| <b>Description</b>              | Establish the graceful restart duration for multicast snooping. You can set this value between 0 and 300 seconds. If you set the duration to 0, graceful restart is effectively disabled. Set this value slightly larger than the IGMP query response interval.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Default</b>                  | 180 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## group (Protocols MSDP)

```
Syntax group group-name {
 disable;
 export [policy-names];
 import [policy-names];
 local-address address;
 mode (mesh-group | standard);
 traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
 }
 peer address; {
 disable;
 active-source-limit {
 maximum number;
 threshold number;
 }
 authentication-key peer-key;
 default-peer;
 export [policy-names];
 import [policy-names];
 local-address address;
 traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
 }
 }
 }
```

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols [msdp](#)],  
 [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols  
[msdp](#)],  
 [edit protocols [msdp](#)],  
 [edit routing-instances *routing-instance-name* protocols [msdp](#)]

**Release Information** Statement introduced before Junos OS Release 7.4.  
 Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Define an MSDP peer group. MSDP peers within groups share common tracing options, if present and not overridden for an individual peer with the [peer](#) statement. To configure multiple MSDP groups, include multiple **group** statements.

By default, the group's options are identical to the global MSDP options. To override the global options, include group-specific options within the **group** statement.

The group must contain at least one peer.

**Options** *group-name*—Name of the MSDP group.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

**Related Documentation** • [Example: Configuring MSDP in a Routing Instance on page 4574](#)

## group (RPF Selection)

**Syntax**

```
group group-address{
 source source-address{
 next-hop next-hop-address;
 }
 wildcard-source {
 next-hop next-hop-address;
 }
}
```

**Hierarchy Level** [edit routing-instances *routing-instance-name* edit protocols pim rpf-selection]

**Release Information** Statement introduced in JUNOS Release 10.4.  
Statement introduced in Junos OS Release 11.3 for the QFX Series.

**Description** Configure the PIM group address for which you configure RPF selection [group \(RPF Selection\)](#).

**Default** By default, PIM RPF selection is not configured.

**Options** *group-address*—PIM group address for which you configure RPF selection.

**Required Privilege Level** view-level—To view this statement in the configuration.  
control-level—To add this statement to the configuration.

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols],  
[edit protocols]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Enable IGMP on the router. IGMP must be enabled for the router to receive multicast packets.

The remaining statements are explained separately.

**Default** IGMP is disabled on the router. IGMP is automatically enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP).

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

| <b>Description</b>         | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |

**NOTE:** Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

| <b>Description</b>              | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>The immediate leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |
|                                 | <p> <b>NOTE:</b> Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b>              | <p>The immediate leave setting is useful for minimizing the leave latency of MLD memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows MLD to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending MLD group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the MLD leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both MLD version 1 and MLD version 2.</p> |
|                                 | <div>  <p><b>NOTE:</b> Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | Apply one or more policies to routes being imported into the routing table from DVMRP. If you specify more than one policy, they are evaluated in the order specified, from first to last, and the first matching policy is applied to the route. If no match is found, DVMRP shares with the routing table only those routes that were learned from DVMRP routers. |
| <b>Options</b>                  | <i>policy-names</i> —Name of one or more policies.                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b>         | Enable PIM on an interface and configure interface-specific properties.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Options** *interface-name*—Name of the interface. Specify the full interface name, including the physical and logical address components. To configure all interfaces, you can specify **all**.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## interface (Routing Options)

**Syntax**

```
interface interface-names {
 maximum-bandwidth bps;
 no-qos-adjust;
 reverse-oif-mapping {
 no-qos-adjust;
 }
 subscriber-leave-timer seconds;
}
```

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options **multicast**],  
[edit logical-systems *logical-system-name* routing-options **multicast**],  
[edit routing-instances *routing-instance-name* routing-options **multicast**],  
[edit routing-options **multicast**]

**Release Information** Statement introduced in Junos OS Release 8.3.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.3 for the QFX Series.

**Description** Enable multicast traffic on an interface.

**TIP:** You cannot enable multicast traffic on an interface by using the **routing-options multicast** interface statement and configure PIM on the interface.

**Options** *interface-name*—Names of the physical or logical interface.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Specify the local unique IP address to send in Automatic Multicast Tunneling (AMT) relay advertisement messages, for use as the IP source of AMT control messages, and as the source of the data tunnel encapsulation. The address can be configured on any interface in the system. Typically, the router's <b>lo0.0</b> loopback address is used for configuring the AMT local address in the default routing instance, and the router's <b>lo0.n</b> loopback address is used for configuring the AMT local address in VPN routing instances. |
| <b>Default</b>                  | None. The local address must be configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Options</b>                  | <i>ip-address</i> —Unique unicast IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b>              | <p>Specify loose authentication checking on the BFD session. Use loose authentication for transitional periods only when authentication might not be configured at both ends of the BFD session.</p> <p>By default, strict authentication is enabled and authentication is checked at both ends of each BFD session. Optionally, to smooth migration from nonauthenticated sessions to authenticated sessions, you can configure <i>loose checking</i>. When loose checking is configured, packets are accepted without authentication being checked at each end of the session.</p> |

```

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols],  
[edit protocols]

**Release Information** Statement introduced before Junos OS Release 7.4.

**Description** Enable MLD on the router. MLD must be enabled for the router to receive multicast packets.

**Default** MLD is disabled on the router. MLD is automatically enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP).

**Options** The statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## mode (Protocols DVMRP)

---

**Syntax** mode (forwarding | unicast-routing);

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols [dvmrp interface interface-name](#)],  
[edit protocols [dvmrp interface interface-name](#)]

**Release Information** Statement introduced before Junos OS Release 7.4.

**Description** Configure DVMRP for multicast traffic forwarding or unicast routing.

**Options** **forwarding**—DVMRP performs unicast routing as well as multicast data forwarding.

**unicast-routing**—DVMRP performs unicast routing only. To forward multicast data, you must configure Protocol Independent Multicast (PIM) on the interface.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

**Related Documentation**

 flag flag <disable>;
 }
 }

```

**Hierarchy Level** [edit dynamic-profiles *profile-name* routing-options],  
 [edit dynamic-profiles *profile-name* routing-instances *routing-instance-name* routing-options],

```
[edit logical-systems logical-system-name routing-instances routing-instance-name
 routing-options],
[edit logical-systems logical-system-name routing-options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

**NOTE:** You cannot apply a scope policy to a specific routing instance. That is, all scoping policies are applied to all routing instances. However, the `scope` statement does apply individually to a specific routing instance.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | Provide multicast snooping for multichassis link aggregation group interfaces. Replicate IGMP join and leave messages from the active link to the standby link of a dual-link multichassis link aggregation group interface, enabling faster recovery of membership information after failover.                                                                                                                                                                                                                         |
| <b>Default</b>                  | If not included, membership information is recovered using a standard IGMP network query.                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Release Information</b> | Statement introduced in Junos OS Release 12.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>         | <p>Disable forwarding for bidirectional PIM routes during graceful restart recovery, both in cases of a routing protocol process (rpd) restart and graceful Routing Engine switchover.</p> <p>Bidirectional PIM accepts packets for a bidirectional route on multiple interfaces. This means that some topologies might develop multicast routing loops if all PIM neighbors are not synchronized with regard to the identity of the designated forwarder (DF) on each link. If one router is forwarding without actively participating in DF elections, particularly after unicast routing changes, multicast routing loops might occur.</p> <p>If graceful restart for PIM is enabled and the forwarding of packets on bidirectional routes is disallowed (by including the <b>no-bidirectional-mode</b> statement in the configuration), PIM behaves conservatively to avoid multicast routing loops during the recovery period. When the routing protocol process (rpd) restarts, all bidirectional routes are deleted. After graceful restart has completed, the routes are re-added, based on the converged unicast and bidirectional PIM state. While graceful restart is active, bidirectional multicast flows drop packets.</p> |
| <b>Default</b>             | If graceful restart for PIM is enabled and the bidirectional PIM is enabled, the default graceful restart behavior is to continue forwarding packets on bidirectional routes. If the gracefully restarting router was serving as a DF for some interfaces to rendezvous points, the restarting router sends a DF Winner message with a metric of 0 on each of these RP interfaces. This ensures that a neighbor router does not become the DF due to unicast topology changes that might occur during the graceful restart period. Sending a DF Winner message with a metric of 0 prevents another PIM neighbor from assuming the DF role until after graceful restart completes. When graceful restart completes, the gracefully restarted router sends another DF Winner message with the actual converged unicast metric.                                                                                                                                                                                                                                                                                                                                                                                                             |

**NOTE:** Graceful Routing Engine switchover operates independently of the graceful restart behavior. If graceful Routing Engine switchover is configured without graceful restart, all PIM routes for all modes are deleted when the rpd process restarts. If graceful Routing Engine switchover is configured with graceful restart, the behavior is the same as described here, except that the recovery happens on the Routing Engine that assumes mastership.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

**Release Information** Statement introduced in Junos OS Release 9.5.  
Statement introduced in Junos OS Release 9.5 for EX Series switches.  
Statement added to [edit routing-instances *routing-instance-name* routing-options **multicast interface** *interface-name*], [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options **multicast interface** *interface-name*], and [edit routing-options **multicast interface** *interface-name*] hierarchy levels in Junos OS Release 9.6.  
Statement introduced in Junos OS Release 11.3 for the QFX Series.

**Description** Disable hierarchical bandwidth adjustment for all subscriber interfaces that are identified by their MLD or IGMP request from a specific multicast interface.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Configure the designated forwarder (DF) election offer period for bidirectional PIM. When a DF election Offer or Winner message fails to be received, the message is retransmitted. The <b>offer-period</b> statement modifies the interval between repeated DF election messages. The <b>robustness-count</b> statement determines the minimum number of DF election messages that must fail to be received for DF election to fail. To prevent routing loops, all routers on the link must have a consistent view of the DF. When the DF election fails because DF election messages are not received, forwarding on bidirectional PIM routes is suspended.</p> <p>If a router receives from a neighbor a better offer than its own, the router stops participating in the election for a period of <b>robustness-count</b> * <b>offer-period</b>. Eventually, all routers except the best candidate stop sending Offer messages.</p> |
| <b>Options</b>                  | <p><b>milliseconds</b>—Interval to wait before retransmitting DF Offer and Winner messages.</p> <p><b>Range:</b> 100 through 10,000 milliseconds</p> <p><b>Default:</b> 100</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | When you configure both static RP mapping and dynamic RP mapping (such as auto-RP) in a single routing instance, allow the static mapping to take precedence for a given group range, and allow dynamic RP mapping for all other groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b>              | Set the maximum time in milliseconds to delay sending override join messages for a multicast network that has join suppression enabled. When a router or switch sees a prune message for a join it is currently suppressing, it waits for the interval specified by the override timer before it sends an override join message.                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b>              | <p>Define an MSDP peering relationship. An MSDP router must know which routers are its peers. You define the peer relationships explicitly by configuring the neighboring routers that are the MSDP peers of the local router. After peer relationships are established, the MSDP peers exchange messages to advertise active multicast sources. To configure multiple MSDP peers, include multiple <b>peer</b> statements.</p> <p>By default, the peer's options are identical to the global or group-level MSDP options. To override the global or group-level options, include peer-specific options within the <b>peer</b> statement.</p> <p>At least one peer must be configured for MSDP to function. You must configure <b>address</b> and <b>local-address</b>.</p> |
| <b>Options</b>                  | <p><b>address</b>—Name of the MSDP peer.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b>              | <p>Configure the rendezvous point (RP) routing device that resides between a customer edge-facing Protocol Independent Multicast (PIM) domain and a core-facing PIM domain to translate PIM join or prune messages into corresponding Internet Group Management Protocol (IGMP) report or leave messages. The routing device then transmits the report or leave messages by proxying them to one or two upstream interfaces that you configure on the RP routing device. Including the <b>pim-to-igmp-proxy</b> statement enables you to use IGMP to forward IPv4 multicast traffic across the PIM sparse mode domains.</p> <p>The remaining statement is explained separately.</p> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b>              | <p>Configure the rendezvous point (RP) routing device that resides between a customer edge-facing Protocol Independent Multicast (PIM) domain and a core-facing PIM domain to translate PIM join or prune messages into corresponding Multicast Listener Discovery (MLD) report or leave messages. The routing device then transmits the report or leave messages by proxying them to one or two upstream interfaces that you configure on the RP routing device. Including the <b>pim-to-mld-proxy</b> statement enables you to use MLD to forward IPv6 multicast traffic across the PIM sparse mode domains.</p> <p>The remaining statement is explained separately.</p> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | Set a delay for implementing a PIM prune message on the upstream router on a multicast network for which join suppression has been enabled. The router waits for the prune pending period to detect whether a join message is currently being suppressed by another router.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b>              | <p>Change the value of a tracking bit (T-bit) field in the LAN prune delay hello option from the default of 1 to 0, which enables join suppression for a multicast interface. When the network starts receiving multiple identical join messages, join suppression triggers a random timer with a value of 66 through 84 milliseconds (<math>1.1 \times</math> periodic through <math>1.4 \times</math> periodic, where periodic is 60 seconds). This creates an interval during which no identical join messages are sent. Eventually, only one of the identical messages is sent. Join suppression is triggered each time identical messages are sent for the same join.</p>                                                          |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | <p>Configure the designated forwarder (DF) election robustness count for bidirectional PIM. When a DF election Offer or Winner message fails to be received, the message is retransmitted. The <b>robustness-count</b> statement sets the minimum number of DF election messages that must fail to be received for DF election to fail. To prevent routing loops, all routers on the link must have a consistent view of the DF. When the DF election fails because DF election messages are not received, forwarding on bidirectional PIM routes is suspended.</p> <p>If a router receives from a neighbor a better offer than its own, the router stops participating in the election for a period of <b>robustness-count</b> * <b>offer-period</b>. Eventually, all routers except the best candidate stop sending Offer messages.</p> |
| <b>Options</b>                  | <p><b><i>number</i></b>—Number of transmission attempts for DF election messages.</p> <p><b>Range:</b> 1 through 10</p> <p><b>Default:</b> 3</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## scope-policy

**Syntax** `scope-policy [ policy-names ];`

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-options **multicast**],  
[edit routing-options **multicast**]

**NOTE:** You can configure a scope policy at these two hierarchy levels only. You cannot apply a scope policy to a specific routing instance, because all scoping policies are applied to all routing instances. However, you can apply the scope statement to a specific routing instance at the [edit routing-instances *routing-instance-name* routing-options **multicast**] or [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options **multicast**] hierarchy level.

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.3 for the QFX Series.

**Description** Apply policies for scoping. The policy must be correctly configured at the **edit policy-options policy-statement** hierarchy level.

**Options** *policy-names*—Name of one or more multicast scope policies.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.0.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Statement introduced in Junos OS Release 11.3 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | Set the SPT threshold to infinity for a source-group address pair. Last-hop multicast routing devices running PIM sparse mode can forward the same stream of multicast packets onto the same LAN through an RPT rooted at the RP or an SPT rooted at the source. By default, last-hop routing devices transition to a direct SPT to the source. You can configure this routing device to set the SPT transition value to infinity to prevent this transition for any source-group address pair.<br><br>The remaining statements are explained separately. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b>              | <p>Configure source-specific multicast (SSM) groups.</p> <p>By default, the SSM group multicast address is limited to the IP address range from 232.0.0.0 through 232.255.255.255. However, you can extend SSM operations into another Class D range by including the <b>ssm-groups</b> statement in the configuration. The default SSM address range from 232.0.0.0 through 232.255.255.255 cannot be used in the <b>ssm-groups</b> statement. This statement is for adding other multicast addresses to the default SSM group addresses. This statement does not override the default SSM group address range.</p> <p>IGMPv3 supports SSM groups. By utilizing inclusion lists, only sources that are specified send to the SSM group.</p> |
| <b>Options</b>                  | <i>ip-addresses</i> —List of one or more additional SSM group addresses separated by a space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## static (Protocols MLD)

**Syntax**

```
static {
 group multicast-group-address {
 exclude;
 group-count number;
 group-increment increment;
 source ip-address {
 source-count number;
 source-increment increment;
 }
 }
}
```

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols **mld interface** *interface-name*],  
[edit protocols **mld interface** *interface-name*]

**Release Information** Statement introduced before Junos OS Release 7.4.

**Description** Test multicast forwarding on an interface.

The **static** statement simulates MLD joins on a routing device statically on an interface without any MLD hosts. It is supported for both MLDv1 and MLDv2 joins. This statement is especially useful for testing multicast forwarding on an interface without a receiver host.

**NOTE:** To prevent joining too many groups accidentally, the **static** statement is not supported with the **interface all** statement.

The remaining statements are explained separately.

**Required Privilege Level** routing and trace—To view this statement in the configuration.  
routing-control and trace-control—To add this statement to the configuration.

## static (Protocols IGMP)

```
Syntax static {
 group multicast-group-address {
 exclude;
 group-count number;
 group-increment increment;
 source ip-address {
 source-count number;
 source-increment increment;
 }
 }
 }
```

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols **igmp interface** *interface-name*],  
[edit protocols **igmp interface** *interface-name*]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Test multicast forwarding on an interface without a receiver host.

The **static** statement simulates IGMP joins on a routing device statically on an interface without any IGMP hosts. It is supported for both IGMPv2 and IGMPv3 joins. This statement is especially useful for testing multicast forwarding on an interface without a receiver host.

**NOTE:** To prevent joining too many groups accidentally, the **static** statement is not supported with the **interface all** statement.

The remaining statements are explained separately.

**Required Privilege Level** routing and trace—To view this statement in the configuration.  
routing-control and trace-control—To add this statement to the configuration.

## threshold (PIM BFD Detection Time)

|                            |                                                                                                                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>threshold <i>milliseconds</i>;</code>                                                                                                                                                                                                                      |
| <b>Hierarchy Level</b>     | [edit protocols pim interface <i>interface-name</i> bfd-liveness-detection detection-time],<br>[edit routing-instances <i>routing-instance-name</i> protocols pim interface <i>interface-name</i> bfd-liveness-detection detection-time]                         |
| <b>Release Information</b> | Statement introduced in Junos OS Release 8.2.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Support for BFD authentication introduced in Junos OS Release 9.6.<br>Statement introduced in Junos OS Release 12.1 for the QFX Series. |
| <b>Description</b>         | Specify the threshold for the adaptation of the BFD session detection time. When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.                                            |

**NOTE:** The threshold value must be equal to or greater than the transmit interval.

The threshold time must be equal to or greater than the value specified in the [minimum-interval](#) or the [minimum-receive-interval](#) statement.

| <b>Default</b>             | Tracing operations are disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. One use of this option is to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>name</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. We recommend that you place multicast snooping tracing output in the file <code>/var/log/multicast-snooping-log</code>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then, the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 1 trace file only</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p>The following are the tracing options:</p> <ul style="list-style-type: none"> <li>• <b>all</b>—All tracing operations</li> <li>• <b>config-internal</b>—Trace configuration internals.</li> <li>• <b>general</b>—Trace general events.</li> <li>• <b>normal</b>—All normal events.</li> </ul> <p><b>Default:</b> If you do not specify this option, only unusual or abnormal operations are traced.</p> <ul style="list-style-type: none"> <li>• <b>parse</b>—Trace configuration parsing.</li> <li>• <b>policy</b>—Trace policy operations and actions.</li> </ul> |

- **route**—Trace routing table changes.
- **state**—Trace state transitions.
- **task**—Trace protocol task processing.
- **timer**—Trace protocol task timer processing.

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB) or megabytes (MB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Release Information</b> | Statement introduced in Junos OS Release 10.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>         | <p>Configure Automatic Multicast Tunneling (AMT) tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the file <b>igmp-log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b><i>trace-file</i></b> reaches its maximum size, it is renamed <b><i>trace-file.0</i></b>, then <b><i>trace-file.1</i></b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b><i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>AMT Tracing Flags</b></p> <ul style="list-style-type: none"> <li>• <b>errors</b>—All error conditions</li> <li>• <b>packets</b>—All AMT packets</li> <li>• <b>tunnels</b>—All AMT tunnel-related information</li> </ul> <p><b>Global Tracing Flags</b></p> <ul style="list-style-type: none"> <li>• <b>all</b>—All tracing operations</li> </ul> |

- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>         | <p>Configure DVMRP tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Default</b>             | The default DVMRP trace options are those inherited from the routing protocols <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the <b>dvmrp-log</b> file.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>DVMRP Tracing Flags</b></p> <ul style="list-style-type: none"> <li>• <b>all</b>—All tracing operations</li> <li>• <b>general</b>—A combination of the <b>normal</b> and <b>route</b> trace operations</li> <li>• <b>graft</b>—Graft messages</li> <li>• <b>neighbor</b>—Neighbor probe messages</li> <li>• <b>normal</b>—All normal operations</li> </ul> |

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **packets**—All DVMRP packets
- **poison**—Poison-route-reverse packets
- **probe**—Probe packets
- **prune**—Prune messages
- **report**—DVMRP route report packets
- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

***flag-modifier***—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file.0***. When ***trace-file*** again reaches this size, ***trace-file.0*** is renamed ***trace-file.1*** and ***trace-file*** is renamed ***trace-file.0***. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Description</b>         | <p>Configure IGMP tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p>To trace the paths of multicast packets, use the <b>mtrace</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>             | The default IGMP trace options are those inherited from the routing protocols <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the file <b>igmp-log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>IGMP Tracing Flags</b></p> <ul style="list-style-type: none"> <li><b>leave</b>—Leave group messages (for IGMP version 2 only).</li> <li><b>mtrace</b>—Mtrace packets. Use the <b>mtrace</b> command to troubleshoot the software.</li> <li><b>packets</b>—All IGMP packets.</li> </ul> |

- **query**—IGMP membership query messages, including general and group-specific queries.
- **report**—Membership report messages.

#### Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Release Information</b> | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>         | Define tracing operations for IGMP snooping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default</b>             | The <b>traceoptions</b> feature is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. All files are placed in the directory <b>/var/log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached (<b>xk</b> to specify KB, <b>xm</b> to specify MB, or <b>xg</b> to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 3 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> <li>• <b>all</b>—All tracing operations.</li> <li>• <b>client-notification</b>—Trace notifications.</li> <li>• <b>general</b>—Trace general IGMP snooping protocol events.</li> <li>• <b>group</b>—Trace group operations.</li> <li>• <b>host-notification</b>—Trace host notifications.</li> <li>• <b>leave</b>—Trace leave group messages (IGMPv2 only).</li> <li>• <b>normal</b>—Trace normal IGMP snooping protocol events.</li> <li>• <b>packets</b>—Trace all IGMP packets.</li> </ul> |

- **policy**—Trace policy processing.
- **query**—Trace IGMP membership query messages.
- **report**—Trace membership report messages.
- **route**—Trace routing information.
- **state**—Trace IGMP state transitions.
- **task**—Trace routing protocol task processing.
- **timer**—Trace routing protocol timer processing.

**no-world-readable**—(Optional) Restrict file access to the user who created the file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the **files** option.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify gigabytes

**Range:** 10 KB through 1 gigabytes

**Default:** 128 KB

**world-readable**—(Optional) Enable unrestricted file access.

|                           |                                                             |
|---------------------------|-------------------------------------------------------------|
| <b>Required Privilege</b> | routing—To view this statement in the configuration.        |
| <b>Level</b>              | routing-control—To add this statement to the configuration. |

|                              |                                                                                                                                                                                               |

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>         | <p>Configure MLD tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p>To trace the paths of multicast packets, use the <b>mtrace</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>             | The default MLD trace options are those inherited from the <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the file <b>mld-log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>MLD Tracing Flags</b></p> <ul style="list-style-type: none"> <li>• <b>leave</b>—Leave group messages.</li> <li>• <b>mtrace</b>—Mtrace packets. Use the <b>mtrace</b> command to troubleshoot the software.</li> <li>• <b>packets</b>—All MLD packets.</li> <li>• <b>query</b>—MLD membership query messages, including general and group-specific queries.</li> </ul> |

- **report**—Membership report messages.

#### Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—Traces errors and significant events during normal packet processing

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Release Information</b> | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 12.1 for the QFX Series.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>         | <p>Configure MSDP tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Default</b>             | <p>The default MSDP trace options are those inherited from the routing protocol's <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the <b>msdp-log</b> file.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

**Range:** 2 through 1000 files

**Default:** 2 files

**flag *flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

#### MSDP Tracing Flags

- **keepalive**—Keepalive messages
- **packets**—All MSDP packets
- **route**—MSDP changes to the routing table
- **source-active**—Source-active packets
- **source-active-request**—Source-active request packets
- **source-active-response**—Source-active response packets

#### Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

***flag-modifier***—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow any user to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>         | <p>Configure PGM tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Default</b>             | The default PGM trace options are those inherited from the routing protocol <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>PGM Tracing Flags</b></p> <ul style="list-style-type: none"><li>• <b>all</b>—Trace all PGM packets.</li><li>• <b>init</b>—Trace all PGM initialization events.</li><li>• <b>packets</b>—Trace all PGM packet processing.</li><li>• <b>parser</b>—Trace all PGM parser processing.</li><li>• <b>route-socket</b>—Trace all PGM route-socket events.</li><li>• <b>show</b>—Trace all PGM <b>show</b> command servicing.</li><li>• <b>state</b>—Trace all PGM state transitions.</li></ul> <p><b>Global Tracing Flags</b></p> <ul style="list-style-type: none"><li>• <b>all</b>—All tracing operations</li><li>• <b>general</b>—A combination of the <b>normal</b> and <b>route</b> trace operations</li><li>• <b>normal</b>—All normal operations</li></ul> <p><b>Default:</b> If you do not specify this option, only unusual or abnormal operations are traced.</p> <ul style="list-style-type: none"><li>• <b>policy</b>—Policy operations and actions</li></ul> |

- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

***flag-modifier***—(Optional) Modifier for the tracing flag. You can specify one or more of the following modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

| <b>Description</b>         | <p>Configure PIM tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>             | The default PIM trace options are those inherited from the routing protocol's <b>traceoptions</b> statement included at the <b>[edit routing-options]</b> hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the <b>pim-log</b> file.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>PIM Tracing Flags</b></p> <ul style="list-style-type: none"> <li>• <b>assert</b>—Assert messages</li> <li>• <b>bidirectional-df-election</b>—Bidirectional PIM designated-forwarder (DF) election events</li> </ul> |

- **bootstrap**—Bootstrap messages
- **cache**—Packets in the PIM sparse mode routing cache
- **graft**—Graft and graft acknowledgment messages
- **hello**—Hello packets
- **join**—Join messages
- **mt**—Multicast tunnel messages
- **nsr-synchronization**—Nonstop active routing (NSR) synchronization messages
- **packets**—All PIM packets
- **prune**—Prune messages
- **register**—Register and register stop messages
- **rp**—Candidate RP advertisements
- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 0 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Description</b>              | <p>Specify the transmit interval for the <b>bfd-liveness-detection</b> statement. The negotiated transmit interval for a peer is the interval between the sending of BFD packets to peers. The receive interval for a peer is the minimum interval between receiving packets sent from its peer; the receive interval is not negotiated between peers. To determine the transmit interval, each peer compares its configured minimum transmit interval with its peer's minimum receive interval. The larger of the two numbers is accepted as the transmit interval for that peer.</p> <p>The remaining statements are explained separately.</p> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.2.<br>Statement introduced in Junos OS Release 10.2 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | <p>List one or more tunnel-capable PICs to be used for creating multicast tunnel (<b>mt</b>) interfaces. Creating a PIC list enables you to control the load-balancing implementation.</p> <p>Tunnel-capable PICs include:</p> <ul style="list-style-type: none"><li>• Adaptive Services PIC</li><li>• Multiservices PIC or Multiservices DPC</li><li>• Tunnel Services PIC</li><li>• On MX Series routers, a PIC created with the <b>tunnel-services</b> statement at the [edit chassis fpc <i>slot-number</i> pic <i>number</i>] hierarchy level.</li></ul> <p>The physical position of the PIC in the routing device determines the multicast tunnel interface name. For example, if you have an Adaptive Services PIC installed in FPC slot 0 and PIC slot 0, the corresponding multicast tunnel interface name is <b>mt-0/0/0</b>. The same is true for Tunnel Services PICs, Multiservices PICs, and Multiservices DPCs.</p> |
| <b>Default</b>                  | Multicast tunnel interfaces are created on all available tunnel-capable PICs, based on a round-robin algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>                  | <b>mt-fpc/pic/port</b> —Interface that is automatically generated when a tunnel-capable PIC is installed in the routing device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b>              | <p>Configure at least one, but not more than two, upstream interfaces on the rendezvous point (RP) routing device that resides between a customer edge-facing Protocol Independent Multicast (PIM) domain and a core-facing PIM domain. The RP routing device translates PIM join or prune messages into corresponding IGMP report or leave messages (if you include the <a href="#">pim-to-igmp-proxy</a> statement), or into corresponding MLD report or leave messages (if you include the <a href="#">pim-to-mld-proxy</a> statement). The routing device then proxies the IGMP or MLD report or leave messages to one or both upstream interfaces to forward IPv4 multicast traffic (for IGMP) or IPv6 multicast traffic (for MLD) across the PIM domains.</p>                                                                                                                                                                                                                        |
| <b>Options</b>                  | <p><b><i>interface-names</i></b>—Names of one or two upstream interfaces to which the RP routing device proxies IGMP or MLD report or leave messages for transmission of multicast traffic across PIM domains. You can specify a maximum of two upstream interfaces on the RP routing device. To configure a set of two upstream interfaces, specify the full interface names, including all physical and logical address components, within square brackets ( [ ] ).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Sample Output

### clear igmp membership

The following sample output displays IGMP group information before and after the **clear igmp membership** command is entered:

```

user@host> show igmp group
Interface Group Last Reported Timeout
so-0/0/0 224.2.127.253 10.1.128.1 186
so-0/0/0 224.2.127.254 10.1.128.1 186
so-0/0/0 239.255.255.255 10.1.128.1 187
so-0/0/0 224.1.127.255 10.1.128.1 188
local 224.0.0.6 (null) 0
local 224.0.0.5 (null) 0
local 224.2.127.254 (null) 0
local 239.255.255.255 (null) 0
local 224.0.0.2 (null) 0
local 224.0.0.13 (null) 0

```

```

user@host> clear igmp membership
Clearing Group Membership Info for so-0/0/0
Clearing Group Membership Info for so-1/0/0
Clearing Group Membership Info for so-2/0/0

```

```

user@host> show igmp group
Interface Group Last Reported Timeout
local 224.0.0.6 (null) 0
local 224.0.0.5 (null) 0
local 224.2.127.254 (null) 0
local 239.255.255.255 (null) 0
local 224.0.0.2 (null) 0
local 224.0.0.13 (null) 0

```

### clear igmp membership interface

The following sample output displays IGMP group information before and after the **clear igmp membership interface** command is issued:

```

user@host> show igmp group
Interface Group Last Reported Timeout
so-0/0/0 224.2.127.253 10.1.128.1 210
so-0/0/0 239.255.255.255 10.1.128.1 210
so-0/0/0 224.1.127.255 10.1.128.1 215
so-0/0/0 224.2.127.254 10.1.128.1 216
local 224.0.0.6 (null) 0
local 224.0.0.5 (null) 0
local 224.2.127.254 (null) 0
local 239.255.255.255 (null) 0
local 224.0.0.2 (null) 0
local 224.0.0.13 (null) 0

```

```

user@host> clear igmp membership interface so-0/0/0
Clearing Group Membership Info for so-0/0/0

```

```

user@host> show igmp group
Interface Group Last Reported Timeout
local 224.0.0.6 (null) 0
local 224.0.0.5 (null) 0
local 224.2.127.254 (null) 0
local 239.255.255.255 (null) 0
local 224.0.0.2 (null) 0
local 224.0.0.13 (null) 0

```

## clear igmp membership group

The following sample output displays IGMP group information before and after the **clear igmp membership group** command is entered:

```
user@host> show igmp group
```

| Interface | Group           | Last Reported | Timeout |

## Sample Output

### clear igmp statistics

The following sample output displays IGMP statistics information before and after the **clear igmp statistics** command is entered:

```

user@host> show igmp statistics
IGMP packet statistics for all interfaces
IGMP Message type Received Sent Rx errors
Membership Query 8883 459 0
V1 Membership Report 0 0 0
DVMRP 19784 35476 0
PIM V1 18310 0 0
Cisco Trace 0 0 0
V2 Membership Report 0 0 0
Group Leave 0 0 0
Mtrace Response 0 0 0
Mtrace Request 0 0 0
Domain Wide Report 0 0 0
V3 Membership Report 0 0 0
Other Unknown types 0 0 0

```

```

IGMP v3 unsupported type 0
IGMP v3 source required for SSM 0
IGMP v3 mode not applicable for SSM 0

```

```

IGMP Global Statistics
Bad Length 0
Bad Checksum 0
Bad Receive If 0
Rx non-local 1227

```

```
user@host> clear igmp statistics
```

```
user@host> show igmp statistics
```

```
IGMP packet statistics for all interfaces
```

| <b>Release Information</b>      | Command introduced in Junos OS Release 10.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | <p>Redistribute the Protocol Independent Multicast (PIM) join states.</p> <p>You can find out if there are multiple paths available for a source (for example, an RP) with the output of the <b>show pim source</b> command.</p> <p>When you include the <b>join-load-balance</b> statement in the configuration, the PIM join states are distributed evenly on available equal-cost multipath links. When an upstream neighbor link fails, Junos OS redistributes the PIM join states to the remaining links. However, when new links are added or the failed link is restored, the existing PIM joins are not redistributed to the new link. New flows will be distributed to the new links. However, in a network without new joins and prunes, the new link is not used for multicast traffic. The <b>clear pim join-distribution</b> command redistributes the existing flows to the new upstream neighbors. Redistributing the existing flows causes traffic to be disrupted, so we recommend that you run the <b>clear pim join-distribution</b> command during a maintenance window.</p> |
| <b>Options</b>                  | <p><b>none</b>—Redistribute the PIM join states for the default master instance.</p> <p><b>instance <i>instance-name</i></b>—(Optional) Redistribute the join states for a specific PIM-enabled routing instance.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Additional Information</b>   | The <b>clear pim join-distribution</b> command cannot be used to redistribute the PIM join states on a backup Routing Engine when nonstop active routing is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Required Privilege Level</b> | clear                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Sample Output

### clear pim statistics

The following sample output displays PIM statistics before and after the **clear pim statistics** command is entered:

```
user@host> show pim statistics
PIM statistics on all interfaces:
PIM Message type Received Sent Rx errors
Hello 0 0 0
Register 0 0 0
Register Stop 0 0 0
Join Prune 0 0 0
Bootstrap 0 0 0
Assert 0 0 0
Graft 0 0 0
Graft Ack 0 0 0
Candidate RP 0 0 0
V1 Query 2111 4222 0
V1 Register 0 0 0
V1 Register Stop 0 0 0
V1 Join Prune 14200 13115 0
V1 RP Reachability 0 0 0
V1 Assert 0 0 0
V1 Graft 0 0 0
V1 Graft Ack 0 0 0
PIM statistics summary for all interfaces:
Unknown type 0
V1 Unknown type 0
Unknown Version 0
Neighbor unknown 0
Bad Length 0
Bad Checksum 0
Bad Receive If 0
Rx Intf disabled 2007
Rx V1 Require V2 0
Rx Register not RP 0
RP Filtered Source 0
Unknown Reg Stop 0
Rx Join/Prune no state 1040
Rx Graft/Graft Ack no state 0
...
```

```
user@host> clear pim statistics
user@host> show pim statistics
PIM statistics on all interfaces:
PIM Message type Received Sent Rx errors
Hello 0 0 0

| <b>Output Fields</b>            | <a href="#">Table 425</a> describes the output fields for the <b>show amt summary</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                   |

**Table 425: show amt summary Output Fields**

| Field Name                 | Field Description                                                                                                                                                                                         | Level of Output |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>AMT anycast prefix</b>  | Prefix advertised by unicast routing protocols to route AMT discovery messages to the router from nearby AMT gateways.                                                                                    | All levels      |
| <b>AMT anycast address</b> | Anycast address configured from which the anycast prefix is derived.                                                                                                                                      | All levels      |
| <b>AMT local address</b>   | Local unique AMT relay IP address configured. Used to send AMT relay advertisement messages, it is the IP source address of AMT control messages and the source address of the data tunnel encapsulation. | All levels      |
| <b>AMT tunnel limit</b>    | Maximum number of AMT tunnels that can be created.                                                                                                                                                        | All levels      |
| <b>active tunnels</b>      | Number of active AMT tunnel interfaces.                                                                                                                                                                   | All levels      |

## Sample Output

### show amt summary

```
user@host> show amt summary
 AMT anycast prefix : 20.0.0.4/32
 AMT anycast address : 20.0.0.4
 AMT local address : 20.0.0.4
 AMT tunnel limit : 1000, active tunnels : 2
```

## show amt tunnel

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |

| <b>Output Fields</b>            | Table 426 describes the output fields for the <b>show amt tunnel</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |

**Table 426: show amt tunnel Output Fields**

| Field Name          | Field Description                                                     | Level of Output |
|---------------------|-----------------------------------------------------------------------|-----------------|
| AMT gateway address | Address of the AMT gateway that is being connected by the AMT tunnel. | All levels      |

Table 426: show amt tunnel Output Fields (*continued*)

| Field Name                           | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>port</b>                          | Client port used by the AMT tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | All levels      |
| <b>AMT tunnel interface</b>          | Dynamically created AMT logical interfaces used by the AMT tunnel in the format <b>ud-FPC/PIC/Port.unit</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | All levels      |
| <b>AMT tunnel state</b>              | State of the AMT tunnel. The state is normally <b>Active</b> . <ul style="list-style-type: none"> <li><b>Active</b>—The tunnel is active.</li> <li><b>Pending</b>—The tunnel creation is pending. This is a transient state.</li> <li><b>Down</b>—The tunnel is in the down state.</li> <li><b>Graceful restart pending</b>—Graceful restart is in progress.</li> <li><b>Reviving</b>—The routing protocol daemon or Routing Engine was restarted (not gracefully). The tunnel remains in the reviving state until the AMT gateway sends a control message. When the message is received the tunnel is moved to the <b>Active</b> state. If no message is received before the AMT tunnel inactivity timer expires, the tunnel is deleted.</li> </ul> | All levels      |
| <b>AMT tunnel inactivity timeout</b> | Number of seconds since the most recent control message was received from an AMT gateway. If no message is received before the AMT tunnel inactivity timer expires, the tunnel is deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | All levels      |
| <b>Number of groups</b>              | Number of multicast groups using the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | All levels      |
| <b>Group</b>                         | Multicast group address or addresses using the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <b>detail</b>   |
| <b>Include Source</b>                | Multicast source address for each IGMPv3 group using the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <b>detail</b>   |
| <b>AMT message count</b>             | Statistics for AMT messages: <ul style="list-style-type: none"> <li><b>AMT Request</b>—Number of AMT relay tunnel request messages received.</li> <li><b>AMT membership update</b>—Number of AMT membership update messages received.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | All levels      |

## Sample Output

### show amt tunnel

```

user@host> show amt tunnel
AMT gateway address : 11.11.11.2, port : 2268
AMT tunnel interface : ud-5/1/10.1120256
AMT tunnel state : Active
AMT tunnel inactivity timeout : 15
Number of groups : 1

AMT message count:
AMT Request AMT membership update
2 2

```

### show amt tunnel detail

```

user@host> show amt tunnel detail
AMT gateway address : 11.11.11.2, port : 2268
AMT tunnel interface : ud-5/3/10.1120512

```

```

AMT tunnel state : Active
AMT tunnel inactivity timeout : 62
Number of groups : 1
Group: 226.2.3.2

AMT message count:
AMT Request AMT membership update
2 2

AMT gateway address : 11.11.11.3, port : 2268
AMT tunnel interface : ud-5/2/10.1120513
AMT tunnel state : Active
AMT tunnel inactivity timeout : 214
Number of groups : 1
Group: 226.2.3.3

AMT message count:
AMT Request AMT membership update
2 2

```

#### show amt tunnel tunnel-interface

```

user@host> show amt tunnel tunnel-interface ud-5/3/10.1120512
AMT gateway address : 11.11.11.2, port : 2268
AMT tunnel interface : ud-5/3/10.1120512
AMT tunnel state : Active
AMT tunnel inactivity timeout : 145
Number of groups : 1

AMT message count:
AMT Request AMT membership update
2 2

```

#### show amt tunnel gateway-address

```

user@host> show amt tunnel gateway-address 11.11.11.3 port 2268
AMT gateway address : 11.11.11.3, port : 2268
AMT tunnel interface : ud-5/2/10.1120513
AMT tunnel state : Active
AMT tunnel inactivity timeout : 214
Number of groups : 1
Group: 226.2.3.3

AMT message count:
AMT Request AMT membership update
2 2

```

#### show amt tunnel gateway-address detail

```

user@host> show amt tunnel gateway-address 11.11.11.2 detail
AMT gateway address : 11.11.11.2, port : 2268
AMT tunnel interface : ud-5/3/10.1120512
AMT tunnel state : Active
AMT tunnel inactivity timeout : 234
Number of groups : 1
Group: 226.2.3.2

AMT message count:
AMT Request AMT membership update
2 2

```

## show dvmrp interfaces

|                                 |                                                                                                                                                                                                                                                                        |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Release Information</b>      | Command introduced before Junos OS Release 7.4.                                                                                                                                                                                                                        |
| <b>Description</b>              | Display information about Distance Vector Multicast Routing Protocol (DVMRP)–enabled interfaces.                                                                                                                                                                       |
| <b>Options</b>                  | <p><b>none</b>—(Same as <b>logical-system all</b>) Display information about DVMRP-enabled interfaces.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                   |
| <b>List of Sample Output</b>    | <a href="#">show dvmrp interfaces on page 4985</a>                                                                                                                                                                                                                     |
| <b>Output Fields</b>            | Table 427 describes the output fields for the <b>show dvmrp interfaces</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                            |

**Table 427: show dvmrp interfaces Output Fields**

| Field Name       | Field Description                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b> | Name of the interface.                                                                                                                                                                                                                                                                                 |
| <b>State</b>     | State of the interface: <b>up</b> or <b>down</b> .                                                                                                                                                                                                                                                     |
| <b>Leaf</b>      | Whether the interface is a leaf (that is, whether it has no neighbors) or whether it has neighbors.                                                                                                                                                                                                    |
| <b>Metric</b>    | Interface metric: a value from 1 through 31.                                                                                                                                                                                                                                                           |
| <b>Announce</b>  | Number of routes the interface is announcing.                                                                                                                                                                                                                                                          |
| <b>Mode</b>      | DVMRP mode: <ul style="list-style-type: none"> <li>• <b>Forwarding</b>—DVMRP does both the routing and the multicast data forwarding.</li> <li>• <b>Unicast-routing</b>—DVMRP does only the routing. Forwarding of the multicast data packets can be done by enabling PIM on the interface.</li> </ul> |

## Sample Output

### show dvmrp interfaces

```
user@host> show dvmrp interfaces
Interface State Leaf Metric Announce Mode
fxp0.0 Up N 1 4 Forwarding
fxp1.0 Up N 1 4 Forwarding
fxp2.0 Up N 1 3 Forwarding
lo0.0 Up Y 1 0 Unicast-routing
```

## show dvmrp neighbors

| <b>Output Fields</b>            | Table 429 describes the output fields for the <b>show dvmrp prefix</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                           |

Table 429: show dvmrp prefix Output Fields

| Field Name             | Field Description                                                    | Level of Output |
|------------------------|----------------------------------------------------------------------|-----------------|
| Prefix                 | DVMRP route.                                                         | All levels      |
| Next hop               | Next hop from which the route was learned.                           | All levels      |
| Age                    | Last time that the route was refreshed.                              | All levels      |
| <i>multicast-group</i> | Multicast group address.                                             | <b>detail</b>   |
| Prunes sent            | Number of prune messages sent to the multicast group.                | <b>detail</b>   |
| Grafts sent            | Number of grafts sent to the multicast group.                        | <b>detail</b>   |
| Cache lifetime         | Lifetime of the group in the multicast cache, in seconds.            | <b>detail</b>   |
| Prune lifetime         | Lifetime remaining and total lifetime of prune messages, in seconds. | <b>detail</b>   |

## Sample Output

### show dvmrp prefix

```
user@host> show dvmrp prefix
Prefix Next hop Age
10.38.0.0 /30 10.38.0.1 00:06:17
10.38.0.4 /30 10.38.0.5 00:06:13
10.38.0.8 /30 10.38.0.2 00:00:04
10.38.0.12 /30 10.38.0.6 00:00:04
10.255.14.114 /32 10.255.14.114 00:06:17
10.255.14.142 /32 10.38.0.2 00:00:04
10.255.14.144 /32 10.38.0.2 00:00:04
10.255.70.15 /32 10.38.0.6 00:00:04

## Sample Output

### show igmp interface

```

user@host> show igmp interface
Interface: at-0/3/1.0
 Querier: 10.111.30.1
 State: Up Timeout: None Version: 2 Groups: 4
 SSM Map Policy: ssm-policy-A
Interface: so-1/0/0.0
 Querier: 10.111.10.1
 State: Up Timeout: None Version: 2 Groups: 2
 SSM Map Policy: ssm-policy-B
Interface: so-1/0/1.0
 Querier: 10.111.20.1
 State: Up Timeout: None Version: 2 Groups: 4
 SSM Map Policy: ssm-policy-C
Immediate Leave: On
Promiscuous Mode: Off

Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2

Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0

```

### show igmp interface brief

The output for the **show igmp interface brief** command is identical to that for the **show igmp interface** command. For sample output, see [show igmp interface on page 4998](#).

### show igmp interface detail

The output for the **show igmp interface detail** command is identical to that for the **show igmp interface** command. For sample output, see [show igmp interface on page 4998](#).

## show igmp snooping interface

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 433: show igmp snooping interface Output Fields**

| Field Name                   | Field Description                                                                              | Level of Output |
|------------------------------|------------------------------------------------------------------------------------------------|-----------------|
| Routing-instance             | Routing instance for IGMP snooping.                                                            | All levels      |
| Learning Domain              | Learning domain for snooping.                                                                  | All levels      |
| IGMP Query Interval          | Frequency (in seconds) with which this router sends membership queries when it is the querier. | <b>detail</b>   |
| IGMP Query Response Interval | Time (in seconds) that the router waits for a response to a general query.                     | <b>detail</b>   |

Table 433: show igmp snooping interface Output Fields (*continued*)

| Field Name                         | Field Description                                                                                                                    | Level of Output |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| IGMP Last Member Query Interval    | Time (in seconds) that the router waits for a report in response to a group-specific query.                                          | detail          |
| IGMP Robustness Count              | Number of times the router retries a query.                                                                                          | detail          |
| immediate-leave                    | State of immediate leave: <b>On</b> or <b>Off</b> .                                                                                  | All levels      |
| router-interface                   | Router interfaces that are part of this learning domain.                                                                             | All levels      |
| Group limit                        | Maximum number of (source,group) pairs allowed per interface. When a group limit is not configured, this field is not shown.         | All levels      |
| interface                          | Interfaces that are being snooped in this learning domain.                                                                           | All levels      |
| Groups                             | Number of groups on the interface.                                                                                                   | none            |
| State                              | State of the interface: <b>Up</b> or <b>Down</b> .                                                                                   | none            |
| Up Groups                          | Number of active multicast groups attached to the logical interface.                                                                 | All levels      |
| IGMP Membership Timeout            | Timeout for group membership. If no report is received for these groups before the timeout expires, the group membership is removed. | none            |
| IGMP Other Querier Present Timeout | Time that the router waits for the IGMP querier to send a query.                                                                     | none            |

## Sample Output

### show igmp snooping interface

```

user@host> show igmp snooping interface
Instance: bridge-domain bar

Learning-Domain: default
Interface: ge-0/1/0.200
 State: Up Groups: 0
 Immediate leave: Off
 Router interface: yes
Interface: ge-0/1/2.200
 State: Up Groups: 2
 Immediate leave: On
 Router interface: no
Interface: ge-0/1/3.200
 State: Up Groups: 1
 Immediate leave: Off
 Router interface: no

Configured Parameters:
IGMP Query Interval: 130.0
IGMP Query Response Interval: 15.0

```

```
IGMP Last Member Query Interval: 2.0
IGMP Robustness Count: 3

Derived Parameters:
IGMP Membership Timeout: 405.0
IGMP Other Querier Present Timeout: 397.500
```

## Sample Output

### show igmp snooping interface (Group Limit Configured)

```
user@host> show igmp snooping interface instance vpls1
Instance: vpls1

Learning-Domain: default
Interface: ge-1/3/9.0
 State: Up Groups: 0
 Immediate leave: Off
 Router interface: yes
Interface: ge-1/3/8.0
 State: Up Groups: 0
 Immediate leave: Off
 Router interface: yes

| <b>Output Fields</b>            | <a href="#">Table 438</a> describes the output fields for the <b>show mld interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                |

**Table 438: show mld interface Output Fields**

| Field Name            | Field Description                                                                              | Level of Output |
|-----------------------|------------------------------------------------------------------------------------------------|-----------------|
| <b>Interface</b>      | Name of the interface.                                                                         | All levels      |
| <b>Querier</b>        | Address of the router that has been elected to send membership queries.                        | All levels      |
| <b>State</b>          | State of the interface: <b>Up</b> or <b>Down</b> .                                             | All levels      |
| <b>SSM Map Policy</b> | Name of the source-specific multicast (SSM) map policy that has been applied to the interface. | All levels      |
| <b>SSM Map Policy</b> | Name of the source-specific multicast (SSM) map policy at the MLD interface.                   | All levels      |
| <b>Timeout</b>        | How long until the MLD querier is declared to be unreachable, in seconds.                      | All levels      |
| <b>Version</b>        | MLD version being used on the interface: 1 or 2.                                               | All levels      |

Table 438: show mld interface Output Fields (*continued*)

| Field Name                   | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Level of Output |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Groups</b>                | Number of groups on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | All levels      |
| <b>Passive</b>               | <p>State of the passive mode option:</p> <ul style="list-style-type: none"> <li>• <b>On</b>—Indicates that the router can run IGMP or MLD on the interface but not send or receive control traffic such as IGMP or MLD reports, queries, and leaves.</li> <li>• <b>Off</b>—Indicates that the router can run IGMP or MLD on the interface and send or receive control traffic such as IGMP or MLD reports, queries, and leaves.</li> </ul> <p>The <b>passive</b> statement enables you to selectively activate up to two out of a possible three available query or control traffic options. When enabled, the following options appear after the <b>on</b> state declaration:</p> <ul style="list-style-type: none"> <li>• <b>send-general-query</b>—The interface sends general queries.</li> <li>• <b>send-group-query</b>—The interface sends group-specific and group-source-specific queries.</li> <li>• <b>allow-receive</b>—The interface receives control traffic</li> </ul> | All levels      |
| <b>OIF map</b>               | Name of the OIF map associated to the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | All levels      |
| <b>SSM map</b>               | Name of the source-specific multicast (SSM) map used on the interface, if configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | All levels      |
| <b>Immediate Leave</b>       | <p>State of the immediate leave option:</p> <ul style="list-style-type: none"> <li>• <b>On</b>—Indicates that the router removes a host from the multicast group as soon as the router receives a multicast listener done message from a host associated with the interface.</li> <li>• <b>Off</b>—Indicates that after receiving a multicast listener done message, instead of removing a host from the multicast group immediately, the router sends a group query to determine if another receiver responds.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                            | All levels      |
| <b>Configured Parameters</b> | <p>Information configured by the user.</p> <ul style="list-style-type: none"> <li>• <b>MLD Query Interval (.1 secs)</b>—Interval at which this router sends membership queries when it is the querier.</li> <li>• <b>MLD Query Response Interval (.1 secs)</b>—Time that the router waits for a report in response to a general query.</li> <li>• <b>MLD Last Member Query Interval (.1 secs)</b>—Time that the router waits for a report in response to a group-specific query.</li> <li>• <b>MLD Robustness Count</b>—Number of times the router retries a query.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                        | All levels      |
| <b>Derived Parameters</b>    | <p>Derived information.</p> <ul style="list-style-type: none"> <li>• <b>MLD Membership Timeout (.1 secs)</b>—Timeout period for group membership. If no report is received for these groups before the timeout expires, the group membership will be removed.</li> <li>• <b>MLD Other Querier Present Timeout (.1 secs)</b>—Time that the router waits for the IGMP querier to send a query.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | All levels      |

## Sample Output

### show mld interface

```

user@host> show mld interface
Interface: fe-0/0/0
 Querier: None
 State: Up Timeout: 0 Version: 1 Groups: 0
 SSM Map Policy: ssm-policy-A
Interface: at-0/3/1.0
 Querier: 8038::c0a8:c345
 State: Up Timeout: None Version: 1 Groups: 0
 SSM Map Policy: ssm-policy-B
Interface: fe-1/0/1.0
 Querier: ::192.168.195.73
 State: Up Timeout: None Version: 1 Groups: 3
 SSM Map Policy: ssm-policy-C
 SSM map: ipv6map1
Immediate Leave: On

Configured Parameters:
MLD Query Interval (.1 secs): 1250
MLD Query Response Interval (.1 secs): 100
MLD Last Member Query Interval (.1 secs): 10
MLD Robustness Count: 2

Derived Parameters:
MLD Membership Timeout (.1secs): 2600
MLD Other Querier Present Timeout (.1 secs): 2550

```

### show mld interface brief

The output for the **show mld interface brief** command is identical to that for the **show mld interface** command. For sample output, see [show mld interface on page 5019](#).

### show mld interface detail

The output for the **show mld interface detail** command is identical to that for the **show mld interface** command. For sample output, see [show mld interface on page 5019](#).

## show mld statistics

| <b>MLD Message type</b>      | Summary of MLD statistics. <ul style="list-style-type: none"> <li>• <b>Listener Query (v1/v2)</b>—Number of membership queries sent and received.</li> <li>• <b>Listener Report (v1)</b>—Number of version 1 membership reports sent and received.</li> <li>• <b>Listener Done (v1/v2)</b>—Number of Listener Done messages sent and received.</li> <li>• <b>Listener Report (v2)</b>—Number of version 2 membership reports sent and received.</li> <li>• <b>Other Unknown types</b>—Number of unknown message types received.</li> <li>• <b>MLD v2 source required for SSM</b>—Number of MLD version 2 messages received that contained no source.</li> <li>• <b>MLD v2 mode not applicable for SSM</b>—Number of MLD version 2 messages received that did not contain a mode applicable for source-specific multicast (SSM).</li> </ul>          |
| <b>MLD Global Statistics</b> | Summary of MLD statistics for all interfaces. <ul style="list-style-type: none"> <li>• <b>Bad Length</b>—Number of messages received with length errors so severe that further classification could not occur.</li> <li>• <b>Bad Checksum</b>—Number of messages received with an invalid IP checksum. No further classification was performed.</li> <li>• <b>Bad Receive If</b>—Number of messages received on an interface not enabled for MLD.</li> <li>• <b>Rx non-local</b>—Number of messages received from nonlocal senders.</li> <li>• <b>Timed out</b>—Number of groups that timed out as a result of not receiving an explicit leave message.</li> <li>• <b>Rejected Report</b>—Number of reports dropped because of the MLD group policy.</li> <li>• <b>Total Interfaces</b>—Number of interfaces configured to support IGMP.</li> </ul> |

## Sample Output

### show mld statistics

```

user@host> show mld statistics
MLD packet statistics for all interfaces
MLD Message type Received Sent Rx errors
Listener Query (v1/v2) 0 2 0
Listener Report (v1) 0 0 0
Listener Done (v1/v2) 0 0 0
Listener Report (v2) 0 0 0
Other Unknown types 0 0 0
MLD v2 source required for SSM 2
MLD v2 mode not applicable for SSM 0

MLD Global Statistics
Bad Length 0
Bad Checksum 0
Bad Receive If 0
Rx non-local 0
Timed out 0

```

|                  |   |
|------------------|---|
| Rejected Report  | 0 |
| Total Interfaces | 2 |

#### show mld statistics interface

```
user@host> show mld statistics interface fe-1/0/1.0
MLD interface packet statistics for fe-1/0/1.0
MLD Message type Received Sent Rx errors
Listener Query (v1/v2) 0 2 0
Listener Report (v1) 0 0 0
Listener Done (v1/v2) 0 0 0
Listener Report (v2) 0 0 0
Other Unknown types 0 0 0
MLD v2 source required for SSM 2
MLD v2 mode not applicable for SSM 0

MLD Global Statistics
Bad Length 0
Bad Checksum 0
Bad Receive If 0
Rx non-local 0
Timed out 0
Rejected Report 0
Total Interfaces 2
```

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 440: show msdp Output Fields**

| Field Name    | Field Description                                                                        | Level of Output |
|---------------|------------------------------------------------------------------------------------------|-----------------|
| Peer address  | IP address of the peer.                                                                  | All levels      |
| Local address | Local address of the peer.                                                               | All levels      |
| State         | Status of the MSDP connection: <b>Listen</b> , <b>Established</b> , or <b>Inactive</b> . | All levels      |
| Last up/down  | Time at which the most recent peer-state change occurred.                                | All levels      |

Table 440: show msdp Output Fields (*continued*)

| Field Name           | Field Description                                                                                                                                                                   | Level of Output |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Peer-Group           | Peer group name.                                                                                                                                                                    | All levels      |
| SA Count             | Number of source-active cache entries advertised by each peer that were accepted, compared to the number that were received, in the format <i>number-accepted/number-received</i> . | All levels      |
| Peer Connect Retries | Number of peer connection retries.                                                                                                                                                  | detail          |
| State timer expires  | Number of seconds before another message is sent to a peer.                                                                                                                         | detail          |
| Peer Times out       | Number of seconds to wait for a response from the peer before the peer is declared unavailable.                                                                                     | detail          |
| SA accepted          | Number of entries in the source-active cache accepted from the peer.                                                                                                                | detail          |
| SA received          | Number of entries in the source-active cache received by the peer.                                                                                                                  | detail          |

## Sample Output

### show msdp

```

user@host> show msdp
Peer address Local address State Last up/down Peer-Group SA Count
198.32.8.193 198.32.8.195 Established 5d 19:25:44 North23 120/150
198.32.8.194 198.32.8.195 Established 3d 19:27:27 North23 300/345
198.32.8.196 198.32.8.195 Established 5d 19:39:36 North23 10/13
198.32.8.197 198.32.8.195 Established 5d 19:32:27 North23 5/6
198.32.8.198 198.32.8.195 Established 3d 19:33:04 North23 2305/3000

```

### show msdp brief

The output for the **show msdp brief** command is identical to that for the **show msdp** command. For sample output, see [show msdp on page 5024](#).

### show msdp detail

```

user@host> show msdp detail
Peer: 10.255.70.15
Local address: 10.255.70.19
State: Established
Peer Connect Retries: 0
State timer expires: 22
Peer Times out: 49
SA accepted: 0
SA received: 0

```

### show msdp source-active brief

The output for the **show msdp source-active brief** command is identical to that for the **show msdp source-active** command. For sample output, see [show msdp source-active on page 5028](#).

### show msdp source-active detail

The output for the **show msdp source-active detail** command is identical to that for the **show msdp source-active** command. For sample output, see [show msdp source-active on page 5028](#).

## show msdp statistics

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Output Fields</b>            | <a href="#">Table 443</a> describes the output fields for the <b>show msdp statistics</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                  |

**Table 443: show msdp statistics Output Fields**

| Field Name                              | Field Description                                                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Global active source limit exceeded     | Number of times all peers have exceeded configured active source limits.                                                    |
| Global active source limit maximum      | Configured number of active source messages accepted by the device.                                                         |
| Global active source limit threshold    | Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages.          |
| Global active source limit log-warning  | Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device). |
| Global active source limit log interval | Time (in seconds) between consecutive log messages.                                                                         |

Table 443: show msdp statistics Output Fields (*continued*)

| Field Name                                 | Field Description                                                                                                                                                                                     |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Peer</b>                                | Address of peer.                                                                                                                                                                                      |
| <b>Last State Change</b>                   | How long ago the peer state changed.                                                                                                                                                                  |
| <b>Last message received from the peer</b> | How long ago the last message was received from the peer.                                                                                                                                             |
| <b>RPF Failures</b>                        | Number of reverse path forwarding (RPF) failures.                                                                                                                                                     |
| <b>Remote Closes</b>                       | Number of times the remote peer closed.                                                                                                                                                               |
| <b>Peer Timeouts</b>                       | Number of peer timeouts.                                                                                                                                                                              |
| <b>SA messages sent</b>                    | Number of source-active messages sent.                                                                                                                                                                |
| <b>SA messages received</b>                | Number of source-active messages received.                                                                                                                                                            |
| <b>SA request messages sent</b>            | Number of source-active request messages sent.                                                                                                                                                        |
| <b>SA request messages received</b>        | Number of source-active request messages received.                                                                                                                                                    |
| <b>SA response messages sent</b>           | Number of source-active response messages sent.                                                                                                                                                       |
| <b>SA response messages received</b>       | Number of source-active response messages received.                                                                                                                                                   |
| <b>SA response messages received</b>       | Entry Count is a field within SA message that defines how many source/group tuples are present in the SA message. The counter is incremented each time an SA with an Entry Count of zero is received. |
| <b>Active source exceeded</b>              | Number of times this peer has exceeded configured source-active limits.                                                                                                                               |
| <b>Active source Maximum</b>               | Configured number of active source messages accepted by this peer.                                                                                                                                    |
| <b>Active source threshold</b>             | Configured threshold on this peer for applying random early discard (RED) to drop some but not all MSDP active source messages.                                                                       |
| <b>Active source log-warning</b>           | Configured threshold on this peer at which a warning message is logged (percentage of the number of active source messages accepted by the device).                                                   |
| <b>Active source log-interval</b>          | Time (in seconds) between consecutive log messages on this peer.                                                                                                                                      |
| <b>Keepalive messages sent</b>             | Number of keepalive messages sent.                                                                                                                                                                    |

Table 443: show msdp statistics Output Fields (*continued*)

| Field Name                  | Field Description                      |
|-----------------------------|----------------------------------------|
| Keepalive messages received | Number of keepalive messages received. |
| Unknown messages received   | Number of unknown messages received.   |
| Error messages received     | Number of error messages received.     |

## Sample Output

### show msdp statistics

```

user@host> show msdp statistics
Global active source limit exceeded: 0
Global active source limit maximum: 10
Global active source limit threshold: 8
Global active source limit log-warning: 60
Global active source limit log interval: 60

Peer: 10.255.245.39
Last State Change: 11:54:49 (00:24:59)
Last message received from peer: 11:53:32 (00:26:16)
RPF Failures: 0
Remote Closes: 0
Peer Timeouts: 0
SA messages sent: 376
SA messages received: 459
SA messages with zero Entry Count received: 0
SA request messages sent: 0
SA request messages received: 0
SA response messages sent: 0
SA response messages received: 0
Active source exceeded: 0
Active source Maximum: 10
Active source threshold: 8
Active source log-warning: 60
Active source log-interval 120
Keepalive messages sent: 17
Keepalive messages received: 19
Unknown messages received: 0
Error messages received: 0

```

| <b>Release Information</b>      | Command introduced in Junos OS Release 9.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | Display backup PE router group information when ingress PE redundancy is configured. Ingress PE redundancy provides a backup resource when point-to-multipoint LSPs are configured for multicast distribution.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Options</b>                  | <p><b>none</b>—Display standard information about all backup PE groups.</p> <p><b>address <i>pe-address</i></b>—(Optional) Display the groups that a PE address is associated with.</p> <p><b>group <i>group</i></b>—(Optional) Display the backup PE group information for a particular group.</p> <p><b>instance <i>instance-name</i></b>—(Optional) Display backup PE group information for a specific multicast instance.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Output Fields</b>            | Table 444 describes the output fields for the <b>show multicast backup-pe-groups</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 444: show multicast backup-pe-groups Output Fields**

| Field Name      | Field Description                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Backup PE Group | Group name.                                                                                                                                                          |
| Designated PE   | Primary PE router. Address of the PE router that is currently forwarding traffic on the static route.                                                                |
| Transitions     | Number of times that the designated PE router has transitioned from the most eligible PE router to a backup PE router and back again to the most eligible PE router. |
| Last Transition | Time of the most recent transition.                                                                                                                                  |
| Local Address   | Address of the local PE router.                                                                                                                                      |
| Backup PE List  | List of PE routers that are configured to be backups for the group.                                                                                                  |

## Sample Output

### show multicast backup-pe-groups

```
user@host> show multicast backup-pe-groups
Instance: master

Backup PE group: b1
 Designated PE: 10.255.165.7
 Transitions: 1
 Last Transition: 03:15:01
 Local Address: 10.255.165.7
 Backup PE List:
 10.255.165.8

Backup PE group: b2
 Designated PE: 10.255.165.7
 Transitions: 2
 Last Transition: 02:58:20
 Local Address: 10.255.165.7
 Backup PE List:
 10.255.165.9
 10.255.165.8
```

## show multicast flow-map

|                                                     |                                                                                                                                                                                                                                                                                                                                          |

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                            |

Table 445: show multicast flow-map Output Fields

| Field Name           | Field Description                                         | Levels of Output |
|----------------------|-----------------------------------------------------------|------------------|
| <b>Name</b>          | Name of the flow map.                                     | All levels       |
| <b>Policy</b>        | Name of the policy associated with the flow map.          | All levels       |
| <b>Cache-timeout</b> | Cache timeout value assigned to the flow map.             | All levels       |
| <b>Bandwidth</b>     | Bandwidth setting associated with the flow map.           | All levels       |
| <b>Adaptive</b>      | Whether or not adaptive mode is enabled for the flow map. | none             |
| <b>Flow-map</b>      | Name of the flow map.                                     | <b>detail</b>    |

Table 445: show multicast flow-map Output Fields (*continued*)

| Field Name                | Field Description                                         | Levels of Output |
|---------------------------|-----------------------------------------------------------|------------------|
| <b>Adaptive Bandwidth</b> | Whether or not adaptive mode is enabled for the flow map. | <b>detail</b>    |
| <b>Redundant Sources</b>  | Redundant sources defined for the same destination group. | <b>detail</b>    |

## Sample Output

### show multicast flow-map

```

user@host> show multicast flow-map
Instance: master
Name Policy Cache timeout Bandwidth Adaptive
map2 policy2 never 2000000 no
map1 policy1 60 seconds 2000000 no

```

## Sample Output

### show multicast flow-map detail

```

user@host> show multicast flow-map detail
Instance: master
Flow-map: map1
 Policy: policy1
 Cache Timeout: 600 seconds
 Bandwidth: 2000000
 Adaptive Bandwidth: yes
 Redundant Sources: 11.11.11.11
 Redundant Sources: 11.11.11.12
 Redundant Sources: 11.11.11.13

```

**Release Information**   Command introduced before Junos OS Release 7.4.  
                                   Command introduced in Junos OS Release 9.0 for EX Series switches.  
                                   inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.  
                                   Command introduced in Junos OS Release 11.3 for the QFX Series.  
                                   Support for bidirectional PIM added in Junos OS Release 12.1.  
                                   Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description**   Display the entries in the IP multicast forwarding table. You can display similar information with the **show route table inet.1** command.

**Options**   **none**—Display standard information about all entries in the multicast forwarding table for all routing instances.

**brief | detail | extensive | summary**—(Optional) Display the specified level of output.

**active | all | inactive**—(Optional) Display all active entries, all entries, or all inactive entries, respectively, in the multicast forwarding table.

**group group**—(Optional) Display the cache entries for a particular group.

**inet | inet6**—(Optional) Display multicast forwarding table entries for IPv4 or IPv6 family addresses, respectively.

**instance instance-name**—(Optional) Display entries in the multicast forwarding table for a specific multicast instance.

**logical-system (all | logical-system-name)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**regular-expression**—(Optional) Display information about the multicast forwarding table entries that match a UNIX OS-style regular expression.

**source-prefix source-prefix**—(Optional) Display the cache entries for a particular source prefix.

**Required Privilege Level** view

**Output Fields** [Table 449](#) describes the output fields for the **show multicast route** command. Output fields are listed in the approximate order in which they appear.

**Table 449: show multicast route Output Fields**

| Field Name                    | Field Description                                                                                                                                                                               | Level of Output         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| family                        | IPv4 address family ( <b>INET</b> ) or IPv6 address family ( <b>INET6</b> ).                                                                                                                    | All levels              |
| Group                         | Group address.<br><br>For any-source multicast routes, for example for bidirectional PIM, the group address includes the prefix length.                                                         | All levels              |
| Source                        | Prefix and length of the source as it is in the multicast forwarding table.                                                                                                                     | All levels              |
| Incoming interface list       | List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.                                          | All levels              |
| Upstream interface            | Name of the interface on which the packet with this source prefix is expected to arrive.                                                                                                        | All levels              |
| Upstream rpf interface list   | When multicast-only fast reroute (MoFRR) is enabled, a PIM router propagates join messages on two upstream RPF interfaces to receive multicast traffic on both links for the same join request. | All levels              |
| Downstream interface list     | List of interface names to which the packet with this source prefix is forwarded.                                                                                                               | All levels              |
| Number of outgoing interfaces | Total number of outgoing interfaces for each (S,G) entry.                                                                                                                                       | <b>extensive</b>        |
| Session description           | Name of the multicast session.                                                                                                                                                                  | <b>detail extensive</b> |

Table 449: show multicast route Output Fields (*continued*)

| Field Name                             | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                             | Level of Output   |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Statistics                             | Rate at which packets are being forwarded for this source and group entry (in Kbps and pps), and number of packets that have been forwarded to this prefix. If one or more of the kilobits per second packet forwarding statistic queries fails or times out, the statistics field displays <b>Forwarding statistics are not available</b> .<br><br><b>NOTE:</b> On QFX Series switches and OCX Series switches, this field does not report valid statistics. | detail extensive  |
| Next-hop ID                            | Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine and is also displayed in the output of the <b>show multicast nexthops</b> command.                                                                                                                                                                                                                                                             | detail extensive  |
| Incoming interface list ID             | For bidirectional PIM, incoming interface list identifier.<br><br>Identifiers for interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.                                                                                                                                                                                                                              | detail extensive  |
| Upstream protocol                      | The protocol that maintains the active multicast forwarding route for this group or source.<br><br>When the <b>show multicast route extensive</b> command is used with the <b>display-origin-protocol</b> option, the field name is only <b>Protocol</b> and not <b>Upstream Protocol</b> . However, this field also displays the protocol that installed the active route.                                                                                   | detail extensive  |
| Route type                             | Type of multicast route. Values can be (S,G) or (*G).                                                                                                                                                                                                                                                                                                                                                                                                         | summary           |
| Route state                            | Whether the group is <b>Active</b> or <b>Inactive</b> .                                                                                                                                                                                                                                                                                                                                                                                                       | summary extensive |
| Route count                            | Number of multicast routes.                                                                                                                                                                                                                                                                                                                                                                                                                                   | summary           |
| Forwarding state                       | Whether the prefix is pruned or forwarding.                                                                                                                                                                                                                                                                                                                                                                                                                   | extensive         |
| Cache lifetime/timeout                 | Number of seconds until the prefix is removed from the multicast forwarding table. A value of <b>never</b> indicates a permanent forwarding entry. A value of <b>forever</b> indicates routes that do not have keepalive times.                                                                                                                                                                                                                               | extensive         |
| Wrong incoming interface notifications | Number of times that the upstream interface was not available.                                                                                                                                                                                                                                                                                                                                                                                                | extensive         |
| Uptime                                 | Time since the creation of a multicast route.                                                                                                                                                                                                                                                                                                                                                                                                                 | extensive         |

## Sample Output

### show multicast route

**Output Fields** Table 450 describes the output fields for the **show multicast rpf** command. Output fields are listed in the approximate order in which they appear.

**Table 450: show multicast rpf Output Fields**

| Field Name           | Field Description                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>      | Name of the routing instance. (Displayed when multicast is configured within a routing instance.)                                                                                                                                                                                                                                                                                                             |
| <b>Source prefix</b> | Prefix and length of the source as it exists in the multicast forwarding table.                                                                                                                                                                                                                                                                                                                               |
| <b>Protocol</b>      | How the route was learned.                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Interface</b>     | Upstream RPF interface.<br><br><b>NOTE:</b> The displayed interface information does not apply to bidirectional PIM RP addresses. This is because the <b>show multicast rpf</b> command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF interface information, always use the <b>show pim join extensive</b> command when bidirectional PIM is configured. |
| <b>Neighbor</b>      | Upstream RPF neighbor.<br><br><b>NOTE:</b> The displayed neighbor information does not apply to bidirectional PIM. This is because the <b>show multicast rpf</b> command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF neighbor information, always use the <b>show pim join extensive</b> command when bidirectional PIM is configured.                 |

## Sample Output

### show multicast rpf

```

user@host> show multicast rpf

Multicast RPF table: inet.0, 12 entries

**Table 451: show multicast scope Output Fields**

| Field Name   | Field Description                                           |
|--------------|-------------------------------------------------------------|
| Scope name   | Name of the multicast scope.                                |
| Group Prefix | Range of multicast groups that are scoped.                  |
| Interface    | Interface that is the boundary of the administrative scope. |

Table 451: show multicast scope Output Fields (*continued*)

| Field Name      | Field Description                 |
|-----------------|-----------------------------------|
| Resolve Rejects | Number of kernel resolve rejects. |

## Sample Output

### show multicast scope

```
user@host> show multicast scope
```

| Scope name | Group Prefix   | Interface  | Resolve Rejects |
|------------|----------------|------------|-----------------|
| 232-net    | 232.232.0.0/16 | fe-0/0/0.1 | 0               |
| local      | 239.255.0.0/16 | fe-0/0/0.1 | 0               |
| local      | ff05::/16      | fe-0/0/0.1 | 0               |
| larry      | ff05::1234/128 | fe-0/0/0.1 | 0               |

### show multicast scope inet

```
user@host> show multicast scope inet
```

| Scope name | Group Prefix   | Interface  | Resolve Rejects |
|------------|----------------|------------|-----------------|
| 232-net    | 232.232.0.0/16 | fe-0/0/0.1 | 0               |
| local      | 239.255.0.0/16 | fe-0/0/0.1 | 0               |

### show multicast scope inet6

```
user@host> show multicast scope inet6
```

| Scope name | Group Prefix   | Interface  | Resolve Rejects |
|------------|----------------|------------|-----------------|
| local      | ff05::/16      | fe-0/0/0.1 | 0               |
| larry      | ff05::1234/128 | fe-0/0/0.1 | 0               |

## show multicast sessions

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b>      | Command introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>              | Display the entries in the IP multicast snooping forwarding table. You can display some of this information with the <b>show route table inet.1</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Options</b>                  | <p><b>none</b>—Display standard information about all entries in the multicast snooping table for all virtual switches and all bridge domains.</p> <p><b>brief   detail   extensive</b>—(Optional) Display the specified level of output.</p> <p><b>active   all   inactive</b>—(Optional) Display all active entries, all entries, or all inactive entries, respectively, in the multicast snooping table.</p> <p><b>bridge-domain <i>bridge-domain</i></b>—(Optional) Display the entries for a particular bridge domain.</p> <p><b>group <i>group</i></b>—(Optional) Display the entries for a particular group.</p> <p><b>instance <i>instance-name</i></b>—(Optional) Display the entries for a multicast instance.</p> <p><b>mesh-group <i>mesh-group-name</i></b>—(Optional) Display the entries for a particular mesh group.</p> <p><b><i>regular-expression</i></b>—(Optional) Display information about the multicast forwarding table entries that match a UNIX-style regular expression.</p> <p><b>source-prefix <i>source-prefix</i></b>—(Optional) Display the entries for a particular source prefix.</p> |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Output Fields</b>            | Table 453 describes the output fields for the <b>show multicast snooping route</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 453: show multicast snooping route Output Fields

| Field Name                    | Field Description                                                                                                                                                                         | Level of Output         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>Nexthop Bulking</b>        | Displays whether next-hop bulk updating is <b>ON</b> or <b>OFF</b> (only for routing-instance type of <b>virtual switch</b> or <b>vpls</b> ).                                             | All levels              |
| <b>Family</b>                 | IPv4 address family ( <b>INET</b> ) or IPv6 address family ( <b>INET6</b> ).                                                                                                              | All levels              |
| <b>Group</b>                  | Group address.                                                                                                                                                                            | All levels              |
| <b>Source</b>                 | Prefix and length of the source as it is in the multicast forwarding table.                                                                                                               | All levels              |
| <b>Routing-instance</b>       | Name of the routing instance to which this routing information applies. (Displayed when multicast is configured within a routing instance.)                                               | All levels              |
| <b>Learning Domain</b>        | Name of the learning domain to which this routing information applies.                                                                                                                    | <b>detail extensive</b> |
| <b>Statistics</b>             | Rate at which packets are being forwarded for this source and group entry (in Kbps and pps), and number of packets that have been forwarded to this prefix.                               | <b>detail extensive</b> |
| <b>Next-hop ID</b>            | Next-hop identifier of the prefix. The identifier is returned by the router's Packet Forwarding Engine and is also displayed in the output of the <b>show multicast nexthops</b> command. | <b>detail extensive</b> |
| <b>Route state</b>            | Whether the group is <b>Active</b> or <b>Inactive</b> .                                                                                                                                   | <b>extensive</b>        |
| <b>Forwarding state</b>       | Whether the prefix is <b>Pruned</b> or <b>Forwarding</b> .                                                                                                                                | <b>extensive</b>        |
| <b>Cache lifetime/timeout</b> | Number of seconds until the prefix is removed from the multicast forwarding table. A value of <b>never</b> indicates a permanent forwarding entry.                                        | <b>extensive</b>        |

## Sample Output

### show multicast snooping route bridge-domain

```

user@host> show multicast snooping route bridge-domain br-dom-1 extensive
Family: INET

Group: 232.1.1.1
Source: 192.168.3.100/32
Downstream interface list:
 ge-0/1/0.200
Statistics: 0 kbps, 0 pps, 1 packets
Next-hop ID: 1048577
Route state: Active
Forwarding state: Forwarding
Cache lifetime/timeout: 240 seconds

```

### show multicast snooping route instance vs

```

user@host> show multicast snooping route instance vs
Nexthop Bulking: ON

Family: INET

```

```
Group: 224.0.0.0

| <b>Release Information</b>      | Command introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | Display IP multicast snooping statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <p><b>none</b>—Display multicast snooping statistics for all supported address families for all routing instances.</p> <p><b>instance <i>instance-name</i></b>—(Optional) Display statistics for a specific routing instance.</p> <p><b>interface <i>interface-name</i></b>—(Optional) Display statistics for a specific interface.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> |
| <b>Additional Information</b>   | The input and output interface multicast snooping statistics are consistent, but not timely. They are constructed from the forwarding statistics, which are gathered at 30-second intervals. Therefore, the output from this command always lags the true count by up to 30 seconds.                                                                                                                                                                                                                |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Output Fields</b>            | Table 454 describes the output fields for the <b>show multicast snooping statistics</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                            |

**Table 454: show multicast snooping statistics Output Fields**

| Field Name       | Field Description                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------|
| Routing-instance | Name of the routing instance. (Displayed when multicast is configured within a routing instance.)           |
| Family           | Protocol family for which multicast statistics are displayed: <b>INET</b> or <b>INET6</b> .                 |
| Interface        | Name of the interface for which statistics are being reported.                                              |
| Routing Protocol | Primary multicast protocol on the interface: <b>PIM</b> , <b>DVMRP for INET</b> , or <b>PIM for INET6</b> . |
| Mismatch         | Number of multicast packets that did not arrive on the correct upstream interface.                          |

Table 454: show multicast snooping statistics Output Fields (*continued*)

| Field Name               | Field Description                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Kernel Resolve</b>    | Number of resolve requests processed by the primary multicast protocol on the interface.                                          |
| <b>Resolve No Route</b>  | Number of resolve requests that were ignored because there was no route to the source.                                            |
| <b>In Kbytes</b>         | Total accumulated incoming packets (in KB) since the last time the <b>clear multicast snooping statistics</b> command was issued. |
| <b>Out Kbytes</b>        | Total accumulated outgoing packets (in KB) since the last time the <b>clear multicast snooping statistics</b> command was issued. |
| <b>Mismatch error</b>    | Number of mismatches that were ignored because of internal errors.                                                                |
| <b>Mismatch No Route</b> | Number of mismatches that were ignored because there was no route to the source.                                                  |
| <b>Routing Notify</b>    | Number of times that the multicast routing system has been notified of a new multicast source by a multicast routing protocol.    |
| <b>Resolve Error</b>     | Number of resolve requests that were ignored because of internal errors.                                                          |
| <b>In packets</b>        | Total number of incoming packets since the last time the <b>clear multicast snooping statistics</b> command was issued.           |
| <b>Out packets</b>       | Total number of outgoing packets since the last time the <b>clear multicast snooping statistics</b> command was issued.           |

## Sample Output

### show multicast snooping statistics

```
user@host> show multicast snooping statistics
Routing-instance: foo
Family: INET
Interface: fe-0/0/2.200
 Routing protocol: PIM Mismatch error: 0

Output fields are listed in the approximate order in which they appear.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Table 455: show multicast usage Output Fields

| Field Name      | Field Description                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b> | Name of the routing instance. (Displayed when multicast is configured within a routing instance.)                                                                                        |
| <b>Group</b>    | Group address.                                                                                                                                                                           |
| <b>Sources</b>  | Number of sources.                                                                                                                                                                       |
| <b>Packets</b>  | Number of packets that have been forwarded to this prefix. If one or more of the packets forwarded statistic queries fails or times out, the packets field displays <b>unavailable</b> . |
| <b>Bytes</b>    | Number of bytes that have been forwarded to this prefix. If one or more of the packets forwarded statistic queries fails or times out, the bytes field displays <b>unavailable</b> .     |
| <b>Prefix</b>   | IP address.                                                                                                                                                                              |
| <b>/len</b>     | Prefix length.                                                                                                                                                                           |
| <b>Groups</b>   | Number of multicast groups.                                                                                                                                                              |

## Sample Output

### show multicast usage

```

user@host> show multicast usage
Group Sources Packets Bytes
228.0.0.0 1 52847 4439148
239.1.1.1 2 13450 1125530

Prefix /len Groups Packets Bytes
10.255.14.144 /32 2 66254 5561304
10.255.70.15 /32 1 43 3374...
```

### show multicast usage brief

The output for the **show multicast usage brief** command is identical to that for the **show multicast usage** command. For sample output, see [show multicast usage on page 5065](#).

### show multicast usage instance

```

user@host> show multicast usage instance VPN-A
Group Sources Packets Bytes
224.2.127.254 1 5538 509496
224.0.1.39 1 13 624
224.0.1.40 1 13 624

Prefix /len Groups Packets Bytes
192.168.195.34 /32 1 5538 509496
10.255.14.30 /32 1 13 624
```

```
10.255.245.91 /32 1 13 624
...
```

#### show multicast usage detail

```
user@host> show multicast usage detail
Group Sources Packets Bytes
228.0.0.0 1 53159 4465356
 Source: 10.255.14.144 /32 Packets: 53159 Bytes: 4465356

| <b>Output Fields</b>            | Table 456 describes the output fields for the <b>show pgm negative-acknowledgments</b> command. Output fields are listed in the approximate order in which they appear.                                       |

**Table 456: show pgm negative-acknowledgments Output Fields**

| Field Name                                | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Global source id</b>                   | Global source identifier (GSI), which combines with the source port to determine the transport session identifier (TSI).                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Network layer address</b>              | Network layer address of the local system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Source port</b>                        | Source port number, which is combined with the GSI to determine the TSI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SPM sequence number</b>                | Numeric sequence identifier of the source-path message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Window (trailing/leading sequence)</b> | Range of sequence numbers used by the source for sequentially numbering and transmitting the most recent packets. The trailing (or left) edge of the transmit window is the sequence number of the oldest data packet available for repair from a source. The leading (or right) edge of the transmit window is defined as the sequence number of the most recent data packet a source has transmitted.                                                                                                                                   |
| <b>Outstanding NAKS</b>                   | <p>Total number of outstanding negative acknowledgments sent or received by the local system. NAK packets indicate that a packet in the expected original data sequence has been detected as missing.</p> <ul style="list-style-type: none"> <li>• <b>Sequence number</b>—Numeric sequence identifier of the source-path message.</li> <li>• <b>Group</b>—Group address.</li> <li>• <b>Source</b>—Multicast source.</li> <li>• <b>Interface</b>—Interface name.</li> <li>• <b>Receiver</b>—IP address receiving the multicast.</li> </ul> |

## Sample Output

**show pgm negative-  
acknowledgments**

```
user@host> show pgm negative-acknowledgments
Global source ID: 010203040506 Source port: 1111
Network layer address: 10.38.0.1
SPM sequence number: 1
Window (trailing/leading sequence): 0/1
Outstanding NAKs:
 Sequence number: 1
 Group: 225.1.1.1
 Source: 192.168.195.121
 Interface: t3-0/2/0:0 Receiver: 10.38.0.10
```

## show pgm source-path-messages

| <b>Output Fields</b>            | Table 458 describes the output fields for the <b>show pgm statistics</b> command. Output fields are listed in the approximate order in which they appear. |

**Table 458: show pgm statistics Output Fields**

| Field Name                                     | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PGM type, # received, # sent                   | <p>Number of packets received and sent for the following PGM packet types:</p> <ul style="list-style-type: none"> <li><b>SPM</b>—Number of total source path messages received and sent by the local system. Source path messages (SPMs) are sent by a source to establish the source path state in network elements and to provide the transmit-window state to receivers.</li> <li><b>POLL</b>—Total number of poll requests received and sent by the local system.</li> <li><b>POLR</b>—Total number of poll responses received and sent by the local system.</li> <li><b>ODATA</b>—Total number of original data packets received and sent by the local system.</li> <li><b>RDATA</b>—Total number of repair data packets received and sent by the local system. RDATA packets are generated in response to negative acknowledgments (NAKs), which indicate a missing packet from the original data sequence.</li> <li><b>NAK</b>—Total number of negative acknowledgments received and sent by the local system. NAK packets indicate that a packet in the expected original data sequence has been detected as missing.</li> <li><b>NULLNAK</b>—Total number of null negative acknowledgments received and sent by the local system. NULLNAKs are transmitted by a designated local repairer that receives NAKs redirected to it by either receivers or network elements to provide flow-control feedback to a source.</li> <li><b>NCF</b>—Total number of NAK confirmations received and sent by the local system. NAK confirmations are generated in response to NAK packets that are received.</li> <li><b>SPMR</b>—Total number of source path message requests (SPMRs) received and sent by the local system. SPMRs are used to solicit a source path message from a source in a nonimplosive way. The typical application is for late-joining receivers to solicit source path messages directly from a source in order to be able to send NAKs for missing packets, without having to wait for a regularly scheduled source path message from that source.</li> <li><b>OTHER</b>—Total number of other PGM packets received and sent by the local system.</li> </ul> |
| packets shorter than minimum PGM header length | Total number of packets received with headers that are shorter than the minimum required PGM header length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 458: show pgm statistics Output Fields (*continued*)

| Field Name                                       | Field Description                                                                                                                                                                                       |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| packets received with incorrect check sum        | Total number of packets received with an incorrect checksum. The checksum field is the 1's complement of the 1's complement sum of the entire PGM packet, including the header.                         |
| packets received with zero check sum             | Total number of packets received with a zero checksum. If the computed checksum is zero, it is transmitted as all ones. A value of zero in this field means that the transmitter generated no checksum. |
| packets received with TSDU length incorrect      | Total number of packets received with an incorrect Transport Service Data Unit (TSDU) length (16 bits).                                                                                                 |
| packets received with SPM length incorrect       | Total number of packets received with an incorrect source path message length.                                                                                                                          |
| packets received with unknown SPM address family | Total number of packets received with an unknown source path message address family indicator (AFI).                                                                                                    |
| packets received with NAK length incorrect       | Total number of packets received with an incorrect NAK length.                                                                                                                                          |
| packets received with unknown NAK address family | Total number of packets received with an unknown NAK address family indicator (AFI).                                                                                                                    |
| packets received with NAK for unknown TSI        | Total number of NAK packets received with an unknown transport session identifier (TSI).                                                                                                                |
| packets received when NAK throttled              | Total number of packets received when NAK is throttled.                                                                                                                                                 |
| packets received with NCF length incorrect       | Total number of packets received with an incorrect NAK confirmation length.                                                                                                                             |
| packets received with unknown NCF address family | Total number of packets received with an unknown NAK confirmation address family indicator (AFI).                                                                                                       |
| packets received with NCF for unknown TSI        | Total number of NAK confirmation packets received with an unknown transport session identifier (TSI).                                                                                                   |
| packets received with RDATA length incorrect     | Total number of packets received with an incorrect RDATA length.                                                                                                                                        |
| packets received with RDATA for unknown TSI      | Total number of RDATA packets received with an unknown transport session identifier (TSI).                                                                                                              |

| Field Name        | Field Description                                                                                                                                                                                                                                                                                                                                                           | Level of Output                                                      |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <b>Interfaces</b> | Bidirectional PIM interfaces on this routing device. An interface can win the DF election ( <b>Win</b> ), lose the DF election ( <b>Lose</b> ), or be the RP link ( <b>RPL</b> ). The RP link is the interface directly connected to a subnet that contains a phantom RP address. A phantom RP address is an RP address that is not assigned to a routing device interface. | All levels<br><br><b>brief</b> displays the DF election winner only. |
| <b>DF</b>         | IP address of the designated forwarder.                                                                                                                                                                                                                                                                                                                                     | All levels                                                           |

| <b>Output Fields</b>            | <a href="#">Table 460</a> describes the output fields for the <b>show pim bidirectional df-election interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                              |

**Table 460: show pim bidirectional df-election interface Output Fields**

| Field Name             | Field Description                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>        | Name of the routing instance.                                                                                                   |
| <b>Family</b>          | IPv4 address family ( <b>INET</b> ) or IPv6 address family ( <b>INET6</b> ).                                                    |
| <b>Interface</b>       | Name of the bidirectional PIM interface.                                                                                        |
| <b>Robustnes Count</b> | Minimum number of DF election messages that must fail to be received for DF election to fail.                                   |
| <b>Offer Period</b>    | Interval between repeated DF election messages.                                                                                 |
| <b>Backoff Period</b>  | Period that the acting DF waits between receiving a better DF Offer and sending the Pass message to transfer DF responsibility. |

Table 460: show pim bidirectional df-election interface Output Fields (*continued*)

| Field Name | Field Description                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RPA        | RP address.                                                                                                                                                  |
| State      | For each RP address, state of each interface with respect to the DF election: <b>Offer</b> (when the election is in progress), <b>Win</b> , or <b>Lose</b> . |
| DF         | IP address of the designated forwarder.                                                                                                                      |

## Sample Output

### show pim bidirectional df-election interface

```

**Table 461: show pim bootstrap Output Fields**

| Field Name           | Field Description                                                            |
|----------------------|------------------------------------------------------------------------------|
| <b>Instance</b>      | Name of the routing instance.                                                |
| <b>BSR</b>           | Bootstrap router.                                                            |
| <b>Pri</b>           | Priority of the routing device as elected to be the bootstrap router.        |
| <b>Local address</b> | Local routing device address.                                                |
| <b>Pri</b>           | Local routing device address priority to be elected as the bootstrap router. |

Table 461: show pim bootstrap Output Fields (*continued*)

| Field Name     | Field Description                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------|
| <b>State</b>   | Local routing device election state: <b>Candidate</b> , <b>Elected</b> , or <b>Ineligible</b> .      |
| <b>Timeout</b> | How long until the local routing device declares the bootstrap router to be unreachable, in seconds. |

## Sample Output

### show pim bootstrap

```
user@host> show pim bootstrap
Instance: PIM.master
```

| BSR                        | Pri                     | Local address | Pri        | State      | Timeout |
|----------------------------|-------------------------|---------------|------------|------------|---------|
| None                       | 0                       | 10.255.71.46  | 0          | InEligible | 0       |
| feco:1:1:1:1:0:aff:785c 34 | feco:1:1:1:1:0:aff:7c12 | 0             | InEligible | 0          |         |

### show pim bootstrap instance

```
user@host> show pim bootstrap instance VPN-A
Instance: PIM.VPN-A
```

| BSR  | Pri | Local address   | Pri | State      | Timeout |
|------|-----|-----------------|-----|------------|---------|
| None | 0   | 192.168.196.105 | 0   | InEligible | 0       |

## show pim interfaces

**List of Syntax** [Syntax on page 5081](#)

[Syntax \(EX Series Switch and the QFX Series\) on page 5081](#)

**Syntax** show pim interfaces  
 <inet | inet6>  
 <instance *instance-name*>  
 <logical-system (all | *logical-system-name*)>

**Syntax (EX Series Switch and the QFX Series)** show pim interfaces  
 <inet | inet6>  
 <instance *instance-name*>

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.0 for EX Series switches.  
**inet6** and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.  
 Command introduced in Junos OS Release 11.3 for the QFX Series.  
 Support for bidirectional PIM added in Junos OS Release 12.1.

**Description** Display information about the interfaces on which Protocol Independent Multicast (PIM) is configured.

**Options** **none**—Display interface information for all family addresses for all routing instances.

**inet | inet6**—(Optional) Display interface information for IPv4 or IPv6 family addresses, respectively.

**instance *instance-name***—(Optional) Display information about interfaces for a specific PIM-enabled routing instance.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**Required Privilege Level** view

**List of Sample Output** [show pim interfaces on page 5082](#)

**Output Fields** [Table 462](#) describes the output fields for the **show pim interfaces** command. Output fields are listed in the approximate order in which they appear.

**Table 462: show pim interfaces Output Fields**

| Field Name      | Field Description                                                                          |
|-----------------|--------------------------------------------------------------------------------------------|
| <b>Instance</b> | Name of the routing instance.                                                              |
| <b>Name</b>     | Interface name.                                                                            |
| <b>State</b>    | State of the interface. The state also is displayed in the <b>show interfaces</b> command. |

| Field Name          | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Mode</b>         | <p>PIM mode running on the interface:</p> <ul style="list-style-type: none"> <li>• <b>B</b>—In bidirectional mode, multicast groups are carried across the network over bidirectional shared trees. This type of tree minimizes PIM routing state, which is especially important in networks with numerous and dispersed senders and receivers.</li> <li>• <b>S</b>—In sparse mode, routing devices must join and leave multicast groups explicitly. Upstream routing devices do not forward multicast traffic to this routing device unless this device has sent an explicit request (using a join message) to receive multicast traffic.</li> <li>• <b>Dense</b>—Unlike sparse mode, where data is forwarded only to routing devices sending an explicit request, dense mode implements a flood-and-prune mechanism, similar to DVMRP (the first multicast protocol used to support the multicast backbone). (Not supported on QFX Series.)</li> <li>• <b>Sparse-Dense</b>—Sparse-dense mode allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as <b>dense</b> is not mapped to a rendezvous point (RP). Instead, data packets destined for that group are forwarded using PIM-Dense Mode (PIM-DM) rules. A group specified as <b>sparse</b> is mapped to an RP, and data packets are forwarded using PIM-Sparse Mode (PIM-SM) rules. (Not supported on QFX Series.)</li> </ul> <p>When sparse-dense mode is configured, the output includes both <b>S</b> and <b>D</b>. When bidirectional-sparse mode is configured, the output includes <b>S</b> and <b>B</b>. When bidirectional-sparse-dense mode is configured, the output includes <b>B</b>, <b>S</b>, and <b>D</b>.</p> |
| <b>IP</b>           | Version number of the address family on the interface: <b>4</b> (IPv4) or <b>6</b> (IPv6).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Release Information**    Command introduced before Junos OS Release 7.4.  
                                   Command introduced in Junos OS Release 9.0 for EX Series switches.  
                                   **summary** option introduced in Junos OS Release 9.6.  
                                   **inet6** and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.  
                                   Support for bidirectional PIM added in Junos OS Release 12.1.  
                                   Command introduced in Junos OS Release 11.3 for the QFX Series.  
                                   Multiple new filter options introduced in Junos OS Release 13.2.  
                                   Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description**    Display information about Protocol Independent Multicast (PIM) groups for all PIM modes.

For bidirectional PIM, display information about PIM group ranges (\*G-range) for each active bidirectional RP group range, in addition to each of the joined (\*G) routes.

**Options**    **none**—Display the standard information about PIM groups for all supported family addresses for all routing instances.

**brief | detail | extensive | summary**—(Optional) Display the specified level of output.

**bidirectional | dense | sparse**—(Optional) Display information about PIM bidirectional mode, dense mode, or sparse and source-specific multicast (SSM) mode entries.

**exact**—(Optional) Display information about only the group that exactly matches the specified group address.

**inet | inet6**—(Optional) Display PIM group information for IPv4 or IPv6 family addresses, respectively.

**instance *instance-name***—(Optional) Display information about groups for the specified PIM-enabled routing instance only.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**range**—(Optional) Address range of the group, specified as *prefix/prefix-length*.

**rp *ip-address/prefix* | source *ip-address/prefix***—(Optional) Display information about the PIM entries with a specified rendezvous point (RP) address and prefix or with a specified source address and prefix. You can omit the prefix.

**sg | star-g**—(Optional) Display information about PIM (S,G) or (\*,G) entries.

**Required Privilege Level**

| <b>Hello Option Bi-Directional PIM supported</b> | Neighbor can process bidirectional PIM messages.                                                                                                                                                                                                                                                                                                 | <b>detail</b>     |
| <b>Hello Option LAN Prune Delay</b>              | Time to wait before the neighbor receives prune messages, in the format <b>delay nnn ms override nnnn ms</b> .                                                                                                                                                                                                                                   | <b>detail</b>     |

Table 464: show pim neighbors Output Fields (*continued*)

| Field Name                 | Field Description                                                                                                                                                                                                                                                                   | Level of Output |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Join Suppression supported | Neighbor is capable of join suppression.                                                                                                                                                                                                                                            | detail          |
| Rx Join                    | Information about joins received from the neighbor. <ul style="list-style-type: none"> <li><b>Group</b>—Group addresses in the join message.</li> <li><b>Source</b>—Address of the source in the join message.</li> <li><b>Timeout</b>—Time for which the join is valid.</li> </ul> | detail          |

## Sample Output

### show pim neighbors

```

user@host> show pim neighbors
Instance: PIM.master
B = Bidirectional Capable, G = Generation Identifier,
H = Hello Option Holdtime, L = Hello Option LAN Prune Delay,
P = Hello Option DR Priority, T = Tracking bit

Interface IP V Mode Option Uptime Neighbor addr
so-1/0/0.0 4 2 HPLG 00:07:10 10.111.10.2

```

### show pim neighbors brief

The output for the **show pim neighbors brief** command is identical to that for the **show pim neighbors** command. For sample output, see [show pim neighbors on page 5107](#).

### show pim neighbors instance

```

user@host> show pim neighbors instance VPN-A
Instance: PIM.VPN-A
B = Bidirectional Capable, G = Generation Identifier,
H = Hello Option Holdtime, L = Hello Option LAN Prune Delay,
P = Hello Option DR Priority, T = Tracking bit

Interface IP V Mode Option Uptime Neighbor addr
at-0/3/1.0 4 2 HPLG 00:07:54 10.111.30.2
mt-1/1/0.32768 4 2 HPLG 00:07:22 10.10.47.101
so-1/0/1.0 4 2 HPLG 00:07:50 10.111.20.2

```

### show pim neighbors detail

```

user@host> show pim neighbors detail
Instance: PIM.master
Interface: ge-0/0/1.0

Address: 10.10.1.1, IPv4, PIM v2, Mode: SparseDense, sg Join Count: 0, tsf
Join Count: 2
Hello Option Holdtime: 65535 seconds
Hello Option DR Priority: 1
Hello Option Generation ID: 2053759302
Hello Option Bi-Directional PIM supported
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported

```

```
Address: 10.10.1.2, IPv4, PIM v2, sg Join Count: 0, tsg Join Count: 2
BFD: Disabled
Hello Option Holdtime: 105 seconds 93 remaining
Hello Option DR Priority: 1
Hello Option Generation ID: 1734018161
Hello Option Bi-Directional PIM supported
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
```

Interface: lo0.0

```
Address: 10.255.179.246, IPv4, PIM v2, Mode: SparseDense, sg Join Count:
0, tsg Join Count: 0
Hello Option Holdtime: 65535 seconds

| RP selected                    | For sparse mode and bidirectional mode, the identity of the RP for the specified group address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <i>group-address</i> |

## Sample Output

### show pim rps

```

user@host> show pim rps
Instance: PIM.master
Address family INET
RP address Type Mode Holdtime Timeout Groups Group prefixes
10.10.1.3 static bidir 150 None 2 224.1.3.0/24
 225.1.3.0/24
10.10.13.2 static bidir 150 None 2 224.1.1.0/24
 225.1.1.0/24

```

### show pim rps brief

The output for the **show pim rps brief** command is identical to that for the **show pim rps** command. For sample output, see [show pim rps on page 5112](#).

### show pim rps <group-address>

```

user@host> show pim rps 235.100.100.0
Instance: PIM.master
Instance: PIM.master

RP selected: 100.100.100.100

```

### show pim rps <group-address> (Bidirectional PIM)

```

user@host> show pim rps 224.1.1.1
Instance: PIM.master

224.1.0.0/16
11.4.12.75 (Bidirectional)

RP selected: 11.4.12.75

```

**show pim rps <group-address> (PIM Dense Mode)**

```
user@host> show pim rps 224.1.1.1
Instance: PIM.master

Dense Mode active for group 224.1.1.1
```

**show pim rps <group-address> (SSM Range Without asm-override-ssm Configured)**

```
user@host> show pim rps 224.1.1.1
Instance: PIM.master

Source-specific Mode (SSM) active for group 224.1.1.1
```

**show pim rps <group-address> (SSM Range With asm-override-ssm Configured and a Sparse-Mode RP)**

```
user@host> show pim rps 224.1.1.1
Instance: PIM.master

Source-specific Mode (SSM) active with Sparse Mode ASM override for group 224.1.1.1

224.1.0.0/16
 11.4.12.75

RP selected: 11.4.12.75
```

**show pim rps <group-address> (SSM Range With asm-override-ssm Configured and a Bidirectional RP)**

```
user@host> show pim rps 224.1.1.1
Instance: PIM.master

Source-specific Mode (SSM) active with Sparse Mode ASM override for group 224.1.1.1

224.1.0.0/16
 11.4.12.75 (Bidirectional)

RP selected: (null)
```

**show pim rps instance**

```
user@host> show pim rps instance VPN-A
Instance: PIM.VPN-A
Address family INET
RP address Type Holdtime Timeout Groups Group prefixes
10.10.47.100 static 0 None 1 224.0.0.0/4

Address family INET6
```

**show pim rps extensive (PIM Sparse Mode)**

```
user@host> show pim rps extensive
Instance: PIM.master

Family: INET
RP: 10.255.245.91
Learned via: static configuration
Time Active: 00:05:48

| <b>Output Fields</b>                                | Table 466 describes the output fields for the <b>show pim source</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 466: show pim source Output Fields

| Field Name         | Field Description                                                     |
|--------------------|-----------------------------------------------------------------------|
| Instance           | Name of the routing instance.                                         |
| Source             | Address of the source or reverse path.                                |
| Prefix/length      | Prefix and prefix length for the route used to reach the RPF address. |
| Upstream interface | RPF interface toward the source address.                              |
| Upstream Neighbor  | Address of the RPF neighbor used to reach the source address.         |

## Sample Output

### show pim source

```

user@host> show pim source
Instance: PIM.master Family: INET

Source 10.255.14.144
 Prefix 10.255.14.144/32
 Upstream interface Local
 Upstream neighbor Local

Source 10.255.70.15
 Prefix 10.255.70.15/32
 Upstream interface so-1/0/0.0
 Upstream neighbor 10.111.10.2

Instance: PIM.master Family: INET6

```

### show pim source brief

The output for the **show pim source brief** command is identical to that for the **show pim source** command. For sample output, see [show pim source on page 5117](#).

### show pim source detail

```

user@host> show pim source detail
Instance: PIM.master Family: INET

Source 10.255.14.144
 Prefix 10.255.14.144/32
 Upstream interface Local
 Upstream neighbor Local
 Active groups:228.0.0.0
 239.1.1.1
 239.1.1.1

Source 10.255.70.15
 Prefix 10.255.70.15/32
 Upstream interface so-1/0/0.0
 Upstream neighbor 10.111.10.2
 Active groups:239.1.1.1

```

Instance: PIM.master Family: INET6

## show pim statistics

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 467: show pim statistics Output Fields

| Field Name              | Field Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>         | <p>Name of the routing instance.</p> <p>This field only appears if you specify an interface, for example:</p> <ul style="list-style-type: none"> <li>• <b>inet</b> interface <i>interface-name</i></li> <li>• <b>inet6</b> interface <i>interface-name</i></li> <li>• <b>interface</b> <i>interface-name</i></li> </ul>                                                                                                 |
| <b>Family</b>           | <p>Output is for IPv4 or IPv6 PIM statistics. <b>INET</b> indicates IPv4 statistics, and <b>INET6</b> indicates IPv6 statistics.</p> <p>This field only appears if you specify an interface, for example:</p> <ul style="list-style-type: none"> <li>• <b>inet</b> interface <i>interface-name</i></li> <li>• <b>inet6</b> interface <i>interface-name</i></li> <li>• <b>interface</b> <i>interface-name</i></li> </ul> |
| <b>PIM statistics</b>   | PIM statistics for all interfaces or for the specified interface.                                                                                                                                                                                                                                                                                                                                                       |
| <b>PIM message type</b> | Message type for which statistics are displayed.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Received</b>         | Number of received statistics.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Sent</b>             | Number of messages sent of a certain type.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Rx errors</b>        | Number of received packets that contained errors.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>V2 Hello</b>         | PIM version 2 hello packets.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>V2 Register</b>      | PIM version 2 register packets.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>V2 Register Stop</b> | PIM version 2 register stop packets.                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>V2 Join Prune</b>    | PIM version 2 join and prune packets.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>V2 Bootstrap</b>     | PIM version 2 bootstrap packets.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>V2 Assert</b>        | PIM version 2 assert packets.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>V2 Graft</b>         | PIM version 2 graft packets.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>V2 Graft Ack</b>     | PIM version 2 graft acknowledgment packets.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>V2 Candidate RP</b>  | PIM version 2 candidate RP packets.                                                                                                                                                                                                                                                                                                                                                                                     |

Table 467: show pim statistics Output Fields (*continued*)

| Field Name                              | Field Description                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>V2 State Refresh</b>                 | PIM version 2 control messages related to PIM dense mode (PIM-DM) state refresh.<br><br>State refresh is an extension to PIM-DM. It not supported in Junos OS. |
| <b>V2 DF Election</b>                   | PIM version 2 send and receive messages associated with bidirectional PIM designated forwarder election.                                                       |
| <b>V1 Query</b>                         | PIM version 1 query packets.                                                                                                                                   |
| <b>V1 Register</b>                      | PIM version 1 register packets.                                                                                                                                |
| <b>V1 Register Stop</b>                 | PIM version 1 register stop packets.                                                                                                                           |
| <b>V1 Join Prune</b>                    | PIM version 1 join and prune packets.                                                                                                                          |
| <b>V1 RP Reachability</b>               | PIM version 1 RP reachability packets.                                                                                                                         |
| <b>V1 Assert</b>                        | PIM version 1 assert packets.                                                                                                                                  |
| <b>V1 Graft</b>                         | PIM version 1 graft packets.                                                                                                                                   |
| <b>V1 Graft Ack</b>                     | PIM version 1 graft acknowledgment packets.                                                                                                                    |
| <b>AutoRP Announce</b>                  | Auto-RP announce packets.                                                                                                                                      |
| <b>AutoRP Mapping</b>                   | Auto-RP mapping packets.                                                                                                                                       |
| <b>AutoRP Unknown type</b>              | Auto-RP packets with an unknown type.                                                                                                                          |
| <b>Anycast Register</b>                 | Auto-RP announce packets.                                                                                                                                      |
| <b>Anycast Register Stop</b>            | Auto-RP announce packets.                                                                                                                                      |
| <b>Global Statistics</b>                | Summary of PIM statistics for all interfaces.                                                                                                                  |
| <b>Hello dropped on neighbor policy</b> | Number of hello packets dropped because of a configured neighbor policy.                                                                                       |
| <b>Unknown type</b>                     | Number of PIM control packets received with an unknown type.                                                                                                   |
| <b>V1 Unknown type</b>                  | Number of PIM version 1 control packets received with an unknown type.                                                                                         |
| <b>Unknown Version</b>                  | Number of PIM control packets received with an unknown version. The version is not version 1 or version 2.                                                     |

Table 467: show pim statistics Output Fields (*continued*)

| Field Name                             | Field Description                                                                                                         |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Neighbor unknown</b>                | Number of PIM control packets received (excluding PIM hello) without first receiving the hello packet.                    |
| <b>Bad Length</b>                      | Number of PIM control packets received for which the packet size does not match the PIM length field in the packet.       |
| <b>Bad Checksum</b>                    | Number of PIM control packets received for which the calculated checksum does not match the checksum field in the packet. |
| <b>Bad Receive If</b>                  | Number of PIM control packets received on an interface that does not have PIM configured.                                 |
| <b>Rx Bad Data</b>                     | Number of PIM control packets received that contain data for TCP Bad register packets.                                    |
| <b>Rx Intf disabled</b>                | Number of PIM control packets received on an interface that has PIM disabled.                                             |
| <b>Rx V1 Require V2</b>                | Number of PIM version 1 control packets received on an interface configured for PIM version 2.                            |
| <b>Rx V2 Require V1</b>                | Number of PIM version 2 control packets received on an interface configured for PIM version 1.                            |
| <b>Rx Register not RP</b>              | Number of PIM register packets received when the router is not the RP for the group.                                      |
| <b>Rx Register no route</b>            | Number of PIM register packets received when the RP does not have a unicast route back to the source.                     |
| <b>Rx Register no decap if</b>         | Number of PIM register packets received when the RP does not have a de-encapsulation interface.                           |
| <b>Null Register Timeout</b>           | Number of NULL register timeout packets.                                                                                  |
| <b>RP Filtered Source</b>              | Number of PIM packets received when the router has a source address filter configured for the RP.                         |
| <b>Rx Unknown Reg Stop</b>             | Number of register stop messages received with an unknown type.                                                           |
| <b>Rx Join/Prune no state</b>          | Number of join and prune messages received for which the router has no state.                                             |
| <b>Rx Join/Prune on upstream if</b>    | Number of join and prune messages received on the interface used to reach the upstream router, toward the RP.             |
| <b>Rx Join/Prune for invalid group</b> | Number of join or prune messages received for invalid multicast group addresses.                                          |

Table 467: show pim statistics Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                           |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Rx Join/Prune messages dropped</b> | Number of join and prune messages received and dropped.                                                                                                     |
| <b>Rx sparse join for dense group</b> | Number of PIM sparse mode join messages received for a group that is configured for dense mode.                                                             |
| <b>Rx Graft/Graft Ack no state</b>    | Number of graft and graft acknowledgment messages received for which the router or switch has no state.                                                     |
| <b>Rx Graft on upstream if</b>        | Number of graft messages received on the interface used to reach the upstream router, toward the RP.                                                        |
| <b>Rx CRP not BSR</b>                 | Number of BSR messages received in which the PIM message type is Candidate-RP-Advertisement, not Bootstrap.                                                 |
| <b>Rx BSR when BSR</b>                | Number of BSR messages received in which the PIM message type is Bootstrap.                                                                                 |
| <b>Rx BSR not RPF if</b>              | Number of BSR messages received on an interface that is not the RPF interface.                                                                              |
| <b>Rx unknown hello opt</b>           | Number of PIM hello packets received with options that Junos OS does not support.                                                                           |
| <b>Rx data no state</b>               | Number of PIM control packets received for which the router has no state for the data type.                                                                 |
| <b>Rx RP no state</b>                 | Number of PIM control packets received for which the router has no state for the RP.                                                                        |
| <b>Rx aggregate</b>                   | Number of PIM aggregate MDT packets received.                                                                                                               |
| <b>Rx malformed packet</b>            | Number of PIM control packets received with a malformed IP unicast or multicast address family.                                                             |
| <b>No RP</b>                          | Number of PIM control packets received with no RP address.                                                                                                  |
| <b>No register encaps if</b>          | Number of PIM register packets received when the first-hop router does not have an encapsulation interface.                                                 |
| <b>No route upstream</b>              | Number of PIM control packets received when the router does not have a unicast route to the the interface used to reach the upstream router, toward the RP. |
| <b>Nexthop Unusable</b>               | Number of PIM control packets with an unusable nexthop. A path can be unusable if the route is hidden or the link is down.                                  |
| <b>RP mismatch</b>                    | Number of PIM control packets received for which the router has an RP mismatch.                                                                             |

Table 467: show pim statistics Output Fields (*continued*)

| Field Name                                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RP mode mismatch</b>                    | RP mode (sparse or bidirectional) mismatches encountered when processing join and prune messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RPF neighbor unknown</b>                | Number of PIM control packets received for which the router has an unknown RPF neighbor for the source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Rx Joins/Prunes filtered</b>            | The number of join and prune messages filtered because of configured route filters and source address filters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Tx Joins/Prunes filtered</b>            | The number of join and prune messages filtered because of configured route filters and source address filters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Embedded-RP invalid addr</b>            | Number of packets received with an invalid embedded RP address in PIM join messages and other types of messages sent between routing domains.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Embedded-RP limit exceed</b>            | Number of times the limit configured with the <b>maximum-rps</b> statement is exceeded. The <b>maximum-rps</b> statement limits the number of embedded RPs created in a specific routing instance. The range is from 1 through 500. The default is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Embedded-RP added</b>                   | <p>Number of packets in which the embedded RP for IPv6 is added.</p> <p>The following receive events trigger extraction of an IPv6 embedded RP address on the router:</p> <ul style="list-style-type: none"> <li>• Multicast Listener Discovery (MLD) report for an embedded RP multicast group address</li> <li>• PIM join message with an embedded RP multicast group address</li> <li>• Static embedded RP multicast group address associated with an interface</li> <li>• Packets sent to an embedded RP multicast group address received on the DR</li> </ul> <p>An embedded RP node discovered through these receive events is added if it does not already exist on the routing platform.</p> |
| <b>Embedded-RP removed</b>                 | Number of packets in which the embedded RP for IPv6 is removed. The embedded RP is removed whenever all PIM join states using this RP are removed or the configuration changes to remove the embedded RP feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Rx Register msgs filtering drop</b>     | Number of received register messages dropped because of a filter configured for PIM register messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Tx Register msgs filtering drop</b>     | Number of register messages dropped because of a filter configured for PIM register messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Rx Bidir Join/Prune on non-Bidir if</b> | Error counter for join and prune messages received on non-bidirectional PIM interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Table 467: show pim statistics Output Fields (*continued*)

| Field Name                              | Field Description                                                                          |
|-----------------------------------------|--------------------------------------------------------------------------------------------|
| <b>Rx Bidir Join/Prune on non-DF if</b> | Error counter for join and prune messages received on non-designated forwarder interfaces. |

Table 468: show policy Output Fields

| Field Name         | Field Description               |
|--------------------|---------------------------------|
| <i>policy-name</i> | Name of the policy listed.      |
| <i>term</i>        | Policy term listed.             |
| <i>from</i>        | Match condition for the policy. |
| <i>then</i>        | Action for the policy.          |

Sample Output

show policy

user@host> show policy

```
Configured policies:
__vrf-export-red-internal__
__vrf-import-red-internal__
red-export
all_routes
```

### **show policy policy-name**

```
user@host> show policy test-statics
Policy test-statics:
 from
 3.0.0.0/8 accept
 3.1.0.0/16 accept
 then reject
```

### **show policy (Multicast Scoping)**

```
user@host> show policy test-statics
Policy test-statics:
 from
 multicast-scoping == 8
```

## Sample Output

### show route table bgp.l2vpn

```

user@host> show route table bgp.l2vpn
bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.24.1:1:4:1/96
 *[BGP/170] 01:08:58, localpref 100, from 192.168.24.1
 AS path: I
 > to 10.0.16.2 via fe-0/0/1.0, label-switched-path am

```

### show route table bgp.l3vpn.0

```

user@host> show route table bgp.l3vpn.0
bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.71.15:100:10.255.71.17/32
 *[BGP/170] 00:03:59, MED 1, localpref 100, from
10.255.71.15
 AS path: I
 > via so-2/1/0.0, Push 100020, Push 100011(top)
10.255.71.15:200:10.255.71.18/32
 *[BGP/170] 00:03:59, MED 1, localpref 100, from
10.255.71.15
 AS path: I
 > via so-2/1/0.0, Push 100021, Push 100011(top)

```

### show route table bgp.l3vpn.0 detail

```

user@host> show route table bgp.l3vpn.0 detail
bgp.l3vpn.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)

### show route table mpls.0 (RSVP Route—Transit LSP)

In the sample output, the 1 in [RSVP/7/1] indicates the secondary preference value. The secondary preference value becomes significant when multiple RSVP LSPs of different types are signaled to the destination. The possible values of RSVP secondary preferences are:

1—Normal Point-to-Point RSVP-TE LSP

2—Point-to-Multipoint (P2MP) RSVP-TE LSP

3—Dynamic RSVP-TE LSP

```

## Sample Output

### show route table bgp.l2vpn

```

user@host> show route table bgp.l2vpn
bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.24.1:1:4:1/96
 *[BGP/170] 01:08:58, localpref 100, from 192.168.24.1
 AS path: I
 > to 10.0.16.2 via fe-0/0/1.0, label-switched-path am

```

### show route table bgp.l3vpn.0

```

user@host> show route table bgp.l3vpn.0
bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.71.15:100:10.255.71.17/32
 *[BGP/170] 00:03:59, MED 1, localpref 100, from
10.255.71.15
 AS path: I
 > via so-2/1/0.0, Push 100020, Push 100011(top)
10.255.71.15:200:10.255.71.18/32
 *[BGP/170] 00:03:59, MED 1, localpref 100, from
10.255.71.15
 AS path: I
 > via so-2/1/0.0, Push 100021, Push 100011(top)

```

### show route table bgp.l3vpn.0 detail

```

user@host> show route table bgp.l3vpn.0 detail
bgp.l3vpn.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)

### show route table mpls.0 (RSVP Route—Transit LSP)

In the sample output, the 1 in [RSVP/7/1] indicates the secondary preference value. The secondary preference value becomes significant when multiple RSVP LSPs of different types are signaled to the destination. The possible values of RSVP secondary preferences are:

1—Normal Point-to-Point RSVP-TE LSP

2—Point-to-Multipoint (P2MP) RSVP-TE LSP

3—Dynamic RSVP-TE LSP

```

|----------------------|------------------------------------------------------------------------------|
| <b>Group address</b> | Address of the group that the local router is listening to for SAP messages. |
| <b>Port</b>          | UDP port number used for SAP.                                                |

## Sample Output

### show sap listen

```
user@host> show sap listen
Group address Port
224.2.127.254 9875
239.255.255.255 9875
```

### show sap listen brief

The output for the **show sap listen brief** command is identical to that for the **show sap listen** command. For sample output, see [show sap listen on page 5161](#).

### show sap listen detail

The output for the **show sap listen detail** command is identical to that for the **show sap listen** command. For sample output, see [show sap listen on page 5161](#).

# Network Address Translation Feature Guide for Security Devices

# Overview

- [Introduction to NAT on page 5165](#)
- [Understanding NAT Rule Sets and Rules on page 5166](#)

## Introduction to NAT

---

Network Address Translation (NAT) is a method for modifying or translating network address information in packet headers. Either or both source and destination addresses in a packet may be translated. NAT can include the translation of port numbers as well as IP addresses.

NAT is described in RFC 1631 to solve IP (version 4) address depletion problems. Since then, NAT has been found to be a useful tool for firewalls, traffic redirect, load sharing, network migrations, and so on.

The following types of NAT are supported on Juniper Networks devices:

- Static NAT
- Destination NAT
- Source NAT

**NOTE:** SRX Series devices perform both policy lookup and service lookup based on the translated destination port.

### Related Documentation

- [Understanding NAT Rule Sets and Rules on page 5166](#)
- [Understanding Static NAT on page 5275](#)
- [Understanding Destination NAT on page 5251](#)

- [Understanding Central Point Architecture Enhancements for NAT on page 5207](#)

## Understanding NAT Rule Sets and Rules

---

NAT processing centers on the evaluation of NAT rule sets and rules. A rule set determines the overall direction of the traffic to be processed. For example, a rule set can select traffic from a particular interface or to a specific zone. A rule set can contain multiple rules. Once a rule set is found that matches specific traffic, each rule in the rule set is evaluated for a match. Each rule in the rule set further specifies the traffic to be matched and the action to be taken when traffic matches the rule.

This topic includes the following sections:

- [NAT Rule Sets on page 5166](#)
- [NAT Rules on page 5167](#)
- [Rule Processing on page 5167](#)
- [NAT Rule Capacity on page 5168](#)

### NAT Rule Sets

A rule set specifies a general set of matching conditions for traffic. For static NAT and destination NAT, a rule set specifies one of the following:

- Source interface
- Source zone
- Source routing instance

For source NAT rule sets, you configure both source and destination conditions:

- Source interface, zone, or routing instance
- Destination interface, zone, or routing instance

It is possible for a packet to match more than one rule set; in this case, the rule set with the more specific match is used. An interface match is considered more specific than a zone match, which is more specific than a routing instance match. If a packet matches both a destination NAT rule set that specifies a source zone and a destination NAT rule set that specifies a source interface, the rule set that specifies the source interface is the more specific match.

Source NAT rule set matching is more complex because you specify both source and destination conditions in a source NAT rule set. In the case where a packet matches more than one source NAT rule set, the rule set chosen is based on the following source/destination conditions (in order of priority):

1. Source interface/destination interface
2. Source zone/destination interface
3. Source routing instance/destination interface
4. Source interface/destination zone

5. Source zone/destination zone
6. Source routing instance/destination zone
7. Source interface/destination routing instance
8. Source zone/destination routing instance
9. Source routing instance/destination routing instance

For example, you can configure rule set A, which specifies a source interface and a destination zone, and rule set B, which specifies a source zone and a destination interface. If a packet matches both rule sets, rule set B is the more specific match.

**NOTE:** You cannot specify the same source and destination conditions for source NAT rule sets.

## NAT Rules

Once a rule set that matches the traffic has been found, each rule in the rule set is evaluated in order for a match. NAT rules can match on the following packet information:

- Source and destination address
- Source port (for source and static NAT only)
- Destination port

The first rule in the rule set that matches the traffic is used. If a packet matches a rule in a rule set during session establishment, traffic is processed according to the action specified by that rule.

You can use the **show security nat source rule** and **show security nat destination rule** and the **show security nat static rule** commands to view the number of sessions for a specific rule.

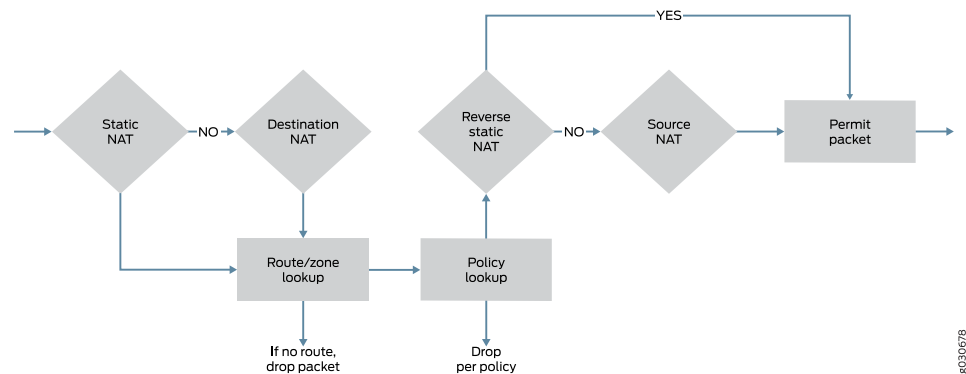

## Rule Processing

The NAT type determines the order in which NAT rules are processed. During the first packet processing for a flow, NAT rules are applied in the following order:

1. Static NAT rules
2. Destination NAT rules
3. Route lookup
4. Security policy lookup
5. Reverse mapping of static NAT rules
6. Source NAT rules

Figure 222 illustrates the order for NAT rule processing.

Figure 222: NAT Rule Processing

Static NAT and destination NAT rules are processed before route and security policy lookup. Static NAT rules take precedence over destination NAT rules. Reverse mapping of static NAT rules takes place after route and security policy lookup and takes precedence over source NAT rules. Source NAT rules are processed after route and security policy lookup and after reverse mapping of static NAT rules.

The configuration of rules and rule sets is basically the same for each type of NAT—source, destination, or static. But because both destination and static NAT are processed before route lookup, you cannot specify the destination zone, interface or routing instance in the rule set.

## NAT Rule Capacity

Table 470 provides the NAT rule capacity requirements per device.

Table 470: Number of Rules on SRX Series Devices

| NAT Rule Type        | SRX100 | SRX210 | SRX240 | SRX650 | SRX1400 | SRX3400<br>SRX3600 | SRX5400<br>SRX5600<br>SRX5800 |
|----------------------|--------|--------|--------|--------|---------|--------------------|-------------------------------|
| Source NAT rule      | 1024   | 1024   | 1024   | 1024   | 8192    | 20480              | 30720                         |
| Destination NAT rule | 1024   | 1024   | 1024   | 1024   | 8192    | 20480              | 30720                         |
| Static NAT rule      | 6144   | 6144   | 6144   | 6144   | 8192    | 20480              | 30720                         |

The restriction on the number of rules per rule set is a device-wide limitation on how many rules a device can support. This restriction is provided to help you better plan and configure the NAT rules for the device.

For memory consumption, there is no guarantee to support these numbers (maximum source rule or rule set + maximum destination rule or rule set + maximum static rule or rule-set) at the same time for SRX3400, SRX3600, SRX5600, and SRX5800 devices.

Table 471 provides the suggested total number of rules and rule sets for SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices.

Table 471: Number of Rules and Rule Sets

| Objects                        | SRX3400<br>SRX3600 | SRX5400<br>SRX5600<br>SRX5800 |
|--------------------------------|--------------------|-------------------------------|
| Total NAT rule sets per system | 20,480             | 30,720                        |
| Total NAT rules per rule set   | 20,480             | 30,720                        |

## Configuring NAT Using the NAT Wizard

---

You can use the NAT Wizard to perform basic NAT configuration. To perform more advanced configuration, use the J-Web interface or the CLI.

To configure NAT using the NAT Wizard:

1. Select **Configure>Tasks>Configure NAT** in the J-Web interface.
2. Click the Launch NAT Wizard button.
3. Follow the wizard prompts.

The upper left area of the wizard page shows where you are in the configuration process. The lower left area of the page shows field-sensitive help. When you click a link under the Resources heading, the document opens in your browser. If the document opens in a new tab, be sure to close only the tab (not the browser window) when you close the document.

## Example: Configuring NAT for Multiple ISPs

---

This example shows how to configure a Juniper Networks device for address translation of multiple ISPs.

- [Requirements on page 5172](#)
- [Overview on page 5172](#)

- [Configuration on page 5172](#)
- [Verification on page 5183](#)

## Requirements

Before you begin:

1. Configure network interfaces on the device. See *Interfaces Feature Guide for Security Devices*.
2. Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on page 1030.

## Overview

In this example, you can configure an SRX Series Services Gateway by connecting the LAN to the Internet by using NAT feature through two ISP connections. In this configuration, trust is the security zone for the private address space and the two untrust security zones for the public address space are used to connect from LAN to the two ISPs and vice versa. The example is a combination of source NAT rules to connect to Internet from the LAN, and destination and static NAT rules to connect to the LAN from Internet.

## Configuration

### Configuring NAT for Multiple ISPs

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set routing-instances isp1 instance-type virtual-router
set routing-instances isp1 interface ge-0/0/2.0
set routing-instances isp1 routing-options static route 10.0.0.0/8 next-table inet.0
set routing-instances isp1 routing-options static route 0.0.0.0/0 next-hop 21.0.1.20
set routing-instances isp2 instance-type virtual-router
set routing-instances isp2 interface ge-0/0/3.0
set routing-instances isp2 routing-options static route 10.0.0.0/8 next-table inet.0
set routing-instances isp2 routing-options static route 0.0.0.0/0 next-hop 37.0.1.251

```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure routing instances.

```

[edit]
user@host# set routing-instances isp1 instance-type virtual-router

```

```

user@host# set routing-instances isp1 interface ge-0/0/2.0
user@host# set routing-instances isp1 routing-options static route 10.0.0.0/8
 next-table inet.0
user@host# set routing-instances isp1 routing-options static route 0.0.0.0/0
 next-hop 21.0.1.20
user@host# set routing-instances isp2 instance-type virtual-router
user@host# set routing-instances isp2 interface ge-0/0/3.0
user@host# set routing-instances isp2 routing-options static route 10.0.0.0/8
 next-table inet.0
user@host# set routing-instances isp2 routing-options static route 0.0.0.0/0
 next-hop 37.0.1.251

```

2. Configure rib groups and routing options.

```

[edit]
user@host# set routing-options interface-routes rib-group inet isp
user@host# set routing-options static route 10.0.0.0/8 next-hop 10.0.21.254
user@host# set routing-options rib-groups isp import-rib inet.0
user@host# set routing-options rib-groups isp import-rib isp1.inet.0
user@host# set routing-options rib-groups isp import-rib isp2.inet.0

```

3. Configure security policies.

```

[edit security policies]
user@host# set from-zone trust to-zone untrust1 policy tr-untr1-pol match
 source-address any
user@host# set from-zone trust to-zone untrust1 policy tr-untr1-pol match
 destination-address any
user@host# set from-zone trust to-zone untrust1 policy tr-untr1-pol match
 application any
user@host# set from-zone trust to-zone untrust1 policy tr-untr1-pol then permit
user@host# set from-zone trust to-zone untrust2 policy tr-untr2-pol match
 source-address any
user@host# set from-zone trust to-zone untrust2 policy tr-untr2-pol match
 destination-address any
user@host# set from-zone trust to-zone untrust2 policy tr-untr2-pol match
 application any
user@host# set from-zone trust to-zone untrust2 policy tr-untr2-pol then permit
user@host# set from-zone untrust1 to-zone untrust2 policy untr1-untr2-pol match
 source-address any
user@host# set from-zone untrust1 to-zone untrust2 policy untr1-untr2-pol match
 destination-address any
user@host# set from-zone untrust1 to-zone untrust2 policy untr1-untr2-pol match
 application any
user@host# set from-zone untrust1 to-zone untrust2 policy untr1-untr2-pol then
 reject
user@host# set from-zone untrust2 to-zone untrust1 policy untr2-untr1-pol match
 source-address any
user@host# set from-zone untrust2 to-zone untrust1 policy untr2-untr1-pol match
 destination-address any
user@host# set from-zone untrust2 to-zone untrust1 policy untr2-untr1-pol match
 application any
user@host# set from-zone untrust2 to-zone untrust1 policy untr2-untr1-pol then
 reject
user@host# set from-zone untrust1 to-zone trust policy untr1-tr-pol match
 source-address any

```

```

user@host# set from-zone untrust1 to-zone trust policy untr1-tr-pol match
destination-address ftp-ser
user@host# set from-zone untrust1 to-zone trust policy untr1-tr-pol match
destination-address telnet-ser
user@host# set from-zone untrust1 to-zone trust policy untr1-tr-pol match
application junos-ftp
user@host# set from-zone untrust1 to-zone trust policy untr1-tr-pol match
application junos-telnet
user@host# set from-zone untrust1 to-zone trust policy untr1-tr-pol then permit
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol match
source-address any
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol match
destination-address 10.171.9.23/32
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol match
destination-address http-ser
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol match
destination-address 10.103.12.0/24
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol match
application junos-http
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol match
application junos-icmp-all
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol match
application junos-dhcp-server
user@host# set from-zone untrust2 to-zone trust policy untr2-tr-pol then permit

```

4. Configure source NAT pools and rules.

```

[edit security nat]
user@host# set source pool pool_1 address 21.0.1.40/32 to 21.0.1.190/32
user@host# set source pool pool_2 address 21.0.1.250/32
user@host# set source pool pool_3 address 37.0.1.20/32 to 37.0.1.30/32
user@host# set source address-persistent
user@host# set source pool-utilization-alarm raise-threshold 90
user@host# set source pool-utilization-alarm clear-threshold 80
user@host# set source rule-set SR_SET_1 from zone trust
user@host# set source rule-set SR_SET_1 to zone untrust1
user@host# set source rule-set SR_SET_1 rule rule1 match source-address 10.11.0.0/16
user@host# set source rule-set SR_SET_1 rule rule1 match source-address
10.147.0.0/16
user@host# set source rule-set SR_SET_1 rule rule1 match destination-address
0.0.0.0/0
user@host# set source rule-set SR_SET_1 rule rule1 then source-nat pool pool_1
user@host# set source rule-set SR_SET_1 rule rule2 match source-address
10.148.1.0/27
user@host# set source rule-set SR_SET_1 rule rule2 match destination-address
0.0.0.0/0
user@host# set source rule-set SR_SET_1 rule rule2 then source-nat interface
user@host# set source rule-set SR_SET_2 from zone trust
user@host# set source rule-set SR_SET_2 to zone untrust2
user@host# set source rule-set SR_SET_2 rule rule3 match source-address
10.140.21.0/27
user@host# set source rule-set SR_SET_2 rule rule3 then source-nat pool pool_3
user@host# set source rule-set SR_SET_2 rule rule4 match source-address
10.150.45.0/24
user@host# set source rule-set SR_SET_2 rule rule4 then source-nat off

```

5. Configure destination NAT pools and rules.

```
[edit security nat]
user@host#set destination pool dppol_1 address 10.101.1.10/32
user@host#set destination pool dppol_1 address port 21
user@host#set destination pool dppol_2 address 10.101.1.11/32
user@host#set destination pool dppol_2 address port 2101
user@host#set destination pool dppol_3 address 10.103.12.251/32
user@host#set destination pool dppol_3 address port 23
user@host#set destination pool dppol_4 address 10.103.12.241/32
user@host#set destination pool dppol_4 address port 23
user@host#set destination pool dppol_5 address 10.103.1.11/32
user@host#set destination pool dppol_5 address port 22
user@host#set destination rule-set DR_SET1 from routing-instance isp1
user@host#set destination rule-set DR_SET1 rule rule1 match destination-address
162.1.0.10/32
user@host#set destination rule-set DR_SET1 rule rule1 match destination-port 7230
user@host#set destination rule-set DR_SET1 rule rule1 then destination-nat pool
dppol_1
user@host#set destination rule-set DR_SET1 rule rule2 match destination-address
167.101.21.0/24
user@host#set destination rule-set DR_SET1 rule rule2 then destination-nat pool
dppol_2
user@host#set destination rule-set DR_SET2 from routing-instance isp2
user@host#set destination rule-set DR_SET2 rule rule3 match destination-address
198.10.67.2/32
user@host#set destination rule-set DR_SET2 rule rule3 match destination-port 7351
user@host#set destination rule-set DR_SET2 rule rule3 then destination-nat pool
dppol_3
user@host#set destination rule-set DR_SET2 rule rule4 match destination-address
197.0.122.171/32
user@host#set destination rule-set DR_SET2 rule rule4 match destination-port
3451
user@host#set destination rule-set DR_SET2 rule rule4 then destination-nat pool
dppol_4
```

6. Configure static NAT rules.

```
[edit security nat]
user@host#set static rule-set ST_SET1 from zone trust
user@host#set static rule-set ST_SET1 rule rule1 match destination-address
10.0.10.0/24
user@host#set static rule-set ST_SET1 rule rule1 then static-nat prefix 27.11.120.0/24
user@host#set static rule-set ST_SET2 from routing-instance isp1
user@host#set static rule-set ST_SET2 rule rule2 match destination-address
213.67.98.0/24
user@host#set static rule-set ST_SET2 rule rule2 then static-nat prefix
10.107.30.0/24
user@host#set static rule-set ST_SET2 rule rule3 match destination-address
162.171.53.2/32
user@host#set static rule-set ST_SET2 rule rule3 then static-nat prefix 10.171.9.23/32
```

**Results** From configuration mode, confirm your configuration by entering **show configuration** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show configuration routing-instances
routing-instances {
```

```
isp1 {
 instance-type virtual-router;

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Interfaces on page 5183](#)

### Verifying Interfaces

**Purpose** Verify that the interfaces are configured correctly.

**Action** From operational mode, enter the following commands:

- **show interfaces**
- **show zones**
- **show routing-instances**
- **show routing-options**
- **show policies**
- **show source nat**
- **show destination nat**
- **show static nat**

**Related Documentation** • [Introduction to NAT on page 5165](#)

## Configuring Proxy ARP (CLI Procedure)

You use NAT proxy ARP functionality to configure proxy ARP entries for IP addresses that require either source or destination NAT and that are in the same subnet as the ingress interface.

**NOTE:** On SRX Series devices, you must explicitly configure NAT proxy ARP.

When configuring NAT proxy ARP, you must specify the logical interface on which to configure proxy ARP. Then you enter an address or address range.

The device performs proxy ARP for the following conditions:

- When addresses defined in the static NAT and source NAT pool are in the same subnet as that of the ingress interface

- When addresses in the original destination address entry in the destination NAT rules are in the same subnet as that of the ingress interface

`user@host# set security nat proxy-arp interface fe-0/0/0.0 address 10.1.1.10 to 10.1.1.20`

## Verifying NAT Configuration

**Purpose** The NAT trace options hierarchy configures trace file and flags for verification purposes.

SRX Series devices have two main components: the Routing Engine (RE) and the Packet Forwarding Engine (PFE). The PFE is divided into the ukernel portion and the real-time portion.

When a NAT configuration is committed, the configuration is first checked and validated on the RE. After validation, the configuration is pushed to the PFE. The configuration is installed on the ukernel PFE, then action is taken on each packet that matches NAT rules on the real-time PFE.

For verification, you can turn on flags individually to debug NAT functionality on the RE, ukernel PFE, or real-time PFE:

- The **nat-re** flag records the trace of the NAT configuration validation on the RE and the configuration push to the PFE.
- The **nat-pfe** flag records the trace of the NAT configuration installation on the ukernel PFE.
- The **nat-rt** flag records the trace of the NAT rule match, and subsequent action on the real-time PFE.

The trace data is written to `/var/log/security-trace` by default, and can be viewed using the command `show log security-trace`.

**NOTE:** If session logging has been enabled in the policy configurations on the device, the session logs will include specific NAT details for each session. See [“Monitoring Policy Statistics” on page 1142](#) for information on how to enable session logging and [“Information Provided in Session Log Entries for SRX Series Services Gateways” on page 1761](#) for a description of information provided in session logs.

**Action** To verify that NAT configurations are correctly updated to the device upon commit, and that the NAT rule match and subsequent actions are correct, use the **security nat traceoptions** statement.

```

user@host# set security nat traceoptions flag all
user@host# set security nat traceoptions flag destination-nat-pfe
user@host# set security nat traceoptions flag destination-nat-re
user@host# set security nat traceoptions flag destination-nat-rti
user@host# set security nat traceoptions flag source-nat-pfe
user@host# set security nat traceoptions flag source-nat-re
user@host# set security nat traceoptions flag source-nat-rt
user@host# set security nat traceoptions flag static-nat-pfe
user@host# set security nat traceoptions flag static-nat-re
user@host# set security nat traceoptions flag static-nat-rt

```

To verify that NAT translations are being applied to the traffic, and to view individual traffic flow processing with NAT translations, use both the **security nat traceoptions** command and the **security flow traceoptions** command together. The commands are used together because the NAT trace, configured using the **security nat traceoptions** command, is not recorded unless the **flow traceoptions** command is also configured.

To filter a specific flow, you can define a packet filter and use it as a traceoption :

```

user@host# set security flow traceoptions packet-filter packet-filter
user@host# set security flow traceoptions packet-filter packet-filter apply-groups
user@host# set security flow traceoptions packet-filter packet-filter apply-groups-except
user@host# set security flow traceoptions packet-filter packet-filter destination-port
user@host# set security flow traceoptions packet-filter packet-filter destination-prefix
user@host# set security flow traceoptions packet-filter packet-filter interface
user@host# set security flow traceoptions packet-filter packet-filter protocol
user@host# set security flow traceoptions packet-filter packet-filter source-port
user@host# set security flow traceoptions packet-filter packet-filter source-prefix

```

To verify NAT traffic and to enable all traffic trace in data plane, use the traceoptions **set security flow traceoptions flag basic-datapath** command, as shown in the following example using a simple packet filter:

```

user@host# set security flow traceoptions file filename
user@host# set security flow traceoptions flag basic-datapath
user@host# set security flow traceoptions packet-filter client-traffic source-prefixprefix
user@host# set security flow traceoptions packet-filter client-traffic
 destination-prefixprefix
user@host# set security nat traceoptions flag all

```

## Understanding Source NAT

---

Source NAT is the translation of the source IP address of a packet leaving the Juniper Networks device. Source NAT is used to allow hosts with private IP addresses to access a public network.

Source NAT allows connections to be initiated only for outgoing network connections—for example, from a private network to the Internet. Source NAT is commonly used to perform the following translations:

- Translate a single IP address to another address (for example, to provide a single device in a private network with access to the Internet).
- Translate a contiguous block of addresses to another block of addresses of the same size.
- Translate a contiguous block of addresses to another block of addresses of smaller size.
- Translate a contiguous block of addresses to a single IP address or a smaller block of addresses using port translation.
- Translate a contiguous block of addresses to the address of the egress interface.

Translation to the address of the egress interface does not require an address pool; all other source NAT translations require configuration of an address pool. One-to-one and many-to-many translations for address blocks of the same size do not require port translation because there is an available address in the pool for every address that would be translated.

If the size of the address pool is smaller than the number of addresses that would be translated, either the total number of concurrent addresses that can be translated is limited by the size of the address pool or port translation must be used. For example, if a block of 253 addresses is translated to an address pool of 10 addresses, a maximum of 10 devices can be connected concurrently unless port translation is used.

The following types of source NAT are supported:

- Translation of the original source IP address to the egress interface's IP address (also called interface NAT). Port address translation is always performed.
- Translation of the original source IP address to an IP address from a user-defined address pool without port address translation. The association between the original source IP address to the translated source IP address is dynamic. However, once there is an association, the same association is used for the same original source IP address for new traffic that matches the same NAT rule.
- Translation of the original source IP address to an IP address from a user-defined address pool with port address translation. The association between the original source IP address to the translated source IP address is dynamic. Even if an association exists, the same original source IP address may be translated to a different address for new traffic that matches the same NAT rule.
- Translation of the original source IP address to an IP address from a user-defined address pool by shifting the IP addresses. This type of translation is one-to-one, static, and without port address translation. If the original source IP address range is larger than the IP address range in the user-defined pool, untranslated packets are dropped.

## Source NAT Configuration Overview

The main configuration tasks for source NAT are as follows:

1. Configure an address pool or an interface NAT mapping of private addresses to the public address of an egress interface.

For an address pool, also do the following:

- a. Specify the name of the pool, the addresses or address ranges, the routing instance, and whether to perform port address translation (PAT).

- b. (Optional) Configure address pool options, such as overflow pool, IP address shifting, address sharing, address pooling, and pool utilization alarms.
  - c. Configure NAT proxy ARP entries for IP addresses in the same subnet of the ingress interface.
2. (Optional) Configure the persistent address.
3. Configure source NAT rules that align with your network and security requirements.

---

## Example: Configuring Source NAT for Egress Interface Translation

This example describes how to configure a source NAT mapping of private addresses to the public address of an egress interface.

- [Requirements on page 5191](#)
- [Overview on page 5191](#)
- [Configuration on page 5193](#)
- [Verification on page 5194](#)

### Requirements

Before you begin:

1. Configure network interfaces on the device. See *Interfaces Feature Guide for Security Devices*.
2. Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on page 1030.

### Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 223](#), devices with private addresses in the trust zone access a public network through the egress interface ge-0/0/0. For packets that enter the Juniper Networks security device from the trust zone with a destination address in the untrust zone, the source IP address is translated to the IP address of the egress interface.

**NOTE:** No source NAT pool is required for source NAT using an egress interface. Proxy ARP does not need to be configured for the egress interface.

**Figure 223: Source NAT Egress Interface Translation**

| Original Source IP | Translated Source IP        |
|--------------------|-----------------------------|
| 0.0.0.0/0          | 203.0.113.63 (Interface IP) |

g030668

This example describes the following configurations:

- Source NAT rule set **rs1** with a rule **r1** to match any packet from the trust zone to the untrust zone. For matching packets, the source address is translated to the IP address of the egress interface.
- Security policies to permit traffic from the trust zone to the untrust zone.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
set security nat source rule-set rs1 rule r1 match source-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 match destination-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 then source-nat interface
set security policies from-zone trust to-zone untrust policy internet-access match
source-address any
set security policies from-zone trust to-zone untrust policy internet-access match
destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
application any
set security policies from-zone trust to-zone untrust policy internet-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT translation to an egress interface:

1. Create a source NAT rule set.

```
[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust
```

2. Configure a rule that matches packets and translates the source address to the address of the egress interface.

```
[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 match destination-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 then source-nat interface
```

3. Configure a security policy that allows traffic from the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 rule-set rs1 {
```

```
from zone trust;
to zone untrust;
rule r1 {
 match {
 source-address 0.0.0.0/0;
 destination-address 0.0.0.0/0;
 }
 then {
 source-nat {
 interface;
 }
 }
}
}
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Rule Usage on page 5194](#)
- [Verifying NAT Application to Traffic on page 5194](#)

---

### Verifying Source NAT Rule Usage

**Purpose** Verify that there is traffic matching the source NAT rule.

**Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

---

### Verifying NAT Application to Traffic

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

## Example: Configuring Source NAT for Single Address Translation

---

This example describes how to configure a source NAT mapping of a single private address to a public address.

- [Requirements on page 5195](#)
- [Overview on page 5195](#)
- [Configuration on page 5197](#)
- [Verification on page 5199](#)

### Requirements

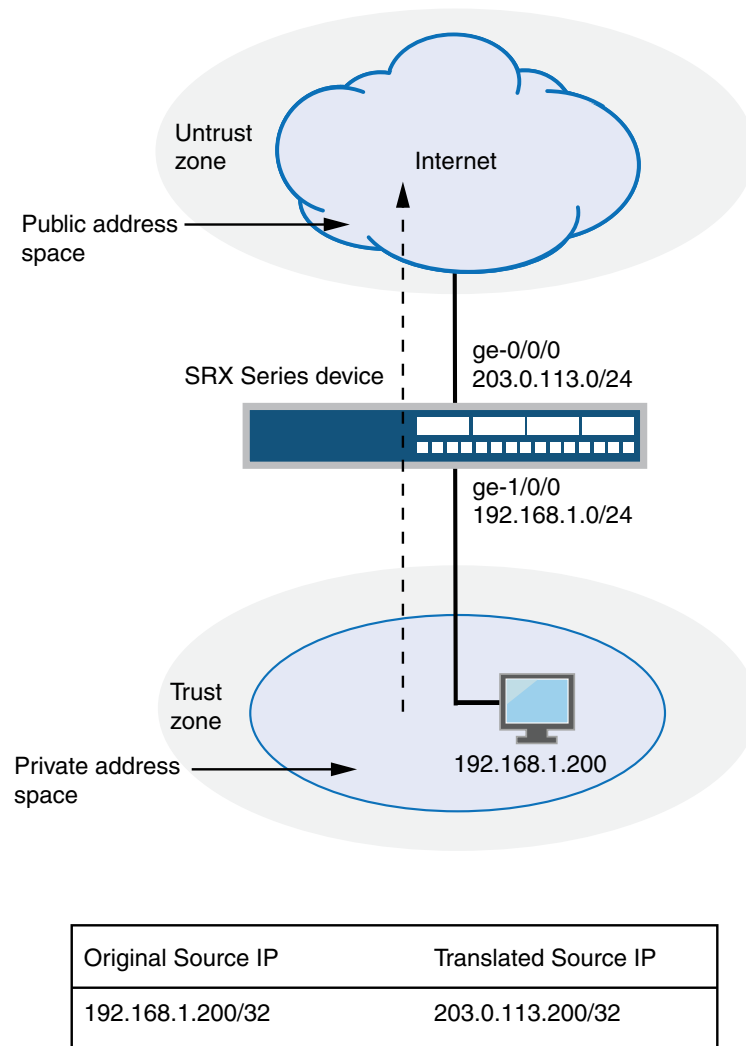

Before you begin:

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
2. Create security zones and assign interfaces to them. See "[Understanding Security Zones](#)" on page 1030.

### Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 224](#), a device with the private address 192.168.1.200 in the trust zone accesses a public network. For packets sent by the device to a destination address in the untrust zone, the Juniper Networks security device translates the source IP address to the public IP address 1.1.1.200/32.

Figure 224: Source NAT Single Address Translation

g030669

This example describes the following configurations:

- Source NAT pool **src-nat-pool-1** that contains the IP address 1.1.1.200/32.
- Source NAT rule set **rs1** with rule **r1** to match packets from the trust zone to the untrust zone with the source IP address 192.168.1.200/32. For matching packets, the source address is translated to the IP address in **src-nat-pool-1** pool.
- Proxy ARP for the address 1.1.1.200 on interface ge-0/0/0.0. This allows the Juniper Networks security device to respond to ARP requests received on the interface for that address.
- Security policies to permit traffic from the trust zone to the untrust zone.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-pool-1 address 1.1.1.200/32
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
set security nat source rule-set rs1 rule r1 match source-address 192.168.1.200/32
set security nat source rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.200/32
set security policies from-zone trust to-zone untrust policy internet-access match
 source-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 application any
set security policies from-zone trust to-zone untrust policy internet-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT translation for a single IP address:

1. Create a source NAT pool.  

```
[edit security nat source]
user@host# set pool src-nat-pool-1 address 1.1.1.200/32
```
2. Create a source NAT rule set.  

```
[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust
```
3. Configure a rule that matches packets and translates the source address to the address in the pool.  

```
[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address 192.168.1.200/32
user@host# set rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
```
4. Configure proxy ARP.  

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.200
```
5. Configure a security policy that allows traffic from the trust zone to the untrust zone.  

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
 destination-address any application any
user@host# set policy internet-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool src-nat-pool-1 {
 address {
 1.1.1.200/32;
 }
 }
}
rule-set rs1 {
 from zone trust;
 to zone untrust;
 rule r1 {
 match {
 source-address 192.168.1.200/32;
 }
 then {
 source-nat {
 pool {
 src-nat-pool-1;
 }
 }
 }
 }
}
}
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.200/32;
 }
 }
}
}

user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Pool Usage on page 5199](#)
- [Verifying Source NAT Rule Usage on page 5199](#)
- [Verifying NAT Application to Traffic on page 5199](#)

---

### Verifying Source NAT Pool Usage

- Purpose** Verify that there is traffic using IP addresses from the source NAT pool.
- Action** From operational mode, enter the **show security nat source pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

---

### Verifying Source NAT Rule Usage

- Purpose** Verify that there is traffic matching the source NAT rule.
- Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

---

### Verifying NAT Application to Traffic

- Purpose** Verify that NAT is being applied to the specified traffic.
- Action** From operational mode, enter the **show security flow session** command.

## Example: Configuring Source and Destination NAT Translations

This example describes how to configure both source and destination NAT mappings.

- [Requirements on page 5199](#)
- [Overview on page 5200](#)
- [Configuration on page 5202](#)
- [Verification on page 5205](#)

## Requirements

Before you begin:

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.

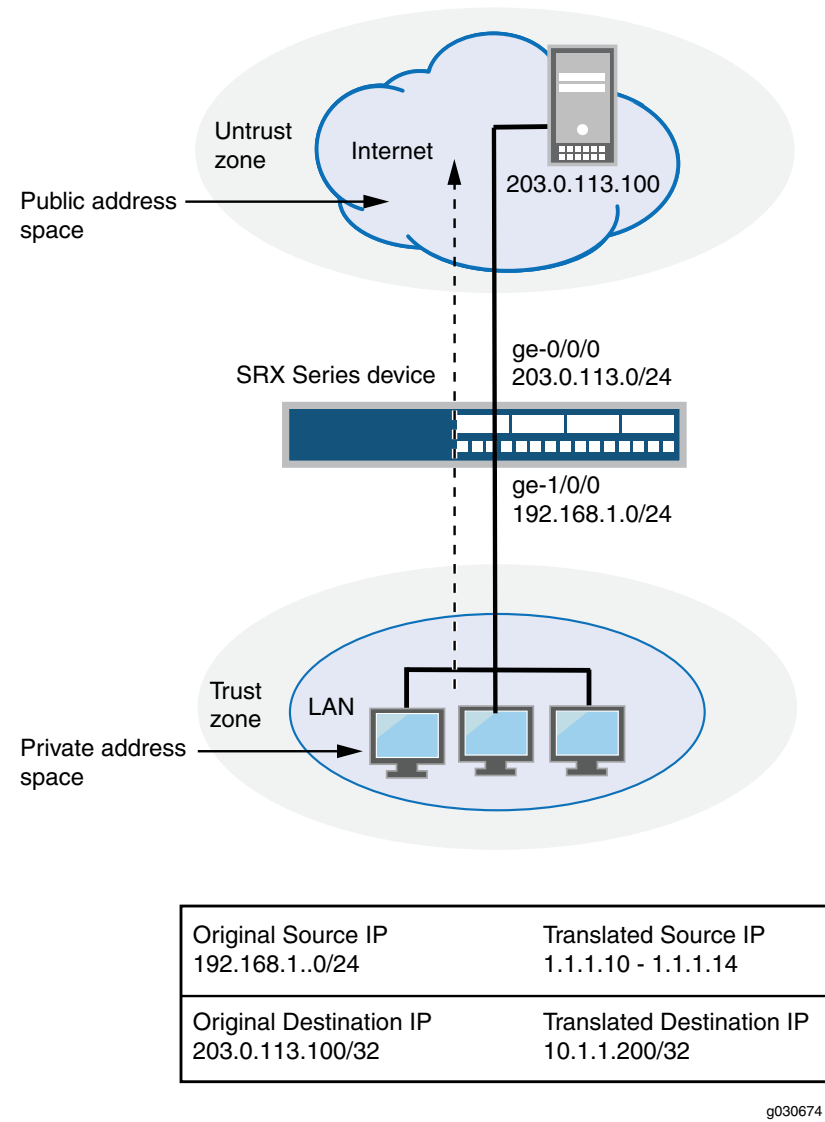

2. Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 225](#), the following translations are performed on the Juniper Networks security device:

- The source IP address in packets sent by the device with the private address 192.168.1.200 in the trust zone to any address in the untrust zone is translated to a public address in the range from 1.1.1.10 through 1.1.1.14.
- The destination IP address 1.1.1.100/32 in packets sent from the trust zone to the untrust zone is translated to the address 10.1.1.200/32.

Figure 225: Source and Destination NAT Translations

This example describes the following configurations:

- Source NAT pool **src-nat-pool-1** that contains the IP address range 1.1.1.10 through 1.1.1.14.
- Source NAT rule set **rs1** with rule **r1** to match any packets from the trust zone to the untrust zone. For matching packets, the source address is translated to an IP address in the **src-nat-pool-1** pool.
- Destination NAT pool **dst-nat-pool-1** that contains the IP address 10.1.1.200/32.

- Destination NAT rule set **rs1** with rule **r1** to match packets from the trust zone with the destination IP address 1.1.1.100. For matching packets, the destination address is translated to the IP address in the **dst-nat-pool-1** pool.
- Proxy ARP for the addresses 1.1.1.10 through 1.1.1.14 and 1.1.1.100/32 on interface ge-0/0/0.0. This allows the Juniper Networks security device to respond to ARP requests received on the interface for those addresses.
- Security policy to permit traffic from the trust zone to the untrust zone.
- Security policy to permit traffic from the untrust zone to the translated destination IP addresses in the trust zone.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-pool-1 address 1.1.1.10/32 to 1.1.1.14/32
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
set security nat source rule-set rs1 rule r1 match source-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 match destination-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
set security nat destination pool dst-nat-pool-1 address 10.1.1.200/32
set security nat destination rule-set rs1 from zone untrust
set security nat destination rule-set rs1 rule r1 match destination-address 1.1.1.100/32
set security nat destination rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.10/32 to 1.1.1.24/32
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.100/32
set security policies from-zone trust to-zone untrust policy internet-access match
 source-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 application any
set security policies from-zone trust to-zone untrust policy internet-access then permit
set security address-book global address dst-nat-pool-1 10.1.1.200/32
set security policies from-zone untrust to-zone trust policy dst-nat-pool-1-access match
 source-address any
set security policies from-zone untrust to-zone trust policy dst-nat-pool-1-access match
 destination-address dst-nat-pool-1
set security policies from-zone untrust to-zone trust policy dst-nat-pool-1-access match
 application any
set security policies from-zone untrust to-zone trust policy dst-nat-pool-1-access then
 permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the source and destination NAT translations:

1. Create a source NAT pool.  

```
[edit security nat source]
user@host# set pool src-nat-pool-1 address 1.1.1.10 to 1.1.1.14
```
2. Create a source NAT rule set.  

```
[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust
```
3. Configure a rule that matches packets and translates the source address to an address in the source NAT pool.  

```
[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 match destination-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
```
4. Create a destination NAT pool.  

```
[edit security nat destination]
user@host# set pool dst-nat-pool-1 address 10.1.1.200/32
```
5. Create a destination NAT rule set.  

```
[edit security nat destination]
user@host# set rule-set rs1 from zone untrust
```
6. Configure a rule that matches packets and translates the destination address to the address in the destination NAT pool.  

```
[edit security nat destination]
user@host# set rule-set rs1 rule r1 match destination-address 1.1.1.100/32
user@host# set rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1
```
7. Configure proxy ARP.  

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.10 to 1.1.1.14
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.100
```
8. Configure a security policy that allows traffic from the trust zone to the untrust zone.  

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit
```
9. Configure an address in the global address book.  

```
[edit security address-book global]
user@host# set address dst-nat-pool-1 10.1.1.200/32
```
10. Configure a security policy that allows traffic from the untrust zone to the trust zone.

```
[edit security policies from-zone untrust to-zone trust]
user@host# set policy dst-nat-pool-1-access match source-address any
destination-address dst-nat-pool-1 application any
user@host# set policy dst-nat-pool-1-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool src-nat-pool-1 {
 address {
 1.1.1.10/32 to 1.1.1.14/32;
 }
 }
}
rule-set rs1 {
 to zone untrust;
 rule r1 {
 match {
 source-address 0.0.0.0/0;
 destination-address 0.0.0.0/0;
 }
 then {
 source-nat {
 pool {
 src-nat-pool-1;
 }
 }
 }
 }
}
}
}
}
destination {
 pool dst-nat-pool-1 {
 address 10.1.1.200/32;
 }
 rule-set rs1 {
 from zone untrust;
 rule r1 {
 match {
 destination-address 1.1.1.100/32;
 }
 then {
 destination-nat pool dst-nat-pool-1;
 }
 }
 }
}
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.10/32 to 1.1.1.24/32;
 1.1.1.100/32;
 }
 }
}
```

```

 }
 }
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 }
 policy internet-access {
 then {
 permit;
 }
 }
}
from-zone untrust to-zone trust {
 policy dst-nat-pool-1-access {
 match {
 source-address any;
 destination-address dst-nat-pool-1;
 application any;
 }
 then {
 permit;
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Pool Usage on page 5205](#)
- [Verifying Source NAT Rule Usage on page 5206](#)
- [Verifying Destination NAT Pool Usage on page 5206](#)
- [Verifying Destination NAT Rule Usage on page 5206](#)
- [Verifying NAT Application to Traffic on page 5206](#)

### Verifying Source NAT Pool Usage

**Purpose** Verify that there is traffic using IP addresses from the source NAT pool.

**Action** From operational mode, enter the **show security nat source pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

### Verifying Source NAT Rule Usage

**Purpose** Verify that there is traffic matching the source NAT rule.

**Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

### Verifying Destination NAT Pool Usage

**Purpose** Verify that there is traffic using IP addresses from the destination NAT pool.

**Action** From operational mode, enter the **show security nat destination pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

### Verifying Destination NAT Rule Usage

**Purpose** Verify that there is traffic matching the destination NAT rule.

**Action** From operational mode, enter the **show security nat destination rule all** command. View the Translation hits field to check for traffic that matches the rule.

### Verifying NAT Application to Traffic

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

## Understanding Central Point Architecture Enhancements for NAT

System session capacity and session ramp-up rate are limited by central point memory capacity and CPU capacity. The central point architecture has been enhanced to handle higher system session capacity and session ramp-up rate for the SRX5000 line. Hence, the workload on the central point is reduced to increase the session capacity and to support more sessions to achieve higher connections per second (CPS). The following list describes the enhancements to NAT to improve performance:

- The central point architecture no longer supports central point sessions. Therefore, NAT needs to maintain a NAT tracker to track the IP address or port allocation and usage. NAT tracker is a global array for SPU session ID to NAT IP or port mapping that is used to manage NAT resources.
- By default, a NAT rule alarm and trap statistics counter update message is sent from the Services Processing Unit (SPU) to the central point at intervals of 1 second instead of updating the statistics based on each session trigger in the central point system.
- To support a specific NAT IP address or port allocated such that the 5-tuple hash after NAT is the same as the original 5-tuple hash before NAT, select a NAT port that results in the same hash as the original hash by the specific calculation. Hence, the forwarding session is reduced. When NAT is used, the reverse wing is hashed to a different SPU. A forward session has to be installed to forward reverse traffic to a session SPU. NAT tries to select a port that can be used by the hash algorithm to make the reverse wing be hashed to the same SPU as the initial wing. So, both NAT performance and throughput are improved with this approach.
- To improve NAT performance, IP shifting pool (non-PAT pool) management is moved from the central point to the SPU so that all local NAT resources for that pool are managed locally instead of sending the NAT request to the central point. Hence, IP address-shifting NAT pool connections per second and throughput are improved.

### Related Documentation

- [Understanding Reverse NAT Enhancements for Central Point Architecture on page 5207](#)

## Understanding Reverse NAT Enhancements for Central Point Architecture

To improve NAT performance, you can enable reverse NAT to select the port based on the predefined algorithms, that is, randomized and round-robin.

**NOTE:** If the selected Services Processing Unit (SPU) of two wings of a session is different, then by default reverse NAT is disabled and forwarding session is installed.

The device enables randomized and round-robin algorithms to select a port by default. However, the randomized algorithm has higher priority than the round robin algorithm. When both randomized and round-robin algorithms are enabled, the randomized algorithm is applied for port selection because randomization has higher priority.

When randomized algorithm is disabled, apply round-robin algorithm for port selection by using the following command:

**set security nat source port-randomization disable**

When round-robin algorithm is disabled, apply randomized algorithm for port selection by using the following command:

**set security nat source port-round-robin disable**

When both randomized and round-robin algorithms are disabled, activate reverse NAT enhancement or session affinity by using the following command:

**set security nat source port-randomization disable**

**set security nat source port-round-robin disable**

## Understanding Source NAT Rules

Source NAT rules specify two layers of match conditions:

- Traffic direction—Allows you to specify combinations of **from interface**, **from zone**, or **from routing-instance** and **to interface**, **to zone**, or **to routing-instance**. You cannot configure the same **from** and **to** contexts for different rule sets.
- Packet information—Can be source and destination IP addresses or subnets, source port numbers or port ranges, destination port numbers or port ranges, protocols, or applications.

For all ALG traffic, except FTP, we recommend that you not use the **source-port** rule option. Data session creation can fail if this option is used because the IP address and the source port value, which is a random value, might not match the rule.

In addition, we recommend that you not use the **destination-port** option or the **application** option as matching conditions for ALG traffic. If these options are used, translation may fail because the port value in the application payload might not match the port value in the IP address.

If multiple source NAT rules overlap in the match conditions, the most specific rule is chosen. For example, if rules A and B specify the same source and destination IP addresses, but rule A specifies traffic from zone 1 to zone 2 and rule B specifies traffic from zone 1 to interface **ge-0/0/0**, rule B is used to perform source NAT. An interface match is considered to be more specific than a zone match, which is more specific than a routing instance match. For more information about rule set matching, see [“Understanding NAT Rule Sets and Rules” on page 5166](#).

The actions you can specify for a source NAT rule are:

- off—Do not perform source NAT.

- pool—Use the specified user-defined address pool to perform source NAT.
- interface—Use the egress interface's IP address to perform source NAT.

Source NAT rules are applied to traffic in the first packet that is processed for the flow or in the fast path for the ALG. Source NAT rules are processed after static NAT rules, destination NAT rules, and reverse mapping of static NAT rules and after route and security policy lookup.

## Example: Configuring Source NAT with Multiple Rules

---

This example describes how to configure source NAT mappings with multiple rules.

- [Requirements on page 5209](#)
- [Overview on page 5209](#)
- [Configuration on page 5211](#)
- [Verification on page 5215](#)

### Requirements

Before you begin:

- Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
- Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on page 1030.

### Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 226](#), the following translations are performed on the Juniper Networks security device for the source NAT mapping for traffic from the trust zone to the untrust zones:

- The source IP address in packets sent by the 10.1.1.0/24 and 10.1.2.0/24 subnets to any address in the untrust zone is translated to a public address in the range from 192.0.0.1 to 192.0.0.24 with port translation.
- The source IP address in packets sent by the 192.168.1.0/24 subnet to any address in the untrust zone is translated to a public address in the range from 192.0.0.100 to 192.0.0.249 with no port translation.
- The source IP address in packets sent by the 192.168.1.250/32 host device is not translated.

Figure 226: Source NAT with Multiple Translation Rules

| Original Source IP       | Translated Source IP                            |
|--------------------------|-------------------------------------------------|
| 10.1.1.0/24, 10.1.2.0/24 | 192.0.2.1 – 192.0.2.24 (w/port translation)     |
| 192.168.1.0/24           | 192.0.2.100 - 192.0.2.249 (no port translation) |
| 192.168.1.250/32         | (no source NAT translation)                     |

g030673

This example describes the following configurations:

- Source NAT pool **src-nat-pool-1** that contains the IP address range 192.0.0.1 through 192.0.0.24.
- Source NAT pool **src-nat-pool-2** that contains the IP address range 192.0.0.100 through 192.0.0.249, with port address translation disabled.

**NOTE:** When port address translation is disabled, the number of translations that the source NAT pool can support concurrently is limited to the number of addresses in the pool, unless the `address-shared` option is enabled. Packets are dropped if there are no addresses available in the source NAT pool. You can optional specify an overflow pool from which IP addresses and port numbers are allocated when there are no addresses available in the original source NAT pool.

- Source NAT rule set **rs1** to match packets from the trust zone to the untrust zone. Rule set **rs1** contains multiple rules:
  - Rule **r1** to match packets with a source IP address in either the 10.1.1.0/24 or 10.1.2.0/24 subnets. For matching packets, the source address is translated to an IP address in the **src-nat-pool-1** pool.
  - Rule **r2** to match packets with a source IP address of 192.168.1.250/32. For matching packets, there is no NAT translation performed.
  - Rule **r3** to match packets with a source IP address in the 192.168.1.0/24 subnet. For matching packets, the source address is translated to an IP address in the **src-nat-pool-2** pool.

**NOTE:** The order of rules in a rule set is important, as the first rule in the rule set that matches the traffic is used. Therefore, rule **r2** to match a specific IP address must be placed before rule **r3** that matches the subnet on which the device is located.

- Proxy ARP for the addresses 192.0.0.1 through 192.0.0.24 and 192.0.0.100 through 192.0.0.249 on interface `ge-0/0/0.0`. This allows the Juniper Networks security device to respond to ARP requests received on the interface for those addresses.
- Security policies to permit traffic from the trust zone to the untrust zone.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-pool-1 address 192.0.0.1/32 to 192.0.0.24/32
set security nat source pool src-nat-pool-2 address 192.0.0.100/32 to 192.0.0.249/32
set security nat source pool src-nat-pool-2 port no-translation
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
set security nat source rule-set rs1 rule r1 match source-address 10.1.1.0/24
set security nat source rule-set rs1 rule r1 match source-address 10.1.2.0/24
set security nat source rule-set rs1 rule r1 match destination-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
set security nat source rule-set rs1 rule r2 match source-address 192.168.1.250/32
```

```

set security nat source rule-set rs1 rule r2 match destination-address 0.0.0.0/0
set security nat source rule-set rs1 rule r2 then source-nat off
set security nat source rule-set rs1 rule r3 match source-address 192.168.1.0/24
set security nat source rule-set rs1 rule r3 match destination-address 0.0.0.0/0
set security nat source rule-set rs1 rule r3 then source-nat pool src-nat-pool-2
set security nat proxy-arp interface ge-0/0/0.0 address 192.0.0.1/32 to 192.0.0.24/32
set security nat proxy-arp interface ge-0/0/0.0 address 192.0.0.100/32 to 192.0.0.249/32
set security policies from-zone trust to-zone untrust policy internet-access match
 source-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 application any
set security policies from-zone trust to-zone untrust policy internet-access then permit

```

### Step-by-Step Procedure

The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure multiple source NAT rules in a rule set:

1. Create a source NAT pool.

```

[edit security nat source]
user@host# set pool src-nat-pool-1 address 192.0.0.1 to 192.0.0.24

```

2. Create a source NAT pool with no port translation.

```

[edit security nat source]
user@host# set pool src-nat-pool-2 address 192.0.0.100 to 192.0.0.249
user@host# set pool src-nat-pool-2 port no-translation

```

**NOTE:** To configure an overflow pool for src-nat-pool-2 using the egress interface:

```

[edit security nat source]
user@host# set pool src-nat-pool-2 overflow-pool interface

```

3. Create a source NAT rule set.

```

[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust

```

4. Configure a rule that matches packets and translates the source address to an address in the pool.

```

[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address [10.1.1.0/24 10.1.2.0/24]
user@host# set rule-set rs1 rule r1 match destination-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 then source-nat pool src-nat-pool-1

```

5. Configure a rule to match packets for which the source address is not translated.

```

[edit security nat source]
user@host# set rule-set rs1 rule r2 match source-address 192.168.1.250/32

```

```

user@host# set rule-set rs1 rule r2 match destination-address 0.0.0.0/0
user@host# set rule-set rs1 rule r2 then source-nat off

```

6. Configure a rule to match packets and translate the source address to an address in the pool with no port translation.

```

[edit security nat source]
user@host# set rule-set rs1 rule r3 match source-address 192.168.1.0/24
user@host# set rule-set rs1 rule r3 match destination-address 0.0.0.0/0
user@host# set rule-set rs1 rule r3 then source-nat pool src-nat-pool-2

```

7. Configure proxy ARP.

```

[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 192.0.0.1 to 192.0.0.24
user@host# set proxy-arp interface ge-0/0/0.0 address 192.0.0.100 to 192.0.0.249

```

8. Configure a security policy that allows traffic from the trust zone to the untrust zone.

```

[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit

```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show security nat
source {
 pool src-nat-pool-1 {
 address {
 192.0.0.1/32 to 192.0.0.24/32;
 }
 }
 pool src-nat-pool-2 {
 address {
 192.0.0.100/32 to 192.0.0.249/32;
 }
 port no-translation;
 }
 rule-set rs1 {
 from zone trust;
 to zone untrust;
 rule r1 {
 match {
 source-address [10.1.1.0/24 10.1.2.0/24];
 destination-address 0.0.0.0/0;
 }
 then {
 source-nat {
 pool {
 src-nat-pool-1;
 }
 }
 }
 }
 }
}

```

```
}
rule r2 {
 match {
 source-address 192.168.1.250/32;
 destination-address 0.0.0.0/0;
 }
 then {
 source-nat {
 off;
 }
 }
}

rule r3 {
 match {
 source-address 192.168.1.0/24;
 destination-address 0.0.0.0/0;
 }
 then {
 source-nat {
 pool {
 src-nat-pool-2;
 }
 }
 }
}

}

proxy-arp {
 interface ge-0/0/0.0 {
 address {
 192.0.0.1/32 to 192.0.0.24/32;
 192.0.0.100/32 to 192.0.0.249/32;
 }
 }
}

user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Pool Usage on page 5215](#)
- [Verifying Source NAT Rule Usage on page 5215](#)
- [Verifying NAT Application to Traffic on page 5215](#)

---

### Verifying Source NAT Pool Usage

- Purpose** Verify that there is traffic using IP addresses from the source NAT pool.
- Action** From operational mode, enter the **show security nat source pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

---

### Verifying Source NAT Rule Usage

- Purpose** Verify that there is traffic matching the source NAT rule.
- Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

---

### Verifying NAT Application to Traffic

- Purpose** Verify that NAT is being applied to the specified traffic.
- Action** From operational mode, enter the **show security flow session** command.

## Disabling Port Randomization for Source NAT (CLI Procedure)

For pool-based source NAT and interface NAT, port numbers are allocated randomly by default. Although randomized port number allocation can provide protection from security threats such as DNS poison attacks, it can also affect performance and memory usage for pool-based source NAT. When port randomization is disabled, ports are allocated, by default, on a round-robin basis: NAT first selects by IP address, then selects by port configuration. For example, if the source pool contains only one IP, when the first packet of a flow arrives, creating a session, it is translated to port N of IP1. Subsequent packets in that flow are allocated the same IP/port. When the first packet or a new flow arrives, it is translated to port N+1 of IP1, and so on. If the source pool contains two IPs, when the first packet of a flow arrives, creating a session, it is translated to port X of IP1. Subsequent packets in that flow are allocated the same IP/port. When the first packet of a new flow

arrives, it is translated to port Y of IP2; and when another packet in a new flow arrives, it is translated to port Y+1 of IP2, and so on.

You can disable port randomization by using the **port-randomization disable** statement at the [edit security nat source] hierarchy level. To re-enable port randomization, delete the **port-randomization** statement at the [edit security nat source] hierarchy level.

```
user@host# set security nat source port-randomization disable
```

## Monitoring Source NAT Information

**Purpose** Display configured information about source Network Address Translation (NAT) rules, pools, persistent NAT, and paired addresses.

**Action** Select **Monitor>NAT>Source NAT** in the J-Web user interface, or enter the following CLI commands:

- **show security nat source summary**
- **show security nat source pool *pool-name***
- **show security nat source persistent-nat-table**
- **show security nat source paired-address**

[Table 474](#) describes the available options for monitoring source NAT.

**Table 474: Source NAT Monitoring Page**

| Field                | Description                                                              | Action                                                                |
|----------------------|--------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <b>Rules</b>         |                                                                          |                                                                       |
| Rule-set Name        | Name of the rule set.                                                    | Select all rule sets or a specific rule set to display from the list. |
| Total rules          | Number of rules configured.                                              | —                                                                     |
| ID                   | Rule ID number.                                                          | —                                                                     |
| Name                 | Name of the rule .                                                       | —                                                                     |
| From                 | Name of the routing instance/zone/interface from which the packet flows. | —                                                                     |
| To                   | Name of the routing instance/zone/interface to which the packet flows.   | —                                                                     |
| Source address range | Source IP address range in the source pool.                              | —                                                                     |

Table 474: Source NAT Monitoring Page (*continued*)

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                         | Action                                                        |

## Understanding Source NAT Pools

---

A NAT pool is a user-defined set of IP addresses that are used for translation. Unlike static NAT, where there is a one-to-one mapping that includes destination IP address translation in one direction and source IP address translation in the reverse direction, with source NAT, you translate the original source IP address to an IP address in the address pool.

For source Network Address Translation (NAT) address pools, specify the following:

- Name of the source NAT address pool.
- Up to eight address or address ranges.

**NOTE:** Do not overlap NAT addresses for source NAT, destination NAT, and static NAT within one routing instance.

- Routing instance—Routing instance to which the pool belongs (the default is the main **inet.0** routing instance).

- **Port** —The Port Address Translation (PAT) for a source pool. By default, PAT is performed with source NAT. If you specify the **no-translation** option, the number of hosts that the source NAT pool can support is limited to the number of addresses in the pool. If you specify **block-allocation**, a block of ports is allocated for translation, instead of individual ports being allocated. If you specify **deterministic**, an incoming (source) IP address and port always map to the specific destination address and port block, based on predefined, deterministic NAT algorithm. If you specify **port-overloading**, you can configure the port overloading capacity in source NAT. If you specify **range**, you can provide the port number range attached to each address in the pool, and the twin port range for source NAT pools.
- **Overflow pool (optional)**—Packets are dropped if there are no addresses available in the designated source NAT pool. To prevent that from happening when the **port no-translation** option is configured, you can specify an overflow pool. Once addresses from the original source NAT pool are exhausted, IP addresses and port numbers are allocated from the overflow pool. A user-defined source NAT pool or an egress interface can be used as the overflow pool. (When the overflow pool is used, the pool ID is returned with the address.)
- **IP address shifting (optional)**—A range of original source IP addresses can be mapped to another range of IP addresses, or to a single IP address, by shifting the IP addresses. Specify the **host-address-base** option with the base address of the original source IP address range.
- **Address sharing (optional)**—Multiple internal IP addresses can be mapped to the same external IP address. This option can be used only when the source NAT pool is configured with no port translation. Specify the **address-shared** option when a source NAT pool has few external IP addresses available, or only one external IP address. With a many-to-one mapping, use of this option increases NAT resources and improves traffic.
- **Address pooling (optional)**—Address pooling can be configured as paired or no-paired. Specify **address-pooling paired** for applications that require all sessions associated with one internal IP address to be mapped to the same external IP address for the duration of a session. This differs from the **persistent-address** option, in which the same internal address is translated to the same external address every time. Specify **address-pooling no-paired** for applications that can be assigned IP addresses in a round-robin fashion. If either **address-pooling paired** or **address-pooling no-paired** is configured for a source NAT pool with PAT, the persistent address option is disabled. If **address-shared** is configured on a source NAT pool without PAT, then the **persistent-address** option is enabled. Both **address-shared** and **address-pooling paired** can be configured on the same source NAT pool without PAT.
- **Pool utilization alarm (optional)**—When the **raise-threshold** option is configured for source NAT, an SNMP trap is triggered if the source NAT pool utilization rises above this threshold. If the optional **clear-threshold** option is configured, an SNMP trap is triggered if the source NAT pool utilization drops below this threshold. If **clear-threshold** is not configured, it is set by default to 80 percent of the **raise-threshold** value.

You can use the **show security nat resource usage source pool** command to view address use in a source NAT pool without PAT, and to view port use in a source NAT pool with PAT.

## Understanding Source NAT Pool Capacities

Maximum capacities for source pools and IP addresses on SRX650 devices are as follows:

| Devices                      | Source NAT Pools | PAT Maximum Address Capacity | Pat Port Number | Source NAT Rules Number |
|------------------------------|------------------|------------------------------|-----------------|-------------------------|
| SRX650 (High Memory devices) | 1024             | 1024                         | 64M             | 1024                    |
| SRX650 (Low Memory devices)  | 256              | 256                          | 16M             | 1024                    |

Maximum capacities for source pools and IP addresses on all high-end SRX Series devices are as follows:

| Pool/PAT Maximum Address Capacity        | SRX1400<br>SRX1500 | SRX3400<br>SRX3600 | SRX5400<br>SRX5600<br>SRX5800 |
|------------------------------------------|--------------------|--------------------|-------------------------------|
| Source NAT pools                         | 8192               | 8192               | 12,288                        |
| IP addresses supporting port translation | 8192               | 8192               | 1M                            |
| PAT port number                          | 256M               | 256M               | 384M                          |

Increasing the capacity of source NAT pools consumes memory needed for port allocation. When source NAT pool and IP address limits are reached, port ranges should be reassigned. That is, the number of ports for each IP address should be decreased when the number of IP addresses and source NAT pools is increased. This ensures NAT does not consume too much memory. Use the **port-range** statement in configuration mode in

the CLI to assign a new port range or the **pool-default-port-range** statement to override the specified default.

Configuring port overloading should also be done carefully when source NAT pools are increased.

For source pool with PAT in range (63,488 through 65,535), two ports are allocated at one time for RTP/RTCP applications, such as SIP, H.323, and RTSP. In these scenarios, each IP address supports PAT, occupying 2048 ports (63,488 through 65,535) for ALG module use.

---

## Understanding Persistent Addresses

By default, port address translation is performed with source NAT. However, an original source address may not be translated to the same IP address for different traffic that originates from the same host. The source NAT **address-persistent** option ensures that the same IP address is assigned from the source NAT pool to a specific host for multiple concurrent sessions.

This option differs from the address-pooling paired option, where the internal address is mapped to an external address within the pool on a first-come, first-served basis, and might be mapped to a different external address for each session.

## Example: Configuring Capacity for Source NAT Pools with PAT

This example describes how to configure the capacity of source NAT pools with Port Address Translation (PAT) if a default port range is not set or you want to override it. Translations are set for each IP address. When the source pool is increased, ports should be reassigned if the current port number exceeds limitations.

- [Requirements on page 5227](#)
- [Overview on page 5227](#)
- [Configuration on page 5227](#)
- [Verification on page 5228](#)

## Requirements

Before you begin:

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
2. Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on page 1030.

## Overview

This example shows how to configure a PAT pool of 2048 IP addresses with 32K ports for each IP address.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
[edit security nat source]
set pool src-nat-pat-addr address 1.1.1.0/32 to 1.1.4.255/32
set pool src-nat-pat-addr address 1.1.5.0/32 to 1.1.8.255/32
set pool-default-port-range 2001
set pool-default-port-range to 32720
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure capacity for a source NAT pool with PAT:

1. Specify a source NAT pool with PAT and an IP address range.

```
[edit security nat source]
user@host# set pool src-nat-pat-addr address 1.1.1.0/32 to 1.1.4.255/32
user@host# set pool src-nat-pat-addr address 1.1.5.0/32 to 1.1.8.255/32
```

2. Specify a default port range for the source pool.

```
[edit security nat source]
user@host# set pool-default-port-range 2001
user@host# set pool-default-port-range to 32720
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat-source-summary** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host> run show security nat source summary
Total port number usage for port translation pool: 16515072
Maximum port number for port translation pool: 134217728
Total pools: 1
```

```
Pool Address Routing PAT Total Name Range Instance Address pool2 30.1.1.1-30.1.1.3
default yes 2048
Name Range Instance Address
pool1 60.0.0.0-60.0.0.225 default yes 256

Total rules: 1
Rule name Rule set From To Action
rule 1 ruleset1 ge-2/2/2.0 ge-2/2/3.0 pool1
rule 1 ge-2/2/4.0 ge-2/2/5.0
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Capacity of Source NAT Pools on page 5228](#)

### Verifying Capacity of Source NAT Pools

## Understanding Source NAT Pools with Address Pooling

---

When a host initiates several sessions that match a policy that requires NAT, and is assigned an IP address from a source pool that has port address translation enabled, a different source IP address is used for each session.

Because some applications require the same source IP address for each session, you can use the **address-pooling paired** feature to enable all sessions associated with one internal IP address to map to the same external IP address for the duration of the sessions. When the sessions end, the mapping between the internal IP address and the external IP address cease. The next time the host initiates a session, a different IP address from the pool might be assigned to it.

This differs from the source NAT **persistent-address** feature, which keeps the mapping static; the same internal IP address is mapped to the same external IP address every time. It also differs from the **persistent-address** feature in that **address-pooling paired** is configured for a specific pool. The **persistent-address** feature is a global configuration that applies to all source pools.

---

## Understanding Source NAT Pools with Address Shifting

---

The match conditions for a source NAT rule set do not allow you to specify an address range; only address prefixes may be specified in a rule. When configuring a source NAT pool, you can specify the **host-base-address** option; this option specifies the IP address where the original source IP address range begins.

The range of original source IP addresses that are translated is determined by the number of addresses in the source NAT pool. For example, if the source NAT pool contains a range of ten IP addresses, then up to ten original source IP addresses can be translated, starting with a specified base address. This type of translation is one-to-one, static, and without port address translation.

The match condition in a source NAT rule may define a larger address range than that specified in the source NAT pool. For example, a match condition might specify an address prefix that contains 256 addresses, but the source NAT pool might contain a range of only a few IP addresses, or only one IP address. A packet's source IP address can match a source NAT rule, but if the source IP address is not within the address range specified in the source NAT pool, the source IP address is not translated.

## Example: Configuring Source NAT with Address Shifting

---

This example describes how to configure a source NAT mapping of a private address range to public addresses, with optional address shifting. This mapping is one-to-one between the original source IP addresses and translated IP addresses and no port translation is performed.

**NOTE:** The match conditions for a source NAT rule set do not allow you to specify an address range; only address prefixes may be specified in a rule. When configuring a source NAT pool, you can specify the `host-base-address` option; this option specifies the IP address where the original source IP address range begins.

The range of original source IP addresses that are translated is determined by the number of addresses in the source NAT pool. For example, if the source NAT pool contains a range of ten IP addresses, then up to ten original source IP addresses can be translated, starting with a specified base address.

The match condition in a source NAT rule may define a larger address range than that specified in the source NAT pool. For example, a match condition might specify an address prefix that contains 256 addresses, but the source NAT pool contains a range of only ten IP addresses. A packet's source IP address can match a source NAT rule, but if the source IP address is not within the address range specified in the source NAT pool, the source IP address is not translated.

- [Requirements on page 5230](#)
- [Overview on page 5230](#)
- [Configuration on page 5232](#)
- [Verification on page 5234](#)

## Requirements

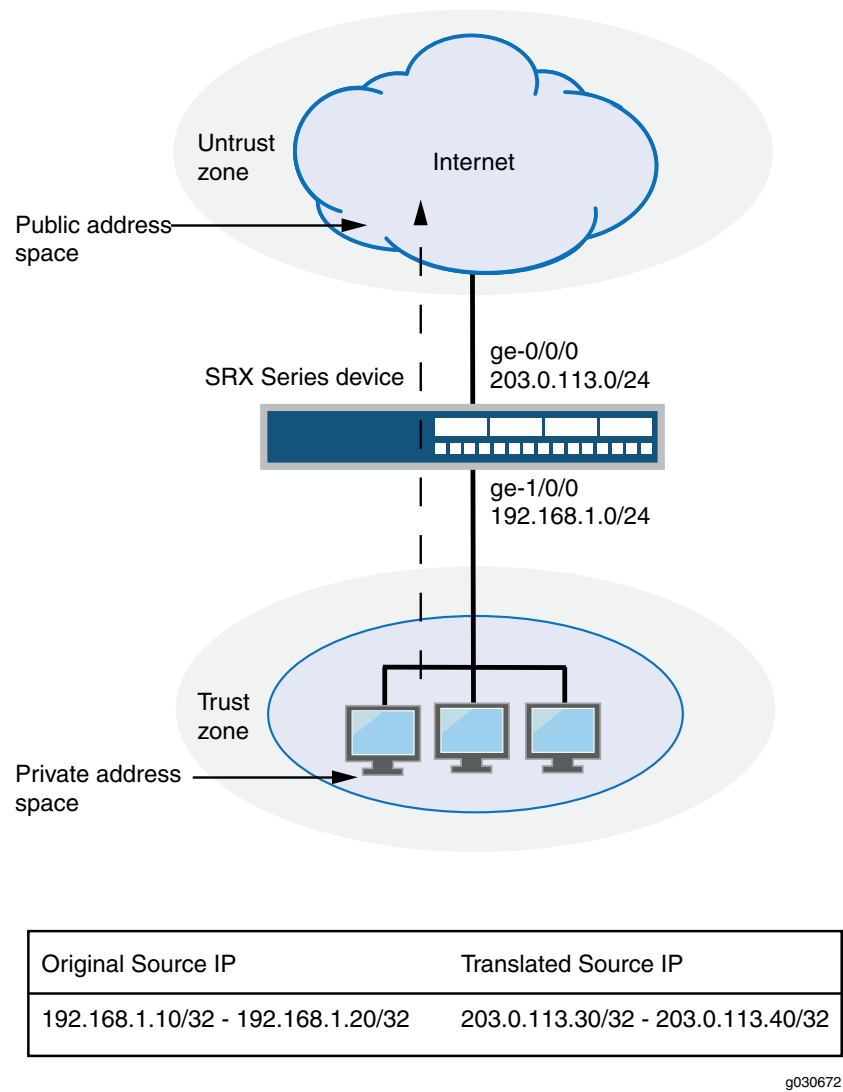

Before you begin:

- Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
- Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 227](#), a range of private addresses in the trust zone is mapped to a range of public addresses in the untrust zone. For packets sent from the trust zone to the untrust zone, a source IP address in the range of 192.168.1.10/32 through 192.168.1.20/32 is translated to a public address in the range of 1.1.1.30/32 through 1.1.1.40/32.

Figure 227: Source NAT with Address Shifting

This example describes the following configurations:

- Source NAT pool **src-nat-pool-1** that contains the IP address range 1.1.1.30/32 through 1.1.1.40/32. For this pool, the beginning of the original source IP address range is 192.168.1.10/32 and is specified with the **host-address-base** option.
- Source NAT rule set **rs1** with rule **r1** to match packets from the trust zone to the untrust zone with a source IP address in the 192.168.1.0/24 subnet. For matching packets that fall within the source IP address range specified by the **src-nat-pool-1** configuration, the source address is translated to the IP address in **src-nat-pool-1** pool.

- Proxy ARP for the addresses 1.1.1.30/32 through 1.1.1.40/32 on interface ge-0/0/0.0. This allows the Juniper Networks security device to respond to ARP requests received on the interface for that address.
- Security policies to permit traffic from the trust zone to the untrust zone.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-pool-1 address 1.1.1.30/32 to 1.1.1.40/32
set security nat source pool src-nat-pool-1 host-address-base 192.168.1.10/32
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
set security nat source rule-set rs1 rule r1 match source-address 192.168.1.0/24
set security nat source rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.30/32 to 1.1.1.40/32
set security policies from-zone trust to-zone untrust policy internet-access match
 source-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 application any
set security policies from-zone trust to-zone untrust policy internet-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT mapping with address shifting:

1. Create a source NAT pool.  

```
[edit security nat source]
user@host# set pool src-nat-pool-1 address 1.1.1.30/32 to 1.1.1.40/32
```
2. Specify the beginning of the original source IP address range.  

```
[edit security nat source]
user@host# set pool src-nat-pool-1 host-address-base 192.168.1.10/32
```
3. Create a source NAT rule set.  

```
[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust
```
4. Configure a rule that matches packets and translates the source address to an address in the pool.  

```
[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address 192.168.1.0/24
user@host# set rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
```
5. Configure proxy ARP.

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.30/32 to 1.1.1.40/32
```

6. Configure a security policy that allows traffic from the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool src-nat-pool-1 {
 address {
 1.1.1.30/32 to 1.1.1.40/32;
 }
 host-address-base 192.168.1.10/32;
 }
 rule-set rs1 {
 from zone trust;
 to zone untrust;
 rule r1 {
 match {
 source-address 192.168.1.0/24;
 }
 then {
 source-nat {
 pool {
 src-nat-pool-1;
 }
 }
 }
 }
 }
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.30/32 to 1.1.1.40/32;
 }
 }
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
```

```
 permit;
 }
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Pool Usage on page 5234](#)
- [Verifying Source NAT Rule Usage on page 5234](#)

## Understanding Source NAT Pools with PAT

Using the source pool with Port Address Translation (PAT), Junos OS translates both the source IP address and the port number of the packets. When PAT is used, multiple hosts can share the same IP address.

Junos OS maintains a list of assigned port numbers to distinguish what session belongs to which host. When PAT is enabled, up to 63,488 hosts can share a single IP address. Each source pool can contain multiple IP addresses, multiple IP address ranges, or both.

For a source pool with PAT, Junos OS may assign different addresses to a single host for different concurrent sessions, unless the source pool or Junos OS has the persistent address feature or the paired address pooling feature enabled.

For interface source pool and source pool with PAT, range (1024, 65535) is available for port number mapping per IP address. Within range (1024, 63487) one port is allocated at a time, for a total of 62,464 ports. In range (63488, 65535), two ports are allocated at a time for RTP/RTCP applications such as SIP, H.323, and RTSP, for a total of 2,048 ports.

When a host initiates several sessions that match a policy that requires network address translation and is assigned an address from a source pool that has PAT enabled, the device assigns a different source IP address for each session. Such random address assignment can be problematic for services that create multiple sessions that require the same source IP address for each session. For example, it is important to have the same IP address for multiple sessions when using the AOL Instant Message (AIM) client.

To ensure that the router assigns the same IP address from a source pool to a host for multiple concurrent sessions, you can enable a persistent IP address per router. To ensure that the device assigns the same IP address from a source pool to a host for the duration of a single session, you can enable paired address pooling.

## Example: Configuring Source NAT for Multiple Addresses with PAT

---

This example describes how to configure a source NAT mapping of a private address block to a smaller public address block using port address translation.

- [Requirements on page 5235](#)
- [Overview on page 5236](#)
- [Configuration on page 5238](#)
- [Verification on page 5240](#)

### Requirements

Before you begin:

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.

2. Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 228](#), the source IP address in packets sent from the trust zone to the untrust zone is mapped to a smaller block of public addresses in the range from 1.1.1.1/32 through 1.1.1.24/32. Because the size of the source NAT address pool is smaller than the number of potential addresses that might need to be translated, port address translation is used.

.....

**NOTE:** Port address translation includes a source port number with the source IP address mapping. This allows multiple addresses on a private network to map to a smaller number of public IP addresses. Port address translation is enabled by default for source NAT pools.

.....

Figure 228: Source NAT Multiple Addresses with PAT

| Original Source IP                           | Translated Source IP                        |
|----------------------------------------------|---------------------------------------------|
| 10.1.1.0/24<br>10.1.2.0/24<br>192.168.1.0/24 | 203.0.113.1 (with port address translation) |

g030670

This example describes the following configurations:

- Source NAT pool **src-nat-pool-1** that contains the IP address range 1.1.1.1/32 through 1.1.1.24/32.
- Source NAT rule set **rs1** to match all packets from the trust zone to the untrust zone. For matching packets, the source IP address is translated to an IP address in the **src-nat-pool-1** pool.

- Proxy ARP for the addresses 1.1.1.1/32 through 1.1.1.24/32 on interface ge-0/0/0.0. This allows the Juniper Networks security device to respond to ARP requests received on the interface for those addresses.
- Security policies to permit traffic from the trust zone to the untrust zone.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-pool-1 address 1.1.1.1/32 to 1.1.1.24/32
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
set security nat source rule-set rs1 rule r1 match source-address 10.1.1.0/24
set security nat source rule-set rs1 rule r1 match source-address 10.1.2.0/24
set security nat source rule-set rs1 rule r1 match source-address 192.168.1.0/24
set security nat source rule-set rs1 rule r1 match destination-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.1/32 to 1.1.1.24/32
set security policies from-zone trust to-zone untrust policy internet-access match
 source-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 application any
set security policies from-zone trust to-zone untrust policy internet-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT mapping from a private address block to a smaller public address block using PAT:

1. Create a source NAT pool.

```
[edit security nat source]
user@host# set pool src-nat-pool-1 address 1.1.1.1 to 1.1.1.24
```

2. Create a source NAT rule set.

```
[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust
```

3. Configure a rule that matches packets and translates the source address to an address in the pool.

```
[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address [10.1.1.0/24 10.1.2.0/24
 192.168.1.0/24]
user@host# set rule-set rs1 rule r1 match destination-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
```

4. Configure proxy ARP.

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.1 to 1.1.1.24
```

5. Configure a security policy that allows traffic from the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool src-nat-pool-1 {
 address {
 1.1.1.1/32 to 1.1.1.24/32;
 }
 }
}
rule-set rs1 {
 from zone trust;
 to zone untrust;
 rule r1 {
 match {
 source-address [10.1.1.0/24 10.1.2.0/24 192.168.1.0/24];
 destination-address 0.0.0.0/0;
 }
 then {
 source-nat {
 pool {
 src-nat-pool-1;
 }
 }
 }
 }
}
}
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.1/32 to 1.1.1.24/32;
 }
 }
}
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 }
}
```

```
 }
 then {
 permit;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Understanding Source NAT Pools Without PAT

When you define a source pool, Junos OS enables PAT by default. To disable PAT, you must specify no port translation when you are defining a source pool.

When using a source pool without PAT, Junos OS performs source Network Address Translation for the IP address without performing PAT for the source port number. For

applications that require that a particular source port number remain fixed, you must use source pool without PAT.

The source pool can contain multiple IP addresses, multiple IP address ranges, or both. For source pool without PAT, Junos OS assigns one translated source address to the same host for all its concurrent sessions unless the address-pooling no-paired option is enabled.

The number of hosts that a source NAT pool without PAT can support is limited to the number of addresses in the pool. When you have a pool with a single IP address, only one host can be supported, and traffic from other hosts is blocked because there are no resources available. If a single IP address is configured for a source NAT pool without PAT when NAT resource assignment is not in active-backup mode in a chassis cluster, traffic through node 1 will be blocked.

Pool utilization for each source pool without PAT is computed. You can turn on pool utilization alarm by configuring alarm thresholds. An SNMP trap is triggered every time pool utilization rises above a threshold and goes below a threshold.

**NOTE:** If a static NAT rule is for one-to-one IP translation, avoid dividing the rule into a destination rule and a source rule when source no-pat pool without address sharing is used. If you choose to divide the rule, you will then have to use source pat-pool with single IP or source no-pat pool with multiple IP.

## Example: Configuring a Single IP Address in a Source NAT Pool Without PAT

---

This example describes how to configure a private address block to a single public address in a source NAT pool without Port Address Translation.

**NOTE:** PAT is enabled by default for source NAT pools. When PAT is disabled, the number of translations that the source NAT pool can concurrently support is limited to the number of addresses in the pool. Packets are dropped if there are no addresses available in the source NAT pool. However, using the **address-shared** option, you can map more than one private IP address to a single public IP address as long as the traffic is from different source ports.

- [Requirements on page 5242](#)
- [Overview on page 5242](#)
- [Configuration on page 5242](#)
- [Verification on page 5244](#)

## Requirements

Before you begin:

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
2. Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. The source IP address of packets sent from the trust zone to the untrust zone are mapped to a single public address.

This example describes the following configurations:

- Source NAT pool **src-nat-pool-1** that contains the IP address 60.1.1.1/30. The **port no-translation** option and the **address shared** option are specified for the pool.
- Source NAT rule set **rs1** to match all packets from the trust zone to the untrust zone. For matching packets, the source IP address is translated to an IP address in the **src-nat-pool-1** pool.
- Security policies to permit traffic from the trust zone to the untrust zone.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-pool-1 address 60.1.1.1/30
set security nat source pool src-nat-pool-1 port no-translation
set security nat source pool src-nat-pool-1 address-shared
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
```

```
set security nat source rule-set rs1 rule r1 match source address 20.1.1.0/24
set security nat source rule-set rs1 rule r1 then source src-nat-pool-1
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT mapping from a private address block to a single public address without PAT:

1. Create a source NAT pool with a single IP address for the shared address.

```
[edit security nat source]
user@host# set pool src-nat-pool-1 address 60.1.1.1/30
```

Specify the **port no-translation** option.

```
[edit security nat source]
user@host# set pool src-nat-pool-1 port no-translation
```

2. Specify the **address-shared** option.

```
[edit security nat source]
user@host# set pool pool-src-nat-pool-1 address-shared
```

3. Create a source NAT rule set.

```
[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust
```

4. Configure a rule that matches packets and translates the source address to an address in the pool.

```
[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address 20.1.1.0/24
user@host# set rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
```

5. Configure a security policy that allows traffic from the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat source pool** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool src-nat-pool-1 {
 address {
 60.1.1.1/30
 }
 }
 port no-translation;
```

```
}
address-shared;
rule-set rs1 {
 from zone trust;
 to zone untrust;
 rule r1 {
 match {
 source-address [20.1.1.0/24]
 }
 then {
 source-nat {
 pool {
 src-nat-pool-1;
 }
 }
 }
 }
}
}
}
}
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Shared Address on page 5244](#)
- [Verifying Shared Address Application to Traffic on page 5244](#)

### Verifying Shared Address

---

**Purpose** Verify that two internal IP addresses, with different source ports, share one external IP address.

**Action** From operational mode, enter the **show security nat source pool** command. View the **Address assignment** field to verify that it is shared.

### Verifying Shared Address Application to Traffic

---

**Purpose** Verify that two sessions are using the same IP address.

**Action** From operational mode, enter the **show security flow session** command.

## Example: Configuring Source NAT for Multiple Addresses Without PAT

This example describes how to configure a source NAT mapping of a private address block to a smaller public address block without port address translation.

**NOTE:** Port address translation is enabled by default for source NAT pools. When port address translation is disabled, the number of translations that the source NAT pool can concurrently support is limited to the number of addresses in the pool. Packets are dropped if there are no addresses available in the source NAT pool. You can optionally specify an overflow pool from which IP addresses and port numbers are allocated when there are no addresses available in the original source NAT pool.

- [Overview on page 5245](#)
- [Configuration on page 5247](#)
- [Verification on page 5249](#)

## Requirements

Before you begin:

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
2. Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on page 1030.

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 229](#), the source IP address in packets sent from the trust zone to the untrust zone is mapped to a smaller block of public addresses in the range from 1.1.1.1/32 through 1.1.1.24/32.

Figure 229: Source NAT Multiple Addresses Without PAT

| Original Source IP                           | Translated Source IP                      |
|----------------------------------------------|-------------------------------------------|
| 10.1.1.0/24<br>10.1.2.0/24<br>192.168.1.0/24 | 203.0.113.1 (no port address translation) |

g030671

This example describes the following configurations:

- Source NAT pool **src-nat-pool-1** that contains the IP address range 1.1.1.1/32 through 1.1.1.24/32. The **port no-translation** option is specified for the pool.
- Source NAT rule set **rs1** to match all packets from the trust zone to the untrust zone. For matching packets, the source IP address is translated to an IP address in the **src-nat-pool-1** pool.
- Proxy ARP for the addresses 1.1.1.1/32 through 1.1.1.24/32 on interface `ge-0/0/0.0`. This allows the Juniper Networks security device to respond to ARP requests received on the interface for those addresses.
- Security policies to permit traffic from the trust zone to the untrust zone.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-pool-1 address 1.1.1.1/32 to 1.1.1.24/32
set security nat source pool src-nat-pool-1 port no-translation
set security nat source rule-set rs1 from zone trust
set security nat source rule-set rs1 to zone untrust
set security nat source rule-set rs1 rule r1 match source-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 match destination-address 0.0.0.0/0
set security nat source rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.1/32 to 1.1.1.24/32
set security policies from-zone trust to-zone untrust policy internet-access match
 source-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 application any
set security policies from-zone trust to-zone untrust policy internet-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT mapping from a private address block to a smaller public address block without PAT:

1. Create a source NAT pool.

```
[edit security nat source]
user@host# set pool src-nat-pool-1 address 1.1.1.1 to 1.1.1.24
```

2. Specify the **port no-translation** option.

```
[edit security nat source]
user@host# set pool src-nat-pool-1 port no-translation
```

3. Create a source NAT rule set.

```
[edit security nat source]
user@host# set rule-set rs1 from zone trust
user@host# set rule-set rs1 to zone untrust
```

4. Configure a rule that matches packets and translates the source address to an address in the pool.

```
[edit security nat source]
user@host# set rule-set rs1 rule r1 match source-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 match destination-address 0.0.0.0/0
user@host# set rule-set rs1 rule r1 then source-nat pool src-nat-pool-1
```

5. Configure proxy ARP.

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.1 to 1.1.1.24
```

6. Configure a security policy that allows traffic from the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool src-nat-pool-1 {
 address {
 1.1.1.1/32 to 1.1.1.24/32;
 }
 port no-translation;
 }
}
rule-set rs1 {
 from zone trust;
 to zone untrust;
 rule r1 {
 match {
 source-address 0.0.0.0/0;
 destination-address 0.0.0.0/0;
 }
 then {
 source-nat {
 pool {
 src-nat-pool-1;
 }
 }
 }
 }
}
}
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.1/32 to 1.1.1.24/32;
 }
 }
}
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy internet-access {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;

```

```
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Pool Usage on page 5249](#)
- [Verifying Source NAT Rule Usage on page 5249](#)
- [Verifying NAT Application to Traffic on page 5249](#)

### Verifying Source NAT Pool Usage

**Purpose** Verify that there is traffic using IP addresses from the source NAT pool.

**Action** From operational mode, enter the **show security nat source pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

### Verifying Source NAT Rule Usage

**Purpose** Verify that there is traffic matching the source NAT rule.

**Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

### Verifying NAT Application to Traffic

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

## Understanding Source NAT Pools with Shared Address

Source NAT pools with no port address translation perform static, one-to-one mappings from one source IP address to one external IP address. When there is only one external IP address, or very few available in a source no-pat pool or IP address shifting pool, the **address-shared** option enables you to map many source IP addresses to one external IP address, which increases NAT resources and improves traffic.

This option cannot be used on source NAT pools with port address translation because address sharing is already their default behavior.

## Understanding Destination NAT

---

Destination NAT is the translation of the destination IP address of a packet entering the Juniper Networks device. Destination NAT is used to redirect traffic destined to a virtual host (identified by the original destination IP address) to the real host (identified by the translated destination IP address).

**NOTE:** When destination NAT is performed, the destination IP address is translated according to configured destination NAT rules and then security policies are applied.

Destination NAT allows connections to be initiated only for incoming network connections—for example, from the Internet to a private network. Destination NAT is commonly used to perform the following actions:

- Translate a single IP address to another address (for example, to allow a device on the Internet to connect to a host on a private network).
- Translate a contiguous block of addresses to another block of addresses of the same size (for example, to allow access to a group of servers).
- Translate a destination IP address and port to another destination IP address and port (for example, to allow access to multiple services using the same IP address but different ports).

The following types of destination NAT are supported:

- Translation of the original destination IP address to an IP address from a user-defined pool. This type of translation does not include Port Address Translation (PAT). If the original destination IP address range is larger than the address range in the user-defined address pool, any untranslated packets are dropped.
- Translation of the original destination IP address (and optional port number) to one specific IP address (and port number) from a user-defined pool.

- [Understanding Destination NAT Rules on page 5253](#)

## Understanding Destination NAT Address Pools

A NAT pool is a user-defined set of IP addresses that are used for translation. Unlike static NAT, where there is a one-to-one mapping that includes destination IP address translation in one direction and source IP address translation in the reverse direction, with destination NAT, you translate the original destination address to an IP address in the address pool.

For destination NAT address pools, specify the following:

- Name of the destination NAT address pool
- Destination address or address range

**NOTE:** Do not overlap NAT addresses for source NAT, destination NAT, and static NAT within one routing instance.

- Destination port that is used for port forwarding
- Routing instance to which the pool belongs—A destination NAT pool that does not specify a specific routing instance will default to the routing instance of the ingress zone.

**NOTE:** You can configure a NAT pool to exist in the default routing instance. Configuration option to specify that a NAT pool exists in the default routing-instance is available. As a result, the NAT pool is reachable from zones in the default routing instance, and from zones in other routing instances.

  - [Example: Configuring Destination NAT for Subnet Translation on page 5267](#)

## Understanding Destination NAT Rules

---

Destination NAT rules specify two layers of match conditions:

- Traffic direction—Allows you to specify **from interface**, **from zone**, or **from routing-instance**.
- Packet information—Can be source IP addresses, destination IP address or subnet, destination port numbers or port ranges, protocols, or applications.

For ALG traffic, we recommend that you not use the **destination-port** option or the **application** option as matching conditions. If these options are used, translation may fail because the port value in the application payload might not match the port value in the IP address.

If multiple destination NAT rules overlap in the match conditions, the most specific rule is chosen. For example, if rules A and B specify the same source and destination IP addresses, but rule A specifies traffic from zone 1 and rule B specifies traffic from interface **ge-0/0/0**, rule B is used to perform destination NAT. An interface match is considered to be more specific than a zone match, which is more specific than a routing instance match.

The actions you can specify for a destination NAT rule are:

- **off**—Do not perform destination NAT.
- **pool**—Use the specified user-defined address pool to perform destination NAT.

Destination NAT rules are applied to traffic in the first packet that is processed for the flow or in the fast path for the ALG. Destination NAT rules are processed after static NAT rules but before source NAT rules.

  - [Example: Configuring Destination NAT for Subnet Translation on page 5267](#)

## Destination NAT Configuration Overview

---

The main configuration tasks for destination NAT are as follows:

1. Configure a destination NAT address pool that aligns with your network and security requirements.
2. Configure destination NAT rules that align with your network and security requirements.
3. Configure NAT proxy ARP entries for IP addresses in the same subnet of the ingress interface.

## Example: Improving Security by Configuring Destination NAT for Single Address Translation

---

This example describes how to configure a destination NAT mapping of a single public address to a private address.

**NOTE:** Mapping one destination IP address to another can also be accomplished with static NAT. Static NAT mapping allows connections to be established from either side of the gateway device, whereas destination NAT only allows connections to be established from one side. However, static NAT only allows translations from one address to another or between blocks of addresses of the same size.

- [Requirements on page 5254](#)
- [Overview on page 5255](#)
- [Configuration on page 5257](#)
- [Verification on page 5259](#)

### Requirements

This example uses the following hardware and software components:

- SRX Series device
- Server

Before you begin:

- Configure network interfaces on the device. See the *Interfaces Feature Guide for Security Devices*.
- Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

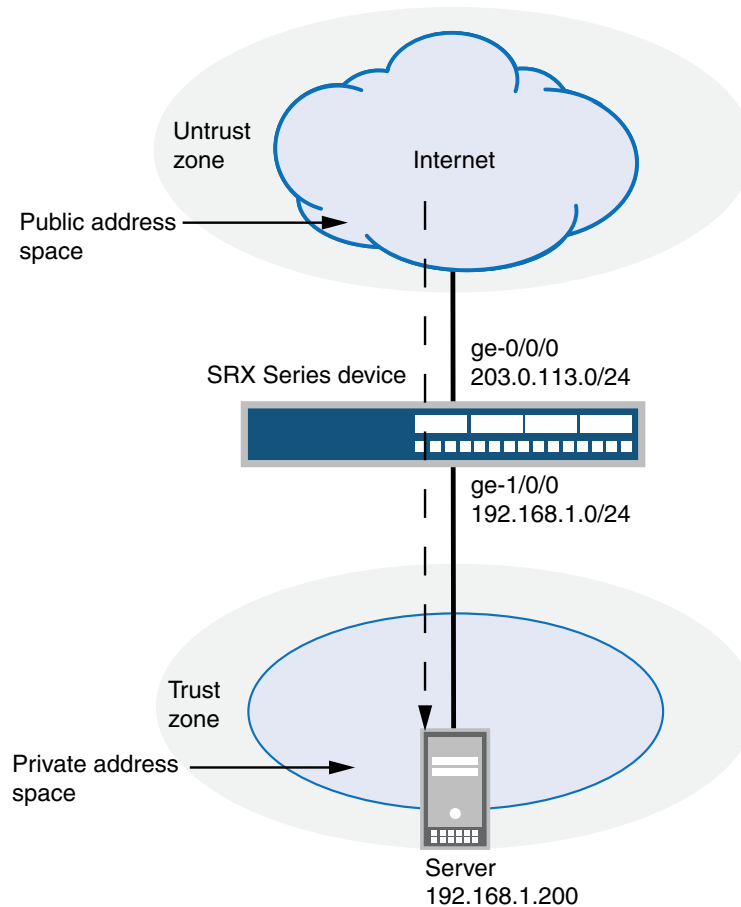

## Overview

Destination NAT is commonly used to distribute a service located in a private network with a publicly accessible IP address. This allows users to use the private service with the public IP address. Destination NAT address pool and destination NAT rules configurations are used to align your network and improve security requirements.

In this example, first you configure the trust security zone for the private address space and then you configure the untrust security zone for the public address space. In [Figure 230](#), devices in the untrust zone access a server in the trust zone by way of public address 1.1.1.200/32. For packets that enter the Juniper Networks security device from the untrust zone with the destination IP address 1.1.1.200/32, the destination IP address is translated to the private address 192.168.1.200/32.

## Topology

Figure 230: Destination NAT Single Address Translation

| Original Destination IP | Translated Destination IP |
|-------------------------|---------------------------|
| 203.0.113.200/32        | 192.168.1.200/32          |

g030665

Table 323 shows the parameters configured in this example.

Table 475: Interfaces, Zones, Server, and IP Address Information

| Parameter    | Description                                  |
|--------------|----------------------------------------------|
| Trust Zone   | Security zone for the private address space. |
| Untrust Zone | Security zone for the public address space.  |

**Table 475: Interfaces, Zones, Server, and IP Address Information** (*continued*)

| Parameter             | Description                                  |
|-----------------------|----------------------------------------------|
| 192.168.1.200/32      | Translated destination NAT IP address.       |
| 192.168.1.0/24        | Private subnet in private zone.              |
| 1.1.1.200/32          | Public address of the server.                |
| Server                | Server address of the private address space. |
| ge-0/0/0 and ge-1/0/0 | NAT interfaces for traffic direction.        |

This example describes the following configurations:

- Destination NAT pool **dst-nat-pool-1** that contains the IP address 192.168.1.200/32.
- Destination NAT rule set **rs1** with rule **r1** to match packets received from the ge-0/0/0.0 interface with the destination IP address 1.1.1.200/32. For matching packets, the destination address is translated to the address in the **dst-nat-pool-1** pool.
- Proxy ARP for the address 1.1.1.200/32 on interface ge-0/0/0.0. This allows the Juniper Networks security device to respond to ARP requests received on the interface for that address.
- Security policies to permit traffic from the untrust zone to the translated destination IP address in the trust zone.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat destination pool dst-nat-pool-1 address 192.168.1.200/32
set security nat destination rule-set rs1 from interface ge-0/0/0.0
set security nat destination rule-set rs1 rule r1 match destination-address 1.1.1.200/32
set security nat destination rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.200/32
set security address-book global address server-1 192.168.1.200/32
set security policies from-zone untrust to-zone trust policy server-access match
 source-address any
set security policies from-zone untrust to-zone trust policy server-access match
 destination-address server-1
set security policies from-zone untrust to-zone trust policy server-access match application
 any
set security policies from-zone untrust to-zone trust policy server-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a destination NAT mapping from a public address to a private address:

1. Create the destination NAT pool.  

```
[edit security nat destination]
user@host# set pool dst-nat-pool-1 address 192.168.1.200/32
```
2. Create a destination NAT rule set.  

```
[edit security nat destination]
user@host# set rule-set rs1 from interface ge-0/0/0.0
```
3. Configure a rule that matches packets and translates the destination address to the address in the pool.  

```
[edit security nat destination]
user@host# set rule-set rs1 rule r1 match destination-address 1.1.1.200/32
user@host# set rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1
```
4. Configure proxy ARP.  

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.200/32
```
5. Configure an address in the global address book.  

```
[edit security address-book global]
user@host# set address server-1 192.168.1.200/32
```
6. Configure a security policy that allows traffic from the untrust zone to the server in the trust zone.  

```
[edit security policies from-zone untrust to-zone trust]
user@host# set policy server-access match source-address any
user@host# set policy server-access match destination-address server-1
user@host# set policy server-access match application any
user@host# set policy server-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, and **show bridge-domains** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show security nat
destination {
 pool dst-nat-pool-1 {
 address 192.168.1.200/32;
 }
 rule-set rs1 {
 from interface ge-0/0/0.0;
 rule r1 {
 match {
 destination-address 1.1.1.200/32;
```

If you are done configuring the device, enter **commit** from configuration mode.

Confirm that the configuration is working properly.

- ## Verifying Destination NAT Pool Usage

|               |                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Action</b> | From operational mode, enter the <b>show security nat destination pool all</b> command. View the Translation hits field to check for traffic using IP addresses from the pool. |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|             |      |
|-------------|------|
| works, Inc. | 5259 |
|-------------|------|

```

Pool id : 1
Total address : 1
Translation hits: 71
Address range Port
192.168.1.200 - 192.168.1.200 0

```

**Meaning** The **show security nat destination pool all** command displays the pool of translated addresses. View the Translation hits field to check for traffic using IP addresses from the pool.

### Verifying Destination NAT Rule Usage

**Purpose** Verify that there is traffic matching the destination NAT rule.

**Action** From operational mode, enter the **show security nat destination rule all** command.

```

user@host>show security nat destination rule all
Total destination-nat rules: 1
Total referenced IPv4/IPv6 ip-prefixes: 1/0

Destination NAT rule: r1 Rule-set: rs1
Rule-Id : 1
Rule position : 1
From interface : ge-0/0/0.0
Destination addresses : 1.1.1.200 - 1.1.1.200
Action : dst-nat-pool-1
Translation hits : 75
Successful sessions : 75
Failed sessions : 0
Number of sessions : 4

```

**Meaning** The **show security nat destination rule all** command displays the destination NAT rule. View the Translation hits field to check for traffic that matches the destination rule.

### Verifying Destination NAT for a Single Address Translation

**Purpose** Verify the configuration of destination NAT for a single address translation.

**Action** From operational mode, enter the **show security nat destination summary** command.

```

user@host>show security nat destination summary
Total pools: 1
Pool name Address Range Routing Instance Port Total Address
dst-nat-pool-1 192.168.1.200 - 192.168.1.200 0 1

Total rules: 1
Rule name Rule set From Action
r1 rs1 ge-0/0/0.0 dst-nat-pool-1

```

**Meaning** The **show security nat destination summary** command displays information about destination NAT configuration. You can verify the following information:

- Rule sets
- Rules

- Address range
- NAT pool
- Port details

### Verifying NAT Application to Traffic

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

```
user@host>show security flow session
```

```
Session ID: 26415, Policy name: server-access/11, Timeout: 2, Valid
 In: 1.1.1.219/30 --> 1.1.1.200/54850;icmp, If: ge-0/0/0.0, Pkts: 1, Bytes: 84
 Out: 192.168.1.200/54850 --> 1.1.1.219/30;icmp, If: ge-0/0/1.0, Pkts: 1, Bytes:
84
```

```
Session ID: 26420, Policy name: server-access/11, Timeout: 2, Valid
 In: 1.1.1.219/31 --> 1.1.1.200/54850;icmp, If: ge-0/0/0.0, Pkts: 1, Bytes: 84
 Out: 192.168.1.200/54850 --> 1.1.1.219/31;icmp, If: ge-0/0/1.0, Pkts: 1, Bytes:
84
```

```
Session ID: 26425, Policy name: server-access/11, Timeout: 4, Valid
 In: 1.1.1.219/32 --> 1.1.1.200/54850;icmp, If: ge-0/0/0.0, Pkts: 1, Bytes: 84
 Out: 192.168.1.200/54850 --> 1.1.1.219/32;icmp, If: ge-0/0/1.0, Pkts: 1, Bytes:
84
```

```
Session ID: 26431, Policy name: server-access/11, Timeout: 4, Valid
 In: 1.1.1.219/33 --> 1.1.1.200/54850;icmp, If: ge-0/0/0.0, Pkts: 1, Bytes: 84
 Out: 192.168.1.200/54850 --> 1.1.1.219/33;icmp, If: ge-0/0/1.0, Pkts: 1, Bytes:
84
```

```
Total sessions: 9
```

**Meaning** The **show security flow session** command displays active sessions on the device and each session's associated security policy. The output shows traffic entering the device using the private source address 1.1.1.219/30 destined to a public host at 1.1.1.200. The return traffic from this flow travels to the translated public address 1.1.1.219.

- **Session ID**—Number that identifies the session. Use this ID to get more information about the session such as policy name or number of packets in and out.
- **server-access**—Policy name that permitted the traffic from the untrust zone to the translated destination IP address in the trust zone.
- **In**—Incoming flow (source and destination IP addresses with their respective source and destination port numbers, the session is ICMP, and the source interface for this session is ge-0/0/0.0).
- **Out**—Reverse flow (source and destination IP addresses with their respective source and destination port numbers, the session is ICMP, and the destination interface for this session is ge-0/0/1.0).

## [Example: Configuring Destination NAT for IP Address and Port Translation](#)

---

This example describes how to configure destination NAT mappings of a public address to private addresses, depending on the port number.

- [Requirements on page 5262](#)
- [Overview on page 5262](#)
- [Configuration on page 5264](#)
- [Verification on page 5266](#)

### Requirements

Before you begin:

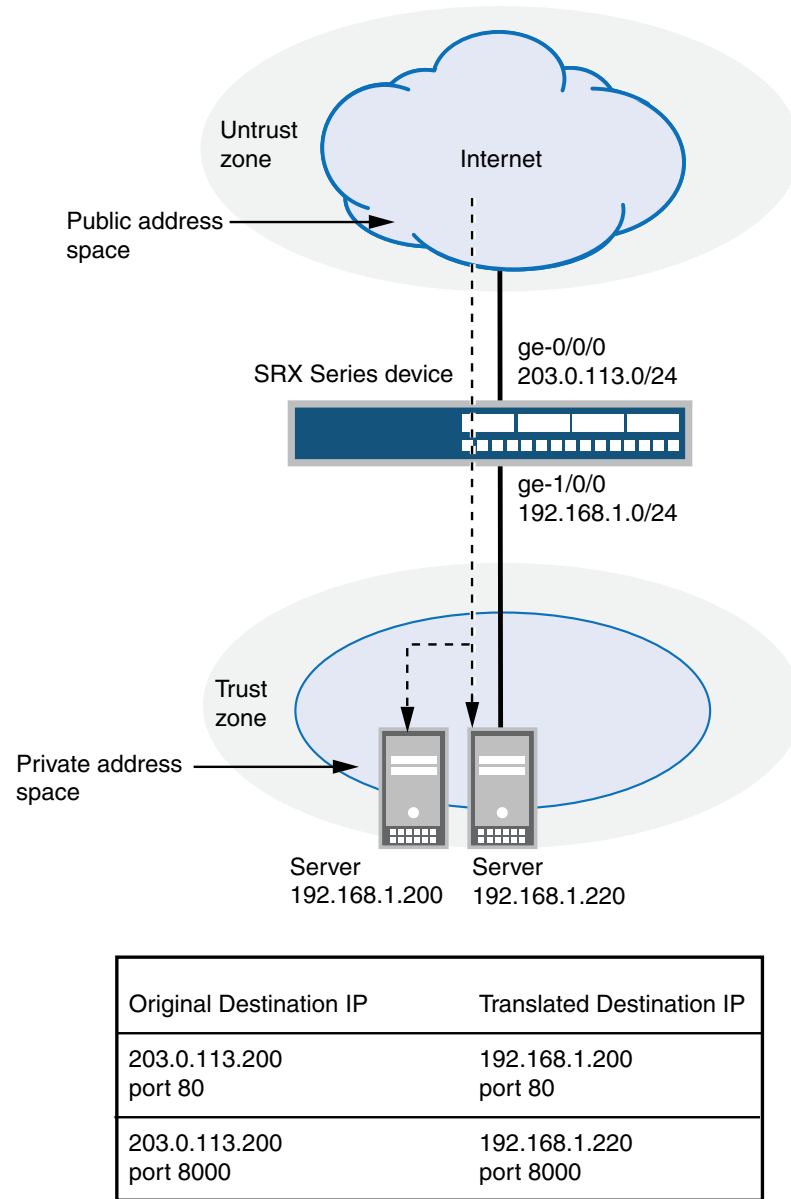

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
2. Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

### Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 231](#), devices in the untrust zone access servers in the trust zone by way of public address 1.1.1.200 on port 80 or 8000. Packets entering the Juniper Networks security device from the untrust zone are mapped to the private addresses of the servers as follows:

- The destination IP address 1.1.1.200 and port 80 is translated to the private address 192.168.1.200 and port 80.
- The destination IP address 1.1.1.200 and port 8000 is translated to the private address 192.168.1.220 and port 8000.

Figure 231: Destination NAT Address and Port Translation

g030666

This example describes the following configurations:

- Destination NAT pool **dst-nat-pool-1** that contains the IP address 192.168.1.200 port 80.
- Destination NAT pool **dst-nat-pool-2** that contains the IP address 192.168.1.220 and port 8000.

- Destination NAT rule set **rs1** with rule **r1** to match packets received from the untrust zone with the destination IP address 1.1.1.200 and destination port 80. For matching packets, the destination address is translated to the address in the **dst-nat-pool-1** pool.
- Destination NAT rule set **rs1** with rule **r2** to match packets received from the untrust zone with the destination IP address 1.1.1.200 and destination port 8000. For matching packets, the destination IP address and port are translated to the address and port in the **dst-nat-pool-2** pool.
- Proxy ARP for the address 1.1.1.200/32. This allows the Juniper Networks security device to respond to ARP requests received on the interface for that address.
- Security policies to permit traffic from the untrust zone to the translated destination IP addresses in the trust zone.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat destination pool dst-nat-pool-1 address 192.168.1.200/32
set security nat destination pool dst-nat-pool-1 address port 80
set security nat destination pool dst-nat-pool-2 address 192.168.1.220/32
set security nat destination pool dst-nat-pool-2 address port 8000
set security nat destination rule-set rs1 from zone untrust
set security nat destination rule-set rs1 rule r1 match destination-address 1.1.1.200/32
set security nat destination rule-set rs1 rule r1 match destination-port 80
set security nat destination rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1
set security nat destination rule-set rs1 rule r2 match destination-address 1.1.1.200/32
set security nat destination rule-set rs1 rule r2 match destination-port 8000
set security nat destination rule-set rs1 rule r2 then destination-nat pool dst-nat-pool-2
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.200/32
set security address-book global address server-2 192.168.1.220/32
set security address-book global address server-1 192.168.1.200/32
set security policies from-zone untrust to-zone trust policy server-access match
 source-address any
set security policies from-zone untrust to-zone trust policy server-access match
 destination-address server-1
set security policies from-zone untrust to-zone trust policy server-access match
 destination-address server-2
set security policies from-zone untrust to-zone trust policy server-access match application
 any
set security policies from-zone untrust to-zone trust policy server-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a destination NAT mapping from a public address to a private address:

1. Create destination NAT pools.  
[edit security nat destination]

```

user@host# set pool dst-nat-pool-1 address 192.168.1.200 port 80
user@host# set pool dst-nat-pool-2 address 192.168.1.220 port 8000

```

2. Create a destination NAT rule set.

```

[edit security nat destination]
user@host# set rule-set rs1 from zone untrust

```

3. Configure a rule that matches packets and translates the destination address to the address in the pool.

```

[edit security nat destination]
user@host# set rule-set rs1 rule r1 match destination-address 1.1.1.200
user@host# set rule-set rs1 rule r1 match destination-port 80
user@host# set rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1

```

4. Configure a rule that matches packets and translates the destination address to the address in the pool.

```

[edit security nat destination]
user@host# set rule-set rs1 rule r2 match destination-address 1.1.1.200
user@host# set rule-set rs1 rule r2 match destination-port 8000
user@host# set rule-set rs1 rule r2 then destination-nat pool dst-nat-pool-2

```

5. Configure proxy ARP.

```

[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.200/32

```

6. Configure addresses in the global address book.

```

[edit security address-book global]
user@host# set address server-2 192.168.1.220/32
user@host# set address server-1 192.168.1.200/32

```

7. Configure a security policy that allows traffic from the untrust zone to the servers in the trust zone.

```

[edit security policies from-zone untrust to-zone trust]
user@host# set policy server-access match source-address any destination-address
[server-1 server-2] application any
user@host# set policy server-access then permit

```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show security nat
destination {
 pool dst-nat-pool-1 {
 address 192.168.1.200/32 port 80;
 }
 pool dst-nat-pool-2 {
 address 192.168.1.220/32 port 8000;
 }
}
rule-set rs1 {
 from zone untrust;
 rule r1 {

```

```

 match {
 destination-address 1.1.1.200/32;
 destination-port 80;
 }
 then {
 destination-nat pool dst-nat-pool-1;
 }
 }
 rule r2 {
 match {
 destination-address 1.1.1.200/32;
 destination-port 8000;
 }
 then {
 destination-nat pool dst-nat-pool-2;
 }
 }
}
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.200/32;
 }
 }
}
user@host# show security policies
from-zone untrust to-zone trust {
 policy server-access {
 match {
 source-address any;
 destination-address [server-1 server-2];
 application any;
 }
 then {
 permit;
 }
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Destination NAT Pool Usage on page 5266](#)
- [Verifying Destination NAT Rule Usage on page 5267](#)
- [Verifying NAT Application to Traffic on page 5267](#)

### Verifying Destination NAT Pool Usage

**Purpose** Verify that there is traffic using IP addresses from the destination NAT pool.

**Action** From operational mode, enter the **show security nat destination pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

---

#### Verifying Destination NAT Rule Usage

---

**Purpose** Verify that there is traffic matching the destination NAT rule.

**Action** From operational mode, enter the **show security nat destination rule all** command. View the Translation hits field to check for traffic that matches the rule.

---

#### Verifying NAT Application to Traffic

---

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

  - [Example: Improving Security by Configuring Destination NAT for Single Address Translation on page 5254](#)
  - [Example: Configuring Destination NAT for Subnet Translation on page 5267](#)

---

### Example: Configuring Destination NAT for Subnet Translation

---

This example describes how to configure a destination NAT mapping of a public subnet address to a private subnet address.

**NOTE:** Mapping addresses from one subnet to another can also be accomplished with static NAT. Static NAT mapping allows connections to be established from either side of the gateway device, whereas destination NAT allows connections to be established from only one side. However, static NAT only allows translations between blocks of addresses of the same size.

- 
- [Requirements on page 5267](#)
  - [Overview on page 5268](#)
  - [Configuration on page 5269](#)
  - [Verification on page 5271](#)

### Requirements

Before you begin:

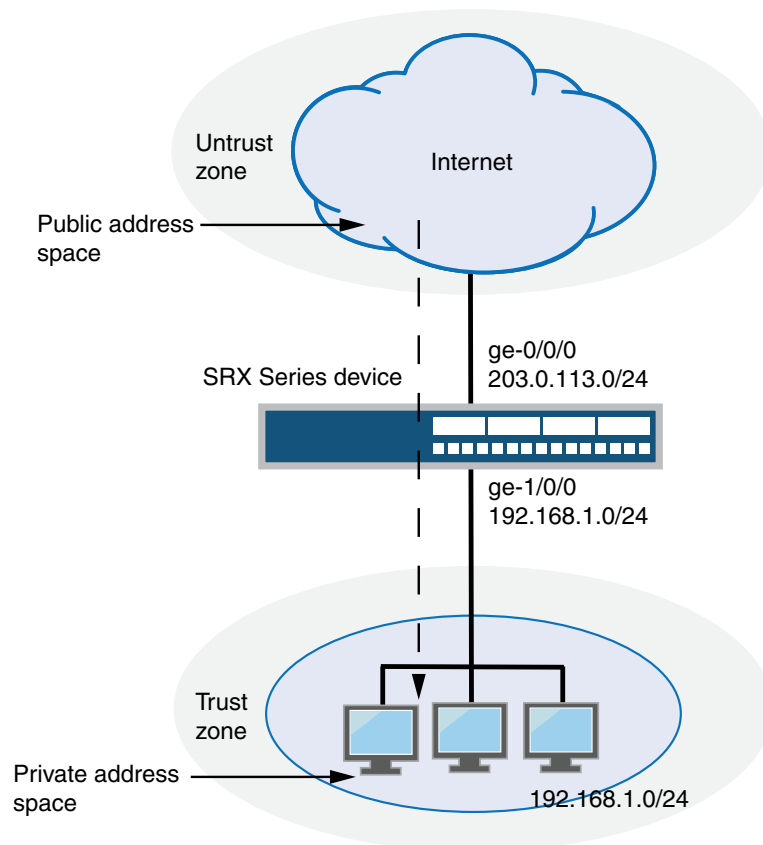

1. Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.

2. Create security zones and assign interfaces to them. See [“Understanding Security Zones”](#) on page 1030.

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 232](#), devices in the untrust zone access devices in the trust zone by way of public subnet address 1.1.1.0/16. For packets that enter the Juniper Networks security device from the untrust zone with a destination IP address in the 1.1.1.0/16 subnet, the destination IP address is translated to a private address on the 192.168.1.0/24 subnet.

**Figure 232: Destination NAT Subnet Translation**

| Original Destination IP | Translated Destination IP |
|-------------------------|---------------------------|
| 203.0.113.0/16          | 192.168.1.0/24            |

g030667

This example describes the following configurations:

- Destination NAT pool **dst-nat-pool-1** that contains the IP address 192.168.1.0/24.
- Destination NAT rule set **rs1** with rule **r1** to match packets received from the ge-0/0/0.0 interface with the destination IP address on the 1.1.1.0/16 subnet. For matching packets, the destination address is translated to the address in the **dst-nat-pool-1** pool.
- Proxy ARP for the addresses 1.1.1.1/32 through 1.1.1.62/32 on the interface ge-0/0/0.0; these are the IP addresses of the hosts that should be translated from the 1.1.1.0/16 subnet. This allows the Juniper Networks security device to respond to ARP requests received on the interface for those addresses. The address 1.1.1.63/32 is assigned to the interface itself, so this address is not included in the proxy ARP configuration. The addresses that are not in the 1.1.1.1/32 through 1.1.1.62/32 range are not expected to be present on the network and would not be translated.
- Security policies to permit traffic from the untrust zone to the translated destination IP addresses in the trust zone.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat destination pool dst-nat-pool-1 address 192.168.1.0/24
set security nat destination rule-set rs1 from interface ge-0/0/0.0
set security nat destination rule-set rs1 rule r1 match destination-address 1.1.1.0/16
set security nat destination rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.1/32 to 1.1.1.62/32
set security address-book global address internal-net 192.168.1.0/24
set security policies from-zone untrust to-zone trust policy internal-access match
 source-address any
set security policies from-zone untrust to-zone trust policy internal-access match
 destination-address internal-net
set security policies from-zone untrust to-zone trust policy internal-access match
 application any
set security policies from-zone untrust to-zone trust policy internal-access then permit
```

### Step-by-Step Procedure

The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a destination NAT mapping from a public subnet address to a private subnet address:

1. Create the destination NAT pool.  

```
[edit security nat destination]
user@host# set pool dst-nat-pool-1 address 192.168.1.0/24
```
2. Create a destination NAT rule set.  

```
[edit security nat destination]
```

```
user@host# set rule-set rs1 from interface ge-0/0/0.0
```

3. Configure a rule that matches packets and translates the destination address to an address in the pool.

```
[edit security nat destination]
user@host# set rule-set rs1 rule r1 match destination-address 1.1.1.0/16
user@host# set rule-set rs1 rule r1 then destination-nat pool dst-nat-pool-1
```

4. Configure proxy ARP.

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.1/32 to 1.1.1.62/32
```

5. Configure an address in the global address book.

```
[edit security address-book global]
user@host# set address internal-net 192.168.1.0/24
```

6. Configure a security policy that allows traffic from the untrust zone to the devices in the trust zone.

```
[edit security policies from-zone untrust to-zone trust]
user@host# set policy internal-access match source-address any
destination-address internal-net application any
user@host# set policy internal-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
destination {
 pool dst-nat-pool-1 {
 address 192.168.1.0/24;
 }
 rule-set rs1 {
 from interface ge-0/0/0.0;
 rule r1 {
 match {
 destination-address 1.1.1.0/16;
 }
 then {
 destination-nat pool dst-nat-pool-1;
 }
 }
 }
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.1/32 to 1.1.1.62/32;
 }
 }
}
user@host# show security policies
from-zone untrust to-zone trust {
```

```

policy internal-access {
 match {
 source-address any;
 destination-address internal-net;
 application any;
 }
 then {
 permit;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Destination NAT Pool Usage on page 5271](#)
- [Verifying Destination NAT Rule Usage on page 5271](#)
- [Verifying NAT Application to Traffic on page 5271](#)

### Verifying Destination NAT Pool Usage

**Purpose** Verify that there is traffic using IP addresses from the destination NAT pool.

**Action** From operational mode, enter the **show security nat destination pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

### Verifying Destination NAT Rule Usage

**Purpose** Verify that there is traffic matching the destination NAT rule.

**Action** From operational mode, enter the **show security nat destination rule all** command. View the Translation hits field to check for traffic that matches the rule.

### Verifying NAT Application to Traffic

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

**Related Documentation**

- [Example: Configuring Destination NAT for IP Address and Port Translation on page 5262](#)

## Monitoring Destination NAT Information

**Purpose** View the destination Network Address Translation (NAT) summary table and the details of the specified NAT destination address pool information.

**Action** Select **Monitor>NAT> Destination NAT** in the J-Web user interface, or enter the following CLI commands:

- **show security nat destination summary**
- **show security nat destination pool *pool-name***

Table 476 summarizes key output fields in the destination NAT display.

**Table 476: Summary of Key Destination NAT Output Fields**

| Field                     | Values                                                                   | Action                                                                |
|---------------------------|--------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <b>Rules</b>              |                                                                          |                                                                       |
| Rule-set Name             | Name of the rule set.                                                    | Select all rule sets or a specific rule set to display from the list. |
| Total rules               | Number of rules configured.                                              | —                                                                     |
| ID                        | Rule ID number.                                                          | —                                                                     |
| Name                      | Name of the rule .                                                       | —                                                                     |
| Ruleset Name              | Name of the rule set.                                                    | —                                                                     |
| From                      | Name of the routing instance/zone/interface from which the packet flows. | —                                                                     |
| Source address range      | Source IP address range in the source pool.                              | —                                                                     |
| Destination address range | Destination IP address range in the source pool.                         | —                                                                     |
| Destination port          | Destination port in the destination pool.                                | —                                                                     |
| IP protocol               | IP protocol.                                                             | —                                                                     |
| Action                    | Action taken for a packet that matches a rule.                           | —                                                                     |
| Alarm threshold           | Utilization alarm threshold.                                             | —                                                                     |

## Understanding Static NAT

---

Static NAT defines a one-to-one mapping from one IP subnet to another IP subnet. The mapping includes destination IP address translation in one direction and source IP address translation in the reverse direction. From the NAT device, the original destination address is the virtual host IP address while the mapped-to address is the real host IP address.

Static NAT allows connections to be originated from either side of the network, but translation is limited to one-to-one or between blocks of addresses of the same size. For each private address, a public address must be allocated. No address pools are necessary.

Static NAT also supports the following types of translation:

- To map multiple IP addresses and specified ranges of ports to a same IP address and different range of ports
- To map a specific IP address and port to a different IP address and port

The port address translation (PAT) is also supported by giving static mapping between destination-port (range) and mapped-port (range).

**NOTE:** The original destination address, along with other addresses in source and destination NAT pools, must not overlap within the same routing instance.

---

In NAT rule lookup, static NAT rules take precedence over destination NAT rules and reverse mapping of static NAT rules take precedence over source NAT rules.

## Understanding Static NAT Rules

---

Static Network Address Translation (NAT) rules specify two layers of match conditions:

- Traffic direction—Allows you to specify **from interface**, **from zone**, or **from routing-instance**.
- Packet information—Can be source addresses and ports, and destination addresses and ports.

For all ALG traffic, except FTP, we recommend that you not use the static NAT rule options **source-address** or **source-port**. Data session creation can fail if these options are used because the IP address and the source port value, which is a random value, might not match the static NAT rule. For FTP ALG traffic, the **source-address** option can be used because an IP address can be provided to match the source address of a static NAT rule.

When both source and destination addresses are configured as match conditions for a rule, traffic is matched to both the source address and destination address. Because static NAT is bidirectional, traffic in the opposite direction reverse matches the rule, and the destination address of the traffic is matched to the configured source address.

If multiple static NAT rules overlap in the match conditions, the most specific rule is chosen. For example, if rules A and B specify the same source and destination IP addresses, but rule A specifies traffic from zone 1 and rule B specifies traffic from interface **ge-0/0/0**, rule B is used to perform static NAT. An interface match is considered to be more specific than a zone match, which is more specific than a routing instance match.

Because static NAT rules do not support overlapping addresses and ports, they should not be used to map one external IP address to multiple internal IP addresses for ALG traffic. For example, if different sites want to access two different FTP servers, the internal FTP servers should be mapped to two different external IP addresses.

For the static NAT rule action, specify the translated address and (optionally) the routing instance.

In NAT lookup, static NAT rules take precedence over destination NAT rules and reverse mapping of static NAT rules takes precedence over source NAT rules.

## Static NAT Configuration Overview

---

The main configuration tasks for static NAT are as follows:

1. Configure static NAT rules that align with your network and security requirements.
2. Configure NAT proxy ARP entries for IP addresses in the same subnet of the ingress interface.

### Related Documentation

- [Understanding Static NAT on page 5275](#)

## Example: Configuring Static NAT for Single Address Translation

---

This example describes how to configure a static NAT mapping of a single private address to a public address.

- [Requirements on page 5277](#)
- [Overview on page 5277](#)
- [Configuration on page 5279](#)
- [Verification on page 5281](#)

### Requirements

Before you begin:

1. Configure network interfaces on the device. See *Interfaces Feature Guide for Security Devices*.
2. Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on page 1030.

### Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space.

In [Figure 233](#), devices in the untrust zone access a server in the trust zone by way of public address 1.1.1.200/32. For packets that enter the Juniper Networks security device from

the untrust zone with the destination IP address 1.1.1.200/32, the destination IP address is translated to the private address 192.168.1.200/32. For a new session originating from the server, the source IP address in the outgoing packet is translated to the public address 1.1.1.200/32.

**Figure 233: Static NAT Single Address Translation**

| Original Destination IP | Translated Destination IP |
|-------------------------|---------------------------|
| 203.0.113.200/32        | 192.168.1.200/32          |

g030663

This example describes the following configurations:

- Static NAT rule set **rs1** with rule **r1** to match packets from the untrust zone with the destination address 1.1.1.200/32. For matching packets, the destination IP address is translated to the private address 192.168.1.200/32.

- Proxy ARP for the address 1.1.1.200 on interface ge-0/0/0.0. This allows the Juniper Networks security device to respond to ARP requests received on the interface for that address.
- Security policies to permit traffic to and from the 192.168.1.200 server.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set rs1 from zone untrust
set security nat static rule-set rs1 rule r1 match destination-address 1.1.1.200/32
set security nat static rule-set rs1 rule r1 then static-nat prefix 192.168.1.200/32
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.200/32
set security address-book global address server-1 192.168.1.200/32
set security policies from-zone trust to-zone untrust policy permit-all match
 source-address server-1
set security policies from-zone trust to-zone untrust policy permit-all match
 destination-address any
set security policies from-zone trust to-zone untrust policy permit-all match application
 any
set security policies from-zone trust to-zone untrust policy permit-all then permit
set security policies from-zone untrust to-zone trust policy server-access match
 source-address any
set security policies from-zone untrust to-zone trust policy server-access match
 destination-address server-1
set security policies from-zone untrust to-zone trust policy server-access match application
 any
set security policies from-zone untrust to-zone trust policy server-access then permit
```

### Step-by-Step Procedure

The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a static NAT mapping from a private address to a public address:

1. Create a static NAT rule set.

```
[edit security nat static]
user@host# set rule-set rs1 from zone untrust
```

2. Configure a rule that matches packets and translates the destination address in the packets to a private address.

```
[edit security nat static]
user@host# set rule-set rs1 rule r1 match destination-address 1.1.1.200/32
user@host# set rule-set rs1 rule r1 then static-nat prefix 192.168.1.200/32
```

3. Configure proxy ARP.

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.200
```

4. Configure an address in the global address book.

```
[edit security address-book global]
user@host# set address server-1 192.168.1.200/32
```

5. Configure a security policy that allows traffic from the untrust zone to the server in the trust zone.

```
[edit security policies from-zone untrust to-zone trust]
user@host# set policy server-access match source-address any destination-address
server-1 application any
user@host# set policy server-access then permit
```

6. Configure a security policy that allows all traffic from the server in the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy permit-all match source-address server-1 destination-address
any application any
user@host# set policy permit-all then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
static {
 rule-set rs1 {
 from zone untrust;
 rule r1 {
 match {
 destination-address 1.1.1.200/32;
 }
 then {
 static-nat prefix 192.168.1.200/32;
 }
 }
 }
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.200/32;
 }
 }
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy permit-all {
 match {
 source-address server-1;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
}
```

```
 }
 }
 from-zone untrust to-zone trust {
 policy server-access {
 match {
 source-address any;
 destination-address server-1;
 application any;
 }
 then {
 permit;
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Static NAT Configuration on page 5281](#)
- [Verifying NAT Application to Traffic on page 5281](#)

---

### Verifying Static NAT Configuration

**Purpose** Verify that there is traffic matching the static NAT rule set.

**Action** From operational mode, enter the **show security nat static rule** command. View the Translation hits field to check for traffic that matches the rule.

---

### Verifying NAT Application to Traffic

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

**Related Documentation**

- [Static NAT Configuration Overview on page 5277](#)
- [Example: Configuring Static NAT for Subnet Translation on page 5281](#)

---

## Example: Configuring Static NAT for Subnet Translation

This example describes how to configure a static NAT mapping of a private subnet address to a public subnet address.

**NOTE:** Address blocks for static NAT mapping must be of the same size.

- [Requirements on page 5282](#)
- [Overview on page 5282](#)
- [Configuration on page 5284](#)
- [Verification on page 5286](#)

## Requirements

Before you begin:

1. Configure network interfaces on the device. See *Interfaces Feature Guide for Security Devices*.
2. Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on [page 1030](#).

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. In [Figure 234](#), devices in the untrust zone access devices in the trust zone by way of public subnet address 1.1.1.0/24. For packets that enter the Juniper Networks security device from the untrust zone with a destination IP address in the 1.1.1.0/24 subnet, the destination IP address is translated to a private address on the 192.168.1.0/24 subnet. For new sessions originating from the 192.168.1.0/24 subnet, the source IP address in outgoing packets is translated to an address on the public 1.1.1.0/24 subnet.

Figure 234: Static NAT Subnet Translation

| Original Destination IP | Translated Destination IP |
|-------------------------|---------------------------|
| 203.0.113.200/32        | 192.168.1.0/24            |

g030664

This example describes the following configurations:

- Static NAT rule set **rs1** with rule **r1** to match packets received on interface **ge-0/0/0.0** with a destination IP address in the **1.1.1.0/24** subnet. For matching packets, the destination address is translated to an address on the **192.168.1.0/24** subnet.
- Proxy ARP for the address ranges **1.1.1.1/32** through **1.1.1.249/32** on interface **ge-0/0/0.0**. This allows the Juniper Networks security device to respond to ARP requests received on the interface for those addresses. The address **1.1.1.250/32** is assigned to the interface itself, so this address is not included in the proxy ARP configuration.
- Security policies to permit traffic to and from the **192.168.1.0/24** subnet.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set rs1 from interface ge-0/0/0.0
set security nat static rule-set rs1 rule r1 match destination-address 1.1.1.0/24
set security nat static rule-set rs1 rule r1 then static-nat prefix 192.168.1.0/24
set security nat proxy-arp interface ge-0/0/0.0 address 1.1.1.1/32 to 1.1.1.249/32
set security address-book global address server-group 192.168.1.0/24
set security policies from-zone trust to-zone untrust policy permit-all match
 source-address server-group
set security policies from-zone trust to-zone untrust policy permit-all match
 destination-address any
set security policies from-zone trust to-zone untrust policy permit-all match application
 any
set security policies from-zone trust to-zone untrust policy permit-all then permit
set security policies from-zone untrust to-zone trust policy server-access match
 source-address any
set security policies from-zone untrust to-zone trust policy server-access match
 destination-address server-group
set security policies from-zone untrust to-zone trust policy server-access match application
 any
set security policies from-zone untrust to-zone trust policy server-access then permit
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a static NAT mapping from a private subnet address to a public subnet address:

1. Create a static NAT rule set.  

```
[edit security nat static]
user@host# set rule-set rs1 from interface ge-0/0/0.0
```
2. Configure a rule that matches packets and translates the destination address in the packets to an address in a private subnet.  

```
[edit security nat static]
user@host# set rule-set rs1 rule r1 match destination-address 1.1.1.0/24
user@host# set rule-set rs1 rule r1 then static-nat prefix 192.168.1.0/24
```
3. Configure proxy ARP.  

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/0.0 address 1.1.1.1/32 to 1.1.1.249/32
```
4. Configure an address in the global address book.  

```
[edit security address-book global]
user@host# set address server-group 192.168.1.0/24
```

5. Configure a security policy that allows traffic from the untrust zone to the subnet in the trust zone.

```
[edit security policies from-zone untrust to-zone trust]
user@host# set policy server-access match source-address any destination-address
server-group application any
user@host# set policy server-access then permit
```

6. Configure a security policy that allows all traffic from the subnet in the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy permit-all match source-address server-group
destination-address any application any
user@host# set policy permit-all then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
static {
 rule-set rs1 {
 from interface ge-0/0/0.0;
 rule r1 {
 match {
 destination-address 1.1.1.0/24;
 }
 then {
 static-nat prefix 192.168.1.0/24;
 }
 }
 }
}
proxy-arp {
 interface ge-0/0/0.0 {
 address {
 1.1.1.1/32 to 1.1.1..249/32;
 }
 }
}
user@host# show security policies
from-zone trust to-zone untrust {
 policy permit-all {
 match {
 source-address server-group;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
}
from-zone untrust to-zone trust {
```

```
policy server-access {
 match {
 source-address any;
 destination-address server-group;
 application any;
 }
 then {
 permit;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Static NAT Configuration on page 5286](#)
- [Verifying NAT Application to Traffic on page 5286](#)

---

### Verifying Static NAT Configuration

**Purpose** Verify that there is traffic matching the static NAT rule set.

**Action** From operational mode, enter the **show security nat static rule** command. View the Translation hits field to check for traffic that matches the rule.

---

### Verifying NAT Application to Traffic

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

**Related Documentation**

- [Understanding Static NAT on page 5275](#)
- [Static NAT Configuration Overview on page 5277](#)
- [Example: Configuring Static NAT for Single Address Translation on page 5277](#)

---

## Example: Configuring Static NAT for Port Mapping

This example describes how to configure static NAT mappings of a public address to private addresses on a specified range of ports.

This topic includes the following sections:

- [Requirements on page 5287](#)
- [Overview on page 5287](#)
- [Configuration on page 5289](#)

- [Verification on page 5291](#)
- [Troubleshooting on page 5292](#)

## Requirements

Before you begin:

- Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
- Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

## Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space.

In [Figure 235](#), devices in the untrust zone access a server in the trust zone by way of public addresses 1.1.1.1/32, 1.1.1.2/32, and 1.1.1.3/32. For packets that enter the Juniper Networks security device from the untrust zone with the destination IP addresses 1.1.1.1/32, 1.1.1.2/32, and 1.1.1.3/32, the destination IP address is translated to the private addresses 10.1.1.1/32, 10.1.1.2/32, and 10.1.1.2/32.

Figure 235: Static NAT for Port Mapping

| Original Source IP               | Translated Source IP          |
|----------------------------------|-------------------------------|
| 203.0.113.1/32 (port 100 to 200) | 10.1.1.1/32 (port 300 to 400) |
| 203.0.113.1/32 (port 300 to 400) | 10.1.1.2/32 (port 300 to 400) |
| 203.0.113.3/32 (port 300)        | 10.1.1.2/32 (port 200)        |

g034403

**NOTE:**

- To configure the destination port, you must use an IP address for the destination address field instead of an IP address prefix.
- You must configure the destination port to configure the mapped port and vice versa.
- Use the same number range for the ports while configuring the destination port and the mapped port.
- If you do not configure the destination port and the mapped port, the IP mapping will be the one-to-one mapping.
- Any address overlapping or any address and port overlapping is not allowed.

This example describes the following configurations:

- Static NAT rule set rs1 with rule r1 to match packets from the untrust zone with the destination address 1.1.1.1/32 and destination port 100 to 200. For matching packets, the destination IP address is translated to the private address 10.1.1.1/32 and mapped to port 300 to 400.
- Static NAT rule set rs1 with rule r2 to match packets from the untrust zone with the destination address 1.1.1.1/32 and destination port 300 to 400. For matching packets, the destination IP address is translated to the private address 10.1.1.2/32 and mapped to port 300 to 400.
- Static NAT rule set rs1 with rule r3 to match packets from the untrust zone with the destination address 1.1.1.3/32 and destination port 300. For matching packets, the destination IP address is translated to the private address 10.1.1.2/32 and mapped to port 200.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set rs from zone untrust
set security nat static rule-set rs rule r1 match destination-address 1.1.1.1/32
set security nat static rule-set rs rule r1 match destination-port 100 to 200
set security nat static rule-set rs rule r1 then static-nat prefix 10.1.1.1/32
set security nat static rule-set rs rule r1 then static-nat prefix mapped-port 300 to 400
set security nat static rule-set rs rule r2 match destination-address 1.1.1.1/32
set security nat static rule-set rs rule r2 match destination-port 300 to 400
set security nat static rule-set rs rule r2 then static-nat prefix 10.1.1.2/32
set security nat static rule-set rs rule r2 then static-nat prefix mapped-port 300 to 400
set security nat static rule-set rs rule r3 match destination-address 1.1.1.3/32
set security nat static rule-set rs rule r3 match destination-port 300
set security nat static rule-set rs rule r3 then static-nat prefix 10.1.1.2/32
set security nat static rule-set rs rule r3 then static-nat prefix mapped-port 200
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see Using the CLI Editor in Configuration Mode.

To configure a static NAT mapping from a private subnet address to a public subnet address:

1. Create a static NAT rule set.

```
[edit security nat static]
user@host# set rule-set rs from zone untrust
```

2. Configure a rule that matches packets and translates the destination address in the packets to a private address.

```
[edit security nat static]
user@host# set rule-set rs rule r1 match destination-address 1.1.1.1/32
user@host# set rule-set rs rule r1 match destination-port 100 to 200
user@host# set rule-set rs rule r1 then static-nat prefix 10.1.1.1/32
user@host# set rule-set rs rule r1 then static-nat prefix mapped-port 300 to 400
```

3. Configure a rule that matches packets and translates the destination address in the packets to a private address.

```
[edit security nat static]
user@host# set rule-set rs rule r2 match destination-address 1.1.1.1/32
user@host# set rule-set rs rule r2 match destination-port 300 to 400
user@host# set rule-set rs rule r2 then static-nat prefix 10.1.1.2/32
user@host# set rule-set rs rule r2 then static-nat prefix mapped-port 300 to 400
```

4. Configure a rule that matches packets and translates the destination address in the packets to a private address.

```
[edit security nat static]
user@host# set rule-set rs rule r3 match destination-address 1.1.1.3/32
user@host# set rule-set rs rule r3 match destination-port 300
user@host# set rule-set rs rule r3 then static-nat prefix 10.1.1.2/32
user@host# set rule-set rs rule r3 then static-nat prefix mapped-port 200
```

---

## Results

From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

[edit]

```
user@host# show security nat
```

```
security {
 nat {
 static {
 rule-set rs {
 from zone untrust;
 rule r1 {
 match {
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verifying Static NAT Configuration

**Action** From operational mode, enter the **show security nat static rule** command. View the Translation hits field to check for traffic that matches the rule.

```
user@host> show security nat static rule all
Total static-nat rules: 3
```

```
Static NAT rule: r2 Rule-set: rs
Rule-Id : 3
Rule position : 2
From zone : untrust
Destination addresses : 1.1.1.1
Destination ports : 300 - 400
Host addresses : 10.1.1.2
Host ports : 300 - 400
Netmask : 32
Host routing-instance : N/A
Translation hits : 0
```

```
Static NAT rule: r3 Rule-set: rs
Rule-Id : 4
Rule position : 3
From zone : untrust
Destination addresses : 1.1.1.3
Destination ports : 300 - 300
Host addresses : 10.1.1.2
Host ports : 200 - 200
Netmask : 32
Host routing-instance : N/A
Translation hits : 0
```

```
Static NAT rule: r1 Rule-set: rs
Rule-Id : 9
Rule position : 1
From zone : untrust
Destination addresses : 1.1.1.1
Destination ports : 100 - 200
Host addresses : 10.1.1.1
Host ports : 300 - 400
Netmask : 32
Host routing-instance : N/A
Translation hits : 0
```

## Troubleshooting

- [Troubleshooting Static NAT Port Configuration on page 5292](#)

### Troubleshooting Static NAT Port Configuration

**Problem** Static NAT port mapping configuration failures occur during a commit.

Invalid configurations with overlapped IP addresses and ports result in commit failure.

The following example shows invalid configurations with overlapped addresses and ports:

- **set security nat static rule-set rs rule r1 match destination-address 1.1.1.1**  
**set security nat static rule-set rs rule r1 then static-nat prefix 10.1.1.1**
- **set security nat static rule-set rs rule r2 match destination-address 1.1.1.1**

```

set security nat static rule-set rs rule r2 match destination-port 300 to 400
set security nat static rule-set rs rule r2 then static-nat prefix 10.1.1.2
set security nat static rule-set rs rule r2 then static-nat prefix mapped-port 300 to 400
• set security nat static rule-set rs rule r1 match destination-address 1.1.1.1
set security nat static rule-set rs rule r1 match destination-port 100 to 200
set security nat static rule-set rs rule r1 then static-nat prefix 10.1.1.1
set security nat static rule-set rs rule r1 then static-nat prefix mapped-port 300 to 400
• set security nat static rule-set rs rule r2 match destination-address 1.1.1.2
set security nat static rule-set rs rule r2 match destination-port 300 to 400
set security nat static rule-set rs rule r2 then static-nat prefix 10.1.1.1
set security nat static rule-set rs rule r2 then static-nat prefix mapped-port 390 to 490

```

The following error message was displayed when the aforementioned configuration was submitted for commit:

```

error: 'prefix/mapped-port' of static nat rule r2 overlaps with
'prefix/mapped-port' of static nat rule r1
error: configuration check-out failed

```

**Solution** To configure the destination port, you must avoid any address overlapping or any address and port overlapping. For an example of valid configuration, see [“Configuration” on page 5289](#).

## Monitoring Static NAT Information

**Purpose** View static NAT rule information.

**Action** Select **Monitor>NAT>Static NAT** in the J-Web user interface, or enter the following CLI command:

```
show security nat static rule
```

[Table 477](#) summarizes key output fields in the static NAT display.

**Table 477: Summary of Key Static NAT Output Fields**

| Field         | Values                | Action                                                                |
|---------------|-----------------------|-----------------------------------------------------------------------|
| Rule-set Name | Name of the rule set. | Select all rule sets or a specific rule set to display from the list. |

Table 477: Summary of Key Static NAT Output Fields (*continued*)

| Field                                  | Values                                                                                                                                                                                                                                                                                                                                              | Action |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| Total rules                            | Number of rules configured.                                                                                                                                                                                                                                                                                                                         | —      |
| ID                                     | Rule ID number.                                                                                                                                                                                                                                                                                                                                     | —      |
| Position                               | Position of the rule that indicates the order in which it applies to traffic.                                                                                                                                                                                                                                                                       | —      |
| Name                                   | Name of the rule.                                                                                                                                                                                                                                                                                                                                   | —      |
| Ruleset Name                           | Name of the rule set.                                                                                                                                                                                                                                                                                                                               | —      |
| From                                   | Name of the routing instance/interface/zone from which the packet comes                                                                                                                                                                                                                                                                             | —      |
| Source addresses                       | Source IP addresses.                                                                                                                                                                                                                                                                                                                                | —      |
| Source ports                           | Source port numbers.                                                                                                                                                                                                                                                                                                                                | —      |
| Destination addresses                  | Destination IP address and subnet mask.                                                                                                                                                                                                                                                                                                             | —      |
| Destination ports                      | Destination port numbers .                                                                                                                                                                                                                                                                                                                          | —      |
| Host addresses                         | Name of the host addresses.                                                                                                                                                                                                                                                                                                                         | —      |
| Host ports                             | Host port numbers.                                                                                                                                                                                                                                                                                                                                  | —      |
| Netmask                                | Subnet IP address.                                                                                                                                                                                                                                                                                                                                  | —      |
| Host routing instance                  | Name of the routing instance from which the packet comes.                                                                                                                                                                                                                                                                                           | —      |
| Alarm threshold                        | Utilization alarm threshold.                                                                                                                                                                                                                                                                                                                        | —      |

## Understanding Persistent NAT and NAT64

---

Persistent NAT allows applications to use the Session Traversal Utilities for NAT (STUN) protocol when passing through NAT firewalls (see [“Understanding Session Traversal Utilities for NAT \(STUN\) Protocol” on page 5299](#)). Persistent NAT ensures that all requests from the same internal transport address (internal IP address and port) are mapped to the same reflexive transport address (the public IP address and port created by the NAT device closest to the STUN server).

NAT64 is a mechanism for translating IPv6 packets to IPv4 packets and vice versa that allows IPv6 clients to contact IPv4 servers using unicast UDP, TCP, or ICMP. It is an enhancement of Network Address Translation-Protocol Translation (NAT-PT).

NAT64 supports the following:

- Endpoint-independent mappings
- Endpoint-independent filtering and address-dependent filtering

**NOTE:** The mapping and filtering behaviors of NAT64 and persistent NAT are identical.

---

The following types of persistent NAT can be configured on the Juniper Networks device:

- Any remote host—All requests from a specific internal IP address and port are mapped to the same reflexive transport address. Any external host can send a packet to the internal host by sending the packet to the reflexive transport address.
- Target host—All requests from a specific internal IP address and port are mapped to the same reflexive transport address. An external host can send a packet to an internal host by sending the packet to the reflexive transport address. The internal host must have previously sent a packet to the external host's IP address.
