOCs) or from the same modular port concentrator (in case of SRX5K-MPC). For a LAG link to qualify for Express Path, all its member links should be connected to Express Path-enabled network processors. If Express Path is disabled on any of the member links in a LAG, a regular session (non-Express Path session) is created. Also, LAG links are not supported between legacy cards such as IOCs or Flex IOCs and the SRX5K-MPC.

#### *LAG and Network Processor Wings*

The network processor checks the egress interface in the Express Path mode for each wing. Per-wing traffic distribution over a LAG interface is achieved by letting the SPU install wings pointing to egress interfaces with a balanced distribution.

The network processor periodically copies a packet (called a *copy-packet*) to the SPU, allowing it to maintain the session. The copy-packet contains the egress interface information, which the SPU uses to handle LAG member change cases; for example, when a link is down or disabled. When there is no member interface that can be used as an egress interface for transmitting traffic, the network processor session is updated from Express Path to non-Express Path and the packet is sent to the SPU. A new Express Path network processor session is then installed using a new, valid egress interface.

- **First wing**—On the egress interface, the SPU selects one LAG active member link as the outgoing interface for a specific fast-forward session. The SPU treats this active member interface just like any physical interface in the Express Path mode and records the interface to the network processor fast-forward session. After that, all traffic that matches this network processor session is directly transmitted through that member link.

- Reverse wing—the reverse network processor session is installed only when all LAG member links are connected to a single network processor. When member links of a LAG are from multiple network processors, the reverse network processor session is initiated by reverse traffic later (it is not preinstalled).

The Express Path network processor session needs to have outgoing interface information to send traffic. If the incoming interface is a physical interface, then it can be used as an outgoing interface for the reverse wing. However, if the incoming interface is an aggregated Ethernet interface, the SPU selects a member interface to be the outgoing interface.

### ***LAG and Network Processor Session Updates***

Some changes in the LAG interfaces can cause network processor session updates:

- LAG interface status changes—The LAG interface status can change due to several reasons—for example, when member interfaces are deleted, when an interface is down, or when an active LAG member is removed. In such cases, a session scan is triggered and network processor sessions related to the LAG interface are removed. The packet then installs a new network processor session, which could be a fast-forward session, if it qualifies.
- An active member is deactivated or removed from the LAG—In cases when the LAG still has an active member, neither a reroute nor session scan is triggered. The traffic is redistributed on the failed LAG member by monitoring outgoing logical interface status in the SPU.
- A new member is added to the LAG—The network processor session is not updated. A new network processor session is created, which might use the newly added interface or not, depending on the member selection algorithm for the LAG.

### ***Redistribution of Traffic on a Failed LAG Interface***

When a LAG member fails, the traffic needs to be redistributed. To redistribute traffic, the system monitors the status of the egress interface in the SPU. When the system detects a failure, it updates the Routing Engine kernel, and passes the physical interface information down to all SPUs. On receiving a copy of the session, the SPU extracts the egress interface index and checks the physical interface information. If the physical interface is down, the SPU uninstalls the session and the ingress network processor deletes the session cache.

For the next ingress packet of the same conversation, the network processor forwards the packet to the SPU to select an active member interface in the LAG as an egress interface. The SPU performs the distribution algorithm to select a new egress interface. A new session with the new egress interface index is installed in the ingress network processor and a new fast-flow path is created.

### ***End-to-End Debugging***

---

For regular flow packets, end-to-end debugging functions are the same as in the non-Express Path mode; packet filter and action items are supported in this flow mode. For traffic that matches Express Path sessions, the end-to-end debugging function

supports one packet copy to the host CPU when the filter and the action are both affirmative in the end-to-end search results.

**NOTE:** End-to-end debugging is not supported on the SRX5K-MPC when Express Path mode is enabled.

### Per-Session Statistics CLI

To enable the per-session statistics, copy and paste the following command into the CLI at the **[edit]** hierarchy level.

```
set chassis fpc <fpc-slot> pic <pic_slot> services-offload per-session-statistics
```

Verify that the **services-offload per-session-statistics** command is enabled.

```
show configuration chassis
user@host> show configuration chassis
fpc 1 {
 pic 1 {
 services-offload {
 per-session-statistics;
 }
 }
}
```

**NOTE:** The **services-offload per-session-statistics** command is not applicable for the SRX5K modular port concentrators when Express Path is configured, because every session has statistics by default.

Use the **show chassis hardware** command to display hardware information.

**show chassis fpc pic-status (SRX5600 and SRX5800 devices When Express Path [Services-Offload] is Configured)**

```
user@host> show chassis fpc pic-status

## Disabling TCP Packet Security Checks

On an SRX Series device, you can disable security checks on TCP packets to ensure interoperability with hosts and devices with faulty TCP implementations.

The **no-sequence-check** option disables TCP sequence checks. It also increases the throughput.

The **set security flow tcp-session no-sequence-check** command disables the TCP sequence checks on all TCP sessions in default or hash-based modes. This command is also supported in Express Path mode.

## Express Path Limitations

The Junos OS Express Path implementation has the following limitations.

- **Unsupported features**—The following features are not supported with Express Path:
  - Transparent mode is not supported. If transparent mode is configured, a normal (non-Express Path) session is installed.
  - Only multicast sessions with one fan-out are supported. If a multicast session with more than one fan-out exists, a normal session is installed.
  - Only active/passive chassis cluster configuration is supported. Active/active chassis cluster configuration is not supported.
  - Fragmented packets are not supported. If fragmented packets exist, a normal session is installed.
  - IPv6 is not supported. If IPv6 is configured, a normal session is installed.
  - When Express Path mode is enabled on an SRX5K-MPC, you might not be able to enable the firewall filter. In general, all processes related to Jflow v5/v8/v9 in an SRX Series device takes place in SPU. When security flow session is of Express Path type, the Jflow configuration will not take effect.
  - Class of Service (CoS) on egress interfaces is not supported.
  - Configuration of protection against a teardrop (Screen) attack is not supported when Express Path is enabled.
  - Asymmetric IOC configuration is not supported in when Express Path is enabled on a device operating in chassis cluster mode.
  - Configuring different MTU size values is not supported on SRX5K-MPC when Express Path is enabled on the device.
- **Performance drop**—The following drops in performance occur when Express Path is enabled:
  - Normal (non-Express Path) sessions—When Express Path is enabled, for normal sessions, the performance can drop by approximately 20 percent for connections per second (CPS) and 15 percent for packets per second (pps) when compared with normal sessions.

- Express Path sessions—When Express Path is enabled, for fast-forward sessions, the performance can drop by approximately 13 percent for connections per second (CPS).
- Chassis cluster—When the device is operating in chassis cluster mode:
  - If a child link goes down from the LACP-enabled redundant Ethernet interface of an IOC with Express Path enabled on its FPC, all traffic on this link is distributed to other active child links of the interface. If the child link comes up and rejoins the redundant Ethernet interface, then the existing traffic or sessions might not be redistributed over this newly rejoined active child link. New sessions might however traverse through this link.
  - If a new child link is added on the LACP-enabled redundant Ethernet interface of an IOC with Express Path enabled on its FPC, then the existing traffic or sessions might not be redistributed over this new child link. New sessions might however traverse through this link.

## Understanding the Express Path Solution

The high-end SRX Series devices have long packet-processing latency because the packets are processed through the Services Processing Unit (SPU) and through several stages of buffers in the data path.

This feature introduces a local forwarding solution where the fast-path packets are processed by the network processor on the I/O Card (IOC), without going through the switch fabric or the SPU. This solution reduces the packet-processing latency.

The behavior of the network processor in different scenarios is as follows:

- **First-path flow**—The first-path flow is the same as the current network processor flow process. When the first packet arrives at the network processor, the network processor parses the TCP or the UDP packet to extract a 5-tuple key and then performs session lookup in the flow table. The network processor then forwards the first packet to the central point. The central point cannot find a match at this time, because this is the first packet. The central point and the SPU create a session and match it against user-configured policies to determine if the session is a normal session or a services-offload session.

If the user has specified the session to be handled with Express Path, the SPU creates a session entry in the network processor flow table, enabling the services-offload flag in the session entry table; otherwise, the SPU creates a normal session entry in the network processor without the services-offload flag.

- **Fast-path flow**—After the session entry is created in the network processor, subsequent packets of the session will match the session entry table.

- If the services-offload flag is not set, then the network processor forwards the packet to the SPU specified in the session entry table. The packet goes through the normal flow process.
- If the network processor finds the services-offload flag in the session entry table, it will process the packet locally and send the packet out directly.

**NOTE:** The fast-forwarding function on the network processor supports one-fanout multicast sessions. The egress port in the session must also be associated with the same network processor of the ingress port. All other multicast cases need to be handled as normal sessions.

- **NAT process**—The SPU is responsible for mapping between the internal IP address or port and the external IP address or port. When the first packet of the session arrives, the SPU allocates the IP address or port mapping and stores the information in the network processor session entry. The network processor does the actual packet modification if the NAT flag is set.
- **Session age-out**—To improve traffic throughput for services-offload sessions, a copy of a packet is sent to the SPU at every predefined time period to reduce the packet processing demand on the SPU. To limit the number of packet copies sent to the SPU, a timestamp is implemented for each services-offload session. This enables the network processor to calculate the elapsed time since the last session match. If the elapsed time is greater than the predefined time period, then the network processor sends a copy of the packet to the SPU, and updates the session timestamp.
- **Session termination and deletion**—If the network processor receives an IP packet with a FIN (finished data) or a RST (reset connection) flag, it forwards the packet to the SPU. The SPU then deletes the session. The network processor does not change session status even after the FIN or RST packet is received. It continues to receive and process any packets during the transit session.

Documentation**

- [Enabling and Disabling Express Path on page 1708](#)

## Enabling and Disabling Express Path

**NOTE:** Prior to Junos OS Release 12.3X48-D10, Express Path was a licensed software feature. Starting with Junos OS Release 12.3X48-D10, the Express Path license is no longer required to enable this functionality. Your previously acquired Express Path license will not be effective anymore.

You can enable Express Path mode as follows:

- Set the Express Path mode on the selected card.
- Reboot the device containing the Express Path network processor to load the Express Path firmware image on the network processors.

- Configure a policy to define the traffic that should take fast-path.

**NOTE:** For SRX5600 and SRX5800 devices, enable Express Path on the IOC PIC. For SRX3400 and SRX3600 devices, enable the Express Path on the network processor. For SRX5K modular port concentrators (SRX5K-MPC), SRX5K-MPC3-100G10G (IOC3), and SRX5K-MPC3-40G10G (IOC3) on SRX5000 line devices, enable Express Path on the FPCs.

**NOTE:** When device is operating in chassis cluster mode, you need to reboot both the nodes when changing FPC(s) to Express Path mode.

To configure the Express Path mode:

- For SRX3400 and SRX3600 devices, use the **set chassis fpc *fpc-number* pic *pic-number* services-offload** command.

**NOTE:** During initialization, when a network processor is configured to perform Express Path, then the FPC CPU will load a special image to the network processor.

- For configuring Express Path on an SRX5000 line device, use the **set chassis fpc *fpc-number* pic *pic-number* services-offload** command.
- For configuring Express Path on an SRX5000 line device with Modular Port Concentrator (MPC), enable NP cache on the IOC using the **set chassis fpc *fpc-number* np-cache** command. Then configure the security policy to determine if the session is for Express Path.

**NOTE:** The **set chassis fpc *fpc-number* services-offload** command is deprecated.

- To disable Express Path on SRX3000 line and SRX5000 line devices, use the **delete chassis fpc *fpc-number* pic *pic-number* services-offload** command.
- To disable Express Path on an SRX5000 line device with Modular Port Concentrator (MPC), use the **delete chassis fpc *fpc-number* np-cache** command.

**NOTE:** The **delete chassis fpc *fpc-number* services-offload** command is deprecated.

**NOTE:** You need to reboot the device when you disable Express Path.

System log files are stored locally on the device in the default `/var/log/security` directory. You can use system log files to retrieve information about the Express Path configuration changes.

## Example: Enabling Express Path in Security Policies

This example shows how to enable Express Path (formerly known as *services offloading*) in security policies.

- [Requirements on page 1710](#)
- [Overview on page 1710](#)
- [Configuration on page 1710](#)
- [Verification on page 1711](#)

### Requirements

Before you begin, see “[Express Path Overview](#)” on [page 1695](#).

### Overview

In this example, you enable Express Path in security policies to specify whether the traffic qualifies for Express Path.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
source-address 1.1.1.0
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
destination-address 2.2.2.0
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
application junos-http
set security policies from-zone untrust to-zone trust policy services-offload-pol1 then
permit services-offload
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Express Path in policies:

1. Configure a policy to process the traffic that goes to the HTTP static ports.

```
[edit security policies from-zone untrust to-zone trust policy services-offload-pol1]
user@host# set match source-address 1.1.1.0
user@host# set match destination-address 2.2.2.0
user@host# set match application junos-http
```

2. Enable Express Path in the security policy.

```
[edit security policies from-zone untrust to-zone trust policy services-offload-pol1]
user@host# set then permit services-offload
```

**Results** From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security policies
from-zone untrust to-zone trust {
 policy services-offload-pol1 {
 match {
 source-address 1.1.1.0;
 destination-address 2.2.2.0;
 application junos-http;
 }
 then {
 permit {
 services-offload;
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying Express Path in Policies

**Purpose** Verify that Express Path is enabled.

**Action** From operational mode, enter the **show security policies** command.

**Related Documentation**

- [Express Path Overview on page 1695](#)

## Example: Configuring an NPC on SRX3000 Line Devices or SRX1400 Devices to Support Express Path

This example shows how to configure an NPC on the SRX3000 line of devices to support Express Path (formerly known as *services offloading*).

- [Requirements on page 1712](#)
- [Overview on page 1712](#)
- [Configuration on page 1712](#)
- [Verification on page 1713](#)

### Requirements

Before you begin, see “[Express Path Overview](#)” on page 1695.

### Overview

In this example, you configure an NPC on SRX3000 line devices to perform Express Path.

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis fpc 6 pic 0 services-offload
```

**Step-by-Step Procedure** To configure the NPC on an SRX3000 line device for Express Path:

1. Enable the Express Path mode on the NPC.

```
[edit]
```

```
user@host# set chassis fpc 6 pic 0 services-offload
```

**NOTE:** For SRX3000 line devices, the NPC slot number is 6.

2. Commit the configuration.

```
[edit]
```

```
user@host# commit
```

```
warning: System restart is required after fpc 6 pic 0 changed to
services-offload mode.
```

```
commit complete
```

3. Reboot the device.

**Results** From configuration mode, confirm your configuration by entering the **show chassis** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host> show chassis fpc pic-status
Slot 0 Online SRX3k SFB 12GE
 PIC 0 Online 8x 1GE-TX 4x 1GE-SFP
Slot 1 Online SRX3k 16xGE SFP
 PIC 0 Online 16x 1GE-SFP
Slot 5 Online SRX3k SPC
 PIC 0 Online SPU Cp-Flow
Slot 6 Online SRX3k NPC
 PIC 0 Online NPC PIC- services-offload
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying the Configuration of NPC for Express Path

**Purpose** Verify that the NPC was configured properly for Express Path.

**Action** From operational mode, enter the **show chassis fpc pic-status** command.

**Related Documentation**

- [Express Path Overview on page 1695](#)

## Example: Configuring an IOC on SRX5000 Line Devices to Support Express Path

This example shows how to configure an IOC on SRX5000 line of devices to support Express Path (formerly known as *services offloading*).

- [Requirements on page 1713](#)
- [Overview on page 1713](#)
- [Configuration on page 1713](#)
- [Verification on page 1714](#)

## Requirements

Before you begin, see “[Express Path Overview](#)” on page 1695.

## Overview

In this example, you configure the IOC on SRX5000 line devices to perform Express Path.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

**set chassis fpc 3 pic 0 services-offload**

**NOTE:** For SRX5000 line devices, the IOC slot number is 3.

### Step-by-Step Procedure

To configure the IOC you need to run the following commands:

1. Set the services offload mode on the IOC.  

```
[edit]
user@host# set chassis fpc 3 pic 0 services-offload
```
2. Commit the configuration.  

```
[edit]
user@host# commit
warning: System restart is required after fpc 3 pic 0 changed to
services-offload mode.
commit complete
```
3. Reboot the device.

### Results

From configuration mode, confirm your configuration by entering the **show chassis** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host> show chassis fpc pic-status

  - [Example: Enabling Express Path in Security Policies on page 1710](#)

## Example: Configuring an NP-IOC on SRX3000 Line Devices or SRX1400 Devices to Support Express Path

This example shows how to configure a network processor I/O card (NP-IOC) on either the SRX3000 line of devices or the SRX1400 device for Express Path (formerly known as *services offloading*).

- [Requirements on page 1715](#)
- [Overview on page 1715](#)
- [Configuration on page 1715](#)
- [Verification on page 1716](#)

### Requirements

Before you begin, see “[Express Path Overview](#)” on [page 1695](#).

This example uses the following software and hardware components:

- Junos OS Release 12.1X44-D10
- One SRX3000 line of devices or one SRX1400 device
- One Services Processing Card (SPC)

### Overview

In this example, you configure an NP-IOC on either an SRX3000 line of devices or the SRX1400 device to perform Express Path. Express Path considerably reduces packet processing latency by 500-600 percent.

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis fpc 10 pic 0 services-offload
```

**Step-by-Step Procedure** To configure an NP-IOC on an SRX3000 line device or an SRX1400 device for Express Path:

1. Enable the services offload mode on the NP-IOC.  

```
[edit]
user@host# set chassis fpc 10 pic 0 services-offload
```

2. Commit the configuration.

```
[edit]
user@host# commit
warning: System restart is required after fpc 10 pic 0 changed to
services-offload mode.
commit complete
```

3. Reboot the device.

**Results** From configuration mode, confirm your configuration by entering the **show chassis** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host> show chassis fpc pic-status
Slot 0 Online SRX3k SFB 12GE
 PIC 0 Online 8x 1GE-TX 4x 1GE-SFP
Slot 1 Online SRX3k SPC
 PIC 0 Online SPU Cp-Flow
Slot 2 Online SRX3k SPC
 PIC 0 Online SPU Flow
Slot 5 Online SRX3k 2x10GE XFP
 PIC 0 Online 2x 10GE-XFP
Slot 10 Online SRX1k3k 2x10GE NP-IOC
 PIC 0 Online 2x 10GE-SFP+ services-offload
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

---

### Verifying the Configuration of NP-IOC for Express Path

---

**Purpose** Verify that the NP-IOC was configured properly for Express Path.

**Action** From operational mode, enter the **show chassis fpc pic-status** command.

## Example: Configuring an SRX5K-MPC on an SRX5000 Line Device to Support Express Path

---

This example shows how to configure an SRX5K-MPC on an SRX5000 line device to support Express Path (formerly known as *services offloading*).

- [Requirements on page 1717](#)
- [Overview on page 1717](#)
- [Configuration on page 1717](#)
- [Verification on page 1718](#)

## Requirements

This example uses the following hardware and software components:

- One SRX5000 line device with an SRX5K-MPC
- Junos OS Release 12.3X48 or later for SRX Series devices

Before you begin, see [“Express Path Overview” on page 1695](#).

No special configuration beyond device initialization is required before configuring this feature.

## Overview

In this example, you configure the SRX5K-MPC on an SRX5000 line device to perform NP cache and Express Path.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis fpc 2 np-cache
set chassis fpc 3 np-cache
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
source-address 1.1.1.0
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
destination-address 2.2.2.0
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
application junos-http
set security policies from-zone untrust to-zone trust policy services-offload-pol1 then
permit services-offload
```

### Step-by-Step Procedure

To configure an SRX5K-MPC on an SRX5000 line device to perform Express Path:

1. Set NP cache mode on the SRX5K-MPC on FPC 1 and FPC 2.  

```
[edit]
user@host# set chassis fpc 2 np-cache
user@host# set chassis fpc 3 np-cache
```
2. Configure a policy to process the traffic that goes to the HTTP static ports.  

```
[edit security policies from-zone untrust to-zone trust policy services-offload-pol1]
user@host# set match source-address 1.1.1.0
user@host# set match destination-address 2.2.2.0
user@host# set match application junos-http
```
3. Enable Express Path in the security policy.  

```
[edit security policies from-zone untrust to-zone trust policy services-offload-pol1]
user@host# set then permit services-offload
```
4. Commit the configuration.

```
[edit]
user@host# commit
```

warning: System or cluster nodes need to reboot after fpc 3 changed to np-cache mode.

5. Reboot the device.

**Results** From configuration mode, confirm your configuration by entering the **show chassis** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
...
fpc 2 {
 np-cache;
}
fpc 3 {
 np-cache;
}
...
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying the Configuration of an SRX5K-MPC for Express Path

**Purpose** Verify that the SRX5K-MPC was configured properly for Express Path.

**Action** From operational mode, enter the **show chassis fpc pic-status** command.

```
Slot 0 Online SRX5k DPC 40x 1GE
PIC 0 Online 10x 1GE RichQ
PIC 1 Online 10x 1GE RichQ
PIC 2 Online 10x 1GE RichQ
PIC 3 Online 10x 1GE RichQ
Slot 2 Online SRX5k IOC II
PIC 0 Online 2x 40GE QSFP+- np-cache/services-offload
Slot 3 Online SRX5k IOC II
PIC 0 Online 10x 10GE SFP+- np-cache/services-offload
PIC 2 Online 10x 10GE SFP+- np-cache/services-offload
Slot 5 Online SRX5k SPC
PIC 0 Online SPU Cp-Flow
PIC 1 Online SPU Flow
```

**Meaning** The output provides the status of PICs with Express Path enabled on them.

## Example: Configuring SRX5K-MPC3-100G10G (IOC3) and SRX5K-MPC3-40G10G (IOC3) on an SRX5000 Line Device to Support Express Path

---

This example shows how to configure an SRX5K-MPC3-100G10G (IOC3) or an SRX5K-MPC3-40G10G (IOC3) on an SRX5000 line device to support Express Path (formerly known as *services offloading*).

- [Requirements on page 1719](#)
- [Overview on page 1719](#)
- [Configuration on page 1719](#)
- [Verification on page 1721](#)

### Requirements

This example uses the following hardware and software components:

- One SRX5000 line device with an SRX5K-MPC3-40G10G (IOC3)
- Junos OS Release 15.1X49-D10 or later for SRX Series devices

Before you begin, see “[Express Path Overview](#)” on page 1695.

No special configuration beyond device initialization is required before configuring this feature.

### Overview

In this example, you configure an SRX5K-MPC3-40G10G (IOC3) on an SRX5000 line device to perform Express Path.

### Configuration

- CLI Quick Configuration**
- To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis fpc 4 np-cache
set chassis fpc 5 np-cache
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
 source-address 1.1.1.0
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
 destination-address 2.2.2.0
set security policies from-zone untrust to-zone trust policy services-offload-pol1 match
 application junos-http
set security policies from-zone untrust to-zone trust policy services-offload-pol1 then
 permit services-offload
```

**Step-by-Step Procedure** To configure an SRX5K-MPC3-40G10G (IOC3) on an SRX5000 line device to perform Express Path:

1. Set the Express Path mode on the SRX5K-MPC3 on FPC 4 and FPC 5.  

```
[edit]
user@host# set chassis fpc 4 np-cache
user@host# set chassis fpc 5 np-cache
```
2. Configure a policy to process the traffic that goes to the HTTP static ports.  

```
[edit security policies from-zone untrust to-zone trust policy services-offload-pol1]
user@host# set match source-address 1.1.1.0
user@host# set match destination-address 2.2.2.0
user@host# set match application junos-http
```
3. Enable Express Path in the security policy.  

```
[edit security policies from-zone untrust to-zone trust policy services-offload-pol1]
user@host# set then permit services-offload
```
4. Commit the configuration.  

```
[edit]
user@host# commit
```

warning: System or cluster nodes need to reboot after fpc 3 changed to np-cache mode.
5. Reboot the device.

**Results** From configuration mode, confirm your configuration by entering the **show chassis** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
...
fpc 4{
 services-offload;
}
fpc 5{
 services-offload;
}
...

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying the Configuration of an SRX5K-MPC3 (IOC3) for Express Path

**Purpose** Verify that the SRX5K-MPC3-40G10G (IOC3) was configured properly for Express Path.

**Action** From operational mode, enter the **show chassis fpc pic-status** command.

```

Slot 0 Offline SRX5k DPC 40x 1GE
Slot 1 Online SRX5k SPC II
 PIC 0 Online SPU Cp
 PIC 1 Online SPU Flow
 PIC 2 Online SPU Flow
 PIC 3 Online SPU Flow
Slot 2 Offline SRX5k SPC
Slot 4 Online SRX5k IOC3 24XGE+6XLG
 PIC 2 Online 3x 40GE QSFP+- np-cache/services-offload
 PIC 3 Online 3x 40GE QSFP+- np-cache/services-offload
Slot 5 Online SRX5k IOC II
 PIC 0 Online 10x 1GE(LAN) SFP- np-cache/services-offload
 PIC 1 Online 10x 1GE(LAN) SFP- np-cache/services-offload
 PIC 2 Online 10x 10GE SFP+- np-cache/services-offload

```

**Meaning** The output provides the status of PICs with Express Path enabled on them.

## Example: Configuring Low Latency

The low latency feature allows you to configure the mode of the network processor's traffic manager (TM) on the egress path. If low latency is enabled, the network processor

is initialized without the traffic manager, thus reducing the overall latency in the Express Path (formerly known as *services offloading*).

**NOTE:** Because all SRX Series CoS functions are supported by the traffic manager, CoS functions are not supported when low latency is enabled.

Low latency reduces the total NPC integrated with an existing IOC (NP-IOC) latency by 0.7 us. This latency reduction brings the NP-IOC card total latency to 8.7 us. The low-latency feature is supported for intra-NP-IOC card traffic only; it is not applicable to inter-NP traffic.

In the low-latency mode, the network processor does not have an egress buffer at the traffic manager. Packets are delivered directly to the system packet interface (SPI) for the field-programmable gate array (FPGA) to process.

**NOTE:** The low latency feature is only applicable to the NP-IOC card. It does not apply to the NPC card in SRX1400, SRX3400, and SRX3600 devices.

- [Overview on page 1722](#)
- [Configuration on page 1722](#)
- [Verification on page 1723](#)

## Requirements

Before you begin, see “[Express Path Overview](#)” on [page 1695](#).

This example uses the following software and hardware components:

- Junos OS Release 12.1X44-D10
- One SRX3000 line of devices or one SRX1400 device
- One Services Processing Card (SPC)

## Overview

In this example, you configure the network processor for low latency mode.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis fpc 7 pic 0 services-offload low-latency
```

**Step-by-Step Procedure**

To enable low-latency mode:

1. Enable the Express Path mode on the NP-IOC.  

```
[edit]
user@host# set chassis fpc 7 pic 0 services-offload
```
2. Enable low latency.  

```
[edit]
user@host# low-latency
```
3. Commit the configuration.  

```
[edit]
user@host# commit
warning: System restart is required after fpc 7 pic 0 changed to
services-offload mode.
commit complete
```
4. Reboot the device.

**Results** From configuration mode, confirm your configuration by entering the **show configuration chassis** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host> show configuration chassis
fpc 7 {
 pic 0 {
 services-offload {
 low-latency;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying Low Latency Configuration

**Purpose** Verify that low-latency was enabled.

**Action** From operational mode, enter the **show chassis fpc pic-status** command.

```
root@kg04> show chassis fpc pic-status
Slot 0 Online SRX3k SFB 12GE
PIC 0 Online 8x 1GE-TX 4x 1GE-SFP
Slot 1 Online SRX3k 2x10GE XFP
PIC 0 Online 2x 10GE-XFP
Slot 2 Online SRX3k SPC
PIC 0 Online SPU Cp-Flow
Slot 7 Online SRX1k3k 2x10GE NP-IOC
PIC 0 Online 2x 10GE-SFP+- services-offload low-latency
```

## IPv6 Advanced Flow

---

IPv6 advanced flow adds IPv6 support for firewall, NAT, NAT-PT, multicast (local link and transit), IPsec, IDP, JSF framework, TCP Proxy, and Session manager on SRX Series devices. MIBs are not used in the IPv6 flow.

In order to avoid the impact on the current IPv4 environment, IPv6 security is used. If IPv6 security is enabled, extended sessions and gates are allocated. The existing address fields and gates are used to store the index of extended sessions or gates. If IPv6 security is disabled, IPv6 security-related resources are not allocated.

New logs are used for IPv6 flow traffic to prevent impact on performance in the existing IPv4 system.

The behavior and implementation of the IPv6 advanced flow are the same as those of IPv4 in most cases.

Some of the differences are explained below:

- **Header Parse** IPv6 advanced flow stops parsing the headers and interprets the packet as the corresponding protocol packet if it encounters the following extension headers:
  - TCP/UDP
  - ESP/AH
  - ICMPv6

IPv6 advanced flow continues parsing headers if it encounters the following extension headers:

- Hop-by-Hop

- Routing and Destination, Fragment

IPv6 advanced flow interprets the packets as an unknown protocol packet if it encounters the extension header **No Next Header**

- **Sanity Checks** IPv6 advanced flow supports the following sanity checks:
  - TCP length
  - UDP length
  - Hop-by-hop
  - IP data length error
  - Layer 3 sanity checks (for example, IP version and IP length)
  - **ICMPv6 Packets** In IPv6 advanced flow, the ICMPv6 packets share the same behavior as normal IPv6 traffic with the following exceptions:
    - Embedded ICMPv6 packet
    - Path MTU message
- **Host Inbound and Outbound Traffic** IPv6 advanced flow supports all route and management protocols running on the Routing Engine (RE), including OSPF v3, RIPng, Telnet, and SSH. Note that no flow label is used in the flow.
- **Tunnel Traffic** IPv6 advanced flow supports the following tunnel types:
  - IPv4 IP-IP
  - IPv4 GRE
  - IPv4 IPsec
  - Dual-stack lite
- **Events and Logs** The following logs are for IPv6-related flow traffic:
  - RT\_FLOW\_IPVX\_SESSION\_DENY
  - RT\_FLOW\_IPVX\_SESSION\_CREATE
  - RT\_FLOW\_IPVX\_SESSION\_CLOSE

The implementations of sessions, gates, ip-actions, processing of multithread, distribution, locking, synchronization, serialization, ordering, packet queuing, asynchronous messaging, IKE traffic issues, sanity check, and queues for IPv6 are similar to IPv4 implementations.

---

## Understanding Sessions for IPv6 Flows

This topic gives an overview of flow-based sessions.

Most packet processing occurs in the context of a flow, including management of policies, zones, and most screens. A session is created for the first packet of a flow for the following purposes:

- To store most of the security measures to be applied to the packets of the flow.
- To cache information about the state of the flow. For example, logging and counting information for a flow is cached in its session. (Also, some stateful firewall screens rely on threshold values that pertain to individual sessions or across all sessions.)
- To allocate resources required for features for the flow.
- To provide a framework for features such as Application Layer Gateways (ALGs).

**Related  
Documentation**

- [Understanding IPv6 Flow Processing on High-End SRX Series Devices on page 1729](#)

## Understanding IPv6 Flow Processing on High-End SRX Series Devices

This topic introduces the architecture for the high-end SRX Series devices and uses it as a model to explain IP version 6 (IPv6) processing. Flow processing is similar on branch SRX Series devices

High-end SRX Series Services Gateway devices include I/O cards (IOCs) and Services Processing Cards (SPCs) that each contain processing units that process a packet as it traverses the device. These processing units have different responsibilities.

- A Network Processing Unit (NPU) runs on an IOC. An IOC has one or more NPUs. An NPU processes packets discretely and performs basic flow management functions.

When an IPv6 packet arrives at an IOC, the packet flow process begins.

- The NPU performs the following IPv6 sanity checks for the packet:
  - For the IPv6 basic header, it performs the following header checks:
    - Version. It verifies that the header specifies IPv6 for the version.
    - Payload length. It checks the payload length to ensure that the combined length of the IPv6 packet and the Layer 2 header is shorter than the Layer 2 frame length.
    - Hop limit. It checks to ensure that the hop limit does not specify 0 (zero).
    - Address checks. It checks to ensure that the source IP address does not specify ::0 or FF::00 and that the destination IP address does not specify ::0 or ::1.
  - The NPU performs IPv6 extension header checks, including the following:
    - Hop-by-hop options. It verifies that this is the first extension header to follow the IPv6 basic header.
    - Routing extension. It verifies that there is only one routing extension header.

- Destination options. It verifies that no more than two destination options extension headers are included.
- Fragment. It verifies that there is only one fragment header.

**NOTE:** The NPU treats any other extension header as a Layer 4 header.

- The NPU performs Layer 4 TCP, UDP, and ICMP6 protocol checks, including the following:
  - UDP. It checks to ensure that IP Payload Length packets, other than a first-fragment packet, are at least 8 bytes long.
  - TCP. It checks to ensure that IP Payload Length packets, other than a first-fragment packet, are at least 20 bytes long.
  - ICMPv6. It checks to ensure that IP Payload Length packets, other than a first-fragment packet, are at least 8 bytes long.
- If the packet specifies a TCP or a UDP protocol, the NPU creates a tuple from the packet header data using the following information:
  - Source IP address
  - Destination IP address
  - Source port
  - Destination port
  - Protocol
  - Virtual router identifier (VRID)

The device looks up the VRID from a VRID table.
- For Internet Control Message Protocol version 6 (ICMPv6) packets, the tuple contains the same information as used for the TCP and the UDP search key, except for the source and destination port fields. The source and destination port fields are replaced with the following information extracted from the ICMPv6 packet:
  - For ICMP error packets: The pattern "0x00010001"
  - For ICMP information packets: The type, or code, field identifier
- For packets with an Authentication Header (AH) or an Encapsulating Security Payload (ESP) header, the search key is the same as that used for the TCP and the UDP tuple, except for the source and destination port fields. In this case, the security parameter index (SPI) field value is used instead of the source and destination ports. For Encapsulating Security Payload (ESP) header and Authentication Header (AH), before enhancements to the central point architecture it is hashed by the 3-tuple and the security parameter index (SPI) field, after enhancements to the central point architecture it is hashed by an IP pair.

- If a session exists for the packet's flow, the NPU sends the packet to the SPU that manages the session.
- If a matching session does not exist,
  - The NPU sends the packet information to the central point, which creates a pending session.
  - The central point selects an SPU to process the packet and create sessions for it.
  - The SPU then sends session creation messages to the central point and the ingress and egress NPUs, directing them to create a session for the packet flow.
- A central point, which can run on a dedicated SPU, or share the resources of one if there is only one SPU. A central point takes care of arbitration and allocation of resources, and it distributes sessions in an intelligent way. The central point assigns an SPU to be used for a particular session when the SPU processes the first packet of its flow.
  - For SRX5000 line devices, the central point architecture is divided into two modules—the application central point and the distributed central point (DCP). The App-CP is responsible for global resource management and loading balancing, while DCP is responsible for traffic identification (global session matching). The App-CP functionality runs on the dedicated central point SPU, while the DCP functionality is distributed to the rest of the SPUs.
  - For SRX3000 line devices, you have the option to use Extreme mode to turn the central point into a full central point and disable combo mode.
- One or more SPUs that run on a Services Processing Card (SPC). All flow-based services for a packet are executed on a single SPU, within the context of a session that is set up for the packet flow.

The SPC for SRX5000 line devices has two SPUs. The SPC for SRX3000 line devices has one SPU.

Several SPCs can be installed in a chassis.

Primarily, an SPU performs the following tasks:

- It manages the session and applies security features and other services to the packet.
- It applies packet-based stateless firewall filters, classifiers, and traffic shapers.
- If a session does not already exist for a packet, the SPU sends a request message to the NPU that performed the search for the packet's session, to direct it to add a session for it.

These discrete, cooperating parts of the system store the information identifying whether a session exists for a stream of packets and the information against which a packet is matched to determine if it belongs to an existing session.

## Enabling Flow-Based Processing for IPv6 Traffic

By default, the SRX Series device drops IP version 6 (IPv6) traffic. To enable processing by security features such as zones, screens, and firewall policies, you must enable flow-based forwarding for IPv6 traffic.

To enable flow-based forwarding for IPv6 traffic, modify the **mode** statement at the **[edit security forwarding-options family inet6]** hierarchy level:

```
security {
 forwarding-options {
 family {
 inet6 {
 mode flow-based;
 }
 }
 }
}
```

The following example shows the CLI commands you use to configure forwarding for IPv6 traffic.

1. Use the **set** command to change the forwarding option mode for IPv6 to flow-based.

```
[edit]
user@host# set security forwarding-options family inet6 mode flow-based
```

2. Use the **show** command to review your configuration.

```
[edit]
user@host# show security forwarding-options
family {
 inet6 {
 mode flow-based;
 }
}
```

3. Check your changes to the configuration before committing.

```
[edit]
user@host# commit check
warning: You have enabled/disabled inet6 flow.
You must reboot the system for your change to take effect.
If you have deployed a cluster, be sure to reboot all nodes.
configuration check succeeds
```

4. Commit the configuration.

```
[edit]
user@host# commit
warning: You have enabled/disabled inet6 flow.
You must reboot the system for your change to take effect.
If you have deployed a cluster, be sure to reboot all nodes.
commit complete
```

5. At an appropriate time, reboot the device.

**NOTE:** SRX Series devices only process IPv6 Routing Header 0 (RH0) to-self packets, the segleft field of which is zero. Other packets will be dropped.

Table 173 summarizes device status upon forwarding option configuration change.

**Table 173: Device Status Upon Configuration Change**

| Configuration Change       | Commit Warning | Reboot Required | Impact on Existing Traffic Before Reboot | Impact on New Traffic Before Reboot |
|----------------------------|----------------|-----------------|------------------------------------------|-------------------------------------|
| Drop to flow-based         | Yes            | Yes             | Dropped                                  | Dropped                             |
| Drop to packet-based       | No             | No              | Packet-based                             | Packet-based                        |
| Flow-based to packet-based | Yes            | Yes             | None                                     | Flow sessions created               |
| Flow-based to drop         | Yes            | Yes             | None                                     | Flow sessions created               |
| Packet-based to flow-based | Yes            | Yes             | Packet-based                             | Packet-based                        |
| Packet-based to drop       | No             | No              | Dropped                                  | Dropped                             |

To process IPv6 traffic, you also need to configure IPv6 addresses for the transit interfaces that receive and forward the traffic. For information on the inet6 protocol family and procedures for configuring IPv6 addresses for interfaces, see the [Interfaces Feature Guide for Security Devices](#).

**Related Documentation**

- [Using Filters to Display IPv6 Session and Flow Information for SRX Series Services Gateways on page 1733](#)

## Using Filters to Display IPv6 Session and Flow Information for SRX Series Services Gateways

**Purpose** You can display flow and session information about one or more sessions with the **show security flow session** command. IPv6 sessions are included in aggregated statistics.

You can use the following filters with the **show security flow session** command: application, destination-port, destination-prefix, family, idp, interface, nat, protocol, resource-manager, session-identifier, source-port, source-prefix, and tunnel.

**NOTE:** Except for the session-identifier filter, the output of all the other filters can be viewed in brief, summary, and extensive mode. Brief mode is the default mode. The output of the session-identifier filter can be viewed only in the brief mode.

You can use the same filter options with the **clear security flow session** command to terminate sessions.

**Action** The following examples show how to use IPv6-related filters to display summaries and details for IPv6 sessions.

#### Filtered summary report based on family

```
root> show security flow session summary family ?

```

Flow Sessions on FPC10 PIC1:

```
Session ID: 410000074, Policy name: default-policy-00/2, Timeout: 2, Valid
In: 200.0.0.10/1 --> 60.0.0.2/26935;icmp, If: ge-7/1/0.0, Pkts: 1, Bytes: 84,
CP Session ID: 410000195
Out: 60.0.0.2/26935 --> 200.0.0.10/1;icmp, If: ge-7/1/1.0, Pkts: 1, Bytes: 84,
CP Session ID: 410000195
Total sessions: 1
```

Flow Sessions on FPC10 PIC2:

```
Session ID: 420000075, Policy name: default-policy-00/2, Timeout: 2, Valid
In: 200.0.0.10/3 --> 60.0.0.2/26935;icmp, If: ge-7/1/0.0, Pkts: 1, Bytes: 84,
CP Session ID: 420000159
Out: 60.0.0.2/26935 --> 200.0.0.10/3;icmp, If: ge-7/1/1.0, Pkts: 1, Bytes: 84,
CP Session ID: 420000159
Total sessions: 1
```

Flow Sessions on FPC10 PIC3:

```
Session ID: 430000085, Policy name: default-policy-00/2, Timeout: 2, Valid
 In: 200.0.0.10/4 --> 60.0.0.2/26935;icmp, If: ge-7/1/0.0, Pkts: 1, Bytes: 84,
CP Session ID: 430000083
 Out: 60.0.0.2/26935 --> 200.0.0.10/4;icmp, If: ge-7/1/1.0, Pkts: 1, Bytes: 84,
CP Session ID: 430000083
Total sessions: 1
```

#### Clearing all sessions, including IPv6 sessions

```
root> clear security flow session all
This command may terminate the current session too.
Continue? [yes,no] (no) yes

0 active sessions cleared
1 active sessions cleared
1 active sessions cleared
1 active sessions cleared
```

#### Clearing only IPv6 sessions

```
root> clear security flow session family ?
Possible completions:
 inet Clear IPv4 sessions
 inet6 Clear IPv6/IPv6-NATPT sessions

root> clear security flow session family inet6
0 active sessions cleared
1 active sessions cleared
1 active sessions cleared
1 active sessions cleared
```

### The IPv6 Packet Header and SRX Series Overview

This topic identifies the IP version 6 (IPv6) packet header and its extensions and options.

Every IPv6 packet at a minimum has a basic packet header, 40 bytes (320 bits) long. They optionally may have extension headers.

For IPv6 packets, flow processing parses the extension headers and transport layer headers in the following way:

- If the software encounters a TCP, a UDP, an ESP, an AH, or an ICMPv6 header, it parses the header and assumes that the packet payload corresponds to the specified protocol type.
- If the software encounters a hop-by-hop header, a routing and destination header, or a fragment header, it continues to parse the next extension header.
- If it encounters the no-next-header extension header, the software detects that the packet is that of an unknown protocol (protocol equals 0).
- For other extension headers, the software parses the header and identifies the packet as belonging to the protocol indicated by the extension header.

## About the IPv6 Basic Packet Header

This topic identifies the IP version 6 (IPv6) basic packet header fields with their bit lengths and uses.

| Header Name    | Bit Length | Purpose                                                                                                                                                                                                                                                                                                                 |
|----------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Version        | 4          | Specifies that IP version 6 is used. The IPv6 version field contains a value of 6 indicating that IPv6 is used, as opposed to 4 for IP version 4.                                                                                                                                                                       |
| Traffic Class  | 8          | Allows source nodes or routers to identify different classes (or priorities for quality of service) for IPv6 packets. (This field replaces the IPv4 Type of Service field.)                                                                                                                                             |
| Flow Label     | 20         | Identifies the flow to which the packet belongs. Packets in a flow share a common purpose, or belong to a common category, as interpreted by external devices such as routers or destination hosts.<br><br><b>NOTE:</b> For IPv6 flow-based packets, Junos OS for SRX Series devices does not use the flow label field. |
| Payload Length | 16         | Specifies the length of the IPv6 packet payload, or contents, expressed in octets.                                                                                                                                                                                                                                      |

| Header Name            | Bit Length | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Next Header            | 8          | <p>Identifies the type of Internet Protocol for the header that immediately follows the IPv6 header. The Next Header field replaces the IPv4 Protocol field. It is an optional field.</p> <p>This protocol can be one of two types:</p> <ul style="list-style-type: none"> <li>• An IPv6 extension header. For example, if the device performs IP security on exchanged packets, the Next Header value is probably 50 (ESP extension header) or 51 (AH extension header). Extension headers are optional.</li> <li>• An upper-layer Protocol Data Unit (PDU). For example, the Next Header value could be 6 (for TCP), 17 (for UDP), or 58 (for ICMPv6).</li> </ul> <p>The flow module processes these headers sequentially within the context of a packet flow.</p> <p>If it encounters one of the following extension headers, the software parses it and regards the packet as a corresponding protocol packet.</p> <ul style="list-style-type: none"> <li>• Internet Control Message Protocol version 6 (ICMPv6)</li> <li>• Transport Control Protocol (TCP)</li> </ul> <p><b>NOTE:</b> The device checks the TCP header length as part of its sanity checks.</p> <ul style="list-style-type: none"> <li>• UDP</li> </ul> <p><b>NOTE:</b> The device checks the UDP length as part of its sanity checks.</p> <ul style="list-style-type: none"> <li>• Enhanced Security Protocol (ESP) or Authentication Header (AH)</li> </ul> |
| Hop Limit              | 8          | <p>Specifies the maximum number of hops the packet can make after transmission from the host device. When the Hop Limit value is zero, the device drops the packet and generates an error message. (This field is similar to the Time to Live IPv4 field.)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Source IP Address      | 128        | <p>Identifies the host device, or interface on a node, that generated the IPv6 packet.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Destination IP Address | 128        | <p>Identifies the host device, or interface on a node, to which the IPv6 packet is to be sent.</p> <p><b>NOTE:</b> The destination address can appear twice, the first instance after the hop limit following the source IP address and the second instance after the final extension header.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Understanding IPv6 Packet Header Extensions

This topic defines IP version 6 (IPv6) packet header extensions.

IPv6 extension headers contain supplementary information used by network devices (such as routers, switches, and endpoint hosts) to decide how to direct or process an IPv6 packet. The length of each extension header is an integer multiple of 8 octets. This allows subsequent extension headers to use 8-octet structures.

Any header followed by an extension header contains a Next Header value that identifies the extension header type. Extension headers always follow the basic IPv6 header in order as shown in [Table 174](#):

**NOTE:** The destination IP address can appear twice, once after the hop-by-hop header and again after the last extension header.

**Table 174: IPv6 Extension Headers**

| Header Name                    | Purpose                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hop-by-Hop Options             | Specifies delivery parameters at each hop on the path to the destination host.<br><br><b>NOTE:</b> A hop-by-hop option can appear only following the IPv6 basic header. If it is used, it should be the first extension header. It cannot appear after another extension header.                                                                        |
| Destination Options            | Specifies packet delivery parameters for either intermediate destination devices or the final destination host. When a packet uses this header, the Next Header value of the previous header must be 60.                                                                                                                                                |
| Routing                        | Defines strict source routing and loose source routing for the packet. (With strict source routing, each intermediate destination device must be a single hop away. With loose source routing, intermediate destination devices can be one or more hops away.) When a packet uses this header, the Next Header value of the previous header must be 43. |
| Fragment                       | Specifies how to perform IPv6 fragmentation and reassembly services. When a packet uses this header, the Next Header value of the previous header must be 44.<br><br>A source node uses the fragment extension header to tell the destination node the size of the packet that was fragmented so that the destination node can reassemble the packet.   |
| Authentication                 | Provides authentication, data integrity, and anti-replay protection. When a packet uses this header, the Next Header value of the previous header must be 51.                                                                                                                                                                                           |
| Encapsulating Security Payload | Provides data confidentiality, data authentication, and anti-replay protection for Encapsulated Security Payload (ESP) packets. When a packet uses this header, the Next Header value of the previous header must be 50.                                                                                                                                |
| Destination IP Address         | Identifies the host device, or interface on a node, to which the IPv6 packet is to be sent.<br><br><b>NOTE:</b> The destination address may appear twice, the first instance after the hop limit following the source IP address and the second instance after the final extension header.                                                              |

## About IPv6 Packet Header Verification Performed by the Flow Module for SRX Series Devices

---

This topic gives an overview of some of the IP version 6 (IPv6) packet header verification that the flow module for SRX Series devices performs.

To ensure the integrity of an IPv6 packet, the flow module performs the following sanity checks.

For all IPv6 packets, it checks the following parts of the header:

- TCP length
- UDP length
- Hop-by-hop extension to ensure that it follows the basic IPv6 header and does not come after another extension header
- That the IP data length error (IP length—total extension header length is not less than zero ( $<0$ ))

In addition to these verifications, the software performs other standard checks such as verifying that the correct IP version is specified and that the length of the IP address is correct.

## Understanding Path MTU Messages for IPv6 Packets

---

This topic describes path maximum transmission unit (MTU) and explains how the flow module for SRX Series devices processes and uses path MTU messages.

Every link has an MTU size that specifies the size of the largest packet the link can transmit. A larger MTU size means that fewer packets are required to transmit a certain amount of data. To achieve the best data transmission performance, IPv6 data packets sent from one node (the source) to another node (the destination) should be the largest possible size that can traverse the path between the nodes. (Larger and fewer packets constrain the cost of packet header processing and routing processes that can affect transmission performance.)

However, for a packet to successfully traverse the path from the source node to the destination node, the MTU size of the source node interface must be no larger than that of the smallest MTU size of all nodes on the path between the source and destination. This value is referred to as the path maximum transmission unit (path MTU). If a packet is larger than a link's MTU size, it is likely that the link will drop it. For IPv6, an intermediate node cannot fragment a packet.

IPv6 defines a standard mechanism called path MTU discovery that a source node can use to learn the path MTU of a path that a packet is likely to traverse. If any of the packets

sent on that path are too large to be forwarded by a node along the path, that node discards the packet and returns an ICMPv6 Packet Too Big message. The source node can then adjust the MTU size to be smaller than that of the node that dropped it and sent the ICMPv6 message, and then retransmit the packet. A source node might receive Packet Too Big messages repeatedly until its packet traverses all nodes along the path successfully.

**NOTE:** On all SRX Series devices, the Routing Engine cannot detect the path MTU of an IPv6 multicast address (with a large size packet).

After the path MTU size is determined and the appropriate MTU size is set, an outgoing packet might be routed along a different path with a node whose link MTU size is smaller than the path MTU size determined previously. In this case, the flow module engages the path MTU discovery process again.

When the flow module receives an ICMP Packet Too Big message with a destination address that belongs to it, it:

- Checks to determine if the embedded 5-tuple data of the packet is for a tunnel interface. (That is, it checks to determine if the embedded 5-tuple data matches a tunnel session.) If there is a match, the flow module updates the tunnel interface's MTU size. Then it performs post-fragment processing for the encrypted packets that follow the first packet. Afterward, the flow module delivers the packet to the ICMPv6 stack on the Routing Engine (RE) for it to continue processing it.
- If the packet is a transit one, the flow module searches for a session that matches the packet's embedded 5-tuple data. If it finds a matching session, it delivers the packet to it. If there is no matching session, it drops the packet.

When the flow module receives a packet, before it transmits it to the egress interface, it checks to determine if the MTU size of the egress interface is greater than the packet length.

- If the MTU size is greater than the packet length, it continues to process the packet.
- If the MTU size is less than the packet length, it drops the packet and sends an ICMPv6 Packet Too Big message to the source node.

**NOTE:** When chassis cluster is configured and the path MTU updates the MTU of the tunnel interface, the flow module does not synchronize the new MTU to peer nodes. The MTU size might be updated again by a larger packet on a peer node, which has no impact on packet transmission.

## Understanding How SRX Series Devices Handle Packet Fragmentation for IPv6 Flows

This topic explains packet fragmentation for IP version 6 (IPv6).

For IPv4 Internet Control Message Protocol (IPv4 ICMP), if a node within the path between a source node and a destination node receives a packet that is larger than its MTU size, it can fragment the packet and transmit the resulting smaller packets. For IPv6, only a source node (the node that sent the packet) can fragment a packet, and this is done to accommodate a path MTU size-adjustment requirement. Nodes along the path of a packet cannot fragment the packet to transmit it.

## Understanding How SRX Series Devices Handle ICMPv6 Packets

This topic explains Internet Control Message Protocol (ICMP), ICMP messages, and how Junos OS for SRX Series Services Gateways uses them.

ICMP provides a framework for reporting packet processing errors, for diagnostic purposes, and for implementation-specific functions. ICMP error messages make it possible for one node to inform another node that something has gone wrong during the course of data transfer. When IP version 6 (IPv6) was defined, the differences between IP version 4 (IPv4) and it were significant enough to require a new version of ICMP.

Every ICMPv6 message is preceded by an IPv6 header and zero or more IPv6 extension headers. The ICMPv6 header is identified by a Next Header value of 58 in the immediately preceding header. This is different from the value used to identify ICMP for IPv4. All ICMPv6 error messages have 32 bits of type-specific data to help the packet recipient locate the embedded invoking packet.

Most ICMPv6 packets have the same characteristics and behavior as normal IPv6 packets, and the Junos OS flow module processes them through first path and fast-path processing in the same way that it does normal IPv6 packets. [Table 175](#) shows the ICMPv6 embedded packet types that the flow module handles differently from normal ICMPv6 packets.

For these packets, the flow module uses a tuple that it creates from the embedded ICMPv6 packet to search for a matching session. It continues to process the packet without modifying the maximum transmission unit (MTU) until it finds a matching session, unless it receives an ICMPv6 Packet Too Big message for the interface. In this case, it modifies the MTU size for that interface. If the flow module does not find a matching session or if it cannot obtain a valid IPv6 header from the embedded payload, it drops the packet.

**NOTE:** A Packet Too Big message is the only kind of ICMPv6 packet that will cause the flow module to modify an interface.

Table 175: ICMPv6 Packets That Junos OS Handles Differently from Other ICMPv6 Packets

| Message                    | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 01-Destination Unreachable | <p>When a packet cannot be delivered because of a problem with the way it is being sent, it is useful to have a feedback mechanism that can tell the source about the problem, including the reason why delivery of the packet failed. For IPv6, the Destination Unreachable message serves this purpose.</p> <p>Each message includes a code that indicates the nature of the problem that caused the packet delivery to fail. It also includes all or part of the packet that could not be delivered, to help the source device resolve the problem.</p> <p>When the flow module encounters a Destination Unreachable ICMP packet whose embedded packet header data matches the 5-tuple data for a session, the software terminates the session.</p>                          |
| 02-Packet Too Big          | <p>When the flow module receives an ICMPv6 Packet Too Big message intended for it, the flow module sends the packet to the ICMP protocol stack on the Routing Engine to engage the path maximum transmission unit (path MTU) discovery process.</p> <p>If the Packet Too Big message does not pertain to the device but rather is a transit packet, the device attempts to match the embedded 5-tuple data with a session.</p> <ul style="list-style-type: none"> <li>• If a matching session exists, the device delivers it to the source node.</li> <li>• If a matching session does not exist, the device drops the packet</li> </ul> <p><b>NOTE:</b> A Packet Too Big message is the only kind of ICMPv6 packet that will cause the flow module to modify an interface.</p> |
| 03-Time Exceeded           | <p>When the flow module receives a packet that cannot be delivered because it has exceeded the hop count specified in the basic header hop-by-hop field, it sends this message to inform the packet's source node that the packet was discarded for this reason.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 04-Parameter Problem       | <p>When the device finds a problem with a field in the IPv6 header or extension headers that makes it impossible for it to process the packet, the software discards it and sends this ICMPv6 message to the packet's source node, indicating the type and location of the problem.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Understanding IPv6 Dual-Stack Lite

---

IPv6 dual-stack lite (DS-Lite) is a technology that enables Internet service providers to move to an IPv6 network while simultaneously handling IPv4 address depletion.

IPv4 addresses are becoming depleted; therefore, broadband service providers (DSL, cable, and mobile) need new addresses to support new users. Providing IPv6 addresses alone is often not workable because most of the systems that make up the public Internet are still enabled and support only IPv4, and many users' systems do not yet fully support IPv6.

DS-Lite allows service providers to migrate to an IPv6 access network without changing end-user software. The device that accesses the Internet remains the same, thus allowing IPv4 users to continue accessing IPv4 internet content with minimum disruption to their home networks, while enabling IPv6 users to access IPv6 content.

[Figure 91](#) illustrates the DS-Lite architecture which uses IPv6-only links between the provider and the user while maintaining the IPv4 (or dual-stack) hosts in the user network.

Figure 91: DS-Lite NAT (IPv4-in-IPv6)

The DS-Lite deployment model consists of the following components:

- Software initiator for the DS-Lite home router--Encapsulates the IPv4 packet and transmits it across an IPv6 tunnel.
- Software concentrator for DS-Lite carrier-grade Network Address Translation (NAT)--Decapsulates the IPv4-in-IPv6 packet and also performs IPv4-IPv4 NAT translations.

When a user's device sends an IPv4 packet to an external destination, DS-Lite encapsulates the IPv4 packet in an IPv6 packet for transport into the provider network. These IPv4-in-IPv6 tunnels are called *softwires*. Tunneling IPv4 over IPv6 is simpler than translation and eliminates performance and redundancy concerns.

The softwires terminate in a software concentrator at some point in the service provider network, which decapsulates the IPv4 packets and sends them through a carrier-grade Network Address Translation (NAT) device. There, the packets undergo source NAT processing to hide the original source address.

IPv6 packets originated by hosts in the subscriber's home network are transported natively over the access network.

The DS-Lite carrier-grade NAT translates IPv4-to-IPv4 addresses to multiple subscribers through a single global IPv4 address. Overlapping address spaces used by subscribers are disambiguated through the identification of tunnel endpoints. One concentrator can be the endpoint of multiple softwires.

The IPv4 packets originated by the end hosts have private (and possibly overlapping) IP addresses. Therefore, NAT must be applied to these packets. If end hosts have overlapping addresses, Network Address Port Translation (NAPT) is needed.

Using NAPT, the system adds the source address of the encapsulating IPv6 packet in the subscriber network to the inside IPv4 source address and port. Because each user's IPv6 address is unique, the combination of the IPv6 source address with the IPv4 source address and port creates an unambiguous mapping.

The system takes the following actions when it receives a responding IPv4 packet from outside the subscriber network:

- Encapsulates the IPv4 packet in an IPv6 packet using the mapped IPv6 address as the IPv6 destination address.
- Forwards the packet to the user.

[Table 176](#) lists the maximum number of software initiators and software concentrators per device.

**Table 176: Software Initiator and Software Concentrator Capacity**

| Description                                      | SRX650 | SRX3400 | SRX3600 | SRX5600 | SRX5800 |
|--------------------------------------------------|--------|---------|---------|---------|---------|
| Maximum software initiators connected per device | 50,000 | 100,000 | 100,000 | 100,000 | 100,000 |

Table 176: Software Initiator and Software Concentrator Capacity (*continued*)

|                                                  |    |    |    |    |    |
|--------------------------------------------------|----|----|----|----|----|
| Maximum software concentrator numbers per device | 16 | 32 | 32 | 32 | 32 |
|--------------------------------------------------|----|----|----|----|----|

**NOTE:** The most recent IETF draft documentation for DS-Lite uses new terminology:

- The term software initiator has been replaced by B4.
- The term software concentrator has been replaced by AFTR.

Junos OS documentation generally uses the original terms when discussing configuration in order to be consistent with the CLI statements used to configure DS-Lite.

## Example: Configuring IPv6 Dual-Stack Lite

When an ISP begins to allocate IPv6 addresses and IPv6-capable equipment to new subscriber homes, dual-stack lite (DS-Lite) provides a method for the private IPv4 addresses behind the IPv6 CE WAN equipment to reach the IPv4 network. DS-Lite enables IPv4 customers to continue to access the Internet using their current hardware by using a software initiator at the customer edge to encapsulate IPv4 packets into IPv6 packets with minimum disruption to their home network, while enabling IPv6 customers to access

IPv6 content. The software concentrator decapsulates the IPv4-in-IPv6 packets and also performs IPv4-IPv4 NAT translations.

This example shows you how to configure a software concentrator for IPv4-in-IPv6 addresses.

- [Requirements on page 1751](#)
- [Overview on page 1751](#)
- [Configuration on page 1751](#)
- [Verification on page 1752](#)

## Requirements

Before you begin:

- Review the overview section on DS-Lite. See “[Understanding IPv6 Dual-Stack Lite](#)” on [page 1747](#).
- Review how ICMPv6 packets are handled by the SRX Series devices. See “[Understanding How SRX Series Devices Handle ICMPv6 Packets](#)” on [page 1745](#).

## Overview

This configuration example shows how to configure a software concentrator, the software name, the concentrator address, and the software type.

**NOTE:** The software concentrator IPv6 address can match an IPv6 address configured on a physical interface or an IPv6 address configured on a loopback interface.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security softwares software-name my_sc1 software-concentrator 2001:100::1
software-type IPv4-in-IPv6
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a DS-Lite software concentrator to convert IPv4 packets into IPv6 packets:

1. Assign a name for the software concentrator.  

```
[edit security]
user@host# edit softwares software-name my_sc1
```

- Specify the address of the software concentrator.

```
[edit security softwares software-name my_sc1]
user@host# set software-concentrator 2001:100::1
```

- Specify the software type for IPv4 to IPv6.

```
[edit security softwares software-name my_sc1 software-concentrator 2001:100::1]
user@host# set software-type IPv4-in-IPv6
```

**Results** From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit security softwares software-name my_sc1]
user@host# show
software-concentrator 2001:100::1;
software-type ipv4-in-ipv6;
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

From operational mode, enter the **show security softwares** command. If a software is not connected, the operational output looks like the following sample:

```
user@host# show security softwares
Software Name SC Address Status Number of SI connected
my-sc1 2001:100::1 Active 0
```

If a software is connected, the operational output looks like the following sample:

```
user@host# show security softwares
Software Name SC Address Status Number of SI connected
my-sc1 2001:100::1 Connected 1
```

## Monitoring Security Flow Sessions Overview

Junos OS allows you to configure and start the monitoring of flow sessions using operational mode commands. Thus, you can debug without having to commit or modify your running configuration. This approach can be especially useful when you do not want to change the state of your device by committing the configuration to turn on trace options.

To configure flow session monitoring, you must define flow filters, specify the output file, and start monitoring. Flow session monitoring does not start unless a filter (at least one) and an output file are specified. Also, defining the filters themselves does not trigger monitoring. You have to explicitly use the **monitor security flow start** and **monitor security flow stop** commands to enable and disable monitoring, respectively.

- Define flow filters—Define the flow sessions that you want to monitor using combinations of match criteria, such as source address, destination address, source port, destination port, IP protocol number, name of the incoming or outgoing interface, and the logical system name. You can delete filters using the **clear monitor security flow filter** command.

**NOTE:** Unlike filters defined in the configuration mode, filters defined using operational mode commands are cleared when you reboot your system.

- Specify the output file—Create an output file in which the security flow monitoring information is to be saved. This file is saved in the `/var/log/` directory. You can view the contents of this file by using the **show log filename** command. Use the **monitor security flow file** command to specify output file characteristics, such as its maximum size, maximum number, and type.
- Start monitoring—Use the **monitor security flow start** command to start monitoring. Once monitoring starts, any traffic that matches the filters is saved in the specified output file in the `/var/log/` directory. The basic-datapath flag is the default flag and turns on as monitoring starts.

Use the **monitor security flow stop** command to stop monitoring. Once monitoring stops, the basic-datapath flag is cleared.

- Display monitoring flow information—Use the **show monitoring security flow** command to display details about the monitoring operation.

**NOTE:** You can configure flow session monitoring and debugging by using the monitoring operational mode commands and flow traceoptions configuration statements. These two operations cannot run in parallel. When you turn on security flow monitoring, the flow traceoption session is blocked and when the flow traceoption session is running, monitoring of the flow session is blocked.

## Understanding How to Obtain Session Information for SRX Series Services Gateways

You can obtain information about the sessions and packet flows active on your device, including detailed information about specific sessions. (The SRX Series device also

displays information about failed sessions.) You can display this information to observe activity and for debugging purposes. For example, you can use the `show security flow session` command:

- To display a list of incoming and outgoing IP flows, including services
- To show the security attributes associated with a flow, for example, the policies that apply to traffic belonging to that flow
- To display the session timeout value, when the session became active, for how long it has been active, and if there is active traffic on the session

**NOTE:** If an interface NAT is configured and sessions are set up with the NAT using that interface IP address, whenever the interface IP address changes, the sessions set up with NAT get refreshed and new sessions will be setup with new IP address. This you can verify using `show security flow session` CLI command.

Session information can also be logged if a related policy configuration includes the logging option. See [“Information Provided in Session Log Entries for SRX Series Services Gateways” on page 1761](#) for details about session information provided in system logs.

For the flow session log on all SRX Series devices, policy configuration has been enhanced. Information on the packet incoming interface parameter in the session log for session-init and session-close and when a session is denied by a policy or by the application firewall is provided to meet Common Criteria (CC) Medium Robustness Protection Profiles (MRPP) compliance:

Policy configuration—To configure the policy for the session for which you want to log matches as log `session-init` or `session-close` and to record sessions in syslog:

- `set security policies from-zone untrustZone to-zone trust zone policy policy13 match source-address extHost1`
- `set security policies from-zone untrustZone to-zone trust zone policy policy13 match source-address extHost1`
- `set security policies from-zone untrustZone to-zone trustZone policy policy13 match application junos-ping`
- `set security policies from-zone untrustZone to-zone trustZone policy policy13 then permit`
- `set security policies from-zone untrustZone to-zone trustZone policy policy13 then log session-init`
- `set security policies from-zone untrustZone to-zone trustZone policy policy13 then log session-close`

**Example :** Flow match policy13 will record the following information in the log:

```

## Displaying a Summary of Sessions for SRX Series Services Gateways

**Purpose** Determine the kinds of sessions on your device, how many of each kind there are—for example, the number of unicast sessions and multicast sessions—the number of failed sessions, the number of sessions that are currently used and the maximum number of sessions that the device supports. This command also displays the details of the sessions that are currently used. For example, valid sessions, pending sessions, invalidated sessions and sessions in other states.

**Action** To view session summary information in the CLI, enter the following CLI command:

```
user@host> show security flow session summary
```

---

## Displaying Session and Flow Information About Sessions for SRX Series Services Gateways

**Purpose** Display information about all sessions on your device, including the session ID, the virtual system the session belongs to, the Network Address Translation (NAT) source pool (if source NAT is used), the configured timeout value for the session and its standard timeout,

and the session start time and how long the session has been active. The display also shows all standard flow information, including the direction of the flow, the source address and port, the destination address and port, the IP protocol, and the interface used for the session.

**Action** To view session flow information in the CLI, enter the following command:

```
user@host> show security flow session
```

## Displaying Session and Flow Information About a Specific Session for SRX Series Services Gateways

---

**Purpose** When you know the session identifier, you can display all session and flow information for a specific session rather than for all sessions.

**Action** To view information about a specific session in the CLI, enter the following command:

```
user@host> show security flow session session-identifier 40000381
```

## Using Filters to Display Session and Flow Information for SRX Series Services Gateways

**Purpose** You can display flow and session information about one or more sessions by specifying a filter as an argument to the **show security flow session** command. You can use the following filters: application, destination-port, destination-prefix, family, idp, interface, nat, protocol, resource-manager, session-identifier, source-port, source-prefix and tunnel. The device displays the information for each session followed by a line specifying the number of sessions reported on. Here is an example of the command using the source-prefix filter.

**Action** To view information about selected sessions using filters in the CLI, enter the following command:

```
user@host> show security flow session source-prefix 10/8
```

## Information Provided in Session Log Entries for SRX Series Services Gateways

Session log entries are tied to policy configuration. Each main session event—create, close, and deny—will create a log entry if the controlling policy has enabled logging.

Different fields are logged for session create, session close, and session deny events as shown in [Table 177](#), [Table 178](#), and [Table 179](#). The same field name under each type indicates that the same information is logged, but each table is a full list of all data recorded for that type of session log.

The following table defines the fields displayed in session log entries.

**Table 177: Session Create Log Fields**

| Field               | Description                                                    |
|---------------------|----------------------------------------------------------------|
| source-address      | Source IP address of the packet that created the session.      |
| source-port         | Source port of the packet that created the session.            |
| destination-address | Destination IP address of the packet that created the session. |

Table 177: Session Create Log Fields (*continued*)

| Field                          | Description                                                                                                                                                                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination-port</b>        | Destination port of the packet that created the session.                                                                                                                                                                            |
| <b>service-name</b>            | Application that the packet traversed (for example, "junos-telnet" for Telnet traffic during the session allowed by a policy that permits native Telnet).                                                                           |
| <b>nat-source-address</b>      | The translated NAT source address if NAT was applied; otherwise, the source address as above.                                                                                                                                       |
| <b>nat-source-port</b>         | The translated NAT source port if NAT was applied; otherwise, the source port as above.                                                                                                                                             |
| <b>nat-destination-address</b> | The translated NAT destination address if NAT was applied; otherwise, the destination address as above.                                                                                                                             |
| <b>nat-destination-port</b>    | The translated NAT destination port if NAT was applied; otherwise, the destination port as above.                                                                                                                                   |
| <b>src-nat-rule-name</b>       | The source NAT rule that was applied to the session (if any). If static NAT is also configured and applied to the session and if source address translation takes place, then this field shows the static NAT rule name.*           |
| <b>dst-nat-rule-name</b>       | The destination NAT rule that was applied to the session (if any). If static NAT is also configured and applied to the session and if destination address translation takes place, then this field shows the static NAT rule name.* |
| <b>protocol-id</b>             | The protocol ID of the packet that created the session.                                                                                                                                                                             |
| <b>policy-name</b>             | The name of the policy that permitted the session creation.                                                                                                                                                                         |
| <b>session-id-32</b>           | The 32-bit session ID.                                                                                                                                                                                                              |

\* Note that some sessions might have both destination and source NAT applied and the information logged.

Table 178: Session Close Log Fields

| Field                      | Description                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>reason</b>              | The reason the session was closed.                                                                                                                        |
| <b>source-address</b>      | Source IP address of the packet that created the session.                                                                                                 |
| <b>source-port</b>         | Source port of the packet that created the session.                                                                                                       |
| <b>destination-address</b> | Destination IP address of the packet that created the session.                                                                                            |
| <b>destination-port</b>    | Destination port of the packet that created the session.                                                                                                  |
| <b>service-name</b>        | Application that the packet traversed (for example, "junos-telnet" for Telnet traffic during the session allowed by a policy that permits native Telnet). |

Table 178: Session Close Log Fields (*continued*)

| Field                          | Description                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nat-source-address</b>      | The translated NAT source address if NAT was applied; otherwise, the source address as above.                                                                                                                                                                                                                                                   |
| <b>nat-source-port</b>         | The translated NAT source port if NAT was applied; otherwise, the source port as above.                                                                                                                                                                                                                                                         |
| <b>nat-destination-address</b> | The translated NAT destination address if NAT was applied; otherwise, the destination address as above.                                                                                                                                                                                                                                         |
| <b>nat-destination-port</b>    | The translated NAT destination port if NAT was applied; otherwise, the destination port as above.                                                                                                                                                                                                                                               |
| <b>src-nat-rule-name</b>       | The source NAT rule that was applied to the session (if any). If static NAT is also configured and applied to the session and if source address translation takes place, then this field shows the static NAT rule name.*                                                                                                                       |
| <b>dst-nat-rule-name</b>       | The destination NAT rule that was applied to the session (if any). If static NAT is also configured and applied to the session and if destination address translation takes place, then this field shows the static NAT rule name.*                                                                                                             |
| <b>protocol-id</b>             | The protocol ID of the packet that created the session.                                                                                                                                                                                                                                                                                         |
| <b>policy-name</b>             | The name of the policy that permitted the session creation.                                                                                                                                                                                                                                                                                     |
| <b>session-id-32</b>           | The 32-bit session ID.                                                                                                                                                                                                                                                                                                                          |
| <b>packets-from-client</b>     | The number of packets sent by the client related to this session.                                                                                                                                                                                                                                                                               |
| <b>bytes-from-client</b>       | The number of data bytes sent by the client related to this session.                                                                                                                                                                                                                                                                            |
| <b>packets-from-server</b>     | The number of packets sent by the server related to this session.                                                                                                                                                                                                                                                                               |
| <b>bytes-from-server</b>       | The number of data bytes sent by the server related to this session.                                                                                                                                                                                                                                                                            |
| <b>elapsed-time</b>            | The total session elapsed time from permit to close, given in seconds.                                                                                                                                                                                                                                                                          |
| <b>unset</b>                   | <p>During the session creation, you can set the session close reason as <b>unset</b>.</p> <p>The session closes with the reason <b>unset</b> if the session installation on the control point is not successful. The reason for session installation varies, for example, nonavailability of memory for nonmanagement session installation.</p> |
| <b>TCP RST</b>                 | RST received from either end.                                                                                                                                                                                                                                                                                                                   |

Table 178: Session Close Log Fields (*continued*)

| Field                                  | Description                                                                                                                                         |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| TCP FIN                                | FIN received from either end.                                                                                                                       |
| response received                      | Response received for a packet request (for example, ICMP req-reply).                                                                               |
| ICMP error                             | ICMP error received.                                                                                                                                |
| aged out                               | Session aged out was reached.                                                                                                                       |
| ALG                                    | ALG errors closed the session (for example, remote access server (RAS) maximum limit reached).                                                      |
| HA                                     | HA message closed the session.                                                                                                                      |
| auth                                   | Authentication failed.                                                                                                                              |
| IDP                                    | IDP closed the session because of security module (SM) internal error.                                                                              |
| synproxy failure                       | SYN proxy failure closed the session.                                                                                                               |
| synproxy limit                         | Reason for failure in allocating minor session, need to free original session.                                                                      |
| parent closed                          | Parent session closed.                                                                                                                              |
| CLI                                    | Session cleared by a CLI statement.                                                                                                                 |
| CP NACK                                | CP NACK response received.                                                                                                                          |
| CP delete                              | CP ACK deletion closed the session.                                                                                                                 |
| policy delete                          | Corresponding policy marked for deletion.                                                                                                           |
| fwd session                            | Session closed because of forwarding session deletion.                                                                                              |
| multicast route change                 | Session closed because multicast route changed.                                                                                                     |
| first path reroute, session recreated  | The first path is rerouted and session is re-created.                                                                                               |
| source NAT allocation failure          | SPU received ACK message from the central point but failed to receive the DIP resource. Therefore this packet is dropped and the session is closed. |
| other                                  | Session closed because of all other reasons (for example, the pim reg tun needed refreshing).                                                       |
| error create IKE pass-through template | IKE pass-through template creation errors.                                                                                                          |

Table 178: Session Close Log Fields (*continued*)

| Field                                 | Description                                                                    |
|---------------------------------------|--------------------------------------------------------------------------------|
| IKE pass-through child session ageout | Session is deleted because the IKE pass through template session has no child. |
| sess timeout on pending state         | Pending session closed because time out timer reached the pending state.       |
| unknown                               | Session closed because of unknown reasons.                                     |

*\* Note that some sessions might have both destination and source NAT applied and the information logged.*

Table 179: Session Deny Log Fields

| Field               | Description                                                                              |
|---------------------|------------------------------------------------------------------------------------------|
| source-address      | Source IP address of the packet that attempted to create the session.                    |
| source-port         | Source port of the packet that attempted to create the session.                          |
| destination-address | Destination IP address of the packet that attempted to create the session.               |
| destination-port    | Destination port of the packet that attempted to create the session.                     |
| service-name        | Application that the packet attempted to traverse.                                       |
| protocol-id         | The protocol ID of the packet that attempted to create the session.                      |
| icmp-type           | The ICMP type if the denied packet was ICMP configured; otherwise, this field will be 0. |
| policy-name         | The name of the policy that denied the session creation.                                 |

# Monitoring X2 Traffic By Configuring Mirror Filters

- [Understanding X2 Traffic Monitoring on page 1767](#)
- [Example: Configuring Mirror Filters for X2 Traffic Monitoring on page 1770](#)

## Understanding X2 Traffic Monitoring

---

In an LTE mobile network, SRX Series devices act as secure gateways and connect Evolved Node Bs (eNodeBs) for signal handover, monitoring, and radio coverage. SRX Series devices use IPsec tunnels to connect eNodeBs. The user plane and control plane traffic that flows from one eNodeB to the other eNodeB is called the X2 traffic.

This topic covers X2 traffic monitoring on SRX Series devices:

- [X2 Traffic Monitoring Overview on page 1767](#)
- [Limitations of X2 Traffic Monitoring on page 1769](#)
- [X2 Traffic Terminology on page 1769](#)

## X2 Traffic Monitoring Overview

The X2 traffic passing through IPsec tunnels is encrypted; thus the mobile network operators need a way to monitor X2 traffic so that they can debug handover issues across eNodeBs. The Junos OS implementation allows monitoring of the X2 traffic by snooping into the cleartext X2 traffic as it flows through the SRX Series device coming out of one IPsec tunnel and going into the other IPsec tunnel—after traffic is decrypted and before it is encrypted again.

[Figure 92](#) shows the flow of X2 traffic within the SRX Series device. As the traffic reaches the SRX Series device on one st0.x interface, it gets decrypted. Then it is encrypted and forwarded to the destination eNodeB through its dedicated st0.y interface. Snooping is performed on the decrypted X2 traffic on the SRX Series device.

Figure 92: SRX Series Device in an LTE Mobile Network

Figure 93 shows a mobile operators network with an SRX Series device providing IPsec tunnel connection between the two eNodeBs. The SRX Series device is analyzer (also called a *sniffing* device) that is used for collecting and checking the X2 interface traffic. The IPsec tunnel from each eNodeB terminates on a dedicated secure tunnel interface on the SRX Series device. Traffic coming out of the IPsec tunnel is decrypted while traffic in the opposite direction is encrypted.

Figure 93: Monitoring X2 Traffic

To monitor the X2 interface, you configure mirror filters on the SRX Series device and filter the traffic that you want to analyze. The filtered packets are duplicated and sent to a physical interface. You also specify the output interface on the SRX Series device and the MAC address of the packet analyzer. Because the output interface is connected to the same Layer 2 network as the packet analyzer, once the mirror filtering is turned on, the packet analyzer collects and verifies the X2 traffic.

## Limitations of X2 Traffic Monitoring

The X2 traffic monitoring feature has a limitation—for X2 traffic in a chassis cluster setup, mirrored packets cannot traverse through the data link (fabric interface).

## X2 Traffic Terminology

Table 180 lists some X2 traffic related terms and their descriptions.

**Table 180: X2 Traffic Terminology**

| Term                                                         | Description                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Evolved packet core (EPC)                                    | Main component of System Architecture Evolution (SAE) and is also known as the SAE core. The EPC supports the IP network and serves as the equivalent of a General Packet Radio Service (GPRS) network, using the mobility management entity (MME), Serving Gateway (SGW), and Packet Data Network Gateway (PGW) subcomponents.                                   |
| Evolved Universal Terrestrial Radio Access Network (E-UTRAN) | A radio access network standard. E-UTRAN is a new air interface system. It provides higher data rates and lower latency and is optimized for packet data. It uses Orthogonal Frequency-Division Multiple Access (OFDMA) for the downlink and Single-carrier Frequency Division Multiple Access for the uplink.                                                    |
| Evolved Node B (eNodeB)                                      | A device connected to the mobile phone network that communicates directly with mobile handsets, like a base transceiver station in Global System for Mobile Communications (GSM) networks. An eNodeB is controlled by a radio network controller (RNC).                                                                                                           |
| Long Term Evolution (LTE)                                    | A standard for wireless communication of high-speed data for mobile phones and data terminals. It increases the capacity and speed using a different radio interface and makes core network improvements.                                                                                                                                                         |
| X2 interface                                                 | A point-to-point logical interface between two eNodeBs with the E-UTRAN. It supports the exchange of signaling information between two eNodeBs and supports the forwarding of protocol data units (PDUs) to the respective tunnel endpoints.                                                                                                                      |
| X2 Application Protocol (X2AP)                               | Protocol used by the X2 interface. It is used for handling the user equipment mobility within the E-UTRAN and provides the following functions: <ul style="list-style-type: none"> <li>• Manages mobility and load</li> <li>• Reports general error situations</li> <li>• Sets and resets the X2 interface</li> <li>• Updates the eNodeB configuration</li> </ul> |

## Example: Configuring Mirror Filters for X2 Traffic Monitoring

This example shows how to configure mirror filters to monitor X2 traffic between two eNodeBs in an LTE mobile network.

- [Requirements on page 1770](#)
- [Overview on page 1770](#)
- [Configuration on page 1771](#)
- [Verification on page 1772](#)

### Requirements

Before you begin:

- Understand X2 traffic monitoring. See [“Understanding X2 Traffic Monitoring” on page 1767](#).
- Configure the interfaces, security zones, security policies, and the route-based VPN tunnels to allow data to be securely transferred between the SRX Series device and the two eNodeBs. See [“Example: Configuring a Route-Based VPN” on page 6370](#).

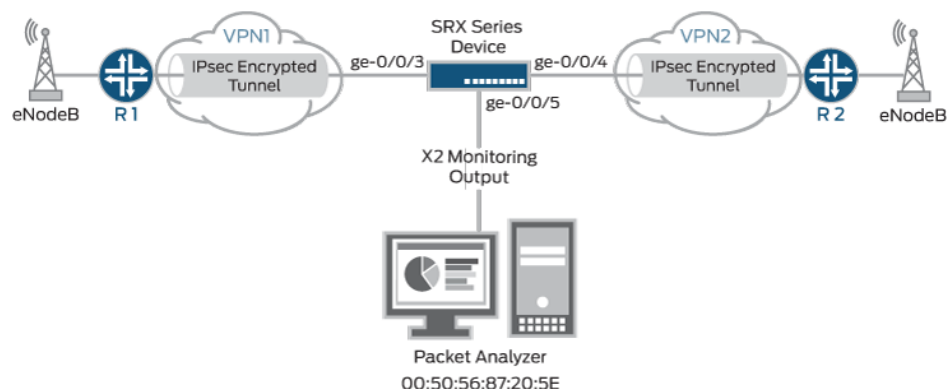

### Overview

In this example, an SRX Series device uses IPsec tunnels to connect two eNodeBs in an LTE mobile network. You, as a network operator, need a way to monitor the X2 traffic to debug any handover issues across eNodeBs. Traffic coming out of an IPsec tunnel is decrypted and then encrypted again to go into the other IPsec tunnel in the opposite direction.

To monitor traffic, you configure mirror filters on the SRX Series device. The traffic that matches your specified filters is mirrored and sent to an output interface that is connected to a packet analyzer (also called a *sniffing* device). The packet analyzer analyzes the traffic allowing you to monitor the X2 traffic.

[Figure 94](#) shows the SRX Series device connecting to the eNodeBs using IPsec tunnels. The SRX Series device is also connected to a packet analyzer.

**Figure 94: Configuring Mirror Filters for X2 Traffic Monitoring**

In this example, you specify the following match conditions for the filters:

- Protocol—ICMP
- Source-prefix—11.1.1.0/24
- Destination-prefix—41.1.1.0/24
- Incoming logical interface—st0.1
- Outgoing logical interface—st0.2

Packets that match these conditions are mirrored and sent through the output interface ge-0/0/5 to the packet analyzer with a MAC address 00:50:56:87:20:5E. The packet analyzer analyzes traffic that you can use for monitoring and debugging the X2 traffic on the SRX Series device.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security forwarding-options mirror-filter m1 protocol icmp
set security forwarding-options mirror-filter m1 source-prefix 11.1.1.0/24
set security forwarding-options mirror-filter m1 destination-prefix 41.1.1.0/24
set security forwarding-options mirror-filter m1 interface-in st0.1
set security forwarding-options mirror-filter m1 interface-out st0.2
set security forwarding-options mirror-filter m1 output interface ge-0/0/5
set security forwarding-options mirror-filter m1 output destination-mac 00:50:56:87:20:5E
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure mirror filters for monitoring X2 traffic:

1. Create a mirror filter.  

```
[edit]
user@host# edit security forwarding-options mirror-filter m1
```
2. Specify the match conditions for the mirror filter.  

```
[edit security forwarding-options mirror-filter m1]
user@host# set protocol icmp
user@host# set source-prefix 11.1.1.0/24
user@host# set destination-prefix 41.1.1.0/24
user@host# set interface-in st0.1
user@host# set interface-out st0.2
```
3. Specify the output interface for the mirrored packets.  

```
[edit security forwarding-options mirror-filter m1]
user@host# set output interface ge-0/0/5
```

- Specify the MAC address of the packet analyzer as a destination for all mirrored packets.

```
[edit security forwarding-options mirror-filter m1]
user@host# set output destination-mac 00:50:56:87:20:5E
```

**Results** From configuration mode, confirm your configuration by entering the **show security forwarding-options** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show security forwarding-options
mirror-filter m1 {
 protocol icmp;
 source-prefix 11.1.1.0/24;
 destination-prefix 41.1.1.0/24;
 interface-in st0.1;
 interface-out st0.2;
 output {
 interface ge-0/0/5;
 destination-mac 00:50:56:87:20:5E;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying the Status of Mirror Filter

---

**Purpose** Verify that mirror filter is active or not.

**Action** From operational mode, enter the **show security forward-options mirror-filter** command.

```
user@host> show security forward-options mirror-filter m1
Security mirror status

mirror-filter-name: m1
interface-in: st0.1
interface-out: st0.2
protocol: 1
source-prefix: 11.1.1.0
destination-prefix: 41.1.1.0
filter-counters: 2
output-counters: 2
```

**Meaning** The output provides the mirror filter status. It shows that a mirror filter named m1 is active. The match conditions for the filter are set—source prefix, destination prefix, protocol and incoming and outgoing interfaces.

This output shows that two packets were matched for mirroring and two packets were sent to the packet analyzer. It also correctly shows that the filter and output counters are the same. This means that the number of packets matched for mirroring and the number of packets sent to the packet analyzer are the same.

## Understanding Packet-Based Processing

Packets that enter and exit a Juniper Networks device running Junos OS can undergo packet-based processing. Packet-based, or stateless, packet processing treats packets discretely. Each packet is assessed individually for treatment. Stateless packet-based forwarding is performed on a packet-by-packet basis without regard to flow or state information. Each packet is assessed individually for treatment.

Figure 95 shows the traffic flow for packet-based forwarding.

Figure 95: Traffic Flow for Packet-Based Forwarding

As packets enter the device, classifiers, filters and policers are applied to it. Next, the egress interface for the packet is determined through a route lookup. Once the egress interface for the packet is found, filters are applied and the packet is sent to the egress interface where it is queued and scheduled for transmission.

Packet-based forwarding does not require any information about either previous or subsequent packets that belong to a given connection, and any decision to allow or deny

traffic is packet specific. This architecture has the benefit of massive scaling because it forwards packets without keeping track of individual flows or state.

On SRX Series devices, the default mode for processing traffic is flow mode. To configure an SRX Series device as a border router, you must change the mode from flow-based processing to packet-based processing. Use the **set security forwarding-options family mpls mode packet-based** statement to configure the SRX device to packet mode. You must reboot the device for the configuration to take effect.

## Understanding Selective Stateless Packet-Based Services

---

Selective stateless packet-based services allow you to use both flow-based and packet-based forwarding simultaneously on a system. You can selectively direct traffic that requires packet-based, stateless forwarding to avoid stateful flow-based forwarding by using stateless firewall filters, also known as access control lists (ACLs). The traffic not so directed follows the default flow-based forwarding path. Bypassing flow-based forwarding can be useful for traffic for which you explicitly want to avoid flow session-scaling constraints.

By default, Juniper Networks devices running Junos OS use flow-based forwarding. Selective stateless packet-based services allows you to configure the device to provide only packet-based processing for selected traffic based on input filter terms. Other traffic is processed for flow-based forwarding. Bypassing flow-based forwarding is useful for deployments where you want to avoid session-scaling constraints and session creation and maintenance costs.

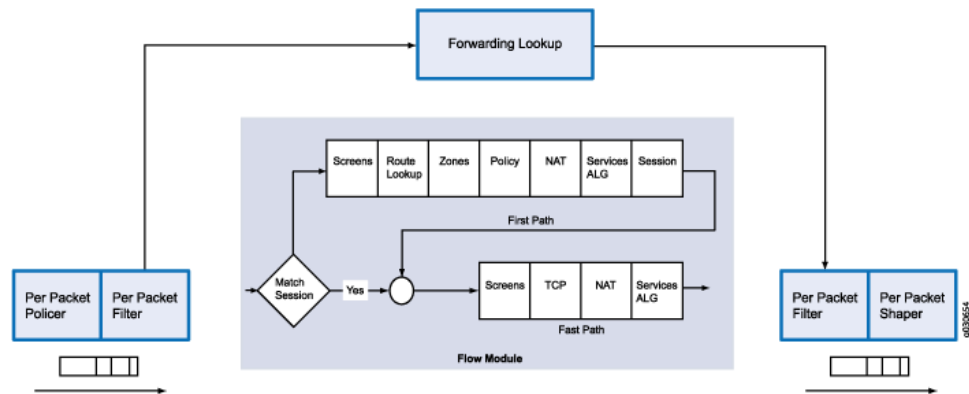

When you configure the device for selective stateless packet-based processing, packets entering the system are treated differently depending on certain conditions:

- If a packet satisfies matching conditions specified in input filter terms, it is marked for packet mode and all configured packet mode features are applied to it. No flow-based security features are applied. It bypasses them.
- If a packet has not been flagged for packet-mode, it undergoes normal processing. All services except for MPLS can be applied to this traffic.

[Figure 96](#) shows traffic flow with selective stateless packet-based services bypassing flow-based processing.

Figure 96: Traffic Flow with Selective Stateless Packet-Based Services

When the packet comes in on an interface, the input packet filters configured on the interface are applied.

- If the packet matches the conditions specified in the firewall filter, a **packet-mode** action modifier is set to the packet. The packet-mode action modifier updates a bit field in the packet key buffer—this bit field is used to determine if the flow-based forwarding needs to be bypassed. As a result, the packet with the packet-mode action modifier bypasses the flow-based forwarding completely. The egress interface for the packet is determined through a route lookup. Once the egress interface for the packet is found, filters are applied and the packet is sent to the egress interface where it is queued and scheduled for transmission.
- If the packet does not match the conditions specified in this filter term, it is evaluated against other terms configured in the filter. If, after all terms are evaluated, a packet matches no terms in a filter, the packet is silently discarded. To prevent packets from being discarded, you configure a term in the filter specifying an action to accept all packets.

A defined set of stateless services is available with selective stateless packet-based services:

- IPv4 routing (unicast and multicast protocols)
- Class of service (CoS)
- Link fragmentation and interleaving (LFI)
- Generic routing encapsulation (GRE)
- Layer 2 switching
- Multiprotocol Label Switching (MPLS)
- Stateless firewall filters
- Compressed Real-Time Transport Protocol (CRTP)

Although traffic requiring MPLS services must be processed in packet mode, under some circumstances it might be necessary to concurrently apply certain services to this traffic that can only be provided in flow mode, such as stateful inspection, NAT, and IPsec. To

direct the system to process traffic in both flow and packet modes, you must configure multiple routing instances connected through a tunnel interface. One routing instance must be configured to process the packets in flow mode and the other routing instance must be configured to process the packets in packet mode. When you use a tunnel interface to connect routing instances, traffic between those routing instances is injected again into the forwarding path and it can then be reprocessed using a different forwarding method.

---

## Selective Stateless Packet-Based Services Configuration Overview

---

You configure selective stateless packet-based services using the stateless firewall filters, also known as access control lists (ACLs). You classify traffic for packet-based forwarding by specifying match conditions in the firewall filters and configure a **packet-mode** action modifier to specify the action. Once match conditions and actions are defined, firewall filters are applied to relevant interfaces.

To configure a firewall filter:

1. Define the address family—First define the address family of the packets that a firewall filter matches. To define the family name, specify **inet** to filter IPv4 packets. Specify **mpls** to filter MPLS packets. Specify **ccc** to filter Layer 2 switching cross-connects.
2. Define terms—Define one or more terms that specify the filtering criteria and the action to take if a match occurs. Each term consists of two components—match conditions and actions.
  - Match conditions—Specify certain characteristics that the packet must match for the action to be performed. You can define various match conditions, such as the IP source address field, IP destination address field, and IP protocol field.
  - Action—Specify what is to be done with the packet if it matches the match conditions. Possible actions are to accept, discard, or reject a packet; go to the next term; or take no action.

You can specify only one **action** statement (or omit it) in a term, but you can specify any combination of action modifiers with it. Action modifiers include a default **accept** action. For example, if you specify an action modifier and do not specify an action, the specified action modifier is implemented and the packet is accepted.

The **packet-mode** action modifier specifies traffic to bypass flow-based forwarding. Like other action modifiers, you can configure the **packet-mode** action modifier along with other actions, such as **accept** or **count**.

3. Apply firewall filters to interfaces—Apply the firewall filter to the interface to have the firewall filter take effect.

When the packet comes in on an interface, the input packet filters configured on the interface are applied. If the packet matches the specified conditions and **packet-mode** action is configured, the packet bypasses the flow-based forwarding completely.

When configuring filters, be mindful of the order of the terms within the firewall filter. Packets are tested against each term in the order in which it is listed in the configuration. When the first matching conditions are found, the action associated with that term is applied to the packet and the evaluation of the firewall filter ends, unless the **next term** action modifier is included. If the **next term** action is included, the matching packet is then evaluated against the next term in the firewall filter; otherwise, the matching packet is not evaluated against subsequent terms in the firewall filter.

When configuring firewall filters for selective stateless packet-based services:

- Accurately identify traffic that needs to bypass flow to avoid unnecessary packet drops.
- Make sure to apply the firewall filter with packet-mode action on all interfaces involved in the packet-based flow path.
- Make sure to configure host-bound TCP traffic to use flow-based forwarding—exclude this traffic when specifying match conditions for the firewall filter term containing the **packet-mode** action modifier. Any host-bound TCP traffic configured to bypass flow is dropped. Asynchronous flow-mode processing is not supported with selective stateless packet-based services.
- Configure input packet filters (not output) with the **packet-mode** action modifier.

**NOTE:** Nested firewall filters (configuring a filter within the term of another filter) are not supported with selective stateless packet-based services.

Some typical deployment scenarios where you can configure selective stateless packet-based services are as follows:

- Traffic flow between private LAN and WAN interfaces, such as for Intranet traffic, where end-to-end forwarding is packet-based
- Traffic flow between private LAN and not-so-secure WAN interfaces, where traffic uses packet-based and flow-based forwarding for secure and not so secure traffic respectively
- Traffic flow between the private LAN and WAN interface with failover to flow-based IPsec WAN when the private WAN link is down
- Traffic flow from flow-based LAN to packet-based MPLS WAN

## Example: Configuring Selective Stateless Packet-Based Services for End-to-End Packet-Based Forwarding

---

This example shows how to configure selective stateless packet-based services for end-to-end packet-based forwarding.

- [Requirements on page 1782](#)
- [Overview on page 1782](#)
- [Configuration on page 1783](#)
- [Verification on page 1789](#)

### Requirements

Before you begin:

- Understand how to configure stateless firewall filters. See the *Junos OS Routing Protocols Library for Security Devices*.
- Establish basic connectivity. See the *Getting Started Guide for Branch SRX Series*.

### Overview

In this example, you configure the IP addresses for the interfaces on each of the devices. For R0 it is 10.1.1.2/24; for R1 they are 10.1.1.1/24, 10.2.1.1/24, and 1.1.1.1/30; for R2 it is 1.1.1.2/30; and for R3 it is 10.2.1.2/24. You create static routes and associate next-hop addresses for the devices as follows: R0 is 10.1.1.1, R1 is 1.1.1.2, R2 is 1.1.1.1, and R3 is 10.2.1.1.

Then on device R1 you configure a zone called untrust and assign it to interface ge-0/0/3. You also create a zone called trust and assign interfaces ge-0/0/1 and ge-0/0/2 to it. You configure trust and untrust zones to allow all supported application services as inbound services. You allow traffic from any source address, destination address, and application to pass between the zones.

You then create the firewall filter bypass-flow-filter and define the terms bypass-flow-term-1 and bypass-flow-term-2 that match the traffic between internal interfaces ge-0/0/1 and ge-0/0/2 and that contain the packet-mode action modifier. You define the term accept-rest to accept all remaining traffic. Finally, you apply the firewall filter bypass-flow-filter to internal interfaces ge-0/0/1 and ge-0/0/2 (not on the external interface). As a result, all internal traffic bypasses flow-based forwarding and the traffic to and from the Internet does not bypass flow-based forwarding.

[Figure 97](#) shows the network topology used in this example.

Figure 97: Intranet Traffic Using End-to-End Packet-Based Services

Your company's branch offices are connected to each other through a private WAN. For this internal traffic, packet forwarding is required because security is not an issue. Hence for this traffic, you decide to configure selective stateless packet-based services to bypass flow-based forwarding. The remaining traffic, to and from the Internet, uses flow-based forwarding.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

{device R0}
[edit]
set interfaces description "Internal 1" ge-0/0/1 unit 0 family inet address 10.1.1.2/24
set routing-options static route 0.0.0.0/0 next-hop 10.1.1.1

{device R1}
set interfaces description "Internal 1" ge-0/0/1 unit 0 family inet address 10.1.1.1/24
set interfaces description "Internal 2" ge-0/0/2 unit 0 family inet address 10.2.1.1/24
set interfaces description "Internet" ge-0/0/3 unit 0 family inet address 1.1.1.1/30
set routing-options static route 0.0.0.0/0 next-hop 1.1.1.2
set security zones security-zone untrust interfaces ge-0/0/3
set security zones security-zone trust interfaces ge-0/0/1
set security zones security-zone trust interfaces ge-0/0/2

set interfaces description "Internal 2" ge-0/0/2 unit 0 family inet filter input
 bypass-flow-filter

{device R2}
set interfaces description "Internet" ge-0/0/3 unit 0 family inet address 1.1.1.2/30
set routing-options static route 0.0.0.0/0 next-hop 1.1.1.1

{device R3}
[edit]
set interfaces description "Internal 2" ge-0/0/2 unit 0 family inet address 10.2.1.2/24
set routing-options static route 0.0.0.0/0 next-hop 10.2.1.1

```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure selective stateless packet-based services for end-to-end packet-based forwarding:

1. Configure the IP addresses for the interfaces on devices R0, R1, R2, and R3.

```

{device R0}
[edit]
user@host# set interfaces description "Internal 1" ge-0/0/1 unit 0 family inet address
 10.1.1.2/24

{device R1}
[edit]
user@host# set interfaces description "Internal 1" ge-0/0/1 unit 0 family inet address
 10.1.1.1/24
user@host# set interfaces description "Internal 2" ge-0/0/2 unit 0 family inet address
 10.2.1.1/24
user@host# set interfaces description "Internet" ge-0/0/3 unit 0 family inet address
 1.1.1.1/30

{device R2}
[edit]
user@host# set interfaces description "Internet" ge-0/0/3 unit 0 family inet address
 1.1.1.2/30

{device R3}
[edit]
user@host# set interfaces description "Internal 2" ge-0/0/2 unit 0 family inet address
 10.2.1.2/24

```

2. Create static routes and associate the appropriate next-hop addresses for devices R0, R1, R2, and R3.

```
{device R0}
[edit]
user@host# set routing-options static route 0.0.0.0/0 next-hop 10.1.1.1

{device R1}
[edit]
user@host# set routing-options static route 0.0.0.0/0 next-hop 1.1.1.2

{device R2}
[edit]
user@host# set routing-options static route 0.0.0.0/0 next-hop 1.1.1.1

{device R3}
[edit]
user@host# set routing-options static route 0.0.0.0/0 next-hop 10.2.1.1
```

3. Configure security zones and assign interfaces.

```
{device R1}
[edit]
user@host# set security zones security-zone untrust interfaces ge-0/0/3
user@host# set security zones security-zone trust interfaces ge-0/0/1
user@host# set security zones security-zone trust interfaces ge-0/0/2
```

4. Configure application services for zones.

```
{device R1}
[edit]
user@host# set security zones security-zone trust host-inbound-traffic
system-services all
user@host# set security zones security-zone untrust host-inbound-traffic
system-services all
```

5. Configure a security policy

```
{device R1}
[edit]
user@host# set security policies from-zone trust to-zone untrust policy
Internet-traffic match source-address any destination-address any application
any
user@host# set security policies from-zone trust to-zone untrust policy
Internet-traffic then permit
user@host# set security policies from-zone untrust to-zone trust policy
Incoming-traffic match source-address any destination-address any application
any
user@host# set security policies from-zone untrust to-zone trust policy
Incoming-traffic then permit
user@host# set security policies from-zone trust to-zone trust policy Intrazone-traffic
match source-address any destination-address any application any
user@host# set security policies from-zone trust to-zone trust policy Intrazone-traffic
then permit
```

6. Create a firewall filter and define terms for all the packet-based forwarding traffic.

```
{device R1}
[edit]
```

```

user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term-1
from source-address 10.1.1.0/24
user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term-1
from destination-address 10.2.1.0/24
user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term-1
then packet-mode
user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term-2
from source-address 10.2.1.0/24
user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term-2
from destination-address 10.1.1.0/24
user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term-2
then packet-mode

```

7. Specify another term for the remaining traffic.

```

{device R1}
[edit]
user@host# set firewall family inet filter bypass-flow-filter term accept-rest then
accept

```

8. Apply the firewall filter to relevant interfaces.

```

{device R1}
[edit]
user@host# set interfaces description "Internal 1" ge-0/0/1 unit 0 family inet filter
input bypass-flow-filter
user@host# set interfaces description "Internal 2" ge-0/0/2 unit 0 family inet filter
input bypass-flow-filter

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show firewall** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

{device R0}
[edit]
user@host# show interfaces

 then packet-mode;
 }
 term accept-rest {
 then accept;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the End-to-End Packet-Based Configuration on page 1789](#)
- [Verifying Session Establishment on Intranet Traffic on page 1789](#)
- [Verifying Session Establishment on Internet Traffic on page 1790](#)

### Verifying the End-to-End Packet-Based Configuration

**Purpose** Verify that the selective stateless packet-based services are configured.

**Action** From configuration mode, enter the **show interfaces**, **show routing-options**, **show security zones**, **show security policies**, and **show firewall** commands.

Verify that the output shows the intended configuration of the firewall filter, interfaces, and policies.

Verify that the terms are listed in the order in which you want the packets to be tested. You can move terms within a firewall filter by using the **insert** command.

### Verifying Session Establishment on Intranet Traffic

**Purpose** Verify that sessions are established when traffic is transmitted to interfaces within the Intranet.

**Action** To verify that sessions are established, perform the following tasks:

1. On device **R1**, enter the operational mode **clear security flow session all** command to clear all existing security flow sessions.
2. On device **R0**, enter the operational mode **ping** command to transmit traffic to device **R3**.
3. On device **R1**, with traffic transmitting from devices **R0** to **R3** through **R1**, enter the operational mode **show security flow session** command.

Flow Sessions on FPC10 PIC1:  
Total sessions: 0

Flow Sessions on FPC10 PIC2:  
Total sessions: 0

Flow Sessions on FPC10 PIC3:  
Total sessions: 0

**NOTE:** To verify established sessions, make sure to enter the **show security flow session** command while the **ping** command is sending and receiving packets.

```
{device R0}
user@host> ping 60.0.0.1 -c 10
```

```
PING 60.0.0.2 (60.0.0.2) 56(84) bytes of data.
64 bytes from 60.0.0.2: icmp_seq=1 ttl=63 time=6.07 ms
64 bytes from 60.0.0.2: icmp_seq=2 ttl=63 time=4.24 ms
64 bytes from 60.0.0.2: icmp_seq=3 ttl=63 time=2.85 ms
64 bytes from 60.0.0.2: icmp_seq=4 ttl=63 time=6.14 ms
...
```

```
{device R1}
user@host> show security flow session
```

```
Flow Sessions on FPC10 PIC1:
```

```
Session ID: 410000077, Policy name: Internet-traffic/5, Timeout: 2, Valid
 In: 200.0.0.10/3 --> 60.0.0.2/32055;icmp, If: ge-7/1/0.0, Pkts: 1, Bytes: 84,
CP Session ID: 410000198
 Out: 60.0.0.2/32055 --> 200.0.0.10/3;icmp, If: ge-7/1/1.0, Pkts: 1, Bytes: 84,
CP Session ID: 410000198
Total sessions: 1
```

```
Flow Sessions on FPC10 PIC2:
```

```
Session ID: 420000079, Policy name: Internet-traffic/5, Timeout: 2, Valid
 In: 200.0.0.10/5 --> 60.0.0.2/32055;icmp, If: ge-7/1/0.0, Pkts: 1, Bytes: 84,
CP Session ID: 420000163
 Out: 60.0.0.2/32055 --> 200.0.0.10/5;icmp, If: ge-7/1/1.0, Pkts: 1, Bytes: 84,
CP Session ID: 420000163
Total sessions: 1
```

```
Flow Sessions on FPC10 PIC3:
```

```
Session ID: 430000090, Policy name: Internet-traffic/5, Timeout: 4, Valid
 In: 200.0.0.10/7 --> 60.0.0.2/32055;icmp, If: ge-7/1/0.0, Pkts: 1, Bytes: 84,
CP Session ID: 430000088
 Out: 60.0.0.2/32055 --> 200.0.0.10/7;icmp, If: ge-7/1/1.0, Pkts: 1, Bytes: 84,
CP Session ID: 430000088
Total sessions: 1
```

The output shows traffic transmitting from **R0** to **R3** and no sessions are established. In this example, you applied the **bypass-flow-filter** with the **packet-mode** action modifier on interfaces **Internal 1** and **Internal 2** for your company's Intranet traffic. This output verifies that the traffic between the two interfaces is correctly bypassing flow-based forwarding and hence no sessions are established.

### Verifying Session Establishment on Internet Traffic

- |                |                                                                                                                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Verify that sessions are established when traffic is transmitted to the Internet.                                                                                                                                                                                                                                                         |
| <b>Action</b>  | <p>To verify that traffic to the Internet is using flow-based forwarding and sessions are established, perform the following tasks:</p> <ol style="list-style-type: none"> <li>1. On device <b>R1</b>, enter the operational mode <b>clear security flow session all</b> command to clear all existing security flow sessions.</li> </ol> |

2. On device **R0**, enter the operational mode **ping** command to transmit traffic to device **R2**.
3. On device **R1**, with traffic transmitting from **R0** to **R2** through **R1**, enter the operational mode **show security flow session** command.

**NOTE:** To verify established sessions, make sure to enter the **show security flow session** command while the **ping** command is sending and receiving packets.

```
{device R0}
user@host> ping 1.1.1.2

PING 1.1.1.2 (1.1.1.2): 56 data bytes
64 bytes from 1.1.1.2: icmp_seq=0 ttl=63 time=2.326 ms
64 bytes from 1.1.1.2: icmp_seq=1 ttl=63 time=2.569 ms
64 bytes from 1.1.1.2: icmp_seq=2 ttl=63 time=2.565 ms
64 bytes from 1.1.1.2: icmp_seq=3 ttl=63 time=2.563 ms
64 bytes from 1.1.1.2: icmp_seq=4 ttl=63 time=2.306 ms
64 bytes from 1.1.1.2: icmp_seq=5 ttl=63 time=2.560 ms
64 bytes from 1.1.1.2: icmp_seq=6 ttl=63 time=4.130 ms
64 bytes from 1.1.1.2: icmp_seq=7 ttl=63 time=2.316 ms
...
```

```
{device R1}
user@host> show security flow session
```

```
Flow Sessions on FPC10 PIC1:
Total sessions: 0
```

```
Flow Sessions on FPC10 PIC2:
Total sessions: 0
```

```
Flow Sessions on FPC10 PIC3:
Total sessions: 0
```

The output shows traffic transmitting from devices **R0** to **R1** and established sessions. In this example, you did not apply the **bypass-flow-filter** with the **packet-mode** action modifier on interface **Internet** for your company's Internet traffic. This output verifies that the traffic to the Internet is correctly using flow-based forwarding and hence sessions are established.

Transmit traffic from device **R3** to **R2** and use the commands in this section to verify established sessions.

## Example: Configuring Selective Stateless Packet-Based Services for Packet-Based to Flow-Based Forwarding

---

This example shows how to configure selective stateless packet-based services for packet-based to flow-based forwarding.

- [Requirements on page 1792](#)
- [Overview on page 1792](#)
- [Configuration on page 1793](#)
- [Verification on page 1798](#)

### Requirements

Before you begin:

- Understand how to configure stateless firewall filters. See the *Junos OS Routing Protocols Library for Security Devices*.
- Establish basic connectivity. See the *Getting Started Guide for Branch SRX Series*.

### Overview

In this example, you configure the IP addresses for the interfaces on each of the devices. For device R0 as 9.9.9.9/24; for R1 the are 9.9.9.10/24 and 5.5.5.5/24; and for R2 it is 5.5.5.9/24. On device R1, you set an internal service interface lt-0/0/0 between routing instances and configure a peer relationship between two virtual devices. You then create a security zone called HOST, assign all interfaces to it, and configure it to allow all supported applications and protocols.

Then you configure policies and specify that all packets are permitted. You configure a virtual device routing instance Internet-VR and assign interfaces for flow-based forwarding. You enable OSPF on devices R0, R1, and R2. On Device R2, you configure the filter bypass-flow-filter with the term bypass-flow-term that contains the packet-mode action modifier. Because you have not specified any match conditions, this filter applies to all traffic that traverses the interfaces on which it is applied.

Finally, on device R1 you apply the firewall filter bypass-flow-filter to internal interfaces ge-0/0/2.0 and lt-0/0/0.0. You do not apply the filter to the interfaces associated with the Internet-VR routing instance. As a result, all traffic that traverses the LAN interfaces associated with the master routing instance uses packet-based forwarding and all traffic that traverses the Internet-VR routing instance uses flow-based forwarding.

[Figure 98](#) shows the network topology used in this example.

Figure 98: Selective Stateless Packet-Based Services for Packet-Based Forwarding

The interface facing the private LAN does not need any security services, but the interface facing the WAN needs security. In this example, you decide to configure both packet-based and flow-based forwarding for secure and not so secure traffic by configuring two routing instances—one handling the packet-based forwarding and the other handling the flow-based forwarding.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
{device R0}
set interfaces description "Connect to Master VR" ge-0/0/2 unit 0 family inet address 9.9.9.9/24
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0

{device R1}
set interfaces description "Connect to R0" ge-0/0/2 unit 0 family inet address 9.9.9.10/24
set interfaces description "Connect to R2" ge-0/0/3 unit 0 family inet address 5.5.5.9/24
set interfaces lt-0/0/0 unit 0 encapsulation frame-relay dlci 100 peer-unit 1 family inet address 1.1.1.1/16
set interfaces lt-0/0/0 unit 1 encapsulation frame-relay dlci 100 peer-unit 0 family inet address 1.1.1.2/16
set security zones security-zone HOST host-inbound-traffic system-services any-service
set security zones security-zone HOST host-inbound-traffic protocols all
set security zones security-zone HOST interfaces all
set security policies default-policy permit-all
set routing-instances Internet-VR instance-type virtual-router interface lt-0/0/0.1
set routing-instances Internet-VR instance-type virtual-router interface ge-0/0/3.0
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
set protocols ospf area 0.0.0.0 interface lt-0/0/0.0
set routing-instances Internet-VR protocols ospf area 0.0.0.0 interface lt-0/0/0.1
set routing-instances Internet-VR protocols ospf area 0.0.0.0 interface ge-0/0/3.0
set firewall family inet filter bypass-flow-filter term bypass-flow-term then accept
```

```

set firewall family inet filter bypass-flow-filter term bypass-flow-term then packet-mode
set interfaces ge-0/0/2 unit 0 family inet bypass-flow-filter
set interfaces lt-0/0/0 unit 0 family inet bypass-flow-filter

{device R2}
set interfaces description "Connect to Internet-VR" ge-0/0/3 unit 0 family inet address
5.5.5.9/24
set protocols ospf area 0.0.0.0 interface ge-0/0/3

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure selective stateless packet-based services for end-to-end packet-based forwarding:

1. Configure the IP addresses for the interfaces.

```

{device R0}
[edit]
user@host# set interfaces description "Connect to Master VR" ge-0/0/2 unit 0
family inet address 9.9.9.9/24

{device R1}
[edit]
user@host# set interfaces description "Connect to R0" ge-0/0/2 unit 0 family inet
address 9.9.9.10/24
user@host# set interfaces description "Connect to R2" ge-0/0/3 unit 0 family inet
address 5.5.5.5/24

{device R2}
[edit]
user@host# set interfaces description "Connect to Internet-VR" ge-0/0/3 unit 0
family inet address 5.5.5.9/24

```

2. Set an internal service interface between routing instances.

```

{device R1}
[edit]
user@host# set interfaces lt-0/0/0 unit 0 encapsulation frame-relay dlci 100
peer-unit 1 family inet address 1.1.1.1/16
user@host# set interfaces lt-0/0/0 unit 1 encapsulation frame-relay dlci 100
peer-unit 0 family inet address 1.1.1.2/16

```

3. Configure security zones.

```

{device R1}
[edit]
user@host# set security zones security-zone HOST host-inbound-traffic
system-services any-service
user@host# set security zones security-zone HOST host-inbound-traffic protocols
all
user@host# set security zones security-zone HOST interfaces all

```

4. Configure policies.

```

{device R1}
[edit]
user@host# set security policies default-policy permit-all

```

5. Configure a virtual device routing instance.

```
{device R1}
[edit]
user@host# set routing-instances Internet-VR instance-type virtual-router interface
lt-0/0/0.1
user@host# set routing-instances Internet-VR instance-type virtual-router interface
ge-0/0/3.0
```

6. Enable OSPF on all interfaces in the network.

```
{device R0}
[edit]
user@host# set protocols ospf area 0.0.0.0 interface ge-0/0/2.0

{device R1 for Master-VR}
[edit]
user@host# set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
user@host# set protocols ospf area 0.0.0.0 interface lt-0/0/0.0

{device R1 for Internet-VR}
[edit]
user@host# set routing-instances Internet-VR protocols ospf area 0.0.0.0 interface
lt-0/0/0.1
user@host# set routing-instances Internet-VR protocols ospf area 0.0.0.0 interface
ge-0/0/3.0

{device R2}
[edit]
user@host# set protocols ospf area 0.0.0.0 interface ge-0/0/3
```

7. Create a firewall filter and define a term for packet-based forwarding traffic.

```
{device R1}
[edit]
user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term
then accept
user@host# set firewall family inet filter bypass-flow-filter term bypass-flow-term
then packet-mode
```

8. Apply the firewall filter to relevant interfaces.

```
{device R1}
[edit]
user@host# set interfaces ge-0/0/2 unit 0 family inet bypass-flow-filter
user@host# set interfaces lt-0/0/0 unit 0 family inet bypass-flow-filter
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show security**, **show routing-instances**, and **show firewall** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
{device R0}
[edit]
user@host# show interfaces
ge-0/0/2 {
 description "Connect to Master-VR"
 unit 0 {
 family inet {
```

```
 address 9.9.9.9/24
 }
}

{device R0}
[edit]
user@host# show protocols

 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Packet-Based to Flow-Based Configuration on page 1798](#)
- [Verifying Session Establishment on LAN Traffic on page 1798](#)
- [Verifying Session Establishment on Internet Traffic on page 1799](#)

---

### Verifying the Packet-Based to Flow-Based Configuration

**Purpose** Verify that the selective stateless packet-based services are configured for packet-based to flow-based forwarding.

**Action** From configuration mode, enter the **show interfaces**, **show protocols**, **show security**, **show routing-instances**, and **show firewall** commands.

Verify that the output shows the intended configuration of the firewall filter, routing instances, interfaces, and policies.

Verify that the terms are listed in the order in which you want the packets to be tested. You can move terms within a firewall filter by using the **insert** command.

---

### Verifying Session Establishment on LAN Traffic

**Purpose** Verify that the sessions are established when traffic is transmitted on interfaces within the LAN.

**Action** To verify that sessions are established, perform the following tasks:

1. On device **R1**, from operational mode enter the **clear security flow session all** command to clear all existing security flow sessions.

2. On device **R0**, from operational mode enter the **ping** command to transmit traffic to device **Master-VR**.
3. On device **R1**, with traffic transmitting from devices **R0** through **R1**, from operational mode enter the **show security flow session** command.

**NOTE:** To verify established sessions, ensure that you enter the **show security flow session** command while the **ping** command is sending and receiving packets.

```
{device R0}
user@host> ping 1.1.1.1

PING 1.1.1.1 (1.1.1.1): 56 data bytes
64 bytes from 1.1.1.1: icmp_seq=0 ttl=63 time=2.208 ms
64 bytes from 1.1.1.1: icmp_seq=1 ttl=63 time=2.568 ms
64 bytes from 1.1.1.1: icmp_seq=2 ttl=63 time=2.573 ms
64 bytes from 1.1.1.1: icmp_seq=3 ttl=63 time=2.310 ms
64 bytes from 1.1.1.1: icmp_seq=4 ttl=63 time=1.566 ms
64 bytes from 1.1.1.1: icmp_seq=5 ttl=63 time=1.569 ms
...
```

```
{device R1}
user@host> show security flow session

0 sessions displayed
```

The output shows traffic transmitting from **R0** to **Master-VR** and no sessions are established. In this example, you applied the **bypass-flow-filter** with the **packet-mode** action modifier on interfaces **ge-0/0/0** and **lt-0/0/0.0** for your company's LAN traffic. This output verifies that the traffic between the two interfaces is correctly bypassing flow-based forwarding and hence no sessions are established.

### Verifying Session Establishment on Internet Traffic

**Purpose** Verify that sessions are established when traffic is transmitted to the Internet.

**Action** To verify that traffic to the Internet is using flow-based forwarding and sessions are established, perform the following tasks:

1. On device **R1**, from operational mode enter the **clear security flow session all** command to clear all existing security flow sessions.
2. On device **R0**, from operational mode enter the **ping** command to transmit traffic to device **R2**.
3. On device **R1**, with traffic transmitting from **R0** to **R2** through **R1**, from operational mode enter the **show security flow session** command.

```
root@host> show security flow session
Flow Sessions on FPC10 PIC1:
Total sessions: 0
```

Flow Sessions on FPC10 PIC2:  
Total sessions: 0

Flow Sessions on FPC10 PIC3:  
Total sessions: 0

**NOTE:** To verify established sessions, ensure that you enter the `show security flow session` command while the `ping` command is sending and receiving packets.

```
{device R0}
user@host> ping 60.0.0.1 -c 10

PING 60.0.0.1 (60.0.0.1) 56(84) bytes of data.
64 bytes from 60.0.0.1: icmp_seq=1 ttl=64 time=1.98 ms
64 bytes from 60.0.0.1: icmp_seq=2 ttl=64 time=1.94 ms
64 bytes from 60.0.0.1: icmp_seq=3 ttl=64 time=1.92 ms
64 bytes from 60.0.0.1: icmp_seq=4 ttl=64 time=1.89 ms

...

{device R1}
user@host> show security flow session

Session ID: 189900, Policy name: default-policy/2, Timeout: 2
 In: 9.9.9.9/0 --> 5.5.5.9/5924;icmp, If: lt-0/0/0.1
 Out: 5.5.5.9/5924 --> 9.9.9.9/0;icmp, If: ge-0/0/3.0

Session ID: 189901, Policy name: default-policy/2, Timeout: 2
 In: 9.9.9.9/1 --> 5.5.5.9/5924;icmp, If: lt-0/0/0.1
 Out: 5.5.5.9/5924 --> 9.9.9.9/1;icmp, If: ge-0/0/3.0

Session ID: 189902, Policy name: default-policy/2, Timeout: 4
 In: 9.9.9.9/2 --> 5.5.5.9/5924;icmp, If: lt-0/0/0.1
 Out: 5.5.5.9/5924 --> 9.9.9.9/2;icmp, If: ge-0/0/3.0

3 sessions displayed
```

The output shows traffic transmitting from devices **R0** to **R2** and established sessions. In this example, you did not apply the **bypass-flow-filter** with the **packet-mode** action modifier on routing instance **Internet-VR** for your company's Internet traffic. This output verifies that the traffic to the Internet is correctly using flow-based forwarding and hence sessions are established.

Note that sessions are established only when traffic is flowing between **lt-0/0/0.1** and **ge-0/0/3** and not when traffic is flowing between **ge-0/0/2** and **lt-0/0/0.0**.

## Security Configuration Statement Hierarchy

Use the statements in the **security** configuration hierarchy to configure actions, certificates, dynamic virtual private networks (VPNs), firewall authentication, flow, forwarding options, group VPNs, Intrusion Detection Prevention (IDP), Internet Key Exchange (IKE), Internet Protocol Security (IPsec), logging, Network Address Translation (NAT), public key infrastructure (PKI), policies, resource manager, rules, screens, secure shell known hosts, trace options, user identification, Unified Threat Management (UTM), and zones. Statements that are exclusive to the SRX Series devices running Junos OS are described in this section.

Each of the following topics lists the statements at a sub-hierarchy of the **[edit security]** hierarchy.

- [\[edit security address-book\] Hierarchy Level on page 634](#)

## aging

**Syntax**

```

aging {
 early-ageout seconds;
 high-watermark percent;
 low-watermark percent;
}

```

**Hierarchy Level** [edit security flow]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Direct the device to begin aggressively aging out sessions when the percentage of entries in the session table exceeds the high-watermark setting and then stops when the percentage of sessions falls below the low-watermark setting.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level**

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | Allow an incoming Domain Name Service (DNS) reply packet without a matched request. By default, if an incoming UDP first-packet has dst-port 53, the device checks the DNS message packet header to verify that the query bit (QR) is 0, which denotes a query message. If the QR bit is 1, which denotes a response message, the device drops the packet, does not create a session, and increments the illegal packet flow counter for the interface. Using the <b>allow-dns-reply</b> statement directs the device to skip the check. |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3X48-D10.                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Allow an embedded ICMP packet to pass through the device even when there is no session match. Once enabled, all packets encapsulated in ICMP pass through and no policy affects this behavior. This feature is useful when you have asymmetric routing in your network and you want to use traceroute and other ICMP applications on your device. |

| <b>Hierarchy Level</b>          | [edit security forwarding-process]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.6. Statement updated in Junos OS Release 10.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | <p>You can configure the device to switch from an integrated firewall mode to maximize IDP mode to increase the capacity of IDP processing with the <b>maximize-idp-sessions</b> option. When you maximize IDP, you are decoupling IDP processes from firewall processes, allowing the device to support the same number of firewall and IDP sessions.</p> <p>You can configure maximum ALG sessions by using the <b>maximize-alg-sessions</b> option. By default the session capacity number for RTSP, FTP, and TFTP ALG sessions is 10K per flow SPU. You must reboot the device (and its peer in chassis cluster mode) for the configuration to take effect. The <b>maximize-alg-sessions</b> option now enables you to increase defaults as follows:</p> <ul style="list-style-type: none"> <li>• RTSP, FTP, and TFTP ALG session capacity: 25K per flow SPU</li> <li>• TCP Proxy connection capacity: 40K per flow SPU</li> </ul> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <b>NOTE:</b> Flow session capacity will be reduced to half per flow SPU and that the above capacity numbers will not change on CP-flow.</p> </div> |
| <b>Options</b>                  | The remaining statements are explained separately. See <a href="#">CLI Explorer</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1X46-D10.                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>              | Configure the TCP session timeout in a half-closed state. This enables the system to apply the configured session timeout on receiving only one FIN packet (either client-to-server or server-to-client). When this statement is not configured, the default behavior takes effect—applying the configured TCP session timeout on receiving both the FIN packets. The default session timeout remains 150 seconds. |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                              |

## forwarding-process

---

**Syntax**

```
forwarding-process {
 application-services {
 maximize-alg-sessions;
 maximize-idp-sessions {
 inline-tap;
 weight (equal | firewall | idp);
 }
 packet-ordering-mode {
 (hardware | software);
 }
 }
}
```

**Hierarchy Level** [edit security]

**Release Information** Statement introduced in Junos OS Release 9.6.

**Description** If you are deploying IDP policies, you can tune the device to increase IDP session capacity. By using the provided commands to change the way the system allocates resources, you can achieve a higher IDP session capacity.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## fru-poweron-sequence

|                            |                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>fru-poweron-sequence <i>fru-poweron-sequence</i>;</code>                                                                |
| <b>Hierarchy Level</b>     | [edit chassis]                                                                                                                |
| <b>Release Information</b> | Statement introduced in Junos OS Release 12.1X44-D10.                                                                         |
| <b>Description</b>         | Configure the power-on sequence for FPCs installed in the chassis.                                                            |
| <b>Options</b>             | <b>fru-poweron-sequence</b> —Power-on sequence for the FPCs in the chassis. The numbers indicate the slot number of the FPCs. |

**NOTE:** If the power-on sequence is not configured by including the `fru-poweron-sequence` statement, Junos OS uses the ascending order of the the FPC slot numbers as the sequence for powering on the FPCs.

**NOTE:** The FPC online sequence is not dependent on the FPC power-on sequence.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | Enable and specify the TCP maximum segment size (TCP MSS) for Generic Routing Encapsulation (GRE) packets that are coming out from an IPsec VPN tunnel. If the device receives a GRE-encapsulated TCP packet with the SYN bit and TCP MSS option set and the TCP MSS option specified in the packet exceeds the TCP MSS specified by the device, the device modifies the TCP MSS value accordingly. By default, a TCP MSS for GRE packets is not set. |
| <b>Options</b>                  | <p><b>mss <i>value</i></b> —TCP MSS for GRE packets. Value is optional.</p> <p><b>Range:</b> 64 through 63535 bytes</p> <p><b>Default:</b> 1320 bytes, if no value is specified</p>                                                                                                                                                                                                                                                                   |
| <b>Required Privilege Level</b> | <p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                      |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.2.                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Enable IDP inline tap mode. The inline tap feature provides passive, inline detection of application layer threats for traffic matching security policies which have the IDP application service enabled. When a device is in inline tap mode, packets pass through firewall inspection and are also copied to the independent IDP module. |

## ipv6-extension-header

**Syntax** `ipv6-extension-header {`  
     `AH-header;`  
     `ESP-header`  
     `HIP-header;`  
     `destination-header {`  
         `ILNP-nonce-option;`  
         `home-address-option;`  
         `line-identification-option;`  
         `tunnel-encapsulation-limit-option;`  
         `user-defined-option-type low | <to high>;`  
     `}`  
     `fragment-header;`  
     `hop-by-hop-header {`  
         `CALIPSO-option;`  
         `RPL-option;`  
         `SFM-DPD-option;`  
         `jumbo-payload-option;`  
         `quick-start-option;`  
         `router-alert-option;`  
         `user-defined-option-type low | <to high>;`  
     `}`  
     `mobility-header;`  
     `no-next-header;`  
     `routing-header;`  
     `shim6-header`  
     `user-defined-option-type low | <to high>;`  
`}`

**Hierarchy Level** [edit security screen ids-option *screen-name* ip]

**Release Information** Statement introduced in Junos OS Release 12.1X46-D10.

**Description** Define the IPv6 extension header for the intrusion detection service (IDS).

**Options**

- AH-header**—Enable the IPv6 Authentication Header screen option.
- ESP-header**—Enable the IPv6 Encapsulating Security Payload header screen option.
- HIP-header**—Enable the IPv6 Host Identify Protocol header screen option.
- fragment-header**—Enable the IPv6 fragment header screen option.
- mobility-header**—Enable the IPv6 mobility header screen option.
- no-next-header**—Enable the IPv6 no next header screen option.
- routing-header**—Enable the IPv6 routing header screen option.
- shim6-header**—Enable the IPv6 shim header screen option.
- user-defined-header-type low | <to high>**—Define the type of header range.  
     **Range:** 0 through 255.

The remaining statements are explained separately. See [CLI Explorer](#).

| <b>Release Information</b> | Support on SRX Series devices for flow-based mode for family inet6 added in Junos OS Release 10.2.                                                                                                                                                  |
| <b>Description</b>         | Specify forwarding options for IPv6 traffic.                                                                                                                                                                                                        |
| <b>Options</b>             | <ul style="list-style-type: none"> <li>• <b>drop</b>—Drop IPv6 packets. This is the default setting.</li> <li>• <b>flow-based</b>—Perform flow-based packet forwarding.</li> <li>• <b>packet-based</b>—Perform simple packet forwarding.</li> </ul> |

**NOTE:** Packet-based processing is not supported on the following SRX Series devices: SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800.

If you change the forwarding option mode for IPv6, you might have to perform a reboot to initialize the configuration change. [Table 182](#) summarizes device status upon configuration change.

**Table 182: Device Status Upon Configuration Change**

| Configuration Change       | Commit Warning | Reboot Required | Impact on Existing Traffic Before Reboot | Impact on New Traffic Before Reboot |
|----------------------------|----------------|-----------------|------------------------------------------|-------------------------------------|
| Drop to flow-based         | Yes            | Yes             | Dropped                                  | Dropped                             |
| Drop to packet-based       | No             | No              | Packet-based                             | Packet-based                        |
| Flow-based to packet-based | Yes            | Yes             | None                                     | Flow sessions created               |
| Flow-based to drop         | Yes            | Yes             | None                                     | Flow sessions created               |
| Packet-based to flow-based | Yes            | Yes             | Packet-based                             | Packet-based                        |
| Packet-based to drop       | No             | No              | Dropped                                  | Dropped                             |

| <b>Description</b>              | Specify that the device does not check sequence numbers in TCP segments during stateful inspection. By default, the device monitors the sequence numbers in TCP segments. The device detects the window scale specified by source and destination hosts in a session and adjusts a window for an acceptable range of sequence numbers according to their specified parameters. The device then monitors the sequence numbers in packets sent between these hosts. If the device detects a sequence number outside this range, it drops the packet. |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Enable or disable the propagation of TCP/IP settings received on the device acting as Dynamic Host Configuration Protocol (DHCP) client. The settings can be propagated to the server pool running on the device. Use the <b>system services dhcp</b> statement to set this feature globally. Use the <b>system services dhcp pool</b> statement to set the feature for the address pool and override the global setting. |
| <b>Options</b>                  | <b>logical-interface-name</b> —Name of the logical interface to receive TCP/IP settings from the external network for propagation to the DHCP pool running on the device.                                                                                                                                                                                                                                                 |
| <b>Required Privilege Level</b> | system—To view this statement in the configuration.<br>system-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>              | Verify that the TCP sequence number in a TCP segment with the RST bit enabled matches the previous sequence number for a packet in that session or is the next higher number incrementally. If the sequence number does not match either of these expected numbers, the device drops the packet and sends the host a TCP ACK message with the correct sequence number. By default, this check is disabled. |

| <b>Description</b>         | Configure security tracing options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>             | <ul style="list-style-type: none"> <li><b>file</b>—Configure the trace file options. <ul style="list-style-type: none"> <li><b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. By default, the name of the file is the name of the process being traced.</li> <li><b>files number</b>—Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed to <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.</li> </ul> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> </li> <li><b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</li> <li><b>size maximum-file-size</b>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches this size, it is renamed <b>trace-file.0</b>. When the <b>trace-file</b> again reaches its maximum size, <b>trace-file.0</b> is renamed <b>trace-file.1</b> and <b>trace-file</b> is renamed <b>trace-file.0</b>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</li> </ul> <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the <b>files</b> option and a filename.</p> <p>Syntax: <b>x K</b> to specify KB, <b>x m</b> to specify MB, or <b>x g</b> to specify GB</p> <p>Range: 10 KB through 1 GB</p> |

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.
  - **all**—Trace all security events
  - **compilation**—Trace security compilation events
  - **configuration**—Trace security configuration events
  - **routing-socket**—Trace routing socket events
- **no-remote-trace**—Set remote tracing as disabled.
- **rate-limit *messages-per-second***—Limit the incoming rate of trace messages.

| <b>Syntax</b>              | <pre> traceoptions {   file {     filename;     files number;     match regular-expression;     size maximum-file-size;     (world-readable   no-world-readable);   }   flag flag;   no-remote-trace;   packet-filter filter-name {     destination-port port-identifier;     destination-prefix address;     interface interface-name;     protocol protocol-identifier;     source-port port-identifier;     source-prefix address;   }   rate-limit messages-per-second;   trace-level (brief   detail   error); } </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Hierarchy Level</b>     | [edit security flow]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Release Information</b> | Statement introduced in Junos OS Release 8.5. Statement updated in Junos OS Release 12.1X46-D10 with the <b>trace-level</b> option and additional flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>         | Configure flow tracing options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>             | <p><b>file</b>—Configure the trace file options.</p> <p><b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. By default, the name of the file is the name of the process being traced.</p> <p><b>files number</b>—Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed to <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option and a filename.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 10 files</p> <p><b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</p> <p><b>size maximum-file-size</b>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches this size, it is renamed <b>trace-file.0</b>. When the <b>trace-file</b> again reaches its maximum size,</p> |

***trace-file.0*** is renamed ***trace-file.1*** and ***trace-file*** is renamed ***trace-file.0***. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and a filename.

Syntax: **x k** to specify KB, **x m** to specify MB, or **x g** to specify GB

**Range:** 0 KB through 1 GB

**Default:** 128 KB

**world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.

**flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.

**all**—Trace with all flags enabled

**basic-datapath**—Trace basic packet flow activity

**fragmentation**—Trace IP fragmentation and reassembly events

**high-availability**—Trace flow high-availability information

**host-traffic**—Trace flow host traffic information

**multicast**—Trace multicast flow information

**route**—Trace route lookup information

**session**—Trace session creation and deletion events

**session-scan**—Trace session scan information

**tcp-basic**—Trace TCP packet flow information

**tunnel**—Trace tunnel information

**no-remote-trace**—Set remote tracing as disabled.

**packet-filter *filter-name***—Packet filter to enable during the tracing operation. Configure the filtering options.

**destination-port *port-identifier***—Match TCP/UDP destination port

**destination-prefix *address***—Destination IP address prefix

**interface *interface-name***—Logical interface

**protocol *protocol-identifier***—Match IP protocol type

**source-port *port-identifier***—Match TCP/UDP source port

**source-prefix *address***—Source IP address prefix

**rate-limit *messages-per-second***—Limit the incoming rate of trace messages.

**trace-level**—Set the level for trace logging. This option is available only when the flag is set.

**brief**—Trace key flow information, such as message types sent between SPU and central point, policy match, and packet drop reasons.

**detail**—Trace extensive flow information, such as detailed information about sessions and fragments. Detail is the default level.

**error**—Trace error information, such as system failure, unknown message type, and packet drop.

**Required Privilege Level** trace—To view this statement in the configuration.  
trace-control—To add this statement to the configuration.

## transport (Security Log)

**Syntax**

```
transport {
 protocol (udp | tcp | tls);
 tls-profile tls-profile-name;
 tcp-connections tcp-connections;
}
```

**Hierarchy Level** [edit security log]

**Release Information** Statement introduced in Junos OS Release 12.1X46-D25.

**Description** Configure security log transport options.

**Options** **protocol**—Specify the type of transport protocol to be used to log the data.

- **UDP**—Set the transport protocol to UDP.
- **TCP**—Set the transport protocol to TCP.
- **TLS**—Set the transport protocol to TLS.

**Default:** UDP.

**tls-profile *tls-profile-name***—Specify the TLS profile name.

**tcp-connections *tcp-connections***—Specify the number of TCP connections per SPU.

**Range:** 1 through 5.

**Default:** 1.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Release Information</b> | Statement introduced in Junos OS Release 9.6.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>         | <p>If you are deploying IDP policies, you can tune the device to increase IDP session capacity. By using the provided commands to change the way the system allocates resources, you can achieve a higher IDP session capacity.</p> <p>Devices ship with an implicit default session capacity setting. This default value gives more weight to firewall sessions. You can manually override the default by using the <b>maximize-idp-sessions</b> command. The command allows you to choose between these weight values: <b>equal</b>, <b>firewall</b>, and <b>idp</b>. The following table displays the available session capacity weight and approximate throughput for each.</p> |

**Table 184: Session Capacity and Resulting Throughput**

| Weight Value    | Firewall Capacity | IDP Capacity | Firewall Throughput | IDP Throughput |
|-----------------|-------------------|--------------|---------------------|----------------|
| Default         | 1,000,000         | 256,000      | 10 Gbps             | 2.4 Gbps       |
| <b>equal</b>    | 1,000,000         | 1,000,000    | 8.5 Gbps            | 2 Gbps         |
| <b>firewall</b> | 1,000,000         | 1,000,000    | 10 Gbps             | 2.4 Gbps       |
| <b>idp</b>      | 1,000,000         | 1,000,000    | 5.5 Gbps            | 1.4 Gbps       |

|                                 |                                                                                                                                                                                                                 |

## CHAPTER 93

# Operational Commands

- clear firewall
- clear monitor security flow filter
- clear security flow ip-action
- clear security flow session all
- clear security flow session application
- clear security flow session destination-port
- clear security flow session family
- clear security flow session interface
- clear security flow session protocol
- clear security flow session resource-manager
- clear security flow session services-offload
- clear security flow session session-identifier
- clear security flow session source-port
- clear security flow session source-prefix
- clear security forward-options mirror filter
- monitor security flow file
- monitor security flow filter
- monitor security flow start
- monitor security flow stop
- show chassis environment (Security)
- show chassis fpc (View)
- show chassis hardware (View)
- show chassis pic (Security)
- show chassis power
- show chassis power sequence
- show firewall (View)
- show interfaces (View Aggregated Ethernet)
- show interfaces (SRX Series)

| <div>  <p><b>NOTE:</b> The <code>clear firewall</code> command cannot be used to clear the Routing Engine filter counters on a backup Routing Engine that is enabled for GRES.</p> </div> <p>If you clear statistics for firewall filters that are applied to Trio-based DPCs and that also use the <code>prefix-action</code> action on matched packets, wait at least 5 seconds before you enter the <code>show firewall prefix-action-stats</code> command. A 5-second pause between issuing the <code>clear firewall</code> and <code>show firewall prefix-action-stats</code> commands avoids a possible timeout of the <code>show firewall prefix-action-stats</code> command.</p> |                                                                                                                                                                                                                                                                                                                                                   |
| Options                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <p><b>all</b>—Clear the packet and byte counts for all filters.</p> <p><b>counter <i>counter-name</i></b>—Clear the packet and byte counts for a filter counter that has been configured with the counter firewall filter action.</p> <p><b>filter <i>filter-name</i></b>—Clear the packet and byte counts for the specified firewall filter.</p> |

## Sample Output

clear firewall all

```
user@host> clear firewall all
```

## clear monitor security flow filter

---

**Syntax** clear monitor security flow filter <*filter-name*>

**Release Information** Command introduced in Junos OS Release 12.1X46-D10.

**Description** Specify the security flow filters to be deleted. Once deleted, the filters are removed from the Packet Forwarding Engine and the Routing Engine. .

**NOTE:** Specifying the filter name is optional. If no filter is specified, all filters are deleted.

**Options** This command has no options.

**Required Privilege Level** clear

**Related Documentation**

**Output Fields** When you enter this command, you are provided feedback on the status of your request.

## Sample Output

## clear security flow ip-action

---

**Syntax**    `clear security flow ip-action [filter]`

**Release Information**    Command introduced in Junos OS Release 10.4. Logical systems option introduced in Junos OS Release 11.2.

**Description**    Clear IP-action entries, based on filtered options, for IP sessions running on the device.

**Options**    *filter*—Filter the display based on the specified criteria.

The following filters display those sessions that match the criteria specified by the filter. Refer to the sample output for filtered output examples.

**all** | [*filter*]—All active sessions on the device.

**destination-port** *destination-port*—Destination port number of the traffic. Range is 1 through 65,535.

**destination-prefix** *destination-prefix*—Destination IP prefix or address.

**family** (*inet* | *inet6*) [*filter*]—IPv4 traffic or IPv6-NATPT traffic and filtered options.

**logical-system** *logical-system-name* | **all** [*filter*]—Specified logical system or all logical systems.

**protocol** *protocol-name* | *protocol-number* [*filter*]—Protocol name or number and filtered options.

- **ah** or 51
- **egp** or 8
- **esp** or 50
- **gre** or 47
- **icmp** or 1
- **icmp6** or 58
- **igmp** or 2
- **ipip** or 4
- **ospf** or 89
- **pim** or 103
- **rsvp** or 46
- **sctp** or 132
- **tcp** or 6
- **udp** or 17

**root-logical-system** [*filter*]  
—Default logical system information and filtered options.

**source-port** *source-port*  
—Source port number of the traffic. Range is 1 through 65,535.

**source-prefix** *source-prefix*  
—Source IP prefix or address of the traffic.

### Sample Output

#### clear security flow session all

```

user@host> clear security flow session all
node0:

1 active sessions cleared
node1:

0 active sessions cleared

```

### Sample Output

#### clear security flow session all node 0

```

user@host> clear security flow session all node 0
node0:

0 active sessions cleared

```

## clear security flow session application

### Sample Output

clear security flow session interface ge-0/0/0.0

```
user@host> clear security flow session interface ge-0/0/0.0
node0:

0 active sessions cleared
node1:

0 active sessions cleared
```

### Sample Output

clear security flow session interface ge-0/0/0.0 node 0

```
user@host> clear security flow session interface ge-0/0/0.0 node 0
node0:

0 active sessions cleared
```

## clear security flow session protocol

## Sample Output

### clear security flow session protocol pim

```
user@host> clear security flow session protocol pim
node0:

0 active sessions cleared
node1:

0 active sessions cleared
```

## Sample Output

### clear security flow session protocol 0

```
user@host> clear security flow session protocol 0
node0:

0 active sessions cleared
node1:

0 active sessions cleared
```

## clear security flow session resource-manager

### Sample Output

#### clear security flow session source-prefix 100.0.0.1

```

user@host> clear security flow session source-prefix 100.0.0.1
node0:

0 active sessions cleared
node1:

0 active sessions cleared

```

#### clear security flow session source-prefix 10::10

```

user@host> clear security flow session source-prefix 10::10
1 active sessions cleared

```

## Sample Output

clear security flow session source-prefix 100.0.0.1 node 0

```
user@host> clear security flow session source-prefix 100.0.0.1 node 0
node0:
```

```

0 active sessions cleared
```

## clear security forward-options mirror filter

---

|                                 |                                                                                                                                                                                                               |

| <b>Release Information</b>      | Command introduced in Junos OS Release 12.1X46-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Configure options for the security flow monitoring output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Options</b>                  | <p><b>filename</b>—Name of the file to receive the output of the monitoring operation. All output is saved in the <code>/var/log/</code> directory.</p> <p><b>files number</b>—Maximum number of output files. If you specify a maximum number of files, you must also specify a maximum file size with the <b>size</b> option.<br/>Range: 2 through 1000 files<br/><br/>Default: 10 files</p> <p><b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</p> <p><b>size maximum-file-size</b>—Maximum size of each output file. When an output file named <b>output</b> reaches this size, it is renamed <b>output.0</b>. When the output file again reaches its maximum size, <b>output.0</b> is renamed <b>output.1</b> and <b>output</b> file is renamed <b>output.0</b>. This renaming scheme continues until the maximum number of output files is reached. Then the oldest output file is overwritten.<br/><br/>If you specify a maximum file size, you also must specify a maximum number of output files with the <b>files</b> option.<br/><br/>Range: 10 KB through 1 GB<br/><br/>Default: 128 KB</p> <p><b>(world-readable   no-world-readable)</b>—By default, the output files can be accessed only by the user who configures the monitoring operation. The <b>world-readable</b> option enables all users to read the file. To explicitly set the default behavior, use the <b>no-world-readable</b> option.</p> |

**Output Fields** This command produces no output.

## monitor security flow filter

**Syntax** monitor security flow filter *filter-name*  
 <destination-port (*port-range* | *protocol-name*)>  
 <destination-prefix *destination-prefix*>  
 <interface *interface-name*>  
 <logical-system *logical-system-name*>  
 <protocol (*protocol name* | *protocol number*)>  
 <root-logical-system>  
 <source-port (*port-range* | *protocol-name*)>  
 <source-prefix *source-prefix*>

**Release Information** Command introduced in Junos OS Release 12.1X46-D10.

**Description** Set security flow filters to define flow sessions that you want to monitor. A maximum of 64 filters is supported at a time.

Defining the filters themselves does not trigger monitoring. You have to explicitly use the **monitor security flow start** command to enable monitoring. Once monitoring starts, any traffic that matches the specified filters is saved in an output file in the **/var/log/** directory.

**NOTE:** Unlike filters defined in the configuration mode, these filters defined using operational mode commands are cleared when you reboot your system.

- Options**
- filter *filter-name***—Specify a name for the filter. The filter name can contain letters, numbers, underscores (\_) and hyphens (-) and can be up to 64 characters long.
  - destination-port (*port-range* | *protocol-name*)**—Specify the TCP or UDP destination port to match. You can also specify a range of TCP or UDP destination ports and monitor all traffic in this group.
  - destination-prefix *destination-prefix***—Specify the destination IPv4 or IPv6 address prefix to match.
  - interface *interface-name***—Specify the logical interface name to match.
  - logical-system *logical-system-name***—Specify the logical system name to match.
  - protocol (*protocol name* | *protocol number*)**—Specify the IP protocol type to match.
  - root-logical-system**—(Default) Specify the root logical system to match.
  - source-port (*port-range* | *protocol-name*)**—Specify the TCP or UDP source port to match. You can also specify a range of TCP or UDP source ports and monitor all traffic in this group.
  - source-prefix *source-prefix***—Specify the source IP address prefix to match.

| <b>Syntax</b>                   | monitor security flow start                                                                                                                                                                                                                                                                                                                                  |
| <b>Release Information</b>      | Command introduced in Junos OS Release 12.1X46-D10.                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | <p>Start the monitoring of security flow session. Once monitoring starts, any traffic that matches the specified filters is saved in an output file in the <b>var/log/</b> directory. At least one filter must be defined for the monitoring to start.</p> <p>Use the <b>monitor security flow stop</b> command to stop the monitoring of flow sessions.</p> |
| <b>Options</b>                  | This command has no options.                                                                                                                                                                                                                                                                                                                                 |

| <b>Output Fields</b>            | Table 185 lists the output fields for the <b>show chassis environment</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 185: show chassis environment Output Fields

| Field Name | Field Description                                                                                    |
|------------|------------------------------------------------------------------------------------------------------|
| Temp       | Temperature of air flowing through the chassis in degrees Celsius (C) and Fahrenheit (F).            |
| Fan        | Fan status: <b>OK</b> , <b>Testing</b> (during initial power-on), <b>Failed</b> , or <b>Absent</b> . |

## Sample Output

### show chassis environment

```

user@host> show chassis environment
user@host> show chassis environment
Class Item Status Measurement
Temp PEM 0 OK 40 degrees C / 104 degrees F
 PEM 1 OK 40 degrees C / 104 degrees F
 PEM 2 OK 40 degrees C / 104 degrees F

```

|                      |        |                              |
|----------------------|--------|------------------------------|
| PEM 3                | OK     | 45 degrees C / 113 degrees F |
| Routing Engine 0     | OK     | 31 degrees C / 87 degrees F  |
| Routing Engine 0 CPU | OK     | 27 degrees C / 80 degrees F  |
| Routing Engine 1     | Absent |                              |
| Routing Engine 1 CPU | Absent |                              |
| CB 0 Intake          | OK     | 28 degrees C / 82 degrees F  |
| CB 0 Exhaust A       | OK     | 27 degrees C / 80 degrees F  |
| CB 0 Exhaust B       | OK     | 29 degrees C / 84 degrees F  |
| CB 0 ACBC            | OK     | 29 degrees C / 84 degrees F  |

## show chassis fpc (View)

**Syntax** `show chassis fpc`  
`<detail < fpc-slot >| <node ( node-id | local | primary)>> |`  
`<node ( node-id | local | primary)> |`  
`<pic-status < fpc-slot >| <node ( node-id | local | primary)>>`

**Release Information** Command modified in Junos OS Release 9.2.  
 Starting with Junos OS Release 15.1X49-D10, the SRX5K-MPC3-100G10G (IOC3) and the SRX5K-MPC3-40G10G (IOC3) are introduced.

**NOTE:** On SRX5K-MPC3-40G10G (IOC3), all four PICs cannot be powered on. A maximum of two PICs can be powered on at the same time. By default, PIC0 and PIC1 are online.

Use the **set chassis fpc <slot> pic <pic> power off** command to choose the PICs you want to power on.

When you use the **set chassis fpc <slot> pic <pic> power off** command to power off PIC0 and PIC1, PIC2 and PIC3 are automatically turned on.

When you switch from one set of PICs to another set of PICs using the **set chassis fpc <slot> pic <pic> power off** command again, ensure that there is 60 seconds duration between the two actions, otherwise core files are seen during the configuration.

The [Table 186](#) summarizes the SRX5K-MPC3-40G10G (IOC3) PICs selected for various configuration scenarios.

**Table 186: SRX5K-MPC3-40G10G (IOC3) PIC Selection Summary**

| CLI Configuration                   | PIC Selection                                 |
|-------------------------------------|-----------------------------------------------|
| Default (i.e. no CLI configuration) | Online: PIC-0, PIC-1<br>Offline: PIC-2, PIC-3 |
| PIC-1, PIC-2 and PIC-3 powered OFF  | Online: PIC-0<br>Offline: PIC-1, PIC-2, PIC-3 |
| PIC-0, PIC-2 and PIC-3 powered OFF  | Online: PIC-1<br>Offline: PIC-0, PIC-2, PIC-3 |
| PIC-0, PIC-1 and PIC-3 powered OFF  | Online: PIC-2<br>Offline: PIC-0, PIC-1, PIC-3 |
| PIC-0, PIC-1 and PIC-2 powered OFF  | Online: PIC-3<br>Offline: PIC-0, PIC-1, PIC-2 |

**Description** Display status information about the installed Flexible PIC Concentrators (FPCs) and PICs.

- Options**
- **none**—Display status information for all FPCs.
  - **detail**—(Optional) Display detailed FPC status information.
  - **fpc-slot** —(Optional) Display information about the FPC in this slot.
  - **node**—(Optional) For chassis cluster configurations, display status information for all FPCs or for the specified FPC on a specific node (device) in the cluster.
    - **node-id** —Identification number of the node. It can be 0 or 1.
    - **local**—Display information about the local node.
    - **primary**—Display information about the primary node.

- **pic-status**—(Optional) Display status information for all FPCs or for the FPC in the specified slot (see *fpc-slot*).

**Output Fields** [Table 187](#) lists the output fields for the **show chassis fpc** command. Output fields are listed in the approximate order in which they appear.

**Table 187: show chassis fpc Output Fields**

| Field Name         | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slot or Slot State | <p>Slot number and state. The state can be one of the following conditions:</p> <ul style="list-style-type: none"> <li>• <b>Dead</b>—Held in reset because of errors.</li> <li>• <b>Diag</b>—Slot is being ignored while the device is running diagnostics.</li> <li>• <b>Dormant</b>—Held in reset.</li> <li>• <b>Empty</b>—No FPC is present.</li> <li>• <b>Online</b>—FPC is online and running.</li> <li>• <b>Present</b>—FPC is detected by the device, but is either not supported by the current version of Junos OS or inserted in the wrong slot. The output also states either <b>Hardware Not Supported</b> or <b>Hardware Not In Right Slot</b>. FPC is coming up but not yet online.</li> <li>• <b>Probed</b>—Probe is complete; awaiting restart of the Packet Forwarding Engine (PFE).</li> <li>• <b>Probe-wait</b>—Waiting to be probed.</li> </ul> |

Table 187: show chassis fpc Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Temp (C) or Temperature       | Temperature of the air passing by the FPC, in degrees Celsius or in both Celsius and Fahrenheit.                                                               |
| Total CPU Utilization (%)     | Total percentage of CPU being used by the FPC's processor.                                                                                                     |
| Interrupt CPU Utilization (%) | Of the total CPU being used by the FPC's processor, the percentage being used for interrupts.                                                                  |
| Memory DRAM (MB)              | Total DRAM, in megabytes, available to the FPC's processor.                                                                                                    |
| Heap Utilization (%)          | Percentage of heap space (dynamic memory) being used by the FPC's processor. If this number exceeds 80 percent, there may be a software problem (memory leak). |
| Buffer Utilization (%)        | Percentage of buffer space being used by the FPC's processor for buffering internal messages.                                                                  |
| Start Time                    | Time when the Routing Engine detected that the FPC was running.                                                                                                |
| Uptime                        | How long the Routing Engine has been connected to the FPC and, therefore, how long the FPC has been up and running.                                            |
| PIC type                      | (pic-status output only) Type of FPC.                                                                                                                          |
