- Target host port—All requests from a specific internal IP address and port are mapped to the same reflexive transport address. An external host can send a packet to an internal host by sending the packet to the reflexive transport address. The internal host must have previously sent a packet to the external host's IP address and port.

**NOTE:** The target-host-port configuration is not supported for NAT64 when configured with IPv6 address.

You configure any of the persistent NAT types with source NAT rules. The source NAT rule action can use a source NAT pool (with or without port translation) or an egress interface. Persistent NAT is not applicable for destination NAT, because persistent NAT bindings are based on outgoing sessions from internal to external.

**NOTE:** Port overloading is used in Junos OS only for normal interface NAT traffic. Persistent NAT does not support port overloading, and you must explicitly disable port overloading with one of the following options at the [edit security nat source] hierarchy level:

- port-overloading off
- port-overloading-factor 1

To configure security policies to permit or deny persistent NAT traffic, you can use two new predefined services—**junos-stun** and **junos-persistent-nat**.

**NOTE:** Persistent NAT is different from the persistent address feature (see [“Understanding Persistent Addresses” on page 5226](#)). The persistent address feature applies to address mappings for source NAT pools configured on the device. The persistent NAT feature applies to address mappings on an external NAT device, and is configured for a specific source NAT pool or egress interface. Also, persistent NAT is intended for use with STUN client/server applications.

## Understanding Session Traversal Utilities for NAT (STUN) Protocol

Many video and voice applications do not work properly in a NAT environment. For example, Session Initiation Protocol (SIP), used with VoIP, encodes IP addresses and port numbers within application data. If a NAT firewall exists between the requestor and receiver, the translation of the IP address and port number in the data invalidates the information.

Also, a NAT firewall does not maintain a pinhole for incoming SIP messages. This forces the SIP application to either constantly refresh the pinhole with SIP messages or use an ALG to track registration, a function that may or may not be supported by the gateway device.

The Session Traversal Utilities for NAT (STUN) protocol, first defined in *RFC 3489, Simple Traversal of User Datagram Protocol (UDP) Through Network Address Translators (NATs)* and then later in *RFC 5389, Session Traversal Utilities for NAT*, is a simple client/server protocol. A STUN client sends requests to a STUN server, which returns responses to the client. A STUN client is usually part of an application that requires a public IP address and/or port. STUN clients can reside in an end system such as a PC or in a network server whereas STUN servers are usually attached to the public Internet.

**NOTE:** Both the STUN client and STUN server must be provided by the application. Juniper Networks does not provide a STUN client or server.

The STUN protocol allows a client to:

- Discover whether the application is behind a NAT firewall.
- Determine the type of NAT binding being used (see [“Understanding Persistent NAT and NAT64” on page 5297](#)).
- Learn the reflexive transport address, which is the IP address and port binding allocated by NAT device closest to the STUN server. (There may be multiple levels of NAT between the STUN client and the STUN server.)

The client application can use the IP address binding information within protocols such as SIP and H.323.

## Understanding NAT64 IPv6 Prefix to IPv4 Address-Persistent Translation

The NAT64 mechanism enables IPv6 clients to contact IPv4 servers by translating IPv6 addresses to IPv4 addresses (and vice versa). However, some IPv4 applications and services cannot work correctly over IPv6-only networks with standard NAT64 in a dual-translation scenario, such as 464XLAT. In those scenarios, address-persistent translation is required.

Figure 236 illustrates the 464XLAT architecture, whereby IPv4 packets are translated to IPv6 packets on the customer-side translator (CLAT), then go across the IPv6-only network, and are translated back to IPv4 packets on the provider-side translator (PLAT) to access global IPv4-only content in the core network. This architecture uses a combination of stateless translation on the CLAT and stateful translation on the PLAT.

Figure 236: 464XLAT Architecture

When an SRX Series device functions as a PLAT, it is responsible for keeping the sticky mapping relationship between one specific IPv6 prefix and one translated IPv4 address. The SRX Series device treats the IPv6 prefix as a single user. This mapping is accomplished by configuring the specific IPv6 prefix length in an IPv4 source NAT pool using the **address-persistent** feature.

Figure 237 illustrates a NAT rule configured in the CLAT, which translates an IPv4 address to an IPv6 address with an address-persistent prefix. With stateless NAT46 translation on the CLAT and stateful NAT64 translation on the PLAT, the traffic from IPv4 host 192.168.1.2 reaches the global server 198.51.100.1 over an IPv6-only network.

Figure 237: NAT64 Translation on the PLAT (SRX Series Device)

Table 478 lists other NAT features and their compatibility with the address-persistent feature.

Table 478: NAT Feature Compatibility with the Address Persistent Feature

| Feature                                                                                   |      |                  | Compatible |
|-------------------------------------------------------------------------------------------|------|------------------|------------|
| PAT pools                                                                                 | IPv4 | NAT IPv4 to IPv6 | No         |
|                                                                                           |      | NAT IPv6 to IPv4 | Yes        |
|                                                                                           | IPv6 | NAT IPv4 to IPv6 | No         |
|                                                                                           |      | NAT IPv6 to IPv4 | No         |
| Non-PAT pools                                                                             |      |                  | No         |
| Port-overloading                                                                          |      |                  | Yes        |
| Persistent NAT in PAT pool                                                                |      |                  | Yes        |
| Port block allocation                                                                     |      |                  | Yes        |
| Deterministic NAT                                                                         |      |                  | No         |
| Address pooling paired                                                                    |      |                  | No         |
| ALG                                                                                       |      |                  | Yes        |
| (Existing ALG NAT translations , such as FTP/PPTP/RTSP/DNS/SIP from native IPv6 clients.) |      |                  |            |

**Related Documentation** • [Introduction to NAT on page 5165](#)

## Persistent NAT and NAT64 Configuration Overview

To configure persistent NAT, specify the following options with the source NAT rule action (for either a source NAT pool or an egress interface):

- The type of persistent NAT—One of the following: any remote host, target host, or target host port (see [“Understanding Persistent NAT and NAT64” on page 5297](#)).
- (Optional) Address mapping—This option allows requests from a specific internal IP address to be mapped to the same reflexive IP address; internal and reflexive ports can be any ports. An external host using any port can send a packet to the internal host by sending the packet to the reflexive IP address (with a configured incoming policy that allows external to internal traffic). If this option is not configured, the persistent NAT binding is for specific internal and reflexive transport addresses.

You can only specify the **address-mapping** option when the persistent NAT type is any remote host and the source NAT rule action is one of the following actions:

- Source NAT pool with IP address shifting
- Source NAT pool with no port translation and no overflow pool
- (Optional) Inactivity timeout—Time, in seconds, that the persistent NAT binding remains in the device’s memory when all the sessions of the binding entry have expired. When the configured timeout is reached, the binding is removed from memory. The default value is 300 seconds. Configure a value from 60 through 7200 seconds.

When all sessions of a persistent NAT binding have expired, the binding remains in a query state in the SRX Series device’s memory for the specified inactivity timeout period. The query binding is automatically removed from memory when the inactivity timeout period expires (the default is 300 seconds). You can explicitly remove all or specific persistent NAT query bindings with the **clear security nat source persistent-nat-table** command.

- (Optional) Maximum session number—Maximum number of sessions with which a persistent NAT binding can be associated. The default is 30 sessions. Configure a value from 8 through 100.

For interface NAT, you need to explicitly disable port overloading with one of the following options at the **[edit security nat source]** hierarchy level:

- port-overloading off
- port-overloading-factor 1

Finally, there are two predefined services that you can use in security policies to permit or deny STUN and persistent NAT traffic:

- **junos-stun**—STUN protocol traffic.
- **junos-persistent-nat**—Persistent NAT traffic.

For the **any remote host** persistent NAT type, the direction of the security policy is from external to internal. For target host or target host port persistent NAT types, the direction of the security policy is from internal to external.

## Example: Configuring Address-Persistent NAT64 Pools

This example shows how to configure address-persistent NAT64 pools to ensure a sticky mapping relationship between one specific IPv6 prefix, which is calculated by the configured IPv6 prefix length, and one translated IPv4 address.

- [Requirements on page 5303](#)
- [Overview on page 5303](#)
- [Configuration on page 5303](#)
- [Verification on page 5305](#)

### Requirements

Before you begin, be sure the existing NAT rules and pool configuration do not conflict with the new one.

### Overview

In this example, you configure an IPv6 prefix length of /64 in an IPv4 source NAT pool for NAT IPv6 to IPv4 translations. Traffic matching the NAT rule and NAT pool perform address persistent translation between the IPv6 prefix and the IPv4 translated address. This configuration can be used on the provider-side translator (PLAT) in a dual-translation scenario, 464XLAT, to enable IPv4 services to work over IPv6-only networks.

### Configuration

- CLI Quick Configuration**
- To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool NAT64 address 31.61.129.240/32 to 31.61.129.254/32
set security nat source pool NAT64 address-persistent subscriber ipv6-prefix-length 64
set security nat source rule-set RS1 from zone trust
set security nat source rule-set RS1 to zone untrust
set security nat source rule-set RS1 rule R1 match source-address 2a00:f41::/32
set security nat source rule-set RS1 rule R1 match destination-address 31.61.132.198/32
set security nat source rule-set RS1 rule R1 then source-nat pool NAT64
```

**Step-by-Step Procedure** The following example requires you to navigate throughout various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

1. Create a source NAT pool.  

```
[edit security nat source]
user@host# set pool NAT64 address 31.61.129.240/32 to 31.61.129.254/32
```
2. Specify the IPv6 prefix length for the source NAT pool.  

```
[edit security nat source]
user@host# set pool NAT64 address-persistent subscriber ipv6-prefix-length 64
```
3. Create a rule set.  

```
[edit security nat source]
user@host# set rule-set RS1 from zone trust
user@host# set rule-set RS1 to zone untrust
```
4. Match the rule.  

```
[edit security nat source]
user@host# set rule-set RS1 rule R1 match source-address 2a00:f41::/32
user@host# set rule-set RS1 rule R1 match destination-address 31.61.132.198/32
```
5. Provide the action to be performed when the rule matches.  

```
[edit security nat source]
user@host# set security nat source rule-set RS1 rule R1 then source-nat pool NAT64
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool NAT64 {
 address {
 31.61.129.240/32 to 31.61.129.254/32;
 }
 address-persistent subscriber ipv6-prefix-length 64;
 }
 rule-set RS1 {
 from zone trust;
 to zone untrust;
 rule R1 {
 match {
 source-address 2a00:f41::/32;
 destination-address 31.61.132.198/32;
 }
 then {
 source-nat {
 pool {
 NAT64;
 }
 }
 }
 }
 }
}
```

```

 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying NAT Application to Traffic

**Purpose** Verify that the same IPv6 prefix is translated to the persistent IPv4 address.

**Action** From operational mode, enter the **show security flow session** command.

**Related Documentation**

- [Understanding NAT64 IPv6 Prefix to IPv4 Address-Persistent Translation on page 5300](#)

## Example: Supporting Network Configuration By Configuring Persistent NAT with Interface NAT

You can configure any of the persistent NAT types with source NAT rules. This example illustrates how to apply persistent NAT with an interface IP address and how to use an interface IP address as a NAT IP address to perform persistent NAT for a specific internal host. It also shows how to maintain persistent address port mapping behavior and persistent NAT filter behavior for the host. You must disable port overloading for interface NAT.

- [Requirements on page 5305](#)
- [Overview on page 5305](#)
- [Configuration on page 5307](#)
- [Verification on page 5309](#)

## Requirements

This example uses the following hardware and software components:

- 1 SRX Series device
- 4 PCs

Before you begin:

- Understand the concepts of persistent NAT. See "[Persistent NAT and NAT64 Configuration Overview](#)" on page 5302 .

## Overview

In a Carrier Grade NAT (CGN) network deployment, you can configure the interface IP address as a NAT address to perform persistent network address translation. In this way, the internal host can create one source NAT mapping relationship by the outgoing traffic

initiated from internal to external. Then the external host sends traffic back to this internal host by sending the traffic to this interface NAT address through the shared NAT mapping relationship.

In this example, you first configure the interface NAT rule set `int1` to match traffic from interface `ge-0/0/1` to interface `ge-0/0/2`, and then you configure the NAT rule `in1` to match the specific source and destination addresses to perform persistent NAT. You configure the **any remote host** persistent NAT type when interface NAT is performed.

For packets with source address `40.1.1.0/24` (internal phones) and destination address `20.20.20.0/24` (including STUN server, SIP proxy server, and external phones), you configure interface NAT with the **any remote host** persistent NAT type. Then you disable port overloading for interface NAT.

Next, you configure a security policy to allow persistent NAT traffic from the external network (external zone) to the internal network (internal zone) for any of the remote host persistent NAT types.

### Topology

Figure 238 shows an interface persistent NAT topology.

#### Figure 238: Interface Persistent NAT Topology

ERROR: Unresolved graphic fileref="g043235.png" not found in `"/cmsxml/default/main/supplemental/STAGING/images/"`.

Table 479 shows the parameters configured in this example.

**Table 479: Interfaces, Zones, Servers, and IP Address Information**

| Parameter             | Description                                  |
|-----------------------|----------------------------------------------|
| External Zone         | External network                             |
| Internal Zone         | Internal network                             |
| External_phones2      | Phone2 address of external network           |
| Internal_phone1       | Phone1 address of internal network           |
| SIP_proxy server      | SIP proxy server address of external network |
| STUN server           | STUN server address of external network      |
| Subnet 20.20.20.1/32  | Destination IP address                       |
| Subnet 40.1.1.2/32    | Source IP address                            |
| ge-0/0/1 and ge-0/0/2 | NAT interfaces for traffic direction         |

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat source rule-set int1 from interface ge-0/0/1.0
set security nat source rule-set int1 to interface ge-0/0/2.0
set security nat source rule-set int1 rule in1 match source-address 40.1.1.0/24
set security nat source rule-set int1 rule in1 match destination-address 20.20.20.0/24
set security nat source rule-set int1 rule in1 then source-nat interface persistent-nat permit
any-remote-host
set security nat source interface port-overloading off
set security policies from-zone internal to-zone external policy stun_traffic match source-address
internal_phones destination-address stun_server application junos-stun
set security policies from-zone internal to-zone external policy sip_proxy_traffic match
source-address internal_phones destination-address sip_proxy_server application junos-sip
set security policies from-zone internal to-zone external policy sip_traffic match source-address
internal_phones destination-address external_phones application junos-persistent-nat
set security policies from-zone internal to-zone external policy sip_traffic then permit
set security policies from-zone internal to-zone external policy stun_traffic then permit
set security policies from-zone internal to-zone external policy sip_proxy_traffic then permit
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an interface NAT rule set:

1. Create a persistent NAT rule for an interface NAT.

```
[edit security nat source rule-set int1]
user@host# set from interface ge-0/0/1.0
user@host# set to interface ge-0/0/2.0
user@host# set rule in1 match source-address 40.1.1.0/24
user@host# set rule in1 match destination-address 20.20.20.0/24
user@host# set rule in1 then source-nat interface persistent-nat permit
any-remote-host
```

2. Disable port overloading for interface NAT.

```
[edit security]
user@host# set nat source interface port-overloading off
```

3. Configure a security policy to allow STUN traffic from internal SIP phones to an external STUN server.

```
[edit security policies]
user@host# set from-zone internal to-zone external policy stun_traffic match
source-address internal_phones destination-address stun_server application
junos-stun
```

4. Configure a security policy to allow SIP proxy traffic from internal SIP phones to an external SIP proxy server.

```
[edit security policies]
```

```

user@host# set from-zone internal to-zone external policy sip_proxy_traffic match
source-address internal_phones destination-address sip_proxy_server application
junos-sip

```

5. Configure a security policy to allow SIP traffic from external SIP phones to internal SIP phones.

```

[edit security policies]
user@host# set from-zone internal to-zone external policy sip_traffic match
source-address internal_phones destination-address external_phones application
junos-persistent-nat
user@host# set from-zone internal to-zone external policy sip_traffic then permit
user@host# set from-zone internal to-zone external policy stun_traffic then permit
user@host# set from-zone internal to-zone external policy sip_proxy_traffic then
permit

```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show security nat
source {
 interface {
 port-overloading off;
 }
 rule-set int1 {
 from interface ge-0/0/1.0;
 to interface ge-0/0/2.0;
 rule in1 {
 match {
 source-address 40.1.1.0/24;
 destination-address 20.20.20.0/24;
 }
 then {
 source-nat {
 interface {
 persistent-nat {
 permit any-remote-host;
 }
 }
 }
 }
 }
 }
}
[edit]
user@host# show security policies
from-zone internal to-zone external {
 policy stun_traffic {
 match {
 source-address internal_phones;
 destination-address stun_server;
 application junos-stun;
 }
 then {

```

```

 permit;
 }
}
policy sip_proxy_traffic {
 match {
 source-address internal_phones;
 destination-address sip_proxy_server;
 application junos-sip;
 }
 then {
 permit;
 }
}
policy sip_traffic {
 match {
 source-address internal_phones;
 destination-address external_phones;
 application junos-persistent-nat;
 }
 then {
 permit;
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying That Rules Are Matched and Used on page 5309](#)
- [Verifying That NAT Traffic Sessions Are Established on page 5310](#)

### Verifying That Rules Are Matched and Used

**Purpose** Verify that all the rules are matched and used.

**Action** From operational mode, enter the **show security nat source persistent-nat-table all** command.

```

user@host>show security nat source persistent-nat-table all

```

| Internal                 | Reflective |          | Source     | Type     |         |           |           |  |
|--------------------------|------------|----------|------------|----------|---------|-----------|-----------|--|
| Left_time/Curr_Sess_Num/ |            | Source   |            |          |         |           |           |  |
| In_IP                    | In_Port    | I_Proto  | Ref_IP     | Ref_Port | R_Proto | NAT Pool  | Conf_time |  |
| Max_Sess_Num             |            | NAT Rule |            |          |         |           |           |  |
| 40.1.1.12                | 17012      | udp      | 20.20.20.1 | 28153    | udp     | interface |           |  |
| any-remote-host          | 3528/3600  | -/-      |            | in1      |         |           |           |  |
| 40.1.1.12                | 7078       | udp      | 20.20.20.1 | 6133     | udp     | interface |           |  |
| any-remote-host          | -/300      | 1/30     |            | in1      |         |           |           |  |

**Meaning** The output displays a summary of persistent NAT information.

### Verifying That NAT Traffic Sessions Are Established

**Purpose** Verify that the sessions are established on the device.

**Action** From operational mode, enter the **show security flow session** command.

```
user@host>show security flow session
```

```
Session ID: 6992, Policy name: sip_proxy_traffic/5, Timeout: 16, Valid
 In: 40.1.1.12/17012 --> 20.20.20.45/5060;udp, If: ge-0/0/1.0, Pkts: 4, Bytes:
1850
 Out: 20.20.20.45/5060 --> 20.20.20.1/28153;udp, If: ge-0/0/2.0, Pkts: 5, Bytes:
2258

Session ID: 7382, Policy name: stun_traffic/4, Timeout: 16, Valid
 In: 40.1.1.12/7078 --> 20.20.20.49/3478;udp, If: ge-0/0/1.0, Pkts: 20, Bytes:
1040
 Out: 20.20.20.49/3478 --> 20.20.20.1/6133;udp, If: ge-0/0/2.0, Pkts: 0, Bytes:
0
```

**Meaning** The **show security flow session** command displays active sessions on the device and each session's associated security policy. The output shows traffic entering the device using the private source address 40.1.1.12 destined to a public host at 20.20.20.45. The return traffic from this flow travels to the translated public address 20.20.20.1.

- **Session ID**—Number that identifies the session. Use this ID to get more information about the session such as policy name or number of packets in and out.
- **sip\_proxy\_traffic**—Policy name that permitted the SIP traffic from the internal SIP phones to the external SIP proxy server.
- **In**—Incoming flow (source and destination IP addresses with their respective source and destination port numbers. The session is UDP, and the source interface for this session is ge-0/0/1.0).
- **Out**—Reverse flow (source and destination IP addresses with their respective source and destination port numbers. The session is UDP, and the destination interface for this session is ge-0/0/2.0).
- **stun\_traffic**—Policy name that permitted the STUN traffic from the internal SIP phones to the external STUN server.

  - [Persistent NAT and NAT64 Configuration Overview on page 5302](#)

### Example: Configuring Persistent NAT with Source NAT Address Pool (CLI)

You can configure any of the persistent NAT types with source NAT rules. The example in this section shows how to configure persistent NAT when source NAT is performed with a user-defined address pool.

The following example configures the target host persistent NAT type when source NAT is performed. In the following configuration, the source NAT address pool **sp1** consists of the address 30.1.1.5/32. The source NAT rule set **srs1** configures the following:

- Traffic direction is from zone **internal** to zone **external**.
- For packets with source address in the 40.1.1.0/24 subnet (internal phones) and destination address 20.20.20.0/24 (including STUN server, SIP proxy server and external phones), use the source NAT pool **sp1** to perform source NAT with the target host persistent NAT type.
- Set the persistent NAT **inactivity-timeout** to 180 seconds.

To configure the source NAT address pool:

```
user@host# set security nat source pool sp1 address 30.1.1.5/32
```

To configure the source NAT rule set:

```
user@host# set security nat source rule-set srs1 from zone internal
user@host# set security nat source rule-set srs1 to zone external
user@host# set security nat source rule-set srs1 rule sr1 match source-address 40.1.1.0/24
user@host# set security nat source rule-set srs1 rule sr1 match destination-address
 20.20.20.0/24
user@host# set security nat source rule-set srs1 rule sr1 then source-nat pool sp1
user@host# set security nat source rule-set srs1 rule sr1 then source-nat pool persistent-nat
 permit target-host
user@host# set security nat source rule-set srs1 rule sr1 then source-nat pool persistent-nat
 inactivity-timeout 180
```

For the target host persistent NAT type, configure a security policy to allow persistent NAT traffic from the internal network (internal zone) to the external network (external zone).

To configure a security policy to allow STUN traffic from internal SIP phones to an external STUN server:

```
user@host# set security policies from-zone internal to-zone external policy stun_traffic
 match source-address internal_phones destination-address stun_server application
 junos-stun
user@host# set security policies from-zone internal to-zone external policy stun_traffic
 then permit
```

To configure a security policy to allow SIP proxy traffic from internal SIP phones to an external SIP proxy server:

```
user@host# set security policies from-zone internal to-zone external policy
 sip_proxy_traffic match source-address internal_phones destination-address
 sip_proxy_server application junos-sip
user@host# set security policies from-zone internal to-zone external policy
 stun_proxy_traffic then permit
```

To configure a security policy to allow SIP traffic from internal to external SIP phones:

```
user@host# set security policies from-zone internal to-zone external policy sip_traffic
 match source-address internal_phones destination-address external_phones application
 junos-persistent-nat
```

```
user@host# set security policies from-zone internal to-zone external policy sip_traffic
then permit
```

## Example: Configuring Address-Dependent Filtering for IPv6 Clients

This example shows how to configure address-dependent filtering for IPv6 clients using NAT64.

- [Requirements on page 5312](#)
- [Overview on page 5312](#)
- [Configuration on page 5312](#)
- [Verification on page 5314](#)

### Requirements

Before you begin:

- Ensure that IPv6 is enabled on the device.
- Ensure that the existing NAT rule and pool configuration do not conflict with the new ones.

### Overview

In this example you use NAT64 to send packets from the IPv6 internal host to the IPv4 external host and from the IPv4 external host to the IPv4 internal host.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set test_rs from interface ge-0/0/1
set security nat static rule-set test_rs rule test_rule match destination-address 27a6::15/128
set security nat static rule-set test_rs rule test_rule then static-nat prefix 10.2.2.15/32
set security nat source pool myipv4 address 1.1.1.2
set security nat source rule-set myipv4_rs from interface ge-0/0/1
set security nat source rule-set myipv4_rs to interface ge-0/0/2
set security nat source rule-set myipv4_rs rule ipv4_rule match source-address 27a6::/96
set security nat source rule-set myipv4_rs rule ipv4_rule match destination-address
 10.2.2.15
set security nat source rule-set myipv4_rs rule ipv4_rule then source-nat pool myipv4
set security nat source rule-set myipv4_rs rule ipv4_rule then source-nat pool persistent-nat
 permit target-host
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure address-dependent filtering for IPv6 clients:

1. Create a set of rules for NAT64.  

```
[edit security nat static]
user@host# set rule-set test_rs from interface ge-0/0/1
```
2. Match the rule.  

```
[edit security nat static]
user@host# set rule-set test_rs rule test_rule match destination-address 27a6::15/128
```
3. Provide the action to be performed when the rule matches.  

```
[edit security nat static]
user@host# set rule-set test_rs rule test_rule then static-nat prefix 10.2.2.15/32
```
4. Define a source address pool and add the address to the pool.  

```
[edit security nat]
user@host# set source pool myipv4 address 1.1.1.2
```
5. Create another set of rules for NAT64.  

```
[edit security nat]
user@host# set source rule-set myipv4_rs from interface ge-0/0/1
```
6. Match the rule with the source address.  

```
[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule match source-address
27a6::/96
```
7. Match the rule with the destination address.  

```
[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule match destination-address
10.2.2.15
```
8. Provide the action to be performed when the rules match.  

```
[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule then source-nat pool myipv4
```
9. Configure persistent NAT.  

```
[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule then source-nat pool
persistent-nat permit target-host
```

**Results** From configuration mode, confirm your configuration by entering the **show nat source** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit security]
user@host# show nat source
```

```
pool myipv4 {
 address {
 1.1.1.2/32;
 }
}
rule-set test_rs {
 rule test_rule {
 match {
 destination-address 27a6::15/128;
 }
 }
}

rule-set myipv4_rs {
 from interface ge-0/0/1.0;
 to interface ge-0/0/2.0;
 rule ipv4_rule {
 match {
 source-address 27a6::/96;
 destination-address 10.2.2.15/32;
 }
 then {
 source-nat {
 pool {
 myipv4;
 persistent-nat {
 permit target-host;
 }
 }
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly:

- [Verifying that the Configuration Is Enabled and Working on page 5314](#)
- [Verifying that Rules Are Matched and Used on page 5315](#)

---

### Verifying that the Configuration Is Enabled and Working

**Purpose** Verify that the configuration is enabled and working.

**Action** From operational mode, enter the following commands.

- **show security nat static rule test\_rule**
- **show security nat source rule ipv4\_rule**

- `show security nat source pool myipv4`

### Verifying that Rules Are Matched and Used

|                              |                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>               | Verify that all the rules are matched and used.                                                                                                                                                                 |
| <b>Action</b>                | From operational mode, enter the <code>show security nat source persistent-nat-table all</code> command.                                                                                                        |

## Example: Configuring Endpoint-Independent Filtering for IPv6 Clients

This example shows how to configure endpoint-independent filtering for IPv6 clients using NAT64.

- [Requirements on page 5315](#)
- [Overview on page 5315](#)
- [Configuration on page 5315](#)
- [Verification on page 5317](#)

### Requirements

Before you begin:

- Ensure that IPv6 is enabled on the device
- Ensure that the existing NAT rules and pool configuration do not conflict with the new ones.

### Overview

In this example you use NAT64 to send packets from the IPv6 internal host to the IPv4 external host and from the IPv4 external host to the IPv4 internal host.

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set test_rs from interface ge-0/0/1
set security nat static rule-set test_rs rule test_rule match destination-address 27a6::15/128
set security nat static rule-set test_rs rule test_rule then static-nat prefix 10.2.2.15/32
set security nat source pool myipv4 address 1.1.1.2
set security nat source rule-set myipv4_rs from interface ge-0/0/1
set security nat source rule-set myipv4_rs to interface ge-0/0/2
set security nat source rule-set myipv4_rs rule ipv4_rule match source-address 27a6::/96
```

```

set security nat source rule-set myipv4_rs rule ipv4_rule match destination-address
10.2.2.15
set security nat source rule-set myipv4_rs rule ipv4_rule then source-nat pool myipv4
set security nat source rule-set myipv4_rs rule ipv4_rule then source-nat pool persistent-nat
permit any-remote-host

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure endpoint-independent filtering for IPv6 clients:

1. Create a set of rules for NAT64.  

```

[edit security nat static]
user@host# set rule-set test_rs from interface ge-0/0/1

```
2. Match the rule.  

```

[edit security nat static]
user@host# set rule-set test_rs rule test_rule match destination-address 27a6::15/128

```
3. Provide the action to be performed when the rule matches.  

```

[edit security nat static]
user@host# set rule-set test_rs rule test_rule then static-nat prefix 10.2.2.15/32

```
4. Define a source address pool and add the address to the pool.  

```

[edit security nat]
user@host# set source pool myipv4 address 1.1.1.2

```
5. Create another set of rules for NAT64.  

```

[edit security nat]
user@host# set source rule-set myipv4_rs from interface ge-0/0/1

```
6. Match the rule with the source address.  

```

[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule match source-address
27a6::/96

```
7. Match the rule with the destination address.  

```

[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule match destination-address
10.2.2.15

```
8. Provide the action to be performed when the rules match.  

```

[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule then source-nat pool myipv4

```
9. Configure persistent NAT.  

```

[edit security nat]
user@host# set source rule-set myipv4_rs rule ipv4_rule then source-nat pool
persistent-nat permit any-remote-host

```

**Results** From configuration mode, confirm your configuration by entering the **show nat source** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit security]
user@host#show nat source
 pool myipv4 {
 address {
 1.1.1.2/32;
 }
 }
 rule-set test_rs {
 rule test_rule {
 match {
 destination-address 27a6::15/128;
 }
 }
 }

 rule-set myipv4_rs {
 from interface ge-0/0/1.0;
 to interface ge-0/0/2.0;
 rule ipv4_rule {
 match {
 source-address 27a6::/96;
 destination-address 10.2.2.15/32;
 }
 then {
 source-nat {
 pool {
 myipv4;
 persistent-nat {
 permit any-remote-host;
 }
 }
 }
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly:

- [Verifying that Configuration is Enabled and Working on page 5317](#)
- [Verifying that Rules Are Matched and Used. on page 5318](#)

### Verifying that Configuration is Enabled and Working

**Purpose** Verify that the configuration is enabled and working.

**Action** From operational mode, enter the following commands.

- `show security nat static rule test_rule`
- `show security nat source rule ipv4_rule`
- `show security nat source pool myipv4`

---

#### Verifying that Rules Are Matched and Used.

**Purpose** Verify that all the rules are matched and used.

**Action** From operational mode, enter the `show security nat source persistent-nat-table all` command.

## Example: Setting Maximum Persistent NAT Bindings

This example shows how to increase the persistent NAT capacity.

### Requirements

Before you begin, see “[Understanding Persistent NAT and NAT64](#)” on page 5297.

### Overview

In this example, you enable the maximize persistent NAT capacity option. To enable this option, the supported central point maximum binding capacity can be approximately increased to 1/8 of the central point session capacity up to 2M and the supported SPU maximum binding capacity can be approximately increased to 1/4 of each SPU session capacity. Accordingly, the flow session capacity will decrease by 1/4 on both the CP and each of the SPU.

By default, the persistent NAT binding capacity on both the central point and the SPU of a high-end SRX Series device is 64K. In this example, you enable the session capacity to maximum 20,000,000 on the central point and maximum 1100K on each of the SPU with maximum session configuration. If you enable the maximize persistent NAT capacity option, a high-end SRX Series device with 4 GB of memory can support maximum 2M persistent NAT bindings on the central point and 275K bindings on each of the SPU.

### Configuration

#### Step-by-Step Procedure

To increase the persistent NAT capacity:

1. Set maximize persistent NAT capacity option.

[edit]

```
user@host# set security forwarding-process application-services
maximize-persistent-nat-capacity
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

3. Restart the system from operational mode.

```
[edit]
user@host# request system reboot
```

**NOTE:** When switching to maximize persistent NAT capacity mode or back to regular mode, you must restart the device.

4. If you want to switch the device back to regular mode, delete the maximize persistent NAT capacity mode configuration.

```
[edit]
user@host# delete security forwarding-process application-services
maximize-persistent-nat-capacity
```

## Verification

To verify the configuration is working properly, enter the **show security forwarding-process application-services** command.

# Configuring NAT Hairpinning

- [Persistent NAT Hairpinning Overview on page 5321](#)
- [Example: Configuring Persistent NAT Hairpinning with Source NAT Pool with Address Shifting on page 5322](#)

## Persistent NAT Hairpinning Overview

---

When traffic is sent between two hosts, the source host of the traffic may only know the destination host by its public IP address. In reality, the destination host may be in the same private address space as the source host. Hairpinning is the process of returning the traffic in the direction from where it came from as a way to get it to its destination host in a private subnetwork.

Generally, a source host in a subnetwork may not recognize that the traffic is intended for a destination host within the same subnetwork, because it identifies the destination host only by its public IP address. The NAT analyzes the IP packets and routes the packet back to the correct host.

NAT hairpinning support is required if two hosts on the internal network want to communicate with each other by using a binding on the NAT device. In this case, the NAT device receives a packet from the internal network and forwards it back to the internal network. If hairpinning is not supported, forwarding the packet will fail and it will be dropped.

---

### NOTE:

- NAT hairpinning behavior is not supported by target host persistent NAT and target host port persistent NAT. Only any remote host persistent NAT supports hairpinning behavior.
  - To allow hairpinning, you must configure a security policy to allow traffic between endpoints in the same zone. Actually the two endpoints can be located in two different zones as well as long as either of the two hosts can only see the public address of the peer.
  - Persistent NAT hairpinning applies only to any remote host persistent NAT type.
-

- Related Documentation**
- [Example: Configuring Persistent NAT Hairpinning with Source NAT Pool with Address Shifting on page 5322](#)
  - [Introduction to NAT on page 5165](#)

## Example: Configuring Persistent NAT Hairpinning with Source NAT Pool with Address Shifting

---

This example shows how to configure persistent NAT hairpinning.

### Requirements

Before you begin:

- Configure network interfaces on the device. See *Junos OS Interfaces Library for Security Devices*.
- Create security zones and assign interfaces to them. See [“Understanding Security Zones” on page 1030](#).

### Overview

Hairpinning allows packets from the private network to be translated and then looped back to the private network rather than being passed through to the public network. Hairpinning feature enables using a corresponding record in the NAT table to recognize that a packet is addressed to a host in the local network. Then it translates the destination IP address and sends the packet back to the local network (as well as in case of port mapping). This ensures that traffic between the two hosts work properly.

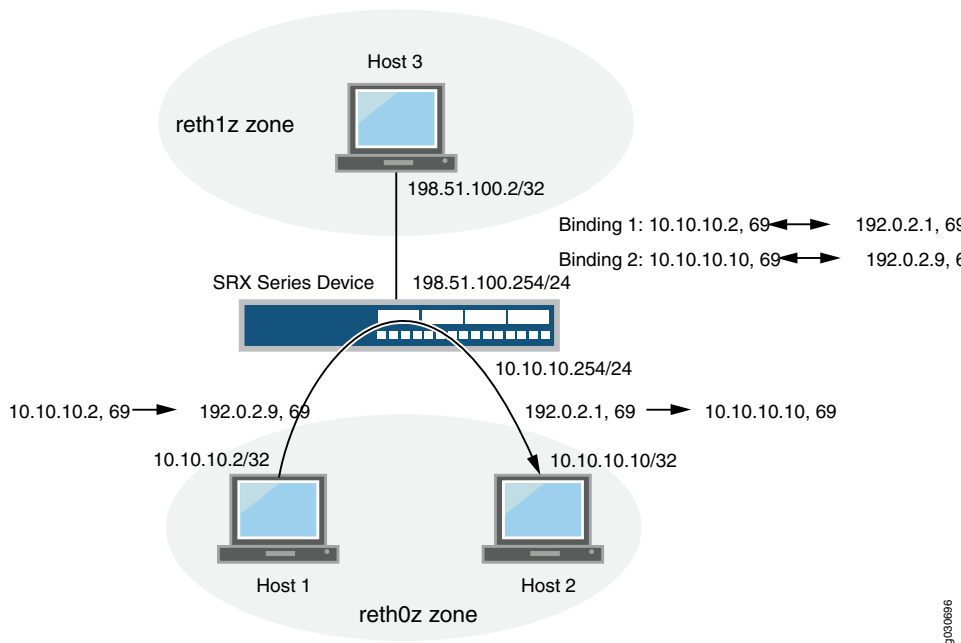

Hairpinning enables two endpoints (Host 1 and Host 2) on the private network to communicate even if they only use each other's external IP addresses and ports. This is explained in [Figure 239](#).

When Host 1 sends traffic to Host 3, a NAT binding between Host 1's internal source IP address and port is associated in the NAT table with its external IP address and port. The same thing happens when Host 2 sends traffic to Host 3. In this way, when Host 1 and Host 2 want to communicate, they can identify each other's external IP addresses.

For example, if Host 1 communicates with Host 2, NAT (with hairpinning support) is used to route the packets, which contain Host 2's external address, back to Host 2's internal address.

Figure 239: Persistent NAT Hairpinning

In [Figure 239](#), the following parameters are used:

- Host 1 IP address - 10.10.10.2/32
- Host 2 IP address - 10.10.10.10/32
- Intra-zone IP address - 10.10.10.254/24
- Host 3 IP address - 20.20.20.2/32
- Inter-zone IP address - 20.20.20.254/24
- Host 1 and Host 2 are in zone **reth0z**, and Host 3 is in **reth1z** zone

[Table 480](#) shows the binding table used in this example.

Table 480: Persistent NAT Binding Table

| Original Source IP Address      | Translated Source IP Address  |
|---------------------------------|-------------------------------|
| 10.10.10.2/32 to 10.10.10.11/32 | 100.0.0.1/32 to 100.0.0.10/32 |

Configuration

Step-by-Step Procedure

To configure persistent NAT hairpinning:

1. Configure interfaces.

```
[edit]
user@host# set interfaces ge-11/0/0 unit 0 family inet address 10.10.10.254/24
user@host# set interfaces ge-11/0/1 unit 0 family inet address 20.20.20.254/24
```

2. Create zones (reth0z and reth1z).

```
[edit]
user@host# set security zones security-zone reth0z host-inbound-traffic
system-services all
user@host# set security zones security-zone reth0z host-inbound-traffic protocols
all
user@host# set security zones security-zone reth0z interfaces ge-11/0/0.0
user@host# set security zones security-zone reth1z host-inbound-traffic
system-services all
user@host# set security zones security-zone reth1z host-inbound-traffic protocols
all
user@host# set security zones security-zone reth1z interfaces ge-11/0/1.0
```

3. Create policies for zones reth0z and reth1z.

```
[edit]
user@host# set security address-book global address subnet10 10.10.10.0/24
user@host# set security address-book global address subnet20 20.20.20.0/24
user@host# set security policies from-zone reth0z to-zone reth1z policy p1 match
source-address subnet10
user@host# set security policies from-zone reth0z to-zone reth1z policy p1 match
destination-address subnet20
user@host# set security policies from-zone reth0z to-zone reth1z policy p1 match
application any
user@host# set security policies from-zone reth0z to-zone reth1z policy p1 then
permit
user@host# set security policies from-zone reth0z to-zone reth0z policy p2 match
source-address subnet10
user@host# set security policies from-zone reth0z to-zone reth0z policy p2 match
destination-address subnet10
user@host# set security policies from-zone reth0z to-zone reth0z policy p2 match
application any
user@host# set security policies from-zone reth0z to-zone reth0z policy p2 then
permit
```

4. Add same zone policy to do persistent NAT hairpinning.

```
user@host# set security policies default-policy deny-all
```

5. Create a source NAT pool for Host 1 and Host 2 (src1).

```
[edit]
user@host# set security nat source pool src1 address 100.0.0.1/32 to 100.0.0.10/32
```

6. Specify the beginning of the original source IP address range for Host 1 and Host 2 (src1).

```
[edit]
user@host# set security nat source pool src1 host-address-base 10.10.10.2/32
```

7. Configure the source NAT rule set r1.

```
[edit]
user@host# set security nat source rule-set r1 from zone reth0z
user@host# set security nat source rule-set r1 to zone reth1z
user@host# set security nat source rule-set r1 to zone reth0z

# Configuring NAT for Multicast Flows

- [Understanding NAT for Multicast Flows on page 5327](#)
- [Example: Configuring NAT for Multicast Flows on page 5328](#)

## Understanding NAT for Multicast Flows

---

Network Address Translation (NAT) can be used to translate source addresses in IPv4 multicast flows and to translate IPv4 multicast group destination addresses.

Either static NAT or destination NAT can be used to perform multicast group address translation. Static NAT allows connections to be originated from either side of the network, but translation is limited to one-to-one addresses or between blocks of addresses of the same size. No address pools are necessary. Use the **static** configuration statement at the **[edit security nat]** hierarchy level to configure static NAT rule sets for multicast traffic. Destination NAT allows connections to be initiated only for incoming network connections—for example, from the Internet to a private network. Use the **destination** configuration statement at the **[edit security nat]** hierarchy level to configure destination NAT pools and rule sets.

Source NAT for multicast traffic is supported only by using IP address shifting to translate the original source IP address to an IP address from a user-defined address pool. This type of translation is one-to-one, static, and without port address translation. If the original source IP address range is larger than the IP address range in the user-defined pool, untranslated packets are dropped. The mapping does not provide bidirectional mapping, which static NAT provides. Use the **source** configuration statement at the **[edit security nat]** hierarchy level to configure source NAT pools and rule sets. When you define the source NAT pool for this type of source NAT, use the **host-address-base** option to specify the start of the original source IP address range.

## Example: Configuring NAT for Multicast Flows

---

This example shows how to configure a Juniper Networks device for address translation of multicast flows.

- [Requirements on page 5328](#)
- [Overview on page 5328](#)
- [Configuration on page 5330](#)
- [Verification on page 5335](#)

### Requirements

Before you begin:

1. Configure network interfaces on the device. See the *Interfaces Feature Guide for Security Devices*.
2. Create security zones and assign interfaces to them. See “[Understanding Security Zones](#)” on page 1030.
3. Configure the device for multicast forwarding. See *Multicast Feature Guide for Security Devices*.

### Overview

This example uses the trust security zone for the private address space and the untrust security zone for the public address space. [Figure 240](#) depicts a typical deployment of the Juniper Networks device for multicast forwarding. The source router R1 sends multicast packets with source addresses in the range 11.1.1.100 through 11.1.1.110 and the group address 225.0.0.1/32 toward the Juniper Networks device. The source router R1 is in the private network (trust zone) upstream of the Juniper Networks device. There are several receivers in the public network (untrust zone) downstream of the device.

The Juniper Networks device translates incoming multicast packets from R1 before forwarding them out on the downstream interfaces. The following translations are applied:

- For the interface to R2, the source address is untranslated, and the group address is translated to 226.0.0.1/32.
- For the interface to R3, the source address is translated to an address in the range 50.50.50.200 through 50.50.50.210, and the group address is translated to 226.0.0.1/32.
- For the interface to R4, the source address is translated to an address in the range 10.10.10.100 through 10.10.10.110, and the group address is translated to 226.0.0.1/32.

Figure 240: NAT Translations for Multicast Flows

| From R1                          | To R2                            | To R3                              | To R4                          |
|----------------------------------|----------------------------------|------------------------------------|--------------------------------|
| Original Group IP                | Group IP                         | Group IP                           | Group IP                       |
| 233.252.0.1/32                   | 233.252.0.2/32                   | 233.252.0.2/32                     | 233.252.0.2/32                 |
| Original Source IP               | Source IP                        | Source IP                          | Source IP                      |
| 203.0.113.100 -<br>203.0.113.110 | 203.0.113.100 -<br>203.0.113.110 | 198.51.100.200 -<br>198.51.100.210 | 10.10.10.100 -<br>10.10.10.110 |

g/30689

This example describes the following configurations:

- Destination NAT pool **dst-nat-pool** that contains the IP address 226.0.0.1/32.
- Destination NAT rule set **rs1** with rule **r1** to match packets arriving on interface **xe-2/0/1.0** with the destination IP address 225.0.0.1/32. For matching packets, the destination address is translated to the IP address in the **dst-nat-pool** pool.
- Source NAT pool **src-nat-shift-1** that contains the IP address range 50.50.50.200/32 through 50.50.50.210/32. For this pool, the beginning of the original source IP address range is 11.1.1.100/32 and is specified with the **host-address-base** option.

- Source NAT rule set **rs-shift1** with rule **r1** to match packets from the trust zone to interface **xe-1/0/1.0** with a source IP address in the **11.1.1.96/28** subnet. For matching packets that fall within the source IP address range specified by the **src-nat-shift-1** configuration, the source address is translated to the IP address in the **src-nat-shift-1** pool.
- Source NAT pool **src-nat-shift-2** that contains the IP address range **10.10.10.100/32** through **10.10.10.110/32**. For this pool, the beginning of the original source IP address range is **11.1.1.100/32** and is specified with the **host-address-base** option.
- Source NAT rule set **rs-shift2** with rule **r1** to match packets from the trust zone to interface **xe-2/0/0.0** with a source IP address in the **11.1.1.96/28** subnet. For matching packets that fall within the source IP address range specified by the **src-nat-shift-2** configuration, the source address is translated to the IP address in the **src-nat-shift-2** pool.
- Proxy ARP for the addresses **11.1.1.100** through **11.1.1.110** on interface **xe-1/0/0.0**, addresses **50.50.50.200** through **50.50.50.210** on interface **xe-1/0/1.0**, and addresses **10.10.10.100** through **10.10.10.110** on interface **xe-2/0/0.0**. This allows the Juniper Networks security device to respond to ARP requests received on the interface for those addresses.
- Security policy to permit traffic from the trust zone to the untrust zone.
- Security policy to permit traffic from the untrust zone to the translated destination IP address in the trust zone.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat source pool src-nat-shift-1 address 50.50.50.200/32 to 50.50.50.210/32
set security nat source pool src-nat-shift-1 host-address-base 11.1.1.100/32
set security nat source pool src-nat-shift-2 address 10.10.10.100/32 to 10.10.10.110/32
set security nat source pool src-nat-shift-2 host-address-base 11.1.1.100/32
set security nat source rule-set rs-shift1 from zone trust
set security nat source rule-set rs-shift1 to interface xe-1/0/1.0
set security nat source rule-set rs-shift1 rule r1 match source-address 11.1.1.96/28
set security nat source rule-set rs-shift1 rule r1 then source-nat pool src-nat-shift1
set security nat source rule-set rs-shift2 from zone trust
set security nat source rule-set rs-shift2 to interface xe-2/0/0.0
set security nat source rule-set rs-shift2 rule r2 match source-address 11.1.1.96/28
set security nat source rule-set rs-shift2 rule r2 then source-nat pool src-nat-shift2
set security nat destination pool dst-nat-pool address 226.0.0.1/32
set security nat destination rule-set rs1 from interface xe-2/0/1.0
set security nat destination rule-set rs1 rule r1 match destination-address 225.0.0.1/32
set security nat destination rule-set rs1 rule r1 then destination-nat pool dst-nat-pool
set security nat proxy-arp interface xe-1/0/0.0 address 11.1.1.100/32 to 11.1.1.110/32
set security nat proxy-arp interface xe-1/0/1.0 address 50.50.50.200/32 to
 50.50.50.210/32
set security nat proxy-arp interface xe-2/0/0.0 address 10.10.10.100/32 to 10.10.10.110/32
set security policies from-zone trust to-zone untrust policy internet-access match
 source-address any
```

```

set security policies from-zone trust to-zone untrust policy internet-access match
 destination-address any
set security policies from-zone trust to-zone untrust policy internet-access match
 application any
set security policies from-zone trust to-zone untrust policy internet-access then permit
set security policies from-zone untrust to-zone trust policy dst-nat-pool-access match
 source-address any
set security policies from-zone untrust to-zone trust policy dst-nat-pool-access match
 destination-address 226.0.0.1/21
set security policies from-zone untrust to-zone trust policy dst-nat-pool-access match
 application any
set security policies from-zone untrust to-zone trust policy dst-nat-pool-access then
 permit

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the destination and source NAT translations for multicast flows:

1. Create a destination NAT pool.  

```

[edit security nat destination]
user@host# set pool dst-nat-pool address 226.0.0.1/32

```
2. Create a destination NAT rule set.  

```

[edit security nat destination]
user@host# set rule-set rs1 from interface xe-2/0/1.0

```
3. Configure a rule that matches packets and translates the destination address to the address in the destination NAT pool.  

```

[edit security nat destination]
user@host# set rule-set rs1 rule r1 match destination-address 225.0.0.1/32
user@host# set rule-set rs1 rule r1 then destination-nat pool dst-nat-pool

```
4. Create a source NAT pool.  

```

[edit security nat source]
user@host# set pool src-nat-shift-1 address 50.50.50.200 to 50.50.50.210

```
5. Specify the beginning of the original source IP address range.  

```

[edit security nat source]
user@host# set pool src-nat-shift-1 host-address-base 11.1.1.100

```
6. Create a source NAT rule set.  

```

[edit security nat source]
user@host# set rule-set rs-shift1 from zone trust
user@host# set rule-set rs-shift1 to interface xe-1/0/1.0

```
7. Configure a rule that matches packets and translates the destination address to the address in the source NAT pool.  

```

[edit security nat source]
user@host# set rule-set rs-shift1 rule r1 match source-address 11.1.1.96/28
user@host# set rule-set rs-shift1 rule r1 then source-nat pool src-nat-shift1

```

8. Create a source NAT pool.  

```
[edit security nat source]
user@host# set pool src-nat-shift-2 address 10.10.10.100 to 10.10.10.110
```
9. Specify the beginning of the original source IP address range.  

```
[edit security nat source]
user@host# set pool src-nat-shift-2 host-address-base 11.1.1.100
```
10. Create a source NAT rule set.  

```
[edit security nat source]
user@host# set rule-set rs-shift2 from zone trust
user@host# set rule-set rs-shift2 to interface xe-2/0/0.0
```
11. Configure a rule that matches packets and translates the destination address to the address in the source NAT pool.  

```
[edit security nat source]
user@host# set rule-set rs-shift2 rule r2 match source-address 11.1.1.96/28
user@host# set rule-set rs-shift2 rule r2 then source-nat pool src-nat-shift2
```
12. Configure proxy ARP.  

```
[edit security nat]
user@host# set proxy-arp interface xe-1/0/0.0 address 11.1.1.100 to 11.1.1.110
user@host# set proxy-arp interface xe-1/0/1.0 address 50.50.50.200 to 50.50.50.210
user@host# set proxy-arp interface xe-2/0/0.0 address 10.10.10.100 to 10.10.10.110
```
13. Configure a security policy that allows traffic from the trust zone to the untrust zone.  

```
[edit security policies from-zone trust to-zone untrust]
user@host# set policy internet-access match source-address any
destination-address any application any
user@host# set policy internet-access then permit
```
14. Configure a security policy that allows traffic from the untrust zone to the trust zone.  

```
[edit security policies from-zone untrust to-zone trust]
user@host# set policy dst-nat-pool-access match source-address any
destination-address 226.0.0.1/32 application any
user@host# set policy dst-nat-pool-access then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Destination NAT Pool Usage on page 5335](#)
- [Verifying Destination NAT Rule Usage on page 5335](#)
- [Verifying Source NAT Pool Usage on page 5335](#)
- [Verifying Source NAT Rule Usage on page 5335](#)
- [Verifying NAT Application to Traffic on page 5336](#)

### Verifying Destination NAT Pool Usage

- Purpose** Verify that there is traffic using IP addresses from the destination NAT pool.
- Action** From operational mode, enter the **show security nat destination pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

### Verifying Destination NAT Rule Usage

- Purpose** Verify that there is traffic matching the destination NAT rule.
- Action** From operational mode, enter the **show security nat destination rule all** command. View the Translation hits field to check for traffic that matches the rule.

### Verifying Source NAT Pool Usage

- Purpose** Verify that there is traffic using IP addresses from the source NAT pool.
- Action** From operational mode, enter the **show security nat source pool all** command. View the Translation hits field to check for traffic using IP addresses from the pool.

### Verifying Source NAT Rule Usage

- Purpose** Verify that there is traffic matching the source NAT rule.
- Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

### Verifying NAT Application to Traffic

---

**Purpose** Verify that NAT is being applied to the specified traffic.

**Action** From operational mode, enter the **show security flow session** command.

### IPv6 NAT Overview

---

IPv6 has a vastly larger address space than the impending exhausted IPv4 address space. IPv4 has been extended using techniques such as Network Address Translation (NAT), which allows for ranges of private addresses to be represented by a single public address, and temporary address assignment. There are a lot of technologies to provide the transition mechanism for the legacy IPv4 host to keep the connection to the Internet. IPv6 NAT provides address translation between IPv4 and IPv6 addressed network devices. It also provides address translation between IPv6 hosts. NAT between IPv6 hosts is done in a similar manner and for similar purposes as IPv4 NAT.

IPv6 NAT in Junos OS provides the following NAT types:

- Source NAT
- Destination NAT
- Static NAT

### Source NAT Translations Supported by IPv6 NAT

Source NAT is the translation of the source IP address of a packet leaving the Juniper Networks device. Source NAT is used to allow hosts with private IP addresses to access a public network.

IPv6 NAT in Junos OS supports the following source NAT translations:

- Translation of one IPv6 subnet to another IPv6 subnet without port address translation
- Translation of IPv4 addresses to IPv6 prefix + IPv4 addresses
- Translation of IPv6 hosts to IPv6 hosts with or without port address translation
- Translation of IPv6 hosts to IPv4 hosts with or without port address translation
- Translation of IPv4 hosts to IPv6 hosts with or without port address translation

## Destination NAT Mappings Supported by IPv6 NAT

Destination NAT is the translation of the destination IP address of a packet entering the Juniper Networks device. Destination NAT is used to redirect traffic destined to a virtual host (identified by the original destination IP address) to the real host (identified by the translated destination IP address).

IPv6 NAT in Junos OS supports the following destination NAT translations:

- Prefix translation between IPv4 and IPv6 prefix
- Mapping of one IPv6 subnet to another IPv6 subnet
- Mapping of one IPv6 subnet to an IPv6 host
- Mapping of one IPv6 subnet to one IPv4 subnet
- Mapping of one IPv4 subnet to one IPv6 subnet
- Mapping of one IPv6 host (and optional port number) to one special IPv6 host (and optional port number)
- Mapping of one IPv6 host (and optional port number) to one special IPv4 host (and optional port number)
- Mapping of one IPv4 host (and optional port number) to one special IPv6 host (and optional port number)

## Static NAT Mappings Supported by IPv6 NAT

Static NAT defines a one-to-one mapping from one IP subnet to another IP subnet. The mapping includes destination IP address translation in one direction and source IP address translation in the reverse direction. From the NAT device, the original destination address is the virtual host IP address while the mapped-to address is the real host IP address.

IPv6 NAT in Junos OS supports the following static NAT translations:

- Translation of one IPv6 subnet to another IPv6 subnet
- Translation of one IPv6 host to another IPv6 host
- Translation of one IPv4 address a.b.c.d to IPv6 address Prefix::a.b.c.d
- Translation of IPv4 hosts to IPv6 hosts

See [“Example: Configuring an IPv4-Initiated Connection to an IPv6 Node Using Default Destination Address Prefix Static Mapping”](#) on page 5341.

- Translation of IPv6 hosts to IPv4 hosts

See [“Example: Configuring an IPv6-Initiated Connection to an IPv4 Node Using Default Destination Address Prefix Static Mapping”](#) on page 5348.

- Mapping of one IPv6 prefix to one IPv4 prefix

See [“Example: Configuring an IPv6-Initiated Connection to an IPv4 Node Using Static Destination Address One-to-One Mapping”](#) on page 5352.

- Mapping of one IPv4 prefix to one IPv6 prefix

See [“Example: Configuring an IPv4-Initiated Connection to an IPv6 Node Using Static Destination Address One-to-One Mapping”](#) on page 5344.

## IPv6 NAT PT Overview

IPv6 Network Address Translation- Protocol Translation (NAT-PT) provides address allocation and protocol translation between IPv4 and IPv6 addressed network devices. The translation process is based on the Stateless IP/ICMP Translation (SIIT) method; however, the state and the context of each communication are retained during the session lifetime. IPv6 NAT-PT supports Internet Control Message Protocol (ICMP), TCP, and UDP packets.

IPv6 NAT-PT supports the following types of NAT-PT:

- **Traditional NAT-PT**— In traditional NAT-PT, the sessions are unidirectional and outbound from the IPv6 network . Traditional NAT-PT allows hosts within an IPv6 network to access hosts in an IPv4 network. There are two variations to traditional NAT-PT: basic NAT-PT and NAPT-PT.

In basic NAT-PT, a block of IPv4 addresses at an IPv4 interface is set aside for translating addresses as IPv6 hosts as they initiate sessions to the IPv4 hosts. The basic NAT-PT translates the source IP address and related fields such as IP, TCP, UDP, and ICMP header checksums for packets outbound from the IPv6 domain . For inbound packets, it translates the the destination IP address and the checksums.

Network Address Port Translation and Protocol Translation (NAPT-PT) can be combined with basic NAT-PT so that a pool of external addresses is used in conjunction with port translation. NAPT-PT allows a set of IPv6 hosts to share a single IPv4 address. NAPT-PT translates the source IP address, source transport identifier, and related fields such as IP, TCP, UDP, and ICMP header checksums, for packets outbound from the IPv6 network. The transport identifier can be a TCP/UDP port or an ICMP query ID. For inbound packets, it translates the destination IP address, destination transport identifier, and the IP and the transport header checksums.

- **Bidirectional NAT-PT**— In bidirectional NAT-PT, sessions can be initiated from hosts in the IPv4 network as well as the IPv6 network. IPv6 network addresses are bound to IPv4 addresses, either statically or dynamically as connections are established in either direction. The static configuration is similar to static NAT translation. Hosts in IPv4 realm access hosts in the IPv6 realm using DNS for address resolution. A DNS ALG must be employed in conjunction with bidirectional NAT-PT to facilitate name-to-address mapping. Specifically, the DNS ALG must be capable of translating IPv6 addresses in DNS queries and responses into their IPv4 address bindings, and vice versa, as DNS packets traverse between IPv6 and IPv4 realms.

**NOTE:** The SRX Series devices partially supports the Bidirectional NAT-PT specification. It supports flow of bidirectional traffic assuming that there are other ways to convey the mapping between the IPv6 address and the dynamically allocated IPv4 address. For example, a local DNS can be configured with the mapped entries for IPv4 nodes to identify the addresses.

**NAT-PT Operation**— The SRX Series devices support the Traditional NAT-PT and allows static mapping for the user to communicate from IPv4 to IPv6. The user needs to statically configure the DNS server with an IPv4 address for the host name and then create a static NAT on the device for the IPv6-only node to communicate from an IPv4-only node to an IPv6-only node based on the DNS.

## IPv6 NAT-PT Communication Overview

**NAT-PT communication with static mapping**— Network Address Translation-Protocol Translation (NAT-PT) can be done in two directions, from IPv6 to IPv4 and vice versa. For each direction, static NAT is used to map the destination host to a local address and a source address NAT is used to translate the source address. There are two types of static NAT and source NAT mapping: one-to-one mapping and prefix-based mapping.

**NAT-PT communication with DNS ALG**—A DNS-based mechanism dynamically maps IPv6 addresses to IPv4-only servers. NAT-PT uses the DNS ALG to transparently do the translations. For example, a company using an internal IPv6 network needs to be able to communicate with external IPv4 servers that do not yet have IPv6 addresses.

To support the dynamic address binding, a DNS should be used for name resolution. The IPv4 host looks up the name of the IPv6 node in its local configured IPv4 DNS server, which then passes the query to the IPv6 DNS server through an SRX Series device using NAT-PT.

The DNS ALG in NAT device :

- Translates the IPv6 address resolution back to IPv4 address resolution.
- Allocates an IPv6 address for the mapping.
- Stores a mapping of the allocated IPv4 address to the IPv6 address returned in the IPv6 address resolution so that the session can be established from any-IPv4 hosts to the IPv6 host.

## Example: Configuring an IPv4-Initiated Connection to an IPv6 Node Using Default Destination Address Prefix Static Mapping

---

This example shows how to configure an IPv4-initiated connection to an IPv6 node using default destination address prefix static mapping.

- [Requirements on page 5341](#)
- [Overview on page 5341](#)
- [Configuration on page 5342](#)
- [Verification on page 5344](#)

### Requirements

Before you begin, configure the interfaces and assign the interfaces to security zones.

### Overview

The following example describes how to configure an IPv4-initiated connection to an IPv6 node that has a static mapping /96-based IPv6 address defined on its interface and static mapping /96 set up on the device. This example assumes the IPv6 addresses to be mapped IPv4 addresses, making the IPv4 addresses a part of the IPv6 address space.

Configuring an IPv4-initiated connection to an IPv6 node is useful when the devices on the IPv4 network must be interconnected to the devices on the IPv6 network and during migration of an IPv4 network to an IPv6 network. The mapping can be used for DNS ALG for reverse lookup of IPv4 addresses from IPv6 addresses, for the traffic initiated from the IPv6 network. This also provides connectivity for sessions initiated from IPv4 nodes with IPv6 nodes on the other side of the NAT/PT device.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set test_rs from interface ge-0/0/1
set security nat static rule-set test_rs rule test_rule match destination-address 10.1.1.45/30
set security nat static rule-set test_rs rule test_rule then static-nat prefix 27a6::/96
set security nat source pool myipv6_prefix address 27a6::/96
set security nat source rule-set myipv6_rs from interface ge-0/0/1
set security nat source rule-set myipv6_rs to interface ge-0/0/2
set security nat source rule-set myipv6_rs rule ipv6_rule match source-address 10.1.1.1/30
set security nat source rule-set myipv6_rs rule ipv6_rule match destination-address 27a6::a0a:a2d/126
set security nat source rule-set myipv6_rs rule ipv6_rule then source-nat pool myipv6_prefix
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an IPv6-initiated connection to an IPv4 node using static destination address one-to-one mapping:

1. Configure the static NAT rule set for an interface.

```
[edit security nat static]
user@host# set rule-set test_rs from interface ge-0/0/1
```

2. Define the rule to match the destination address prefix.

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule match destination-address 10.1.1.45/30
```

3. Define the static NAT prefix for the device.

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule then static-nat prefix 27a6::/96
```

4. Configure the source NAT pool with an IPv6 address prefix.

```
[edit security nat source]
user@host# set pool myipv6_prefix address 27a6::/96
```

5. Configure the source NAT rule set for the interface.

```
[edit security nat source]
user@host# set rule-set myipv6_rs from interface ge-0/0/1
user@host# set rule-set myipv6_rs to interface ge-0/0/2
```

6. Configure the IPv6 source NAT source address.  

```
[edit security nat source rule-set myipv6_rs]
user@host# set rule ipv6_rule match source-address 10.1.1/30
```
7. Configure the IPv6 source NAT destination address.  

```
[edit security nat source rule-set myipv6_rs]
user@host# set rule ipv6_rule match destination-address 27a6::a0a:a2d/126
```
8. Define the configured source NAT IPv6 pool in the rule.  

```
[edit security nat source rule-set myipv6_rs]
user@host# set rule ipv6_rule then source-nat pool myipv6_prefix
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool myipv6_prefix {
 address {
 27a6::/96;
 }
 }
}
rule-set myipv6_rs {
 from interface ge-0/0/1.0;
 to interface ge-0/0/2.0;
 rule ipv6_rule {
 match {
 source-address 10.1.1/30;
 destination-address 27a6::a0a:a2d/126;
 }
 then {
 source-nat {
 pool {
 myipv6_prefix;
 }
 }
 }
 }
}
static {
 rule-set test_rs {
 from interface ge-0/0/1.0;
 rule test_rule {
 match {
 destination-address 10.1.1.45/30;
 }
 then {
 static-nat prefix 27a6::/96;
 }
 }
 }
}
```

```
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Overview on page 5345](#)
- [Configuration on page 5345](#)
- [Verification on page 5347](#)

## Requirements

Before you begin, configure the interfaces and assign the interfaces to security zones.

## Overview

The following example describes how to configure an IPv4 node to communicate with an IPv6 node using one-to-one static NAT on the device.

The communication of an IPv4 node with an IPv6 node is useful for IPv4 hosts accessing an IPv6 server, for new servers that support IPv6 only and that need to be connected to the IPv6 network, and for migrating of old hosts to the new server when most of the machines have already moved to IPv6. For example, you can use this feature to connect an IPv4-only node to an IPv6-only printer. This mapping can also be used for DNS ALG for reverse lookup of IPv4 addresses from IPv6 addresses for traffic that is initiated from the IPv6 network.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set test_rs from interface ge-0/0/1
set security nat static rule-set test_rs rule test_rule match destination-address 10.1.1.25/32
set security nat static rule-set test_rs rule test_rule then static-nat prefix 3ffe::25/128
set security nat source pool myipv6_prefix address 27a6::/96
set security nat source rule-set myipv6_rs from interface ge-0/0/1
set security nat source rule-set myipv6_rs to interface ge-0/0/2
set security nat source rule-set myipv6_rs rule ipv6_rule match source-address 10.10.10.1/30
set security nat source rule-set myipv6_rs rule ipv6_rule match destination-address 322f::25
set security nat source rule-set myipv6_rs rule ipv6_rule then source-nat pool myipv6_prefix
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure an IPv4-initiated connection to an IPv6 node using static destination address one-to-one mapping:

1. Configure the static NAT rule set for an interface.  

```
[edit security nat static]
user@host# set rule-set test_rs from interface ge-0/0/1
```
2. Define the rule and the destination address.  

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule match destination-address 10.1.1.25/32
```
3. Define the static NAT prefix.  

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule then static-nat prefix 3ffe::25/128
```
4. Configure a source NAT pool with an IPv6 prefix address.

```
[edit security]
user@host# set nat source pool myipv6_prefix address 27a6::/96
```

5. Configure the source NAT rule set.

```
[edit security nat source]
user@host# set rule-set myipv6_rs from interface ge-0/0/1
user@host# set rule-set myipv6_rs from interface ge-0/0/2
```

6. Configure the source NAT source address.

```
[edit security nat source rule-set myipv6_rs]
user@host# set rule ipv6_rule match source-address 10.10.10.1/30
```

7. Configure the source NAT destination address.

```
[edit security nat source rule-set myipv6_rs]
user@host# set rule ipv6_rule match destination-address 322f::25
```

8. Define a configured source NAT IPv6 pool in the rule.

```
[edit security nat source rule-set myipv6_rs]
user@host# set rule ipv6_rule then source-nat pool myipv6_prefix
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
netscreen@srx220-tp# show security nat
source {
 pool myipv6_prefix {
 address {
 27a6::/96;
 }
 }
 rule-set myipv6_rs {
 from interface ge-0/0/1.0;
 to interface ge-0/0/2.0;
 rule ipv6_rule {
 match {
 source-address 10.10.10.1/30;
 destination-address 322f::25/128;
 }
 then {
 source-nat {
 pool {
 myipv6_prefix;
 }
 }
 }
 }
 }
}
static {
 rule-set test_rs {
 from interface ge-0/0/1.0;
 rule test_rule {
```

```

 match {
 destination-address 10.1.1.25/32;
 }
 then {
 static-nat prefix 3ffe::25/128;
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That Static NAT Is Configured on page 5347](#)
- [Verifying That Source NAT Is Configured on page 5347](#)

### Verifying That Static NAT Is Configured

**Purpose** Verify whether static NAT is configured with an interface, a destination address, and a prefix.

**Action** From operational mode, enter the **show security nat static** command.

### Verifying That Source NAT Is Configured

**Purpose** Verify whether source NAT is configured.

**Action** From operational mode, enter the **show security nat source** command.

## Example: Configuring an IPv6-Initiated Connection to an IPv4 Node Using Default Destination Address Prefix Static Mapping

This example shows how to configure an IPv6-initiated connection to an IPv4 node using default destination address prefix static mapping. This example does not show how to configure the NAT translation for the reverse direction.

- [Requirements on page 5348](#)
- [Overview on page 5348](#)
- [Configuration on page 5348](#)
- [Verification on page 5350](#)

### Requirements

Before you begin, configure the interfaces and assign the interfaces to security zones.

### Overview

The following example describes the communication of an IPv6 node with an IPv4 node that has prefix-based static NAT defined on the device. The static NAT assumes that the IPv4 network is a special IPv6 network (that is, an IPv4-mapped IPv6 network), and hides the entire IPv4 network behind an IPv6 prefix.

The communication of an IPv6 node with an IPv4 node is useful when IPv6 is used in the network and must be connected to the IPv4 network, or when both IPv4 and IPv6 are used in the network and a mechanism is required to interconnect the two networks during migration. This also provides connectivity for sessions initiated from IPv6 nodes with IPv4 nodes on the other side of the NAT/PT device.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule-set test_rs from interface ge-0/0/1
set security nat static rule-set test_rs rule test_rule match destination-address 27a6::/96
set security nat static rule-set test_rs rule test_rule then static-nat inet
set security nat source pool myipv4 address 1.1.1.2 to 1.1.1.5
set security nat source rule-set myipv4_rs from interface ge-0/0/1
set security nat source rule-set myipv4_rs to interface ge-0/0/2
set security nat source rule-set myipv4_rs rule ipv4_rule match destination-address
 10.1.1.15/30
set security nat source rule-set myipv4_rs rule ipv4_rule match source-address 2ffe::/96
set security nat source rule-set myipv4_rs rule ipv4_rule then source-nat pool myipv4
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure an IPv6-initiated connection to an IPv4 node using default destination address prefix static mapping:

1. Configure the static NAT for an interface.  

```
[edit security nat static]
user@host# set rule test_rs from interface ge-0/0/1
```
2. Define the rule and destination address with the prefix for the static NAT translation defined on the device.  

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule match destination-address 27a6::/96
```
3. Define the static NAT as inet to translate to an IPv4 address.  

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule then static-nat inet
```
4. Configure the IPv4 source NAT pool address.  

```
[edit security nat source]
user@host# set pool myipv4 address 1.1.1.2 to 1.1.1.5
```
5. Configure the source NAT rule set.  

```
[edit security nat source]
user@host# set rule-set myipv4_rs from interface ge-0/0/1
user@host# set rule-set myipv4_rs from interface ge-0/0/2
```
6. Configure the IPv4 source NAT destination address.  

```
[edit security nat source rule-set myipv4_rs]
user@host# set rule ipv4_rule match destination-address 10.1.1.15/30
```
7. Define the source address with the prefix for the source NAT defined on the device.  

```
[edit security nat source rule-set myipv4_rs]
user@host# set rule ipv4_rule match source-address 2ffe::/96
```
8. Define a configured source NAT IPv4 pool in the rule.  

```
[edit security nat source rule-set myipv4_rs]
user@host# sset rule ipv4_rule then source-nat pool myipv4
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool myipv4 {
 address {
 1.1.1.2/32 to 1.1.1.5/32;
 }
 }
}
```

```

}
rule-set myipv4_rs {
 from interface ge-0/0/1.0;
 to interface ge-0/0/2.0;
 rule ipv4_rule {
 match {
 source-address 2ffe::/96;
 destination-address 10.1.1.15/30;
 }
 then {
 source-nat {
 pool {
 myipv4;
 }
 }
 }
 }
}
}
static {
 rule-set test_rs {
 from interface ge-0/0/1.0;
 rule test_rule {
 match {
 destination-address 27a6::/96;
 }
 then {
 static-nat inet;
 }
 }
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That Static NAT Is Configured on page 5350](#)
- [Verifying That Source NAT Is Configured on page 5351](#)

### Verifying That Static NAT Is Configured

**Purpose** Verify whether static NAT is configured with an interface, a destination address, and a prefix.

**Action** From operational mode, enter the **show security nat static rule** command.

```

user@host> show security nat static rule test_rule
Static NAT rule: test_rule Rule-set: test_rs
Rule-Id : 2
Rule position : 2
From interface : ge-0/0/1.0
Destination addresses : 27a6::

```

```

Host addresses : 0.0.0.0
Netmask : 96
Host routing-instance : N/A
Translation hits : 0
 Successful sessions : 0
 Failed sessions : 0
Number of sessions : 0

```

### Verifying That Source NAT Is Configured

**Purpose** Verify whether source NAT is configured.

**Action** From operational mode, enter the **show security nat source rule** command.

```

user@host> show security nat source rule ipv4_rule
source NAT rule: ipv4_rule Rule-set: myipv4_rs
Rule-Id : 2
Rule position : 2
From interface : ge-0/0/1.0
To interface : ge-0/0/2.0
Match
 Source addresses : 2ffe:: - 2ffe::ffff:ffff
 Destination addresses : 10.1.1.15 - 10.1.1.15
Action : myipv4
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0
 Max session number : 0
Translation hits : 0
 Successful sessions : 0
 Failed sessions : 0
Number of sessions : 0

```

From operational mode, enter the **show security nat source pool** command.

```

user@host> show security nat source pool myipv4
Pool name : myipv4
Pool id : 5
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Twin port : [63488, 65535]
Port overloading : 1
Address assignment : no-paired
Total addresses : 4
Translation hits : 0
Address range : 1.1.1.2 - 1.1.1.5
Single Ports : 0
Twin Ports : 0

```

## Example: Configuring an IPv6-Initiated Connection to an IPv4 Node Using Static Destination Address One-to-One Mapping

This example shows how to configure an IPv6-initiated connection to an IPv4 node using static destination address one-to-one mapping.

- [Requirements on page 5352](#)
- [Overview on page 5352](#)
- [Configuration on page 5352](#)
- [Verification on page 5354](#)

### Requirements

Before you begin, configure the interfaces and assign the interfaces to security zones.

### Overview

The following example describes the communication of an IPv6 node with an IPv4 node that has a one-to-one static NAT address defined on the device. The communication of an IPv6 node with an IPv4 node allows IPv6 hosts to access an IPv4 server when neither of the devices has a dual stack and must depend on the NAT/PT device to communicate. This enables some IPv4 legacy server applications to work even after the network has migrated to IPv6.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, then enter **commit** from configuration mode.

```
set security nat static rule test_rs from interface ge-0/0/1
set security nat static rule test_rs rule test_rule match destination-address 27a6::15/128
set security nat static rule test_rs rule test_rule then static-nat prefix 10.2.2.15/32
set security nat source pool myipv4 address 1.1.1.2 to 1.1.1.3
set security nat source rule myipv4_rs from interface ge-0/0/1
set security nat source rule myipv4_rs to interface ge-0/0/2
set security nat source rule myipv4_rs rule ipv4_rule match source-address 27a6::/96
set security nat source rule myipv4_rs rule ipv4_rule match destination-address 10.2.2.15
set security nat source rule myipv4_rs rule ipv4_rule then source-nat pool myipv4
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure an IPv6-initiated connection to an IPv4 node using static destination address one-to-one mapping:

1. Configure the static NAT rule set for an interface.  

```
[edit security nat static]
user@host# set rule-set test_rs from interface ge-0/0/1
```
2. Define a rule to match the destination address.  

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule match destination-address 27a6::15/128
```
3. Define the static NAT prefix to the rule.  

```
[edit security nat static rule-set test_rs]
user@host# set rule test_rule then static-nat prefix 10.2.2.15/32
```
4. Configure a source NAT pool with an IPv4 addresses.  

```
[edit security nat]
user@host# set source pool myipv4 address 1.1.1.2 1.1.1.3
```
5. Configure the IPv4 address for the interface.  

```
[edit security nat source]
user@host# set rule-set myipv4_rs from interface ge-0/0/1
```
6. Configure the source address to the IPv4 source NAT address.  

```
[edit security nat source rule-set myipv4_rs]
user@host# set rule ipv4_rule match source-address 27a6::/96
```
7. Configure the destination address to IPv4 source NAT address.  

```
[edit security nat source rule-set myipv4_rs]
user@host# set rule ipv4_rule match destination-address 10.2.2.15
```
8. Define the configured source NAT IPv4 pool in the rule.  

```
[edit security nat source rule-set myipv4_rs]
user@host# set rule ipv4_rule then source-nat pool myipv4
```

**Results** From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
 pool myipv4 {
 address {
 1.1.1.2/32 to 1.1.1.3/32;
 }
 }
}
rule-set myipv4_rs {
```

```
from interface ge-0/0/1.0;
to interface ge-0/0/2.0;
rule ipv4_rule {
 match {
 source-address 27a6::/96;
 destination-address 10.2.2.15/32;
 }
 then {
 source-nat {
 pool {
 myipv4;
 }
 }
 }
}
}
static {
 rule-set test_rs {
 from interface ge-0/0/1.0;
 rule test_rule {
 match {
 destination-address 27a6::15/128;
 }
 then {
 static-nat prefix 10.2.2.15/32;
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That Static NAT Is Configured on page 5354](#)
- [Verifying That Source NAT Is Configured on page 5354](#)

---

### Verifying That Static NAT Is Configured

**Purpose** Verify whether static NAT is configured with an interface, a destination address, and a prefix.

**Action** From operational mode, enter the **show security nat static** command.

---

### Verifying That Source NAT Is Configured

**Purpose** Verify whether source NAT is configured.

**Action** From operational mode, enter the **show security nat source** command.

# Configuring IPv6 Dual-Stack

- [Understanding IPv6 Dual-Stack Lite on page 5357](#)
- [Example: Configuring IPv6 Dual-Stack Lite on page 5360](#)

## Understanding IPv6 Dual-Stack Lite

---

IPv6 dual-stack lite (DS-Lite) is a technology that enables Internet service providers to move to an IPv6 network while simultaneously handling IPv4 address depletion.

IPv4 addresses are becoming depleted; therefore, broadband service providers (DSL, cable, and mobile) need new addresses to support new users. Providing IPv6 addresses alone is often not workable because most of the systems that make up the public Internet are still enabled and support only IPv4, and many users' systems do not yet fully support IPv6.

DS-Lite allows service providers to migrate to an IPv6 access network without changing end-user software. The device that accesses the Internet remains the same, thus allowing IPv4 users to continue accessing IPv4 internet content with minimum disruption to their home networks, while enabling IPv6 users to access IPv6 content.

[Figure 91](#) illustrates the DS-Lite architecture which uses IPv6-only links between the provider and the user while maintaining the IPv4 (or dual-stack) hosts in the user network.

Figure 241: DS-Lite NAT (IPv4-in-IPv6)

The DS-Lite deployment model consists of the following components:

- Software initiator for the DS-Lite home router--Encapsulates the IPv4 packet and transmits it across an IPv6 tunnel.
- Software concentrator for DS-Lite carrier-grade Network Address Translation (NAT)--Decapsulates the IPv4-in-IPv6 packet and also performs IPv4-IPv4 NAT translations.

When a user's device sends an IPv4 packet to an external destination, DS-Lite encapsulates the IPv4 packet in an IPv6 packet for transport into the provider network. These IPv4-in-IPv6 tunnels are called *softwires*. Tunneling IPv4 over IPv6 is simpler than translation and eliminates performance and redundancy concerns.

The softwires terminate in a software concentrator at some point in the service provider network, which decapsulates the IPv4 packets and sends them through a carrier-grade Network Address Translation (NAT) device. There, the packets undergo source NAT processing to hide the original source address.

IPv6 packets originated by hosts in the subscriber's home network are transported natively over the access network.

The DS-Lite carrier-grade NAT translates IPv4-to-IPv4 addresses to multiple subscribers through a single global IPv4 address. Overlapping address spaces used by subscribers are disambiguated through the identification of tunnel endpoints. One concentrator can be the endpoint of multiple softwires.

The IPv4 packets originated by the end hosts have private (and possibly overlapping) IP addresses. Therefore, NAT must be applied to these packets. If end hosts have overlapping addresses, Network Address Port Translation (NAPT) is needed.

Using NAPT, the system adds the source address of the encapsulating IPv6 packet in the subscriber network to the inside IPv4 source address and port. Because each user's IPv6 address is unique, the combination of the IPv6 source address with the IPv4 source address and port creates an unambiguous mapping.

The system takes the following actions when it receives a responding IPv4 packet from outside the subscriber network:

- Encapsulates the IPv4 packet in an IPv6 packet using the mapped IPv6 address as the IPv6 destination address.
- Forwards the packet to the user.

[Table 176](#) lists the maximum number of software initiators and software concentrators per device.

**Table 481: Software Initiator and Software Concentrator Capacity**

| Description                                      | SRX650 | SRX3400 | SRX3600 | SRX5600 | SRX5800 |
|--------------------------------------------------|--------|---------|---------|---------|---------|
| Maximum software initiators connected per device | 50,000 | 100,000 | 100,000 | 100,000 | 100,000 |

Table 481: Software Initiator and Software Concentrator Capacity (*continued*)

|                                                  |    |    |    |    |    |
|--------------------------------------------------|----|----|----|----|----|
| Maximum software concentrator numbers per device | 16 | 32 | 32 | 32 | 32 |
|--------------------------------------------------|----|----|----|----|----|

**NOTE:** The most recent IETF draft documentation for DS-Lite uses new terminology:

- The term software initiator has been replaced by B4.
- The term software concentrator has been replaced by AFTR.

Junos OS documentation generally uses the original terms when discussing configuration in order to be consistent with the CLI statements used to configure DS-Lite.

- [Understanding How SRX Series Devices Handle ICMPv6 Packets on page 1745](#)
- [About the IPv6 Basic Packet Header on page 1740](#)

## Example: Configuring IPv6 Dual-Stack Lite

When an ISP begins to allocate IPv6 addresses and IPv6-capable equipment to new subscriber homes, dual-stack lite (DS-Lite) provides a method for the private IPv4 addresses behind the IPv6 CE WAN equipment to reach the IPv4 network. DS-Lite enables IPv4 customers to continue to access the Internet using their current hardware by using a software initiator at the customer edge to encapsulate IPv4 packets into IPv6 packets with minimum disruption to their home network, while enabling IPv6 customers to access

IPv6 content. The softwire concentrator decapsulates the IPv4-in-IPv6 packets and also performs IPv4-IPv4 NAT translations.

This example shows you how to configure a softwire concentrator for IPv4-in-IPv6 addresses.

- [Requirements on page 5361](#)
- [Overview on page 5361](#)
- [Configuration on page 5361](#)
- [Verification on page 5362](#)

## Requirements

Before you begin:

- Review the overview section on DS-Lite. See “[Understanding IPv6 Dual-Stack Lite](#)” on [page 1747](#).
- Review how ICMPv6 packets are handled by the SRX Series devices. See “[Understanding How SRX Series Devices Handle ICMPv6 Packets](#)” on [page 1745](#).

## Overview

This configuration example shows how to configure a softwire concentrator, the softwire name, the concentrator address, and the softwire type.

**NOTE:** The softwire concentrator IPv6 address can match an IPv6 address configured on a physical interface or an IPv6 address configured on a loopback interface.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security softwires software-name my_sc1 software-concentrator 2001:100::1
software-type IPv4-in-IPv6
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a DS-Lite softwire concentrator to convert IPv4 packets into IPv6 packets:

1. Assign a name for the softwire concentrator.
 

```
[edit security]
user@host# edit softwires software-name my_sc1
```

- Specify the address of the software concentrator.

```
[edit security softwares software-name my_sc1]
user@host# set software-concentrator 2001:100::1
```

- Specify the software type for IPv4 to IPv6.

```
[edit security softwares software-name my_sc1 software-concentrator 2001:100::1]
user@host# set software-type IPv4-in-IPv6
```

**Results** From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit security softwares software-name my_sc1]
user@host# show
software-concentrator 2001:100::1;
software-type ipv4-in-ipv6;
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

From operational mode, enter the **show security softwares** command. If a software is not connected, the operational output looks like the following sample:

```
user@host# show security softwares
Software Name SC Address Status Number of SI connected
my-sc1 2001:100::1 Active 0
```

If a software is connected, the operational output looks like the following sample:

```
user@host# show security softwares
Software Name SC Address Status Number of SI connected
my-sc1 2001:100::1 Connected 1
```

address (Security ARP Proxy)

**Syntax** address *ip-address* < to *ip-address*>;

**Hierarchy Level** [edit security nat proxy-arp interface *interface-name*],

**Release Information** Statement modified in Junos OS Release 9.6.

**Description** Specify a single address or an address range of ARP proxy.

**Options** to—Specify the upper limit of the address range.

*ip-address*—IP address of an ARP proxy.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b>              | <p>Allows requests from a specific internal IP address to be mapped to the same reflexive IP address (the public IP address created by the NAT device closest to the STUN server); internal and external ports can be any ports. An external host using any port can send a packet to the internal host by sending the packet to the reflexive IP address (with a configured incoming policy that allows external to internal traffic). If this option is not configured, the persistent NAT binding is for specific internal and reflexive transport addresses.</p> <p>You can only specify this option when the persistent NAT type is <b>any-remote-host</b> and the source NAT rule action is one of the following:</p> <ul style="list-style-type: none"><li>• Source NAT pool with IP address shifting</li><li>• Source NAT pool with no port translation and no overflow pool</li></ul> |
| <b>Required Privilege Level</b> | <b>security</b> —To view this statement in the configuration.<br><b>security-control</b> —To add this statement to the configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b>              | <p>Enable the device to assign the same, statically chosen, IP address from a source pool to a host for multiple sessions that require the same source IP address for each session. This option is a global configuration and is applied to all source pools. After a session is established from a host and NAT is performed, the subsequent session from the same host will always use the same translated address.</p> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1X45-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>              | <p>Use the <b>address-pooling paired</b> option for applications that require all sessions associated with one internal IP address to be translated to the same external IP address for multiple sessions. Unlike the <b>address-persistent</b> option, this option is configured per pool, not globally. After a session is established from a host and NAT is performed, the subsequent sessions from the same host use the same translated address as long as the sessions are active.</p> <p>Specify <b>address-pooling no-paired</b> for applications that can be assigned IP addresses in a round-robin fashion.</p> <p>If either <b>address-pooling paired</b> or <b>address-pooling no-paired</b> is configured for a source NAT pool with port address translation, the persistent address option is disabled. If only <b>address-shared</b> is configured (no <b>address-pooling</b>) on a source NAT pool with no port translation, then the persistent address option is enabled. Both <b>address-shared</b> and <b>address-pooling paired</b> can be configured on the same source NAT pool with no port translation.</p> |
|                                 | <div>  <p><b>NOTE:</b> The <b>address-shared</b> and <b>address-pooling</b> options are supported only on SRX Series devices.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b>              | <p>Specifies that multiple internal IP addresses can be mapped to the same external IP address. Use this option only when the source NAT pool is configured with no port translation.</p> <p>When a source NAT pool configured with no port translation has few external IP addresses available, or only one external IP address, the <b>address-shared</b> option, with a many-to-one mapping, increases NAT resources and improves traffic.</p> |

| <b>Hierarchy Level</b>          | [edit security forwarding-process]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.6. Statement updated in Junos OS Release 10.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | <p>You can configure the device to switch from an integrated firewall mode to maximize IDP mode to increase the capacity of IDP processing with the <b>maximize-idp-sessions</b> option. When you maximize IDP, you are decoupling IDP processes from firewall processes, allowing the device to support the same number of firewall and IDP sessions.</p> <p>You can configure maximum ALG sessions by using the <b>maximize-alg-sessions</b> option. By default the session capacity number for RTSP, FTP, and TFTP ALG sessions is 10K per flow SPU. You must reboot the device (and its peer in chassis cluster mode) for the configuration to take effect. The <b>maximize-alg-sessions</b> option now enables you to increase defaults as follows:</p> <ul style="list-style-type: none"> <li>• RTSP, FTP, and TFTP ALG session capacity: 25K per flow SPU</li> <li>• TCP Proxy connection capacity: 40K per flow SPU</li> </ul> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <b>NOTE:</b> Flow session capacity will be reduced to half per flow SPU and that the above capacity numbers will not change on CP-flow.</p> </div> |
| <b>Options</b>                  | The remaining statements are explained separately. See <a href="#">CLI Explorer</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## destination (Security Destination NAT)

```
Syntax destination {
 pool pool-name {
 address <ip-address> {
 (port port-number | to ip-address);
 }
 description text;
 routing-instance (routing-instance-name | default);
 }
 rule-set rule-set-name {
 description text;
 from {
 interface [interface-name];
 routing-instance [routing-instance-name];
 zone [zone-name];
 }
 rule rule-name {
 description text;
 match {
 application {
 [application];
 any;
 }
 (destination-address ip-address | destination-address-name address-name);
 destination-port (port-or-low <to high>);
 protocol [protocol-name-or-number];
 source-address [ip-address];
 source-address-name [address-name];
 }
 then {
 destination-nat (off | pool pool-name | rule-session-count-alarm (clear-threshold
 value | raise-threshold value));
 }
 }
 }
}
```

**Hierarchy Level** [edit security nat]

**Release Information** Statement modified in Junos OS Release 9.6. The **description** option added in Junos OS Release 12.1. Statement modified in Junos OS Release 12.1X45-D10. Statement modified in Junos OS Release 12.1X47-D10.

**Description** Configure destination NAT, which allows you to configure the following:

- Translate destination IP address or addresses to a specific IP address.
- Translate destination IP address or addresses and port number(s) to a specific IP address and one port number.
- Translate a range of destination IP addresses to another range of IP addresses. This mapping is one-to-one, static, and without PAT.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

**Related Documentation** • [Security Configuration Statement Hierarchy on page 595](#)

## destination-address (Security Destination NAT)

**Syntax** destination-address <*ip-address*>;

**Hierarchy Level** [edit security nat destination rule-set *rule-set-name* rule *rule-name* match]

**Release Information** Statement modified in Junos OS Release 9.6.

**Description** Specify a destination address to match the rule. You can configure one address or a subnet.

### NOTE:

- If the destination address is IPv4 and the pool is an IPv6 prefix, the length of the IPv6 prefix must be 96.
- If the destination address is an IPv6 prefix and the pool is an IPv6 prefix, their length must be the same.

**Options** *ip-address*— Destination address or a subnet.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

**Related Documentation** • [Security Configuration Statement Hierarchy on page 595](#)

| <b>Release Information</b> | Statement modified in Junos OS Release 9.6. The <b>rule-session-count-alarm</b> option added in Junos OS Release 12.1X45-D10.                                                                                                                                                                                                                                                                        |
| <b>Description</b>         | Specify the action of the destination NAT rule.                                                                                                                                                                                                                                                                                                                                                      |
| <b>Options</b>             | <p><b>off</b>—Do not perform destination NAT operation.</p> <p><b>pool</b>—Use user-defined destination NAT pool to perform destination NAT.</p> <p><b>rule-session-count-alarm</b>—Define session count alarm thresholds for a specific destination NAT rule. When the session count exceeds the upper (raise) threshold or falls below the lower (clear) threshold, an SNMP trap is triggered.</p> |

**NOTE:** If you enter a value for **raise-threshold** but not for **clear-threshold**, **clear-threshold** is automatically set to 80 percent of **raise-threshold**.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1X44-D10.                                                                                                                                                               |
| <b>Description</b>              | Specify a destination port or port range to allow static NAT to map ports.                                                                                                                                          |
| <b>Options</b>                  | <ul style="list-style-type: none"><li>• <b>lower-port-range</b>—Specify the lower limit of the port range.</li><li>• <b>upper-port-range</b>—Specify the upper limit of the port range.</li></ul>                   |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                               |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"><li>• <a href="#">Security Configuration Statement Hierarchy on page 595</a></li></ul>                                                                                            |

## match (Security Destination NAT)

**Syntax**

```
match {
 application {
 [application];
 any;
 }
 (destination-address ip-address | destination-address-name address-name);
 destination-port (port-or-low <to high>);
 protocol [protocol-name-or-number];
 source-address [ip-address];
 source-address-name [address-name];
}
```

**Hierarchy Level** [edit security nat destination rule-set *rule-set-name* rule *rule-name*]

**Release Information** Statement modified in Junos OS Release 9.6. Statement modified in Junos OS Release 12.1X47-D10.

**Description** Specify the destination rules to be used as match criteria.

**NOTE:** If the options **destination-port** and **protocol** are configured as match conditions, then you cannot also configure the **application** option as a match condition. The reverse is also true: if you configure the **application** option as a match condition for a rule, you cannot also configure the **destination-port** and **protocol** options.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level**

- security—To view this statement in the configuration.
- security-control—To add this statement to the configuration.

## match (Security Source NAT)

**Syntax**

```
match {
 application {
 [application];
 any;
 }
 (destination-address <ip-address> | destination-address-name <address-name>);
 destination-port (port-or-low <to high>);
 protocol [protocol-name | protocol-number];
 source-address [ip-address];
 source-address-name [address-name];
 source-port (port-or-low <to high>);
}
```

**Hierarchy Level** [edit security nat source rule-set *rule-set-name* rule *rule-name*]

**Release Information** Statement modified in Junos OS Release 9.6. Statement modified in Junos OS Release 12.1X45-D10. Statement modified in Junos OS Release 12.1X47-D10.

**Description** Specify the source rules to be used as match criteria.

**NOTE:** If the options **source-port**, **destination-port**, and **protocol** are configured as match conditions, then you cannot also configure the **application** option as a match condition. The reverse is also true: if you configure the **application** option as a match condition for a rule, you cannot also configure the **source-port**, **destination-port**, and **protocol** options.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

## overflow-pool

|                            |                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>overflow-pool (interface   <i>pool-name</i>);</code>                                                                              |
| <b>Hierarchy Level</b>     | [edit security nat source pool <i>pool-name</i> ]                                                                                       |
| <b>Release Information</b> | Statement modified in Junos OS Release 9.6.                                                                                             |
| <b>Description</b>         | Specify a source pool to use when the current address pool is exhausted. Currently the statement is applicable for IPv4 addresses only. |

**NOTE:** The length of the IPv6 prefix must be 96 when the pool is used for NAT-PT.

- Options**
- **interface** — Allow the interface pool to support overflow.
  - **pool-name** — Name of the source address pool.

**NOTE:** The source pool must have Port Address Translation (PAT) enabled. PAT is not supported when the address is an IPv6 prefix address.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.6. Support for address-mapping added in Junos OS Release 10.2.                                                                                                                                                                                                                                                            |
| <b>Description</b>              | Use the <b>persistent-nat</b> feature to ensure that all requests from the same internal transport address are mapped to the same reflexive transport address (the public IP address and port created by the NAT device closest to the STUN server). The source NAT rule action can use a source NAT pool (with or without port translation) or an egress interface. |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | <p>Set the global default single port range for source NAT pools with port translation. If the port range in source NAT pools is not specified, the configured default port range is used. If neither the port range in source NAT pools nor the default port range are configured, the default single port range is 1024 through 63,487.</p> <p>To set the global twin port range for source NAT pools with port translation, use the <b>pool-default-twin-port-range</b> statement at the [edit security nat source] hierarchy. The twin port range is 63,488 through 65,535.</p> <p>To set the single port range for a specific pool, use the <b>port range port-low (to port-high)</b> statement at the [edit security nat source pool] hierarchy level.</p> |
| <b>Options</b>                  | <ul style="list-style-type: none"> <li>• <b>lower-port-range</b>—Specify the lower limit of the port range.</li> <li>• <b>upper-port-range</b>—Specify the upper limit of the port range.</li> </ul> <p><b>Range:</b> 1024 through 63,487. To view pool information, use the <b>show security nat source pool</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b>              | <p>Specify the global default twin port range for all source pools. Two ports within range (63488, 65535) are allocated at a time for RTP/RTCP applications such as SIP, H.323, and RTSP for source pools with PAT.</p> <p>The default twin port range is 2048. If you have an SRX5400, SRX5600, or SRX5800 device that supports a maximum of 1 million IP addresses, use this option to limit the twin port range and avoid exceeding the port capacity of 384 million.</p> <p>To set the twin port range for a specific pool, use the <b>port range twin-port <i>port-low</i> (to <i>port-high</i>)</b> statement at the [edit security nat source pool] hierarchy level.</p> |

| <b>Release Information</b>      | Statement modified in Junos OS Release 9.2.                                                                                                                                                                                                                                                    |
| <b>Description</b>              | Define the global pool utilization alarm thresholds for Network Address Translation (NAT) source IP address pools without Port Address Translation (PAT). When the pool utilization exceeds the upper (raise) threshold or falls below the lower (clear) threshold, an SNMP trap is triggered. |
| <b>Options</b>                  | <p><b>clear-threshold <i>value</i></b>—Lower threshold at which an SNMP trap is triggered.<br/><b>Range:</b> 40 through 100.</p> <p><b>raise-threshold <i>value</i></b>—Upper threshold at which an SNMP trap is triggered.<br/><b>Range:</b> 50 through 100.</p>                              |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                                                                                                          |

## port (Security Source NAT)

```
Syntax port {
 block-allocation {
 active-block-timeout timeout-interval;
 block-size block-size;
 log disable;
 maximum-blocks-per-host maximum-block-number;
 }
 deterministic {
 block-size block-size;
 host {
 address ip-address;
 address-name address-name ;
 }
 }
 no-translation;
 port-overloading-factor number;
 range {
 port-low <to port-high>;
 to port-high;
 twin-port port-low <to port-high>;
 }
 }
```

**Hierarchy Level** [edit security nat source pool *pool-name*]

**Release Information** Statement introduced in Junos OS Release 9.2. Statement updated with **block-allocation**, **deterministic**, and **twin-port** options in Junos OS Release 12.1X47-D10.

**Description** Specify the Port Address Translation (PAT) for a source pool.

- Options**
- **block-allocation**—Allocates a block of ports for translation, instead of allocating individual ports.
  - **deterministic**—An incoming (source) IP address and port always map to the specific destination address and port block, based on pre-defined deterministic NAT algorithm.
  - **no-translation**—If set, no Port Address Translation is required.
  - **port-overloading-factor *number***—Configure the port overloading capacity in source NAT.
  - **range *port-low* <to *port-high*>**—Specify the port number range attached to each address in the pool.
  - **twin port**—Configure the twin port range for source NAT pools to avoid port overloading.

The remaining statements are explained separately.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## port-overloading (Security Source NAT Interface)

---

|                            |                                                                |
|----------------------------|----------------------------------------------------------------|
| <b>Syntax</b>              | port-overloading off                                           |
| <b>Hierarchy Level</b>     | [edit security nat source interface]                           |
| <b>Release Information</b> | Statement introduced in Junos OS Release 9.6.                  |
| <b>Description</b>         | Enable interface NAT with or without port overloading.         |
| <b>Options</b>             | <b>off</b> —Specify off to disable interface port overloading. |

**NOTE:** The port-overloading option should not be used in conjunction with the port-overloading-factor option because they can override each other. For example, if port-overloading has been set to off to disable interface port overloading, and subsequently the port-overloading-factor is configured with any value greater than 1, the port-overloading-factor setting will override the port-overloading setting. (Configuring port-overloading-factor 1 is equivalent to configuring port-overloading off.)

## port-overloading-factor (Security Source NAT Pool)

---

**Syntax** port-overloading-factor

**Hierarchy Level** [edit security nat source pool *source-pool-name* port]

**Release Information** Statement introduced in Junos OS Release 11.2

**Description** Configures the port overloading capacity in source NAT. If the port-overloading-factor is set to x, each translated IP address will have x number of ports available.

**NOTE:** The port-overloading-factor statement cannot be configured with port no-translation (source NAT pool without PAT) or port-range configuration statements.

**Options** **Range:** 2 through 32

For example, If you set **port-overloading-factor** to 2 for a source pool with two IP addresses, each with the single port range of 1024 through 2047, the ports are multiplied by 2, increasing the port capacity for each from 1024 to 2048. If the configured port-overloading-factor setting exceeds the maximum port capacity of the pool, an error message is generated during the configuration commit.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.6.                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>              | Disable random port allocation for pool-based and interface source NAT.                                                                                                                                                                                                                                                                                                              |
| <b>Options</b>                  | <b>disable</b> —Disables random port allocation for pool-based and interface source NAT. For pool-based source NAT and interface NAT, port numbers are allocated randomly by default. Although randomized port number allocation can provide protection from security threats such as DNS poison attacks, it can also affect performance and memory usage for pool-based source NAT. |

## rule-set (Security Destination NAT)

```
Syntax rule-set rule-set-name {
 description text;
 from {
 interface [interface-name];
 routing-instance [routing-instance-name];
 zone [zone-name];
 }
 rule rule-name {
 description text;
 match {
 application {
 [application];
 any;
 }
 destination-address ip-address [destination-address-name address-name];
 destination-port (port-or-low <to high>);
 protocol [protocol-name-or-number];
 source-address [ip-address];
 source-address-name [address-name];
 }
 then {
 destination-nat (off | pool pool-name | rule-session-count-alarm (clear-threshold
 value | raise-threshold value));
 }
 }
 }
```

**Hierarchy Level** [edit security nat destination]

**Release Information** Statement modified in Junos OS Release 9.6. The **description** option added in Junos OS Release 12.1. Statement modified in Junos OS Release 12.1X45-D10. Statement modified in Junos OS Release 12.1X47-D10.

**Description** Configure a set of rules for destination NAT.

**Options** *rule-set-name*—Name of the rule set.

**description**—Description of the rule set.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## static (Security NAT)

```
Syntax static {
 rule-set rule-set-name {
 description text;
 from {
 interface [interface-name];
 routing-instance [routing-instance-name];
 zone [zone-name];
 }
 rule rule-name {
 description text;
 match {
 (destination-address <ip-address> | destination-address-name <address-name>);
 destination-port (port-or-low | <to high>);
 source-address [ip-address];
 source-address-name [ip-address-name];
 source-port (port-or-low <to high>);
 }
 then {
 static-nat {
 inet {
 routing-instance (routing-instance-name | default);
 }
 prefix {
 address-prefix;
 mapped-port lower-port-range to upper-port-range;
 routing-instance (routing-instance-name | default);
 }
 prefix {
 address-prefix-name;
 mapped-port lower-port-range to upper-port-range;
 routing-instance (routing-instance-name | default);
 }
 }
 rule-session-count-alarm (clear-threshold value | raise-threshold value);
 }
 }
 }
 }
```

**Hierarchy Level** [edit security nat]

**Release Information** Statement introduced in Junos OS Release 9.3. The **description** option added in Junos OS Release 12.1. Statement modified in Junos OS Release 12.1X45-D10.

**Description** Configure static NAT.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

---

## static-nat

---

**Syntax**

```
static-nat {
 inet {
 routing-instance (default | routing-instance-name);
 }
 prefix {
 address-prefix;
 routing-instance (default | routing-instance-name);
 }
 prefix-name {
 address-prefix-name;
 routing-instance (default | routing-instance-name);
 }
 rule-session-count-alarm (clear threshold value | raise threshold value);
}
```

**Hierarchy Level** [edit security nat static rule-set *rule-set-name* rule *rule-name* then]

**Release Information** Statement modified in Junos OS Release 9.6. Statement modified in Junos OS Release 12.1X45-D10.

**Description** Specify the translated address of the static NAT rule.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Description</b>         | Configure NAT tracing options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>             | <ul style="list-style-type: none"> <li>• <b>file</b>—Configure the trace file options. <ul style="list-style-type: none"> <li>• <b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. By default, the name of the file is the name of the process being traced.</li> <li>• <b>files number</b>—Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed to <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.</li> </ul> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> </li> <li>• <b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</li> <li>• <b>size maximum-file-size</b>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches this size, it is renamed <b>trace-file.0</b>. When the <b>trace-file</b> again reaches its maximum size, <b>trace-file.0</b> is renamed <b>trace-file.1</b> and <b>trace-file</b> is renamed <b>trace-file.0</b>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</li> </ul> <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the <b>files</b> option and a filename.</p> <p>Syntax: <b>x K</b> to specify KB, <b>x m</b> to specify MB, or <b>x g</b> to specify GB</p> <p>Range: 10 KB through 1 GB</p> |

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.
  - **all**—Trace with all flags enabled
  - **destination-nat-pfe**—Trace destination NAT events on PFE-ukernel side
  - **destination-nat-re**—Trace destination NAT events on Routing Engine (RE) side
  - **destination-nat-rt**—Trace destination NAT events on Packet Forwarding Engine real-time (PFE-RT) side
  - **source-nat-pfe**—Trace source NAT events on PFE-ukernel side
  - **source-nat-re**—Trace source NAT events on RE side
  - **source-nat-rt**—Trace source NAT events on PFE-RT side
  - **static-nat-pfe**—Trace static NAT events on PFE-ukernel side
  - **static-nat-re**—Trace static NAT events on RE side
  - **static-nat-rt**—Trace static NAT events on PFE-RT side
- **no-remote-trace**—Set remote tracing as disabled.

**Required Privilege Level**    **trace**—To view this statement in the configuration.  
                                      **trace-control**—To add this statement to the configuration.

| <b>Output Fields</b>            | Table 482 lists the output fields for the <b>show security nat destination pool</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                 |

**Table 482: show security nat destination pool Output Fields**

| Field Name       | Field Description                       |
|------------------|-----------------------------------------|
| Pool name        | Name of the destination pool.           |
| Description      | Description of the destination pool.    |
| Pool id          | Pool identification number.             |
| Routing instance | Name of the routing instance.           |
| Total address    | Number of IP addresses that are in use. |

Table 482: show security nat destination pool Output Fields (*continued*)

| Field Name       | Field Description                            |
|------------------|----------------------------------------------|
| Translation hits | Number of translation hits.                  |
| Address range    | IP address or IP address range for the pool. |

## Sample Output

### show security nat destination pool dst-nat-pool1

```

user@host> show security nat destination pool dst-p1

Pool name : dst-p1
Description : The destination pool dst-p1 is for the sales team
Pool id : 1
Routing instance: default
Total address : 1
Translation hits : 0
Address range : 1.1.1.1 - 1.1.1.1 Port
 0

```

## Sample Output

### show security nat destination pool all

```

user@host> show security nat destination pool all

Total destination-nat pools: 2

Pool name : dst-p1
Description : The destination pool dst-p1 is for the sales team
Pool id : 1
Routing instance: default
Total address : 1
Translation hits : 0
Address range : 1.1.1.1 - 1.1.1.1 Port
 0

Pool name : dst-p2
Description : The destination pool dst-p2 is for the sales team
Pool id : 2
Routing instance: default
Total address : 1
Translation hits : 0
Address range : 2001::1 - 2001::1 Port
 0

```

| <b>Output Fields</b>            | Table 400 lists the output fields for the <b>show security nat destination rule</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                          |

**Table 483: show security nat destination rule Output Fields**

| Field Name                             | Field Description                                                                                                                                                                             |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total destination-nat rules            | Number of destination NAT rules.                                                                                                                                                              |
| Total referenced IPv4/IPv6 ip-prefixes | Number of IP prefixes referenced in source, destination, and static NAT rules. This total includes the IP prefixes configured directly as address names and as address set names in the rule. |
| Destination NAT rule                   | Name of the destination NAT rule.                                                                                                                                                             |

Table 483: show security nat destination rule Output Fields (*continued*)

| Field Name            | Field Description                                                                                                                                                                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description           | Description of the destination NAT rule.                                                                                                                                                                                                                                                         |
| Rule-Id               | Rule identification number.                                                                                                                                                                                                                                                                      |
| Rule position         | Position of the destination NAT rule.                                                                                                                                                                                                                                                            |
| From routing instance | Name of the routing instance from which the packets flow.                                                                                                                                                                                                                                        |
| From interface        | Name of the interface from which the packets flow.                                                                                                                                                                                                                                               |
| From zone             | Name of the zone from which the packets flow.                                                                                                                                                                                                                                                    |
| Source addresses      | Name of the source addresses that match the rule. The default value is any.                                                                                                                                                                                                                      |
| Destination addresses | Name of the destination addresses that match the rule. The default value is any.                                                                                                                                                                                                                 |
| Action                | The action taken when a packet matches the rule's tuples. Actions include the following: <ul style="list-style-type: none"> <li>• <b>destination NAT pool</b>—Use user-defined destination NAT pool to perform destination NAT.</li> <li>• <b>off</b>—Do not perform destination NAT.</li> </ul> |
| Destination ports     | Destination ports number that match the rule. The default value is any.                                                                                                                                                                                                                          |
| Application           | Indicates whether the application option is configured.                                                                                                                                                                                                                                          |
| Translation hits      | Number of translation hits.                                                                                                                                                                                                                                                                      |
| Successful sessions   | Number of successful session installations after the NAT rule is matched.                                                                                                                                                                                                                        |
| Failed sessions       | Number of unsuccessful session installations after the NAT rule is matched.                                                                                                                                                                                                                      |
| Number of sessions    | Number of sessions that reference the specified rule.                                                                                                                                                                                                                                            |

## Sample Output

### show security nat destination rule dst2-rule

```

user@host>show security nat destination rule dst2-rule

Destination NAT rule: dst2-rule Rule-set: dst2
Description : The destination rule dst2-rule is for the sales
team
Rule-Id : 1
Rule position : 1
From routing instance : ri1
 : ri2
Match
Source addresses : add1

```

```

 add2
Destination addresses : add9
Action : off

Destination port : 0
Translation hits : 68
Successful sessions : 25
Failed sessions : 43
Number of sessions : 2

```

## Sample Output

### show security nat destination rule all

```
user@host> show security nat destination rule all
```

```
Total destination-nat rules: 1
```

```
Total referenced IPv4/IPv6 ip-prefixes: 2/0
```

```

Destination NAT rule: r4 Rule-set: rs4
Rule-Id : 2
Rule position : 2
From zone : untrust
Match
 Source addresses : 40.40.40.0 - 40.40.40.255
 Destination addresses : 60.60.60.0 - 60.60.60.255
 Application : configured
Action : off
Translation hits : 0
Successful sessions : 0
Failed sessions : 0
Number of sessions : 0

```

## show security nat destination rule-application

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                   |

**Table 484: show security nat destination rule-application Output Fields**

| Field Name           | Field Description                           |
|----------------------|---------------------------------------------|
| Destination NAT rule | Name of the destination NAT rule.           |
| Rule-set             | Rule set identification number.             |
| Rule-Id              | Rule identification number.                 |
| Application          | Name of the application or application set. |
| IP protocol          | IP protocol identifier.                     |
| Source port range    | Source port range identifier.               |

Table 484: show security nat destination rule-application Output Fields (*continued*)

| Field Name             | Field Description                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Destination port range | Destination port identifier.                                                                                                             |
| ICMP information       | <ul style="list-style-type: none"> <li>• type—ICMP message type.</li> <li>• code—Code corresponding to the ICMP message type.</li> </ul> |

## Sample Output

### show security nat destination rule-application for port application

```

user@host>show security nat destination rule-application all

Destination NAT rule: r4 Rule-set: rs4
Rule-Id : 2
 Application: app-set1
 IP protocol: 17
 Source port range: [40-50]
 Destination port range: [50-60]
 IP protocol: 17
 Source port range: [100-200]
 Destination port range: [300-500]

```

## Sample Output

### show security nat destination rule-application for ICMP application

```

user@host>show security nat destination rule-application all

Destination NAT rule: r1 Rule-set: rs1
Rule-Id : 1
 Application: junos-icmp-all
 IP protocol: icmp
 ICMP Information: type=255, code=0
 Application: icmp1
 IP protocol: icmp
 ICMP Information: type=1, code=1
 Application: junos-icmp6-all
 IP protocol: 58
 ICMP Information: type=255, code=0

```

## show security nat destination summary

**Table 485: show security nat destination summary Output Fields**

| Field Name                        | Field Description                             |
|-----------------------------------|-----------------------------------------------|
| Total destination nat pool number | Number of destination NAT pools.              |
| Pool name                         | Name of the destination address pool.         |
| Address range                     | IP address or IP address range for the pool.  |
| Routing Instance                  | Name of the routing instance.                 |
| Port                              | Port number.                                  |
| Total                             | Number of IP addresses that are in use.       |
| Available                         | Number of IP addresses that are free for use. |
| Total destination nat rule number | Number of destination NAT rules.              |

Table 485: show security nat destination summary Output Fields (*continued*)

| Field Name              | Field Description                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Total hit times</b>  | Number of times a translation in the translation table is used for all the destination NAT rules.             |
| <b>Total fail times</b> | Number of times a translation in the translation table failed to translate for all the destination NAT rules. |

## Sample Output

### show security nat destination summary

```
user@host> show security nat destination summary
```

```
Total pools: 2
```

| Pool name | Address Range     | Routing Instance | Port | Total Address |
|-----------|-------------------|------------------|------|---------------|
| dst-p1    | 1.1.1.1 - 1.1.1.1 | default          | 0    | 1             |
| dst-p2    | 2001::1 - 2001::1 | default          | 0    | 1             |

```
Total rules: 171
```

| Rule name | Rule set | From | Action |
|-----------|----------|------|--------|
| dst2-rule | dst2     | ri1  |        |
|           |          | ri2  |        |
|           |          | ri3  |        |
|           |          | ri4  |        |
|           |          | ri5  |        |
|           |          | ri6  |        |
|           |          | ri7  |        |
| dst3-rule | dst3     | ri9  | off    |
|           |          | ri1  |        |
|           |          | ri2  |        |
|           |          | ri3  |        |
|           |          | ri4  |        |
|           |          | ri5  |        |

```
...
```

## show security nat incoming-table

**Syntax** `show security nat incoming-table`  
`<node ( node-id | all | local | primary )>`

**Release Information** Command introduced in Junos OS Release 8.5. The **node** options added in Junos OS Release 9.0.

**Description** Display Network Address Translation (NAT) table information.

**NOTE:** The incoming dip NAT table is replaced with ALG cone NAT binding table and the `show security nat incoming-table` command is obsolete from Junos OS Release 11.2 onward. The `show security nat incoming-table` command works as is in the previous releases.

- Options**
- **none**—Display all information NAT incoming table.
  - **node**—(Optional) For chassis cluster configurations, display incoming table information on a specific node.
    - ***node-id***—Identification number of the node. It can be 0 or 1.
    - **all**—Display information about all nodes.
    - **local**—Display information about the local node.
    - **primary**—Display information about the primary node.

**Required Privilege Level** view

**Output Fields** [Table 486](#) lists the output fields for the `show security nat incoming-table` command. Output fields are listed in the approximate order in which they appear.

**Table 486: show security nat incoming-table Output Fields**

| Field Name              | Field Description                                    |
|-------------------------|------------------------------------------------------|
| In use                  | Number of entries in the NAT table.                  |
| Maximum                 | Maximum number of entries possible in the NAT table. |
| Entry allocation failed | Number of entries failed for allocation.             |

Table 486: show security nat incoming-table Output Fields (*continued*)

| Field Name  | Field Description                                                          |
|-------------|----------------------------------------------------------------------------|
| Destination | Destination IP address and port number.                                    |
| Host        | Host IP address and port number that the destination IP address is mapped. |
| References  | Number of sessions referencing the entry.                                  |
| Timeout     | Timeout, in seconds, of the entry in the NAT table.                        |
| Source-pool | Name of source pool where translation is allocated.                        |

## Sample Output

### show security nat incoming-table

```
user@host> show security nat incoming-table
In use: 1, Maximum: 1024, Entry allocation failed: 0
Destination Host References Timeout Source-pool
10.1.1.26:1028 1.1.1.10:5060 1 3600 p1
```

| <b>Output Fields</b>            | Table 488 lists the output fields for the <b>show security nat resource-usage source-pool</b> command. Output fields are listed in the approximate order in which they appear. You can use the <b>clear security nat statistics</b> command to reset the peak usage statistics.                                                                                                                                                                                   |

**Table 488: show security nat resource-usage source-pool Output Fields**

| Field Name    | Field Description                    |
|---------------|--------------------------------------|
| Pool          | Name of the pool.                    |
| Address       | Address of the pool.                 |
| Factor-index  | Port pool index.                     |
| Total address | Number of addresses in the pool.     |
| Port-range    | Number of ports allocated at a time. |

Table 488: show security nat resource-usage source-pool Output Fields (*continued*)

| Field Name              | Field Description                                                             |
|-------------------------|-------------------------------------------------------------------------------|
| Used                    | Number of used resources in the pool.                                         |
| Avail                   | Number of available resources in the pool.                                    |
| Usage                   | Percent of resources used. In a PAT pool, use includes single and twin ports. |
| Current usage           | Percent of current resources used.                                            |
| Peak usage              | Percent of resources used during the peak date and time.                      |
| Total                   | Number of used and available resources.                                       |
| Total ports             | Number of used and available ports.                                           |
| Port-overloading-factor | Port overloading capacity for the pool.                                       |

## Sample Output

### show security nat resource-usage resource-pool all

```

user@host> show security nat resource-usage source-pool all

PAT pools(including address-shared pool) port utilization:
Pool Address Used Avail Total Usage
SpoolA 512 2387968 29593600 31981568 7%
SpoolB 128 393216 655360 1048576 38%

Non-PAT pools address utilization:
Pool Used Avail Total Usage
Spool1 300 3796 4096 7%
Spool2 512 512 1024 50%

```

### show security nat resource-usage resource-pool pool-name (Without PAT)

```

user@host> show security nat resource-usage source-pool Spool1
Logical system: root
Peak usage: 60% @ 2012-08-26 20:16:20 UTC

Pool Used Avail Total Usage
Spool1 300 3796 4096 7%

```

### show security nat resource-usage resource-pool pool-name (with PAT)

```

user@host> show security nat resource-usage source-pool sp3
Logical system: root
Pool name: sp3
Total address: 2
Port-overloading-factor: 2
Total ports: 258048 Used: 60563 Avail: 197485

```

Current usage: 23% Peak usage: 35% at 2012-11-12 20:15:26 CST

| Address         | Factor-index | Port-range   | Used  | Avail | Total  | Usage |

Table 489: show security nat source deterministic Output Fields

| Field Name              | Field Description                                                            |
|-------------------------|------------------------------------------------------------------------------|
| Pool name               | Name of pool.                                                                |
| Port-overloading-factor | Factor of port overloading for the source pool.                              |
| Port block size         | Number of ports that a port block contains.                                  |
| Used/total port blocks  | Port block used number and port block total number for this source NAT pool. |
| Host IP                 | IP address of host.                                                          |
| External IP             | IP address of external router.                                               |
| Port_Range              | The range of ports in a block, ranging from lowest to highest.               |
| Ports_Used/Total        | Number of ports used and total ports.                                        |

## Sample Output

### show security nat source deterministic

```

user@host> show security nat source deterministic
Pool name: SRC_P_3
Port-overloading-factor: 1 Port block size: 10000
Used/total port blocks: 0/12
Host_IP External_IP Port_Range
Ports_Used/Total
10.2.0.1 3.2.0.1 1024-11023
0/10000*1
10.2.0.2 3.2.0.1 11024-21023
0/10000*1

```

## show security nat source paired-address

**Syntax** show security nat source paired-address  
 <internal-ip *internal-ip-address*>  
 <logical-system *logical-system-name*>  
 <pool-name *pool-name*>  
 <root-logical-system>  
 <xlated-ip *x-lated-ip-address*>

**Release Information** Command introduced in Junos OS Release 12.1X45-D10.

**Description** Display information about the Network Address Translation (NAT) source paired addresses.

**Options** none—Display all paired IP address information.

**internal-ip *internal-ip-address***—Display information about the specified internal IP address.

**logical-system *logical-system-name***—Display information about the source NAT pools for the specified logical system.

**pool-name *pool-name***—Display paired address information for the specified pool.

**root-logical-system**—Display information about the source NAT pools for the master (root) logical system.

**x-lated-ip *x-lated-ip-address***—Display information about the specified translated external IP address.

**Output Fields** [Table 490](#) lists the output fields for the **show security nat source paired-address** command. Output fields are listed in the approximate order in which they appear.

**Table 490: show security nat source paired-address Output Fields**

| Field Name       | Field Description        |
|------------------|--------------------------|
| Pool name        | Name of the source pool. |
| Internal address | Internal IP address.     |

Table 490: show security nat source paired-address Output Fields (*continued*)

| Field Name       | Field Description    |
|------------------|----------------------|
| External address | External IP address. |

## Sample Output

### show security nat source paired-address

```

user@host> show security nat source paired-address
Pool name: sp1
Internal address External address
20.1.1.240 70.1.1.105

Pool name: sp2
Internal address External address
20.1.2.126 100.1.1.1
20.1.2.127 100.1.1.1
20.1.2.125 100.1.1.1
20.1.2.130 100.1.1.1
20.1.2.128 100.1.1.1
20.1.2.129 100.1.1.1

```

### show security nat source paired-address pool-name

```

user@host> show security nat source paired-address pool-name sp1
Pool name: sp1

| <b>Output Fields</b>            | <a href="#">Table 491</a> lists the output fields for the <b>show security nat source persistent-nat-table</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 491: show security nat source persistent-nat-table Output Fields**

| Field Name          | Field Description                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------|
| Internal IP/Port    | Internal transport IP address and port number of the outgoing session from internal to external. |
| Reflexive IP/Port   | Translated IP address and port number of the source IP address and port.                         |
| Source NAT Pool     | The name of the source pool where persistent NAT is used.                                        |
| Type                | Persistent NAT type.                                                                             |
| Left_time/Conf_time | The inactivity timeout period that remains and the configured timeout value.                     |

Table 491: show security nat source persistent–nat–table Output Fields (*continued*)

| Field Name                    | Field Description                                                          |
|-------------------------------|----------------------------------------------------------------------------|
| Current_Sess_Num/Max_Sess_Num | The number of current sessions associated with the persistent NAT binding. |
| Source NAT Rule               | Name of the source NAT rule to which this persistent NAT binding applies.  |

## Sample Output

| <b>Output Fields</b>            | Table 492 lists the output fields for the <b>show security nat source pool</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                             |

Table 492: show security nat source pool Output Fields

| Field Name  | Field Description               |
|-------------|---------------------------------|
| Pool name   | Name of the source pool.        |
| Description | Description of the source pool. |

Table 492: show security nat source pool Output Fields (*continued*)

| Field Name            | Field Description                                                                                                                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pool id               | Pool identification number.                                                                                                                                                                                                        |
| Routing Instance      | Name of the routing instance.                                                                                                                                                                                                      |
| Host address base     | Base address of the original source IP address range.                                                                                                                                                                              |
| Port                  | Port numbers used for the source pool.                                                                                                                                                                                             |
| Twin port             | Upper and lower limits of the twin port.                                                                                                                                                                                           |
| port overloading      | Number of port overloading for the source pool.                                                                                                                                                                                    |
| Address assignment    | Type of address assignment.                                                                                                                                                                                                        |
| Total addresses       | Number of IP addresses that are in use.                                                                                                                                                                                            |
| Translation hits      | Number of translation hits.                                                                                                                                                                                                        |
| Port block size       | Block size for the deterministic pool.                                                                                                                                                                                             |
| Determ host range num | Host range for the deterministic pool.                                                                                                                                                                                             |
| Address range         | IP address or IP address range for the source pool.                                                                                                                                                                                |
| Address-Persistent    | Address persistent information for IPv4 source pools: <ul style="list-style-type: none"> <li>IPv6 prefix length—Configured IPv6 prefix length.</li> <li>IPv6 subscriber out of port—Number of port allocation failures.</li> </ul> |
| Single Ports          | Number of allocated single ports.                                                                                                                                                                                                  |
| Twin Ports            | Number of allocated twin ports.                                                                                                                                                                                                    |

## Sample Output

### show security nat source pool src-p1

```

user@host> show security nat source pool src-p1

Pool name : src-p1
Description : The source pool src-p1 is for the sales team
Pool id : 4
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Address assignment : paired
port overloading : 1
Total addresses : 4
Translation hits : 0

```

| Address range     | Single Ports | Twin Ports |
|-------------------|--------------|------------|
| 3.3.3.0 - 3.3.3.3 | 0            | 0          |

## Sample Output

### show security nat source pool all

```
user@host> show security nat source pool all
```

Total pools: 4

```
Pool name : src-p1
Description : The source pool src-p1 is for the sales team
Pool id : 4
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Address assignment : paired
port overloading : 1
Total addresses : 4
Translation hits : 0
```

| Address range     | Single Ports | Twin Ports |
|-------------------|--------------|------------|
| 3.3.3.0 - 3.3.3.3 | 0            | 0          |

```
Pool name : src-p2
Description : The source pool src-p2 is for the sales team
Pool id : 5
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Address assignment : no-paired
port overloading : 1
Total addresses : 4
Translation hits : 0
```

| Address range     | Single Ports | Twin Ports |
|-------------------|--------------|------------|
| 4.4.4.0 - 4.4.4.3 | 0            | 0          |

```
Pool name : src-p3
Description : The source pool src-p3 is for the sales team
Pool id : 6
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Address assignment : no-paired
port overloading : 1
Total addresses : 1
Translation hits : 0
```

| Address range     | Single Ports | Twin Ports |
|-------------------|--------------|------------|
| 2003::1 - 2003::1 | 0            | 0          |

```
Pool name : src-p4
Description : The source pool src-p4 is for the sales team
Pool id : 7
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Address assignment : no-paired
port overloading : 1
Total addresses : 1
Translation hits : 0
```

**show security nat source pool sp1**

```

user@host>show security nat source pool sp1
Pool name : sp1
Description : The source pool src-p1 is for the sales team
Pool id : 12
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Twin port : [63488, 64515]
Port overloading : 1
Address assignment : no-paired
Total addresses : 1
Translation hits : 0
Address range :
 55.1.1.1 - 55.1.1.1
 Single Ports Twin Ports
 0 0

```

**show security nat source pool P\_1**

```

user@host>show security nat source pool P_1
Pool name : P_1
Pool id : 4
Routing instance : default
Port : [12345, 17890]
Port overloading : 1
Address assignment : no-paired
Total addresses : 256
Translation hits : 0
Port block size : 1000
Determ host range num: 3
Address range :
 3.3.3.0 - 3.3.3.255
 Single Ports Twin Ports
 0 0

```

**show security nat source pool src-nat-v4-with-pat**

```

user@host>how security nat source pool src-nat-v4-with-pat

Pool name : src-nat-v4-with-pat
Pool id : 5
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
Port overloading : 1
Address assignment : no-paired
Total addresses : 10
Translation hits : 0
Address-persistent
 IPv6 prefix length: 64
 IPv6 subscriber out of port: 0
Address range :
 3.3.3.1 - 3.3.3.10
 Single Ports Twin Ports
 0 0

```

## show security nat source port-block

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Output Fields</b>            | Table 493 lists the output fields for the <b>show security nat source port-block</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 493: show security nat source port-block Output Fields**

| Field Name               | Field Description                                               |
|--------------------------|-----------------------------------------------------------------|
| Pool name                | Name of pool.                                                   |
| Port-overloading-factor  | Factor of port overloading for the source pool.                 |
| Port block size          | Number of ports that a port block contains.                     |
| Max port blocks per host | Maximum number of blocks that one host can use for translation. |

| Field Name                         | Field Description                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b>                 | Description of the source NAT rule.                                                                                                                                                                                                                                                                                                                                                  |
| <b>Rule-Id</b>                     | Rule identification number.                                                                                                                                                                                                                                                                                                                                                          |
| <b>Rule position</b>               | Position of the source NAT rule.                                                                                                                                                                                                                                                                                                                                                     |
| <b>From zone</b>                   | Name of the zone from which the packets flow.                                                                                                                                                                                                                                                                                                                                        |
| <b>To zone</b>                     | Name of the zone to which the packets flow.                                                                                                                                                                                                                                                                                                                                          |
| <b>From routing instance</b>       | Name of the routing instance from which the packets flow.                                                                                                                                                                                                                                                                                                                            |
| <b>To routing instance</b>         | Name of the routing instance to which the packets flow.                                                                                                                                                                                                                                                                                                                              |
| <b>From interface</b>              | Name of the interface from which the packets flow.                                                                                                                                                                                                                                                                                                                                   |
| <b>To interface</b>                | Name of the interface to which the packets flow.                                                                                                                                                                                                                                                                                                                                     |
| <b>Source addresses</b>            | Name of the source addresses that match the rule.                                                                                                                                                                                                                                                                                                                                    |
| <b>Source port</b>                 | Source port numbers that match the rule.                                                                                                                                                                                                                                                                                                                                             |
| <b>Destination address</b>         | Name of the destination addresses that match the rule.                                                                                                                                                                                                                                                                                                                               |
| <b>Destination ports</b>           | Destination port numbers that match the rule.                                                                                                                                                                                                                                                                                                                                        |
| <b>Application</b>                 | Indicates whether the application option is configured.                                                                                                                                                                                                                                                                                                                              |
| <b>Action</b>                      | <p>The action taken in regard to a packet that matches the rule's tuples. Actions include the following:</p> <ul style="list-style-type: none"> <li>• <b>off</b>—Do not perform source NAT.</li> <li>• <b>source NAT pool</b>—Use user-defined source NAT pool to perform source NAT</li> <li>• <b>interface</b>—Use egress interface's IP address to perform source NAT.</li> </ul> |
| <b>Persistent NAT type</b>         | Persistent NAT type.                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Persistent NAT mapping type</b> | Persistent NAT mapping type.                                                                                                                                                                                                                                                                                                                                                         |
| <b>Inactivity timeout</b>          | Inactivity timeout for persistent NAT binding.                                                                                                                                                                                                                                                                                                                                       |
| <b>Max session number</b>          | Maximum number of sessions.                                                                                                                                                                                                                                                                                                                                                          |
| <b>Translation hits</b>            | Number of translation hits.                                                                                                                                                                                                                                                                                                                                                          |
| <b>Successful sessions</b>         | Number of successful session installations after the NAT rule is matched.                                                                                                                                                                                                                                                                                                            |

Table 494: show security nat source rule Output Fields (*continued*)

| Field Name         | Field Description                                                           |
|--------------------|-----------------------------------------------------------------------------|
| Failed sessions    | Number of unsuccessful session installations after the NAT rule is matched. |
| Number of sessions | Number of sessions that reference the specified rule.                       |

## Sample Output

### show security nat source rule r2

```

user@host> show security nat source rule r2

source NAT rule: r2 Rule-set: src-nat
Description : The source rule r2 is for the sales team
Rule-Id : 1
Rule position : 1
From zone : zone1
To zone : zone9
Match
 Source addresses : add1
 : add2
 Destination addresses : add9
 : add10
 Destination port : 1002 - 1002
Action : off
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0
 Max session number : 0
Translation hits : 4719
 Successful sessions : 2000
 Failed sessions : 2719
 Number of sessions : 5

```

## Sample Output

### show security nat source rule all

```

user@host> show security nat source rule all
Logical system: root
Total rules: 1
Total referenced IPv4/IPv6 ip-prefixes: 3/0

source NAT rule: r2 Rule-set: rs2
Rule-Id : 2
Rule position : 1
From zone : trust
To zone : untrust
Match
 Source addresses : 40.40.40.0 - 40.40.40.255
 Destination addresses : 50.50.50.0 - 50.50.50.255
 : 60.60.60.0 - 60.60.60.255
 Application : configured
Action : off
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0

```

```
Max session number : 0
Translation hits : 0
 Successful sessions : 0
 Failed sessions : 0
Number of sessions : 0
```

## Sample Output

### show security nat source rule-application for port application

```

user@host>show security nat source rule-application all

source NAT rule: r2 Rule-set: rs2
Rule-Id : 2
 Application: app1
 IP protocol: 3
 Source port range: [90-90]
 Destination port range: [0-0]
 IP protocol: 4
 Source port range: [100-100]
 Destination port range: [200-200]
 Application: app2
 IP protocol: 7
 Source port range: [400-500]
 Destination port range: [80-80]

```

## Sample Output

### show security nat source rule-application for ICMP application

```

user@host>show security nat source rule-application all

source NAT rule: r1 Rule-set: rs1
Rule-Id : 1
 Application: junos-icmp-all
 IP protocol: icmp
 ICMP Information: type=255, code=0
 Application: icmp1
 IP protocol: icmp
 ICMP Information: type=1, code=1
 Application: junos-icmp6-all
 IP protocol: 58
 ICMP Information: type=255, code=0

```

## show security nat source summary

|                                 |                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Output Fields</b>            | Table 403 lists the output fields for the <b>show security nat source summary</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                |

**Table 496: show security nat source summary Output Fields**

| Field Name                   | Field Description                                              |
|------------------------------|----------------------------------------------------------------|
| Total source nat pool number | Number of source NAT pools.                                    |
| Pool name                    | Name of the source address pool.                               |
| Address range                | IP address or IP address range for the pool.                   |
| Routing Instance             | Name of the routing instance.                                  |
| PAT                          | Whether Port Address Translation (PAT) is enabled (yes or no). |
| Total Address                | Number of IP addresses that are in use.                        |
| Total source nat rule number | Number of source NAT rules.                                    |

Table 496: show security nat source summary Output Fields (*continued*)

| Field Name                                        | Field Description                                                 |
|---------------------------------------------------|-------------------------------------------------------------------|
| Total port number usage for port translation pool | Number of ports assigned to the pool.                             |
| Maximum port number for port translation pool     | Maximum number of NAT or PAT transactions done at any given time. |

## Sample Output

### show security nat source summary

```

user@host> show security nat source summary logical-system all

Logical system: root-logical-system
Total port number usage for port translation pool: 67108864
Maximum port number for port translation pool: 134217728

Logical system: lsys1

**Table 497: show security nat static rule Output Fields**

| Field Name                             | Field Description                                                                                                                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Static NAT rule                        | Name of the static NAT rule.                                                                                                                                                                    |
| Total referenced IPv4/IPv6 ip-prefixes | Number of IP prefixes referenced in source, destination, and static NAT rules. This total includes the IP prefixes configured directly, as address names, and as address set names in the rule. |
| Rule-set                               | Name of the rule set. Currently, you can configure 8 rules within the same rule set.                                                                                                            |
| Description                            | Description of the static NAT rule.                                                                                                                                                             |

Table 497: show security nat static rule Output Fields (*continued*)

| Field Name             | Field Description                                                                     |
|------------------------|---------------------------------------------------------------------------------------|
| Rule-Id                | Rule identification number.                                                           |
| Rule position          | Position of the rule that indicates the order in which it applies to traffic.         |
| From interface         | Name of the interface from which the packets flow.                                    |
| From routing instance  | Name of the routing instance from which the packets flow.                             |
| From zone              | Name of the zone from which the packets flow.                                         |
| Destination addresses  | Name of the destination addresses that match the rule.                                |
| Source addresses       | Name of the source addresses that match the rule.                                     |
| Host addresses         | Name of the host addresses that match the rule.                                       |
| Netmask                | Subnet IP address.                                                                    |
| Host routing-instance  | Name of the host routing instance.                                                    |
| Destination port       | Destination port numbers that match the rule. The default value is any.               |
| Source port            | Source port numbers that match the rule.                                              |
| Total static-nat rules | Number of static NAT rules.                                                           |
| Translation hits       | Number of times a translation in the translation table is used for a static NAT rule. |
| Successful sessions    | Number of successful session installations after the NAT rule is matched.             |
| Failed sessions        | Number of unsuccessful session installations after the NAT rule is matched.           |
| Number of sessions     | Number of sessions that reference the specified rule.                                 |

## Sample Output

### show security nat static rule sta-r2

```
user@host> show security nat static rule sta-r2
```

```

Static NAT rule: sta-r2 Rule-set: sta-nat
Description : The static rule sta-r2 is for the sales team
Rule-Id : 1
Rule position : 1
From zone : zone9
Destination addresses : add3
Host addresses : add4
Netmask : 24
Host routing-instance : N/A

```

```

Translation hits : 2
Successful sessions : 2
Failed sessions : 0
Number of sessions : 2

```

## Sample Output

### show security nat static rule all

```
user@host> show security nat static rule all
```

```

Static NAT rule: r1 Rule-set: rs1
 Rule-Id : 1
 Rule position : 1
 From zone : trust
 Source addresses : 40.10.10.0 - 40.10.10.3
 : addr1
 Source ports : 200 - 300
 Destination addresses : 20.1.1.0
 Host addresses : 3.3.3.0
 Netmask : 24
 Host routing-instance : N/A
 Translation hits : 4
 Successful sessions : 4
 Failed sessions : 0
 Number of sessions : 4
Static NAT rule: r2 Rule-set: rs1
 Rule-Id : 2
 Rule position : 2
 From zone : trust
 Source addresses : 40.10.10.0 - 40.10.10.255
 Destination addresses : 30.1.1.1
 Destination ports : 100 - 200
 Host addresses : 40.1.1.1
 Host ports : 300 - 400
 Netmask : 32
 Host routing-instance : N/A
 Translation hits : 4
 Successful sessions : 4
 Failed sessions : 0
 Number of sessions : 4

# Authentication and Integrated User Firewalls Feature Guide for Security Devices

## PART 68

# Overview

- [Introduction to User Authentication on page 5499](#)

# Introduction to User Authentication

- [Understanding User Authentication for Security Devices on page 5499](#)
- [Understanding the Three-Tiered User Firewall Features on page 5499](#)

## Understanding User Authentication for Security Devices

---

Firewall user authentication lets you define firewall users and create policies that require the users to authenticate themselves through one of two authentication schemes: pass-through authentication or web authentication.

User role firewall policies can be integrated with firewall authentication both to authenticate users and to retrieve username and role information. The information is mapped to the IP address of the traffic, stored in the firewall authentication table, and used for user role firewall policy enforcement.

Infranet authentication occurs when an SRX Series device acts as an Infranet Enforcer for an IC Series device. You deploy the Infranet Enforcer in front of the servers and resources that you want to protect. Authentication occurs on the IC Series device and provides policies to the Enforcer to determine whether or not to allow an endpoint access to protected resources.

## Understanding the Three-Tiered User Firewall Features

---

Juniper Networks offers three tiers of user firewall. The three features have different characteristics that are appropriate in different environments. [Figure 242](#) illustrates the relative security level of the three tiers. [Table 498](#) compares them to help you decide which best suits your implementation.

Figure 242: Three-Tiered User Firewall Features

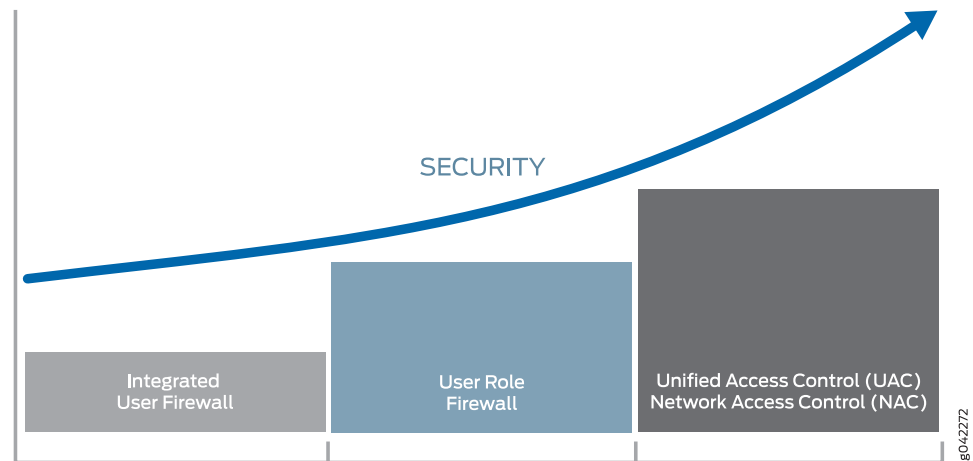

Table 498 describes the basic differences among the three features.

Table 498: Comparison of User Firewall Features

|                          | Integrated User Firewall                                                                                                                                                | User Role Firewall                                                                                                   | Unified Access Control (UAC) Network Access Control (NAC)                                                                                  |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Authentication           | Passive authentication—Does not interact with client directly; polls the Active Directory for login information.                                                        | Active authentication—Queries the client.                                                                            | End-to-end—Authenticates the user down to the access level where user connects, whether wired or wireless.                                 |
| Extent of Authentication | Best effort.                                                                                                                                                            | Deterministic—User is identified.                                                                                    | Deterministic—User is identified.                                                                                                          |
| Where Enforced           | Enforced at firewall.                                                                                                                                                   | Enforced at firewall.                                                                                                | Enforced at access (switch or WiFi) and firewall.                                                                                          |
| Devices Needed           | SRX Series                                                                                                                                                              | SRX Series and MAG Series                                                                                            | SRX Series and MAG Series                                                                                                                  |
| Ideal Environments       | <ul style="list-style-type: none"> <li>Needs visibility into who is accessing the SRX Series</li> <li>Small-to-medium business</li> <li>Low-scale deployment</li> </ul> | <ul style="list-style-type: none"> <li>Security-conscious environments</li> <li>Scales up to 50,000 users</li> </ul> | <ul style="list-style-type: none"> <li>Large-scale deployment</li> <li>Interface for Metadata Access Points (IF-MAP) federation</li> </ul> |

- You can upgrade to a higher tier if you choose. From integrated user firewall, simply add the MAG Series to get user role firewall. From there, add licenses to get full UAC NAC.
- The three offerings provide maximum flexibility; they are supported on all SRX Series hardware platforms.

## Firewall User Authentication Overview

---

A firewall user is a network user who must provide a username and password for authentication when initiating a connection across the firewall. Junos OS enables administrators to restrict and permit firewall users to access protected resources (different zones) behind a firewall based on their source IP address and other credentials.

**NOTE:** Junos OS also supports the administrator and Point-to-Point Protocol (PPP) user types.

After you define firewall users, you can create a policy that requires the users to authenticate themselves through one of two authentication schemes:

- **Pass-Through Authentication**—A host or a user from one zone tries to access resources on another zone. You must use an FTP, a Telnet, an HTTP client or HTTPS to access the IP address of the protected resource and to get authenticated by the firewall. The device uses FTP, Telnet, HTTP, or HTTPS to collect username and password information, and subsequent traffic from the user or host is allowed or denied based on the result of this authentication. When the device is using HTTPS server, and after the authentication is done, the subsequent traffic from the user is always terminated whether the authentication is successful or not.
- **Web Authentication**—Users try to connect, using HTTP or HTTPS, to an IP address on the device that is enabled for Web authentication; in this scenario, you do not use HTTP or HTTPS to get to the IP address of the protected resource. You are prompted for the username and password that are verified by the device. Subsequent traffic from the user or host to the protected resource is allowed or denied based on the result of this authentication.

A message is displayed to inform you about the successful Web authentication. After successful authentication, the browser launches your original destination URL without your needing to retype the URL.

The following message is displayed:

Redirecting to the original url, please wait

## Obtaining Username and Role Information Through Firewall Authentication

---

User role firewall policies can be integrated with firewall authentication both to authenticate users and to retrieve username and role information. The information is mapped to the IP address of the traffic, stored in the firewall authentication table, and used for user role firewall policy enforcement.

The following CLI statements configure firewall authentication for user role firewall enforcement.

1. If not already established, define the access profile to be used for firewall authentication. You can skip this step if an existing access profile provides the client data needed for your implementation.

The access profile is configured in the **[edit access profile]** hierarchy as with other firewall authentication types. It defines clients as firewall users and the passwords that provide them access. Use the following command to define a profile and add client names and passwords for firewall authentication.

```
set access profile profile-name client client-name firewall-user password pwd
```

2. If HTTPS traffic is expected, define the access profile to be used for SSL termination services. You can skip this step if an existing SSL termination profile provides the services needed for your implementation.

The SSL termination profile is configured in the **[edit services ssl]** hierarchy.

```
set services ssl termination profile ssl-profile-name server-certificate certificate-type
```

3. Enable the firewall authentication table as an authentication source.

```
set security user-identification authentication-source firewall-authentication priority priority
```

The priority value determines the sequence in which authentication sources are checked. The default value is 150 for the firewall authentication table. (It is 100 for the local authentication table and 200 for the Unified Access Control authentication table.) By default, the local authentication table is checked first, the firewall authentication table is next, and the UAC authentication table is third if it is enabled. You can change this sequence by changing the priority value of one or more of the tables.

4. Configure policies that permit traffic for user firewall authentication.

```
edit security policies from-zone zone to-zone zone policy policy-name
set match source-identity unauthenticated-user
set then permit firewall-authentication user-firewall access-profile profile-name
ssl-termination-profile profile-name
```

When unauthenticated traffic is permitted for firewall authentication, the user is authenticated based on the access profile configured in this statement. The **ssl-termination-profile** option is needed only for HTTPS traffic.

By specifying the authentication type **user-firewall**, the firewall authentication table is propagated with the IP address, username, and any group names associated with the authenticated user. (Group names from firewall authentication are interpreted as roles by the user role firewall.) Any further traffic from this IP address will match the IP address in the firewall authentication table, and not require authentication. The associated username and roles are retrieved from the table for use as potential match criteria in subsequent security policies.

## Understanding Pass-Through Authentication

---

Pass-through user authentication is a form of active authentication because the user is prompted to enter a username and password when pass-through authentication is invoked. If the user's identity is validated, the user is allowed to pass through the firewall and gain access to the requested resources.

When a user attempts to initiate an HTTP, an HTTPS, an FTP, or a Telnet connection request that has a policy requiring authentication, the device intercepts the request and prompts the user to enter a username and password. Depending on the configuration, the device validates the username and password by checking them against those stored in the local database or on an external authentication server.

If you use an external authentication server, after the user's credentials are collected, they are processed through firewall user authentication. The following external authentication servers are supported:

- RADIUS authentication and authorization (compatible with Juniper Steel-Belted Radius servers)

You can use an external RADIUS server, if, in addition to authentication, you want to obtain authorization information about the user's access rights, that is, what the user can do on the network.

- LDAP authentication only (supports LDAP version 3 compatible with Windows AD)
- SecurID authentication only (uses an RSA SecurID external authentication server)

A firewall user is a network user who must provide a username and password for authentication when initiating a connection across the firewall

```
user@host# set access profile profile1 client joan firewall-user password talk
```

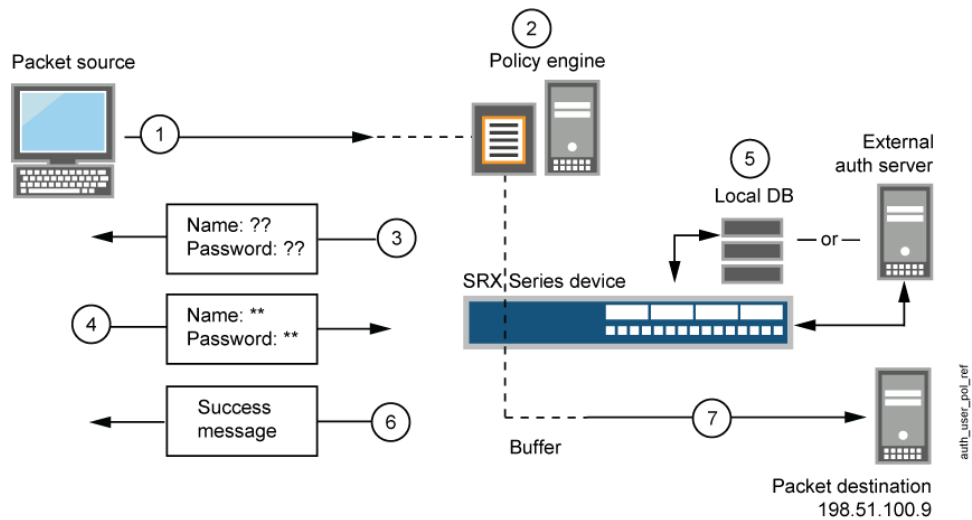

You can put several user accounts together to form a user group, which you can store on the local database or on a RADIUS, an LDAP, or a SecurID server. When you reference

an authentication user group and an external authentication server in a policy, the traffic matching the policy provokes an authentication check.

**NOTE:** You use `family inet` to assign an IPv4 address. You use `family inet6` to assign an IPv6 address. An interface can be configured with both an IPv4 and an IPv6 address. For the sake of brevity, these examples use IPv4 addresses only.

**Figure 243: Policy Lookup for a User**

The steps in Figure 243 are as follows:

1. A client user sends an FTP, an HTTP, an HTTPS or a Telnet packet to 1.2.2.2.
2. The device intercepts the packet, notes that its policy requires authentication from either the local database or an external authentication server, and buffers the packet.
3. The device prompts the user for login information through FTP, HTTP, HTTPS or Telnet.
4. The user replies with a username and password.
5. The device either checks for an authentication user account on its local database or it sends the login information to the external authentication server as specified in the policy.
6. Finding a valid match (or receiving notice of such a match from the external authentication server), the device informs the user that the login has been successful.
7. For HTTP or Telnet traffic, the device forwards the packet from its buffer to its destination IP address 1.2.2.2. However, for FTP traffic, after successful authentication the device closes the session and the user must reconnect to the FTP server at IP address 1.2.2.2.

After the device authenticates a user at a particular source IP address, it subsequently permits traffic—as specified in the policy requiring authentication through pass

through—from any other user at that same address. This might be the case if the user originates traffic from behind a NAT device that changes all original source addresses to a single translated address.

**NOTE:** The pass-through user authentication method is recommended in situations when security has a higher priority than convenience. This authentication method applies only to the session and child sessions matching the policy that triggered it. You can apply this method on Internet-facing links, if used with caution.

## Example: Configuring Pass-Through Authentication

This example shows how to configure pass-through authentication to authenticate firewall users. A firewall user is a network user who must provide a username and password when initiating a connection across the firewall.

Pass-through authentication allows SRX Series administrators to restrict users who attempt to access a resource in another zone using FTP, Telnet, or HTTP. If the traffic matches a security policy whose action is pass-through authentication, the user is required to provide login information.

- [Requirements on page 5511](#)
- [Overview on page 5511](#)
- [Configuration on page 5512](#)
- [Verification on page 5516](#)

## Requirements

Before you begin, define firewall users. See [Firewall User Authentication Overview](#).

This example uses the following hardware and software components:

- SRX Series device
- firewall user's system
- packet destination system

## Overview

The pass-through authentication process is triggered when a client, referred to as a firewall user, attempts to initiate an FTP, a Telnet, or an HTTP session to access a resource in another zone. The SRX Series firewall acts as a proxy for an FTP, a Telnet, or an HTTP

server so that it can authenticate the firewall user before allowing him access to the actual FTP, Telnet, or HTTP server behind the firewall.

If traffic generated from a connection request sent by a firewall user matches a security policy rule bidirectionally and that rule specifies pass-through firewall authentication as the action of its **then** clause, the SRX Series device requires the firewall user to authenticate to a Junos OS proxy server.

If the authentication is successful, subsequent traffic from the same source IP address is automatically allowed to pass through the SRX Series device if the traffic matches the security policy tuples.

Figure 244 shows the topology used in this example.

Figure 244: Configuring Pass-Through Firewall Authentication

**NOTE:** Although the topology shows use of an external server, it is not covered in the configuration. It is outside the scope of this example.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces ge-0/0/1 unit 0 family inet address 20.20.20.1/24
set interfaces ge-5/0/0 unit 0 family inet address 30.30.30.1/24
set access profile FWAUTH client FWClient1 firewall-user password pwd
set access firewall-authentication pass-through default-profile FWAUTH
set access firewall-authentication pass-through telnet banner success "WELCOME TO JUNIPER TELNET SESSION"
set security zones security-zone UT-ZONE host-inbound-traffic system-services all
set security zones security-zone UT-ZONE interfaces ge-0/0/1.0 host-inbound-traffic protocols all
set security zones security-zone T-ZONE host-inbound-traffic system-services all
set security zones security-zone T-ZONE interfaces ge-5/0/0.0 host-inbound-traffic protocols all
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 match source-address any
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 match destination-address any
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 match application junos-telnet

```

```
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 then permit
firewall-authentication pass-through client-match FWClient1
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure pass-through authentication:

1. Configure two interfaces and assign IP addresses to them.

**NOTE:** For this example, it is optional to assign two addresses to the interfaces.

[edit]

```
user@host# set interfaces ge-0/0/1 unit 0 family inet address 20.20.20.1/24
user@host# set interfaces ge-5/0/0 unit 0 family inet address 30.30.30.1/24
```

2. Create the FWAUTH access profile for the FWClient1 user, specify the user's password, and define a success banner for Telnet sessions.

[edit access]

```
user@host# set access profile FWAUTH client FWClient1 firewall-user password
pwd
user@host# set firewall-authentication pass-through default-profile FWAUTH
user@host# set firewall-authentication pass-through telnet banner success
"WELCOME TO JUNIPER TELNET SESSION"
```

3. Configure security zones.

**NOTE:** For this example, it is optional to configure a second interface for a security zone.

[edit security zones]

```
user@host# set security-zone UT-ZONE host-inbound-traffic system-services all
user@host# set security-zone UT-ZONE interfaces ge-0/0/1.0 host-inbound-traffic
protocols all
user@host# set security-zone T-ZONE host-inbound-traffic system-services all
user@host# set security-zone T-ZONE interfaces ge-5/0/0.0 host-inbound-traffic
protocols all
```

4. Assign security policy P1 to the security zones.

[edit security policies]

```
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 match
source-address any
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 match
destination-address any
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 match application
junos-telnet
```

```
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 then permit
firewall-authentication pass-through client-match FWClient1
```

5. Use Telnet to authenticate the FWClient1 firewall user to host2.

```
user@FWClient1# run telnet 30.30.30.2
Trying 30.30.30.2...
Connected to 30.30.30.2.
Escape character is '^]'.
Firewall User Authentication
Username: FWClient1
Password:***
WELCOME TO JUNIPER TELNET SESSION
Host1 (ttyp0)
login: user
Password:
--- JUNOS 10.1R1.1 built 2009-10-12 13:30:18 UTC
%
```

**Results** From configuration mode, confirm your configuration by entering these commands.

- show interfaces
- show access
- show security zones
- show security policies

If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, the output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@host# show interfaces
ge-0/0/1 {
 unit 0 {
 family inet {
 address 20.20.20.1/24;
 }
 }
}
ge-5/0/0 {
 unit 0 {
 family inet {
 address 30.30.30.1/24;
 }
 }
}
...

user@host# show access
profile FWAUTH {
 authentication-order password;
 client FWClient1 {
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
 }
}
```

```

 }
 }
 firewall-authentication {
 pass-through {
 default-profile FWAUTH;
 telnet {
 banner {
 success "WELCOME TO JUNIPER TELNET SESSION";
 }
 }
 }
 }
}

user@host# show security zones
security-zone UT-ZONE {
 host-inbound-traffic {
 system-services {
 all;
 }
 }
 interfaces {
 ge-0/0/1.0 {
 host-inbound-traffic {
 protocols {
 all;
 }
 }
 }
 }
}
security-zone T-ZONE {
 host-inbound-traffic {
 system-services {
 all;
 }
 }
 interfaces {
 ge-5/0/0.0 {
 host-inbound-traffic {
 protocols {
 all;
 }
 }
 }
 }
}

user@host# show security policies
...
from-zone UT-ZONE to-zone T-ZONE {
 policy P1 {
 match {
 source-address any;
 destination-address any;
 application junos-telnet;
 }
 then {
 permit {

```

```

 firewall-authentication {
 pass-through {
 client-match FWClient1;
 }
 }
 }
}

```

If you are done configuring the device, enter `commit` from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Firewall User Authentication and Monitoring Users and IP Addresses in the Authentication Table on page 5516](#)

### Verifying Firewall User Authentication and Monitoring Users and IP Addresses in the Authentication Table

**Purpose** Display firewall authentication user history and verify the number of firewall users who successfully authenticated and firewall users who failed to log in.

**Action** From operational mode, enter these **show** commands:

```

user@host> show security firewall-authentication history
History of firewall authentication data:
Authentications: 2
Id Source Ip Date Time Duration Status User
1 20.20.20.2 2010-10-12 21:24:02 0:00:24 Failed FWClient1
2 20.20.20.2 2010-10-12 21:24:48 0:00:22 Success FWClient1

```

```

user@host> show security firewall-authentication history identifier 1
Username: FWClient1
Source IP: 20.20.20.2
Authentication state: Success
Authentication method: Pass-through using Telnet

## Example: Configuring HTTPS Traffic to Trigger Pass-Through Authentication

This example shows how to configure HTTPS traffic to trigger pass-through authentication. HTTPS is more secure than HTTP, so it has become more popular and is more widely used.

- [Requirements on page 5517](#)
- [Overview on page 5518](#)
- [Configuration on page 5519](#)
- [Verification on page 5523](#)

### Requirements

This example uses the following hardware and software components:

- A high-end SRX Series device
- Two personal computers (PCs) running Linux and Open SSL. One PC acts as a client and another as an HTTPS server. The two PCs are used to create key files and to send traffic.
- Junos OS Release 12.1X44-D10 or later for SRX Series Services Gateways

Before you begin:

An SRX Series device has to decode HTTPS traffic to trigger pass-through authentication. Then, SSL termination proxy creates and installs a private key file and a certification file. The following list describes the steps to create and install a private key file and a certification key file.

**NOTE:** If you have an official .crt file and .key file, then you can directly upload and install the files on the SRX Series device. If you do not have a .crt file and .key file, follow the procedure to create and install the files. Instructions specified in Step 1 and Step 2 must be run on a personal computer (PC) which has Linux and OpenSSL installed. Instructions specified in Step 3 and Step 4 must be run in operational mode.

To create and install a private key file and a certification file:

1. On a PC create the .key file.

```
openssl genrsa -out /tmp/device.key 1024
```

2. On a PC create the .crt file.

```
openssl req -new -x509 -days 365 -key /tmp/server.key -out /tmp/device.crt -subj
"/C=CN/ST=BJ/L=BJ/O=JNPR/OU=CNRD/CN=2.2.2.10/emailAddress=device@example.net"
```

3. Upload the .key and .crt files to an SRX Series device and install the files on the device using the following command from operational mode:

```
user@host> request security pki local-certificate load filename /var/tmp/device.crt
key /var/tmp/device.key certificate-id device
```

## Overview

Firewall authentication initiates a secure connection to be established across two devices. A network user must provide a username and password for authentication when initiating a connection across the firewall. Firewall authentication supports HTTPS traffic for pass-through authentication.

In this example, HTTPS traffic is used to trigger pass-through authentication because HTTPS is more secure than HTTP. For HTTPS traffic to trigger pass-through authentication you must first configure the SSL termination profile.

[Figure 245](#) shows an example of pass-through authentication using HTTPS traffic. In this example, a host or a user from an untrust zone tries to access resources on the trust zone. The SRX Series device uses HTTPS to collect the username and password information. Subsequent traffic from the host or user is allowed or denied based on the result of this authentication.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces ge-0/0/0 unit 0 family inet address 1.1.0/24
set interfaces ge-1/0/0 unit 0 family inet address 192.168.1.0/24
set security policies from-zone trust to-zone untrust policy p1 match source-address any
set security policies from-zone trust to-zone untrust policy p1 match destination-address
 any
set security policies from-zone trust to-zone untrust policy p1 match application any
set security policies from-zone trust to-zone untrust policy p1 then permit
 firewall-authentication pass-through access-profile local_pf
set security policies from-zone trust to-zone untrust policy p1 then permit
 firewall-authentication pass-through ssl-termination-profile ssl_pf
set security policies from-zone trust to-zone untrust policy p1 then log session-init
set security policies from-zone trust to-zone untrust policy p1 then log session-close
set security zones security-zone trust interfaces ge-0/0/0.0 host-inbound-traffic
 system-services all
set security zones security-zone trust interfaces ge-0/0/0.0 host-inbound-traffic protocols
 all
set security zones security-zone untrust interfaces ge-1/0/0.0 host-inbound-traffic
 system-services all
set security zones security-zone untrust interfaces ge-1/0/0.0 host-inbound-traffic protocols
 all
set access profile local_pf client user1 firewall-user password user1
set access firewall-authentication pass-through default-profile local_pf
set services ssl termination profile ssl_pf server-certificate device

```

#### Step-by-Step Procedure

To configure HTTPS traffic to trigger pass-through authentication:

1. Configure interfaces and assign IP addresses.  

```

[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet address 1.1.0/24
user@host# set ge-1/0/0 unit 0 family inet address 192.168.1.0/24

```
2. Configure security policies to permit firewall authenticated traffic from zone trust to zone untrust.  

```

[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 then permit
 firewall-authentication pass-through access-profile local_pf
user@host# set from-zone trust to-zone untrust policy p1 then permit
 firewall-authentication pass-through ssl-termination-profile ssl_pf

```
3. Specify a policy action to take when a packet matches the criteria.  

```

[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 match source-address
 any
user@host# set from-zone trust to-zone untrust policy p1 match destination-address
 any
user@host# set from-zone trust to-zone untrust policy p1 match application any
user@host# set from-zone trust to-zone untrust policy p1 then log session-init
user@host# set from-zone trust to-zone untrust policy p1 then log session-close

```
4. Configure security zones and assign interfaces.  

```

[edit security zones]
user@host# set security-zone trust interfaces ge-0/0/0.0 host-inbound-traffic
 protocols all

```

```
user@host# set security-zone trust interfaces ge-0/0/0.0 host-inbound-traffic
system-services all
```

5. Configure application services for zones.

```
[edit security zones]
user@host# set security-zone trust host-inbound-traffic system-services all
protocols all
user@host# set security-zone untrust host-inbound-traffic system-services all
protocols all
```

6. Create an access profile and configure the client as a firewall user and set the password.

```
[edit access]
user@host# set profile local_pf client user1 firewall-user password user1
```

7. Configure the type of firewall and the default profile name where the authentication settings are defined.

```
[edit access]
user@host# set firewall-authentication pass-through default-profile local_pf
```

8. Configure the SSL termination profile and enter a local certificate identifier name.

```
[edit services]
user@host# set ssl termination profile ssl_pf server-certificate device
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security policies**, **show security zones**, **show access**, and **show services ssl termination** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show interfaces
...
interfaces
 ge-0/0/0 {
 unit 0 {
 family inet {
 address 1.1.1.0/24;
 }
 }
 }
 ge-1/0/0 {
 unit 0 {
 family inet {
 address 192.168.1.0/24;
 }
 }
 }
}

user@host# show security policies
...
policies
 from-zone trust to-zone untrust {
 policy p1 {
 match {
 source-address any;
```

```
 destination-address any;
 application any;
 }
 then {
 permit {
 firewall-authentication {
 pass-through {
 access-profile local_pf;
 ssl-termination-profile ssl_pf;
 }
 }
 }
 log {
 session-init;
 session-close;
 }
 }
}
}
```

user@host# show security zones

```
...
zones {
 security-zone trust {
 interfaces {
 ge-0/0/0.0 {
 host-inbound-traffic {
 system-services {
 all;
 }
 protocols {

 }
 }
 }
 }
 }
 security-zone untrust {
 interfaces {
 ge-1/0/0.0 {
 host-inbound-traffic {
 system-services {
 all;
 }
 protocols {
 all;
 }
 }
 }
 }
 }
}
```

user@host# show access

```
...
access {
 profile local_pf {
```

```

client user1 {
 firewall-user {
 password "user1";
 }
}
firewall-authentication {
 pass-through {
 default-profile local_pf;
 }
}

user@host# show services ssl termination
...
services {
 ssl {
 termination {
 profile ssl_pf {
 server-certificate device;
 }
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying the Configuration

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Verify that the configuration is correct.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Action</b>  | From operational mode, enter the <b>show security firewall-authentication users</b> command for identifier 1.                                                                                                                                                                                                                                                                                                                       |
|                | <pre> user@host&gt; show security firewall-authentication users identifier 1 Username: user1 Source IP: 192.168.1.0/24 Authentication state: Success Authentication method: Pass-through using HTTPS Age: 0 Access time remaining: 10 Lsys: root-logical-system Source zone: trust Destination zone: untrust Access profile: local_pf Interface Name: ge-0/0/0.0 Bytes sent by this user: 946 Bytes received by this user: 0 </pre> |
| <b>Meaning</b> | The <b>show security firewall-authentication users</b> command displays the firewall authentication user information for the specified identifier. If the output displays Pass-through using HTTPS in the Authentication method field and Success in the Authentication state field, then your configuration is correct.                                                                                                            |

# Configuring Web Authentication

- [Understanding Web Authentication on page 5525](#)
- [Example: Configuring Web Authentication on page 5527](#)
- [Example: Configuring HTTPS Traffic to Trigger Web Authentication on page 5534](#)

## Understanding Web Authentication

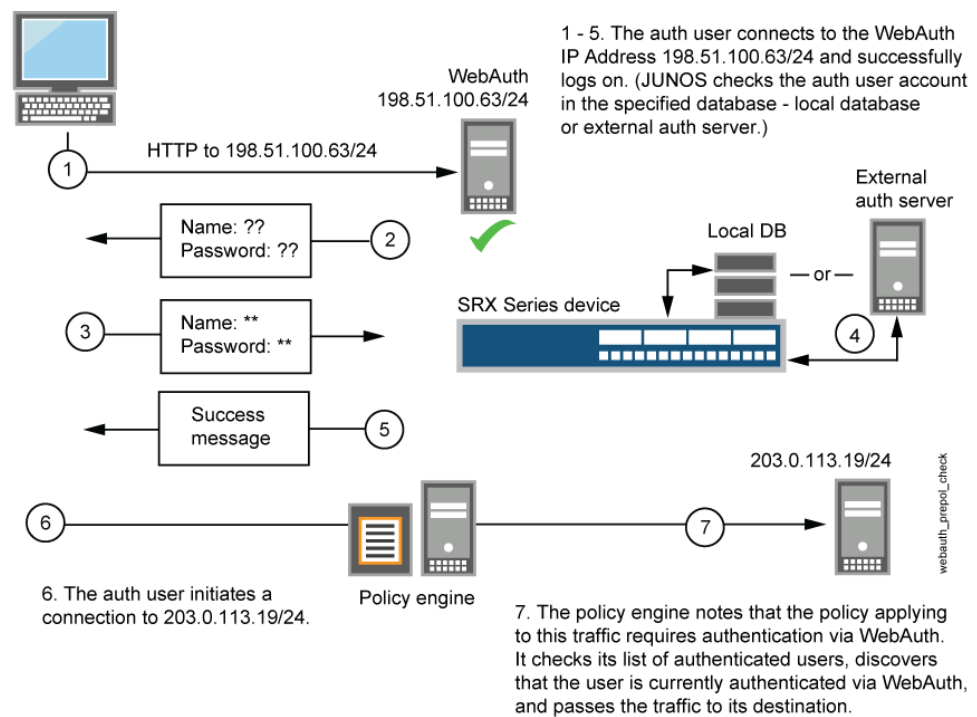

---

Web authentication is an alternative to pass-through user authentication. Instead of pointing to the resource that you want to connect to from your client browser, you point the browser to an IP address on the device that is enabled for Web authentication. This initiates an HTTP session to the IP address hosting the Web authentication feature on the device. The device then prompts you for your username and password and caches the result in the device. Later, when traffic encounters a Web authentication policy, you are allowed or denied access based on the prior Web authentication results, as shown in [Figure 246](#).

**NOTE:** You use `family inet` to assign an IPv4 address. You use `family inet6` to assign an IPv6 address. An interface can be configured with both an IPv4 and an IPv6 address. For the sake of brevity, these examples use IPv4 addresses only.

Figure 246: Web Authentication Example

Follow these Web authentication guidelines:

- You can leave the default Web authentication server as the local database or you can choose an external authentication server for the role. The default Web authentication profile determines if the user authenticates using the local database or the external authentication server. An access profile stores usernames and passwords of users or points to external authentication servers where such information is stored.
- The Web authentication address must be in the same subnet as the interface that you want to use to host it. For example, if you want authentication users to connect using Web authentication through ethernet3, which has IP address 1.1.1.1/24, then you can assign Web authentication an IP address in the 1.1.1.0/24 subnet.
- You can put a Web authentication address in the same subnet as the IP address of any physical interface or virtual security interface (VSI). (For information about different types of interfaces, see [“Security Zones and Interfaces Overview” on page 1029.](#))
- You can put Web authentication addresses on multiple interfaces.
- After a device authenticates a user at a particular source IP address, it subsequently permits traffic—as specified in the policy requiring authentication through Web authentication—from any other user at that same address. This might be the case if the user originates traffic from behind a NAT device that changes all original source addresses to a single translated address.
- With Web authentication enabled, any HTTP traffic to the IP address will get the Web authentication login page instead of the administrator login page. Disabling this option

will show the administrator login page (assuming that **[system services web-management HTTP]** is enabled).

- We recommend that you have a separate primary or preferred IP address, if an address is used for Web authentication.

**NOTE:** The Web authentication method is recommended in situations when the client devices are immediately adjacent to the security gateway and there is high assurance that the client devices are not multiuser hosts. This authentication method is best applied to wireless links and DMZ, or conference room links.

## Example: Configuring Web Authentication

This example shows how to enable Web authentication and set up a policy that allows access to a user when traffic encounters a policy that has Web authentication enabled.

- [Requirements on page 5527](#)
- [Overview on page 5527](#)
- [Configuration on page 5528](#)
- [Verification on page 5532](#)

### Requirements

Before you begin:

- Define firewall users. See “[Firewall User Authentication Overview](#)” on page 5505.
- Add the Web authentication HTTP flag under the interface's address hierarchy to enable Web authentication.

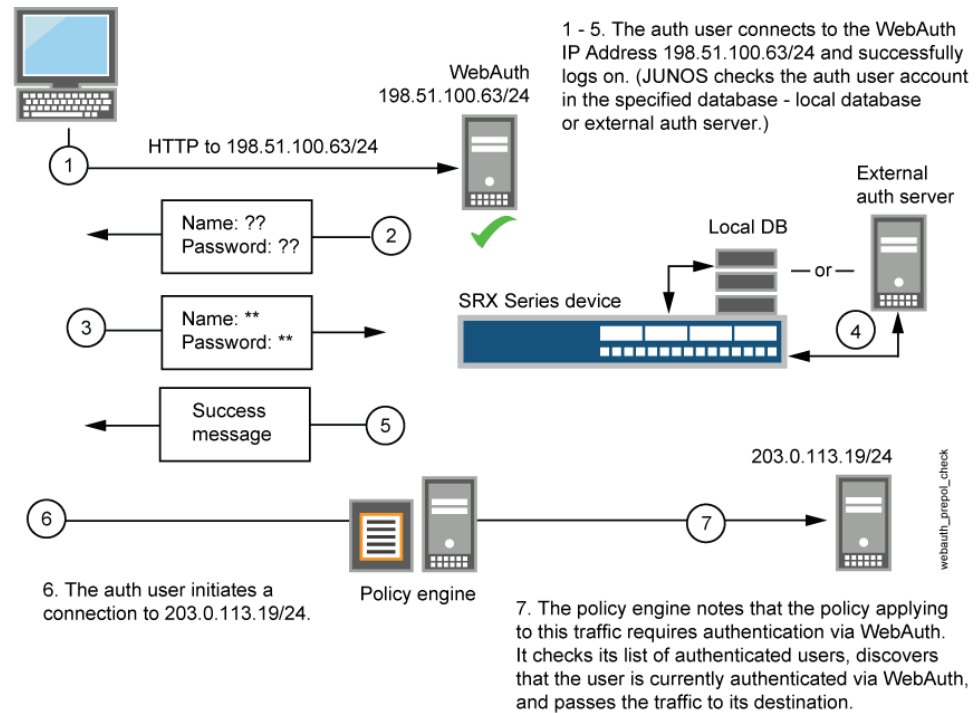

### Overview

To enable Web authentication, you must specify the IP address of the device hosting the HTTP session. These settings are used if the firewall user accessing a protected resource wants to be authenticated by directly accessing the webserver or Web authentication. The following instructions show how to set up a policy that allows access to the FWClient1 user when traffic encounters a policy that has Web authentication enabled (Policy-W). (See [Figure 247](#).) In this example, FWClient1 has already authenticated through the Web authentication login page.

The FWClient1 firewall user does the following to get authenticated:

- a. Points the browser to the Web authentication IP (20.20.20.1) to get authenticated first
- b. Starts traffic to access resources specified by the policy-W policy

Figure 247: Web Authentication Example

When you configure the device as described in these instructions and the user successfully authenticates, the screen illustrated in Figure 248 appears.

Figure 248: Web Authentication Success Banner

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/1 unit 0 family inet address 20.20.20.1/24
set interfaces ge-0/0/1 unit 0 family inet address 20.20.20.3/24 web-authentication http
set interfaces fe-5/0/0 unit 0 family inet address 30.30.30.1/24
set access profile WEBAUTH client FWClient1 firewall-user password pwd
set access firewall-authentication web-authentication default-profile WEBAUTH
set access firewall-authentication web-authentication banner success "WEB AUTH LOGIN SUCCESS"
set security zones security-zone UT-ZONE host-inbound-traffic system-services all
set security zones security-zone UT-ZONE interfaces ge-0/0/1.0 host-inbound-traffic protocols all
```

```

set security zones security-zone T-ZONE host-inbound-traffic system-services all
set security zones security-zone T-ZONE interfaces ge-5/0/0.0 host-inbound-traffic protocols
all
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 match source-address any
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 match destination-address
any
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 match application any
set security policies from-zone UT-ZONE to-zone T-ZONE policy P1 then permit
firewall-authentication web-authentication client-match FWClient1
set system services web-management http interface ge-0/0/1.0

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure Web authentication:

1. Configure two interfaces and assign IP addresses to them.

**NOTE:** For this example, it is optional to assign two addresses to the interfaces.

[edit]

```
user@host# set interfaces ge-0/0/1 unit 0 family inet address 20.20.20.1/24
```

```
user@host# set interfaces ge-0/0/1 unit 0 family inet address 20.20.20.3/24
web-authentication http
```

```
user@host# set interfaces fe-5/0/0 unit 0 family inet address 30.30.30.1/24
```

2. Create the WEBAUTH access profile for the FWClient1 user, specify the user's password, and define a success banner.

[edit access]

```
user@host# set profile WEBAUTH client FWClient1 firewall-user password pwd
```

```
user@host# set firewall-authentication web-authentication default-profile
WEBAUTH
```

```
user@host# set firewall-authentication web-authentication banner success "WEB
AUTH LOGIN SUCCESS"
```

3. Configure security zones.

**NOTE:** For this example, it is optional to configure a second interface for a security zone.

[edit security zones]

```
user@host# set security-zone UT-ZONE host-inbound-traffic system-services all
```

```
user@host# set security-zone UT-ZONE interfaces ge-0/0/1.0 host-inbound-traffic
protocols all
```

```
user@host# set security-zone T-ZONE host-inbound-traffic system-services all
```

```
user@host# set security-zone T-ZONE interfaces ge-5/0/0.0 host-inbound-traffic
protocols all
```

4. Assign security policy P1 to the security zones.

```
[edit security policies]
```

```
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 match
source-address any
```

```
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 match
destination-address any
```

```
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 match application
any
```

```
user@host# set from-zone UT-ZONE to-zone T-ZONE policy P1 then permit
firewall-authentication web-authentication client-match FWClient1
```

5. Activate the HTTP daemon on your device.

```
[edit]
```

```
user@host# set system services web-management http interface ge-0/0/1.0
```

**Results** From configuration mode, confirm your configuration by entering these commands:

- **show interfaces**
- **show access**
- **show security zones**
- **show security policies**
- **show system services**

If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@host# show interfaces
...
}
ge-0/0/1{
 unit 0 {
 family inet {
```

```

 address 20.20.20.1/24 {
 address 20.20.20.3/24 {
 web-authentication http;
 }
 }
}
fe-5/0/0 {
 unit 0 {
 family inet {
 address 30.30.30.1/24;
 }
 }
}
...

user@host# show access
profile WEBAUTH {
 client FWClient1 {
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
 }
}

 }
 }
 }
 }
}
security-zone T-ZONE {
 host-inbound-traffic {
 system-services {
 all;
 }
 }
 interfaces {
 ge-5/0/0.0 {

```

```

 host-inbound-traffic {
 protocols {
 all;
 }
 }
 }
}

user@host# show security policies
...
from-zone UT-ZONE to-zone T-ZONE {
 policy P1 {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit {
 firewall-authentication {
 web-authentication {
 client-match FWClient1;
 }
 }
 }
 }
 }
}

user@host# show system services
...
ftp;
ssh;
telnet;
web-management {
 http {
 interface g-0/0/1.0;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Firewall User Authentication and Monitoring Users and IP Addresses in the Authentication Table on page 5532](#)

### Verifying Firewall User Authentication and Monitoring Users and IP Addresses in the Authentication Table

**Purpose** Display firewall authentication user history and verify the number of firewall users who successfully authenticated and firewall users who failed to log in.

**Action** From operational mode, enter these **show** commands:

```

user@host> show security firewall-authentication history
user@host> show security firewall-authentication history identifier 1
user@host> show security firewall-authentication users
user@host> show security firewall-authentication users identifier 3

user@host> show security firewall-authentication history
History of firewall authentication data:
Authentications: 1
Id Source Ip Date Time Duration Status User
5 20.20.20.2 2010-04-24 01:08:57 0:10:30 Success FWClient1

user@host> show security firewall-authentication history identifier 1
Username: FWClient1
Source IP: 20.20.20.2
Authentication state: Success
Authentication method: Web-authentication
Access start date: 2010-10-12
Access start time: 21:24:02

## Example: Configuring HTTPS Traffic to Trigger Web Authentication

This example shows how to configure HTTPS traffic to trigger Web authentication. HTTPS traffic is used to trigger Web authentication because HTTPS is more secure than HTTP, so it becomes more popular and is most widely used.

- [Requirements on page 5534](#)
- [Overview on page 5535](#)
- [Configuration on page 5535](#)
- [Verification on page 5538](#)

### Requirements

Before you begin:

This example uses the following hardware and software components:

- SRX high-end device
- Two personal computers with Linux and Open SSL installed. One PC acts as a client and another as an HTTPS server. The two PCs are used to create key files and to send traffic.
- Junos OS Release 12.1X44-D10 or later for SRX Series Services Gateways

An SRX Series device has to decode the HTTPS traffic to trigger Web authentication. The following list describes the steps to create and install a private key file and a certification key file.

**NOTE:** If you have an official .crt file and .key file, then you can directly upload and install the files on the SRX Series device. If you do not have .crt file and .key file, then follow the procedure to create and install the files. Instructions specified in Step 1 and Step 2 must be run on a personal computer (PC) which has Linux and OpenSSL installed. Instructions specified in Step 3 and Step 4 must be run in operational mode.

1. From the PC, create the .key file.

```
openssl genrsa -out /tmp/device.key 1024
```

2. From the PC, create the .crt file.

```
openssl req -new -x509 -days 365 -key /tmp/server.key -out /tmp/device.crt -subj
"/C=CN/ST=BJ/L=BJ/O=JNPR/OU=CNRD/CN=2.2.2.10/emailAddress=device@example.net"
```

3. From the SRX Series device, upload the .key and .crt files and install the files on the device using the following command:

```
user@host> request security pki local-certificate load filename /var/tmp/device.crt
key /var/tmp/device.key certificate-id device
```

## Overview

Firewall authentication initiates a secure connection to be established across two devices. A network user must provide a username and password for authentication when initiating a connection across the firewall. Firewall authentication supports HTTPS traffic for Web authentication.

In this example, HTTPS traffic is used to trigger Web authentication because HTTPS is more secure than HTTP.

Users try to connect, using HTTPS to an IP address on the device that is enabled for Web authentication; in this scenario, you do not use HTTPS to get to the IP address of the protected resource. You are prompted for the username and password that are verified by the device. Subsequent traffic from the user or host to the protected resource is allowed or denied based on the result of this Web authentication.

Figure 249 shows an example of Web authentication using HTTPS traffic.

**Figure 249: Web Authentication Using HTTPS Traffic**

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set system services web-management https pki-local-certificate device
```

```

set interfaces ge-0/0/0 unit 0 family inet address 1.1.1/24
set interfaces ge-0/0/0 unit 0 family inet address 1.1.11/24 web-authentication https
set interfaces ge-0/0/1 unit 0 family inet address 2.2.2/24
set security policies from-zone trust to-zone untrust policy p1 match source-address any
set security policies from-zone trust to-zone untrust policy p1 match destination-address
 any
set security policies from-zone trust to-zone untrust policy p1 match application any
set security policies from-zone trust to-zone untrust policy p1 then permit
set access profile local_pf client user1 firewall-user password user1
set access firewall-authentication web-authentication default-profile local_pf
set security policies from-zone trust to-zone untrust policy p1 then permit
 firewall-authentication web-authentication

```

### Step-by-Step Procedure

To configure HTTPS traffic to trigger Web authentication:

1. Enable web-management support to HTTPS traffic.  

```

[edit system services]
user@host# set web-management https pki-local-certificate device

```
2. Configure interfaces and assign IP addresses. Enable Web authentication at ge-0/0/0 interface.  

```

[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet address 1.1.1/24
set ge-0/0/0 unit 0 family inet address 1.1.11/24 web-authentication https
user@host# set ge-0/0/1 unit 0 family inet address 2.2.2/24

```
3. Configure security policies to permit firewall authenticated traffic from zone trust to zone untrust.  

```

[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 match source-address
 any destination-address any application any
user@host# set security policies from-zone trust to-zone untrust policy p1 then
 permit

```
4. Create an access profile, configure the client as a firewall user, and set the password.  

```

[edit access]
user@host# set profile local_pf client user1 firewall-user password user1

```
5. Configure the type of firewall authentication settings.  

```

[edit access]
user@host# set firewall-authentication web-authentication default-profile local_pf

```
6. Specify a policy action to take when a packet matches the criteria.  

```

[edit security policies]
user@host# set from-zone trust to-zone untrust policy p1 then permit
 firewall-authentication web-authentication

```

**Results** From configuration mode, confirm your configuration by entering the **show system services**, **show interfaces**, **show security policies**, and **show access** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@host# show system services

```

```

web-management {
 https {
 pki-local-certificate device;
 }
}

user@host# show interfaces
ge-0/0/0 {
 unit 0 {
 family inet {
 address 1.1.1.1/24 {
 web-authentication https;
 }
 }
 }
}
ge-0/0/1 {
 unit 0 {
 family inet {
 address 2.2.2.1/24;
 }
 }
}

user@host# show security policies
from-zone trust to-zone untrust {
 policy p1 {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit {
 firewall-authentication {
 web-authentication;
 }
 }
 }
 }
}

user@host# show access
profile local_pf {
 client user1 {
 firewall-user {
 password "user1";
 }
 }
}
firewall-authentication {
 web-authentication {
 default-profile local_pf;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying the Configuration

---

- Purpose** Verify that the configuration is correct.
- Action** From operational mode, enter the **show security firewall-authentication users identifier *identifier*** command.

## Sample Output

```
user@host> show security firewall-authentication users identifier 1
Username: user1
Source IP: 1.1.1.10
Authentication state: Success
Authentication method: Web-authentication
Age: 0
Access time remaining: 10
Lsys: root-logical-system
Source zone: N/A
Destination zone: N/A
Access profile: local_pf
Bytes sent by this user: 0
Bytes received by this user: 0
```

- Meaning** The **show security firewall-authentication users identifier *identifier*** command displays the firewall authentication user information using the identifier ID of the user. If the authentication method parameter displays Web authentication and the authentication state parameter displays success in your output then your configuration is correct.

## Understanding External Authentication Servers

---

Authentication, authorization, and accounting (AAA) servers provide an extra level of protection and control for user access in the following ways:

- Authentication determines the firewall user.
- Authorization determines what the firewall user can do.
- Accounting determines what the firewall user did on the network.

You can use authentication alone or with authorization and accounting. Authorization always requires a user to be authenticated first. You can use accounting alone, or with authentication and authorization.

Once the user's credentials are collected, they are processed using firewall user authentication, which supports the following types of servers:

- Local authentication and authorization
- RADIUS authentication and authorization (compatible with Juniper Steel-Belted Radius server)
- LDAP authentication only (supports LDAP version 3 and is compatible with Windows AD)
- SecurID authentication only (using an RSA SecurID external authentication server)

**NOTE:** Junos OS also supports administrative authentication using local, RADIUS, and TACACS+ servers.

---

This topic includes the following sections:

- [Understanding SecurID User Authentication on page 5540](#)

## Understanding SecurID User Authentication

SecurID is an authentication method that allows users to enter either static or dynamic passwords as their credentials. A dynamic password is a combination of a user's PIN and a randomly generated token that is valid for a short period of time, approximately one minute. A static password is set for the user on the SecurID server. For example, the SecurID server administrator might set a temporary static password for a user who lost his or her SecurID token.

When a user attempts to access a resource protected by a policy and SecurID is configured in the profile **authentication-order** parameter as either the only authentication mode or the first one to be used, the device forwards the user's credentials to the SecurID server for authentication. If the user enters valid values, the user is allowed access to the requested resource.

**NOTE:** The SecurID server includes a feature that presents a user with a challenge if the user provides wrong credentials repeatedly. However, Junos OS does not support the challenge feature. Instead, the SecurID server administrator must resynchronize the RSA token for the user.

For SecurID, you configure information about the Juniper Networks device on the SecurID server, and this information is exported to a file called `sdconf.rec`.

To install the `sdconf.rec` file on the device, you must use an out-of-band method such as FTP. Install the file in a directory whose files are not deleted regularly. Do not put it in a temporary directory. For example, you might install it in `/var/db/secureid/server1/sdconf.rec`.

The `sdconf.rec` file contains information that provides the Juniper Networks device with the address of the SecurID server. You do not need to configure this information explicitly when you configure the SecurID server to be used as the external authentication server.

## Example: Configuring RADIUS and LDAP User Authentication

This example shows how to configure a device for external authentication.

- [Requirements on page 5541](#)
- [Overview on page 5541](#)

- [Configuration on page 5541](#)
- [Verification on page 5544](#)

## Requirements

Before you begin, create an authentication user group.

## Overview

You can put several user accounts together to form a user group, which you can store on the local database or on a RADIUS, an LDAP, or a SecurID server. When you reference an authentication user group and an external authentication server in a policy, the traffic matching the policy provokes an authentication check.

This example shows how access profile Profile-1 is configured for external authentication. Two RADIUS servers and one LDAP server are configured in the access profile. However, the order of authentication specifies RADIUS server only, so if the RADIUS server authentication fails, then the firewall user fails to authenticate. The local database is not accessed.

**NOTE:** If the firewall clients are authenticated by the RADIUS server, then the group-membership VSA returned by the RADIUS server should contain alpha, beta, or gamma client groups in the RADIUS server configuration or in the access profile, Profile-1. Access profiles store usernames and passwords of users or point to external authentication servers where such information is stored.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set access profile Profile-1 authentication-order radius
set access profile Profile-1 client Client-1 client-group alpha
set access profile Profile-1 client Client-1 client-group beta
set access profile Profile-1 client Client-1 client-group gamma
set access profile Profile-1 client Client-1 firewall-user password pwd
set access profile Profile-1 client Client-2 client-group alpha
set access profile Profile-1 client Client-2 client-group beta
set access profile Profile-1 client Client-2 firewall-user password pwd
set access profile Profile-1 client Client-3 firewall-user password pwd
set access profile Profile-1 client Client-4 firewall-user password pwd
set access profile Profile-1 session-options client-group alpha
set access profile Profile-1 session-options client-group beta
set access profile Profile-1 session-options client-group gamma
set access profile Profile-1 session-options client-idle-timeout 255
set access profile Profile-1 session-options client-session-timeout 4
set access profile Profile-1 ldap-options base-distinguished-name
CN=users,DC=junos,DC=example,DC=net
set access profile Profile-1 ldap-options search search-filter sAMAccountName=
```

```
set access profile Profile-1 ldap-options search admin-search distinguished-name
cn=administrator,cn=users,dc=junos,dc=example,dc=net
set access profile Profile-1 ldap-options search admin-search password 1.2.3.4
set access profile Profile-1 ldap-server 3.3.3.3
set access profile Profile-1 radius-server 4.4.4.4 secret juniper
set access profile Profile-1 radius-server 4.4.4.4 retry 10
set access profile Profile-1 radius-server 5.5.5.5 secret example
```

**Step-by-Step  
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a device for external authentication:

1. Specify the RADIUS server for external authentication order.

[edit]

```
user@host# set access profile Profile-1 authentication-order radius
```

2. Configure Client1-4 firewall users and assign the Client-1 firewall user and Client-2 firewall user to client groups.

[edit access profile Profile-1]

```
user@host# set client Client-1 client-group alpha
```

```
user@host# set client Client-1 client-group beta
```

```
user@host# set client Client-1 client-group gamma
```

```
user@host# set client Client-1 firewall-user password pwd
```

```
user@host# set client Client-2 client-group alpha
```

```
user@host# set client Client-2 client-group beta
```

```
user@host# set client Client-2 firewall-user password pwd
```

```
user@host# set client Client-3 firewall-user password pwd
```

```
user@host# set client Client-4 firewall-user password pwd
```

3. Configure client groups in the session options.

[edit access profile Profile-1]

```
user@host# set session-options client-group alpha
```

```
user@host# set session-options client-group beta
```

```
user@host# set session-options client-group gamma
```

```
user@host# set session-options client-idle-timeout 255
```

```
user@host# set session-options client-session-timeout 4
```

4. Configure the IP address for the LDAP server and server options.

```
[edit access profile Profile-1]
```

```
user@host# set ldap-options base-distinguished-name
CN=users,DC=junos,DC=example,DC=net
```

```
user@host# set ldap-options search search-filter sAMAccountName=
```

```
user@host# set ldap-options search admin-search password example
```

```
user@host# set ldap-options search admin-search distinguished-name
cn=administrator,cn=users,dc=junos,dc=example,dc=net
```

```
user@host# set ldap-server 3.3.3.3
```

5. Configure the IP addresses for the two RADIUS servers.

```
[edit access profile Profile-1]
```

```
user@host# set radius-server 4.4.4.4 secret example-secret
```

```
user@host# set radius-server 4.4.4.4 retry 10
```

```
user@host# set radius-server 5.5.5.5 secret example-secret
```

**Results** From configuration mode, confirm your configuration by entering the **show access profile Profile-1** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show access profile Profile-1
authentication-order radius;
client Client-1 {
 client-group [alpha beta gamma];
 firewall-user {
 password $ABC123; ## SECRET-DATA
 }
}
client Client-2 {
 client-group [alpha beta];
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
}
client Client-3 {
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
}
client Client-4 {
 firewall-user {
```

```

 password "$ABC123"; ## SECRET-DATA
 }
}
session-options {
 client-group [alpha beta gamma];
 client-idle-timeout 255;
 client-session-timeout 4;
}
ldap-options {
 base-distinguished-name CN=users,DC=junos,DC=example,DC=net;
 search {
 search-filter sAMAccountName=;
 admin-search {
 distinguished-name
cn=administrator,cn=users,dc=junos,dc=example,dc=net;
 password "$ABC123"; ## SECRET-DATA
 }
 }
}
ldap-server {
 3.3.3.3;
}
radius-server {
 4.4.4.4 {
 secret "$ABC123"; ## SECRET-DATA
 retry 10;
 }
 5.5.5.5 {
 secret "$ABC123"; ## SECRET-DATA
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Troubleshooting with Logs on page 5544](#)

### Troubleshooting with Logs

| <b>Related Documentation</b> | <ul style="list-style-type: none"> <li>• <a href="#">Understanding External Authentication Servers on page 5539</a></li> <li>• <a href="#">Example: Configuring SecurID User Authentication on page 5545</a></li> <li>• <a href="#">Example: Deleting the SecurID Node Secret File on page 5548</a></li> </ul> |

## Example: Configuring SecurID User Authentication

This example shows how to configure SecurID as the external authentication server.

- [Requirements on page 5545](#)
- [Overview on page 5545](#)
- [Configuration on page 5545](#)
- [Verification on page 5547](#)
- [Troubleshooting on page 5548](#)

### Requirements

Before you begin, create an authentication user group.

### Overview

SecurID is an authentication method that allows users to enter either static or dynamic passwords as their credentials. A dynamic password is a combination of a user's PIN and a randomly generated token that is valid for a short period of time, approximately one minute. A static password is set for the user on the SecurID server. For example, the SecurID server administrator might set a temporary static password for a user who lost his or her SecurID token.

When a user attempts to access a resource protected by a policy and SecurID is configured in the profile **authentication-order** parameter as either the only authentication mode or the first one to be used, the device forwards the user's credentials to the SecurID server for authentication. If the user enters valid values, the user is allowed access to the requested resource.

Specify that Server-1 is to be used as the SecurID server and that its configuration file resides on the device in the `/var/db/secuid/Server-1/sdconf.rec` file. From configuration mode, enter this command:

```
user@host# set access secuid-server Server-1 configuration-file
"/var/db/secuid/Server-1/sdconf.rec"
```

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set access profile Profile-2 authentication-order secuid
set access profile Profile-2 client Client-1 client-group alpha
set access profile Profile-2 client Client-1 client-group beta
set access profile Profile-2 client Client-1 client-group gamma
set access profile Profile-2 client Client-1 firewall-user password pwd
set access profile Profile-2 client Client-2 client-group alpha
set access profile Profile-2 client Client-2 client-group beta
set access profile Profile-2 client Client-2 firewall-user password pwd
set access profile Profile-2 client Client-3 firewall-user password pwd
```

```
set access profile Profile-2 client Client-4 firewall-user password pwd
set access profile Profile-2 session-options client-group alpha
set access profile Profile-2 session-options client-group beta
set access profile Profile-2 session-options client-group gamma
set access profile Profile-2 session-options client-idle-timeout 255
set access profile Profile-2 session-options client-session-timeout 4
```

**Step-by-Step  
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure SecurID as the external authentication server:

1. For the Profile-2 profile, configure SecurID as the server to be used for external authentication.

[edit]

```
user@host# set access profile Profile-2 authentication-order securid
```

To share a single SecurID server across multiple profiles, for each profile set the **authentication-order** parameter to include **securid** as the authentication mode.

2. Configure clients 1 through 4 as firewall users, and assign Client-1 and Client-2 to client groups.

[edit access profile Profile-2]

```
user@host# set client Client-1 client-group alpha
```

```
user@host# set client Client-1 client-group beta
```

```
user@host# set client Client-1 client-group gamma
```

```
user@host# set client Client-1 firewall-user password pwd
```

```
user@host# set client Client-2 client-group alpha
```

```
user@host# set client Client-2 client-group beta
```

```
user@host# set client Client-2 firewall-user password pwd
```

```
user@host# set client Client-3 firewall-user password pwd
```

```
user@host# set client Client-4 firewall-user password pwd
```

3. Configure client groups in the session options.

[edit access profile Profile-2]

```
user@host# set session-options client-group alpha
```

```
user@host# set session-options client-group beta
```

```
user@host# set session-options client-group gamma
```

```
user@host# set session-options client-idle-timeout 255
```

```
user@host# set session-options client-session-timeout 4
```

**Results** From configuration mode, confirm your configuration by entering the **show access profile Profile-2** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show access profile Profile-2
authentication-order securid;
client Client-1 {
 client-group [alpha beta gamma];
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
}
client Client-2 {
 client-group [alpha beta];
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
}
client Client-3 {
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
}
client Client-4 {
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
}
session-options {
 client-group [alpha beta gamma];
 client-idle-timeout 255;
 client-session-timeout 4;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Troubleshooting with Logs on page 5547](#)

### Troubleshooting with Logs

**Purpose** Use these logs to identify any issues.

**Action** From operational mode, enter the **show log messages** command and the **show log dcd** command.

## Troubleshooting

- [Troubleshooting Unsuccessful Authentication In a Dynamic VPN Configuration on page 5548](#)

### Troubleshooting Unsuccessful Authentication In a Dynamic VPN Configuration

**Problem** Device fails to locate client address in a dynamic VPN configuration.

**Solution** 1. Verify that the device host name, the domain-search, and the name server are configured properly.

[edit system]

user@host# set host-name srx101.uaclab.net

user@host# set domain-search uaclab.net

user@host# set name-server 10.204.91.25

2. Verify that the device host name is getting resolved on the RSA server.

  - [Example: Deleting the SecurID Node Secret File on page 5548](#)

## Example: Deleting the SecurID Node Secret File

This example shows how to delete the node secret file.

- [Requirements on page 5548](#)
- [Overview on page 5548](#)
- [Configuration on page 5549](#)
- [Verification on page 5549](#)

## Requirements

Before you begin, confirm that it is necessary to delete the SecurID node secret file.

## Overview

When the Juniper Networks device initially communicates successfully with the SecurID server, a node secret file is created for it automatically. The file is created as a result of the handshake between the Juniper Networks device and the SecurID server after the software authenticates the first user successfully. All subsequent communication between the Juniper Networks device and the SecurID server relies on this secret as a representation of trust between the two nodes instead of repeating the handshake with each authentication request.

Under normal circumstances you should not delete the node secret file. In the rare case that you must do so, for example, to debug a serious problem, you can use the **clear** command to remove the file.

**WARNING:** If you delete the file, you must deselect a box on the SecurID server to indicate that the node secret file for the Juniper Networks device and the SecurID server no longer exists. Otherwise, authentication attempts will fail.

## Configuration

### Step-by-Step Procedure

To delete the node secret file:

1. Use the **clear** command to remove the node secret file. During subsequent user authentication, the device reestablishes a shared secret with the SecurID server and re-creates the node secret file. From operational mode, enter the **clear network-access** command to clear the **securid-node-secret-file** for the Juniper Networks device.

```
user@host> clear network-access securid-node-secret-file
```

2. From operational mode, confirm your deletion by entering the **show network-access securid-node-secret-file** command. If the output does not display, repeat the instructions in this example to correct it.

```
user@host> show network-access securid-node-secret-file
```

## Verification

Verify the deletion by entering the **show network-access securid-node-secret-file** command.

- [Example: Configuring Local Users for Client Groups on page 5552](#)

## Understanding Client Groups for Firewall Authentication

---

To manage a number of firewall users, you can create user or client groups and store the information either on the local Juniper Networks device or on an external RADIUS or LDAP server.

A client group is a list of groups to which the client belongs. As with client-idle timeout, a client group is used only if the external authentication server does not return a value in its response. (For example, LDAP servers do not return such information.)

The RADIUS server sends the client's group information to the Juniper Networks device using Juniper VSA (46). The client-match portion of the policy accepts a string that can be either the username or the groupname to which the client belongs.

The reason to have a single database for different types of clients (except admins) is based on the assumption that a single client can be of multiple types. For example, a firewall user client can also be an L2TP client.

## Example: Configuring the Access Profile

---

The following example shows you how to configure the access profile:

```
[edit access]
profile westcoast_bldg_1 {
 client white {
 chap-secret "$9$3s2690leK8X7VKM7VwgaJn/Ctu1hclv87Ct87";
 # SECRET-DATA
 ppp {
 idle-timeout 22;
 primary-dns 192.120.65.10;
```

```
 framed-ip-address 12.12.12/32;
 }
 group-profile westcoast_users;
}
client blue {
 chap-secret "9eq1KWxbwgZUHNdjmqmTF3uO1Rhr-dsoJDNd";
 # SECRET-DATA
 group-profile sunnyvale_users;
}
authentication-order password;
}
profile westcoast_bldg_1_tunnel {
 client test {
 l2tp {
 shared-secret "9r3HKvLg4ZUDkX7JGjif5p0BIRS8LN";
 # SECRET-DATA
 maximum-sessions-per-tunnel 75;
 ppp-authentication chap;
 }
 group-profile westcoast_tunnel;
 }
 client production {
 l2tp {
 shared-secret "9R2QErv8X-goGylVwg4jiTz36/t0BEleWFnRh
rlXxbs2aJDHqf3nCP5";
 # SECRET-DATA
 ppp-authentication chap;
 }
 group-profile westcoast_tunnel;
 }
}
```

## Example: Configuring Local Users for Client Groups

This example shows how to configure a local user for client groups in a profile.

- [Requirements on page 5552](#)
- [Overview on page 5553](#)
- [Configuration on page 5553](#)
- [Verification on page 5554](#)

### Requirements

Before you begin, create an access profile. See “[Example: Configuring the Access Profile](#)” on page 5551.

## Overview

A client group is a list of groups to which the client belongs. As with client-idle timeout, a client group is used only if the external authentication server does not return a value in its response (for example, LDAP servers do not return such information).

This example shows how to configure a local user called Client-1 for client groups G1, G2, and G3 in a profile called Managers. Within this example, client groups are configured for a client. If a client group is not defined for the client, then the client group under the **access profile session-options** hierarchy is used.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set access profile Managers client Client-1 client-group G1
set access profile Managers client Client-1 client-group G2
set access profile Managers client Client-1 client-group G3
set access profile Managers client Client-1 firewall-user password pwd
set access profile Managers session-options client-group G1
set access profile Managers session-options client-group G2
set access profile Managers session-options client-group G3
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a local user for client groups in a profile:

1. Configure the firewall user profile Managers, and assign client groups to it.

```
user@host# edit access profile Managers
[edit access profile Managers]
user@host# set client Client-1 client-group G1
user@host# set client Client-1 client-group G2
user@host# set client Client-1 client-group G3
user@host# set client Client-1 firewall-user password pwd
```

2. Configure client groups in the session options.

```
[edit access profile Managers]
user@host# set session-options client-group G1
user@host# set session-options client-group G2
user@host# set session-options client-group G3
```

**Results** Confirm your configuration by entering the **show access profile Managers** command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show access profile Managers

client Client-1 {
 client-group [G1 G2 G3];
```

```
 firewall-user {
 password "$ABC123"; ## SECRET-DATA
 }
}
session-options {
 client-group [G1 G2 G3];
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

# Customizing the Firewall Authentication Banner

- [Understanding Firewall Authentication Banner Customization on page 5555](#)
- [Example: Customizing a Firewall Authentication Banner on page 5555](#)

## Understanding Firewall Authentication Banner Customization

---

A banner is a message that appears on a monitor in different places depending on the type of login.

**Figure 250: Banner Customization**

- At the top of a browser screen after a user has successfully logged into a Web authentication address as shown [Figure 250](#).
- Before or after a Telnet, an FTP, or an HTTP login prompt, success message, and fail message for users

All banners, except for a console login banner, have default messages. You can customize the messages that appear on the banners to better suit the network environment in which you use the device.

**Related  
Documentation**

- [Firewall User Authentication Overview on page 5505](#)
- [Example: Customizing a Firewall Authentication Banner on page 5555](#)

## Example: Customizing a Firewall Authentication Banner

---

This example shows how to customize the banner text that appears in the browser.

- [Requirements on page 5556](#)
- [Overview on page 5556](#)
- [Configuration on page 5556](#)
- [Verification on page 5557](#)

## Requirements

Before you begin, create an access profile.

## Overview

A banner is a message that appears on a monitor in different places depending on the type of login. This example shows how to change the banner that appears in the browser to indicate that a user has successfully authenticated after successfully logging in through Web authentication. The new message is “Web authentication is successful.” If the authentication fails, then the new message reads “Authentication failed.”

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set access firewall-authentication pass-through default-profile Profile-1
set access firewall-authentication pass-through ftp banner fail " Authentication failed"
set access firewall-authentication web-authentication default-profile Profile-1
set access firewall-authentication web-authentication banner success " Web authentication is successful"
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To customize the banner text that appears in the browser:

1. Specify the banner text for failed pass-through authentication through FTP.

[edit]

```
user@host# set access firewall-authentication pass-through default-profile Profile-1
```

```
user@host# set access firewall-authentication pass-through ftp banner fail "
Authentication failed"
```

2. Specify the banner text for successful Web authentication.

[edit]

```
user@host# set access web-authentication default-profile Profile-1
```

```
user@host# set access web-authentication banner success " Web authentication
is successful"
```

**Results** From configuration mode, confirm your configuration by entering the **show access firewall-authentication** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show access firewall-authentication
```

```
pass-through {
 default-profile Profile-1;
 ftp {
 banner {
 fail "Authentication failed";
 }
 }
}
web-authentication {
 default-profile Profile-1;
 banner {
 success "Web authentication is successful";
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Troubleshooting with Logs on page 5557](#)

# Configuring UAC in a Junos OS Environment

- [Understanding UAC in a Junos OS Environment on page 5561](#)
- [Enabling UAC in a Junos OS Environment \(CLI Procedure\) on page 5563](#)

## Understanding UAC in a Junos OS Environment

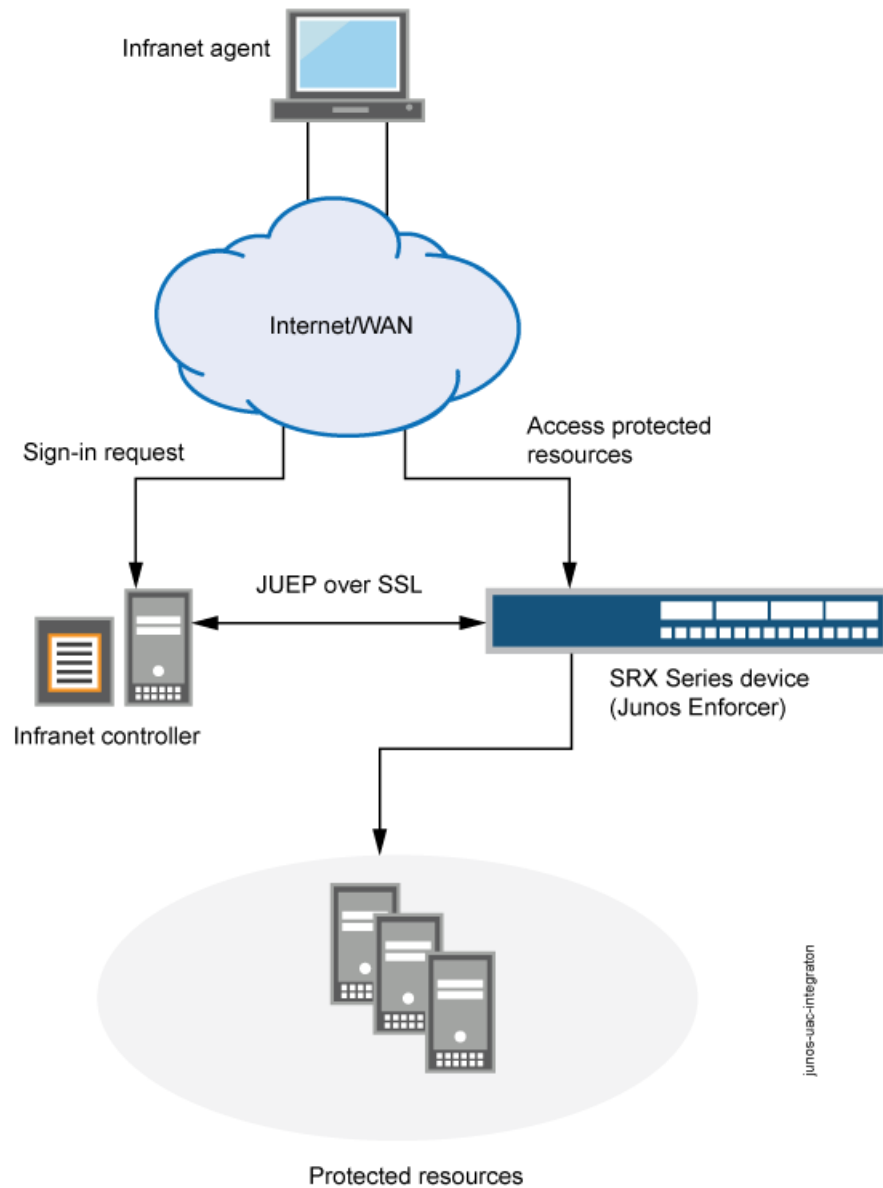

---

A Unified Access Control (UAC) deployment uses the following components to secure a network and ensure that only qualified end users can access protected resources:

- **IC Series UAC Appliances**—An IC Series appliance is a policy decision point in the network. It uses authentication information and policy rules to determine whether or not to provide access to individual resources on the network. You can deploy one or more IC Series appliances in your network.
- **Infranet Enforcers**—An Infranet Enforcer is a policy enforcement point in the network. It receives policies from the IC Series appliance and uses the rules defined in those policies to determine whether or not to allow an endpoint access to a resource. You deploy the Infranet Enforcers in front of the servers and resources that you want to protect.
- **Infranet agents**—An Infranet agent is a client-side component that runs directly on network endpoints (such as users' computers). The agent checks that the endpoint complies to the security criteria specified in Host Checker policies and relays that compliance information to the Infranet Enforcer. The Infranet Enforcer then allows or denies the endpoint access based on the compliance results.

An SRX Series device can act as an Infranet Enforcer in a UAC network. Specifically, it acts as a Layer 3 enforcement point, controlling access by using IP-based policies pushed down from the IC Series appliance. When deployed in a UAC network, an SRX Series device is called a Junos OS Enforcer. See [Figure 251](#).

Figure 251: Integrating a Junos OS Security Device into a Unified Access Control Network

**NOTE:** You can use the Junos OS Enforcer with the IC Series appliance and Secure Access devices in an IF-MAP Federation network. In a federated network, multiple IC Series appliances and Secure Access devices that are not directly connected to the Junos OS Enforcer can access resources protected by the security device. There are no configuration tasks for IF-MAP Federation on the Junos OS Enforcer. You configure policies on IC Series appliances that can dynamically create authentication table entries on the Junos OS Enforcer.

- Related Documentation**
- [Enabling UAC in a Junos OS Environment \(CLI Procedure\) on page 5563](#)

## Enabling UAC in a Junos OS Environment (CLI Procedure)

---

Junos OS security policies enforce rules for transit traffic, defining what traffic can pass through the Juniper Networks device. The policies control traffic that enters from one zone (from-zone) and exits another (to-zone). To enable an SRX Series device as a Junos OS Enforcer in a UAC deployment, you must:

- Identify the source and destination zones through which UAC traffic will travel. It also needs the list of interfaces, including which zones they are in. The IC Series UAC Appliance uses the destination zone to match its own IPsec routing policies configured on IC Series appliance.
- Identify Junos OS security policies that encompass those zones, and enable UAC for those policies.

Before you begin:

1. Set up the interfaces through which UAC traffic should enter the SRX Series device.
2. Group interfaces with identical security requirements into zones. See [“Example: Creating Security Zones” on page 1031](#).
3. Create security policies to control the traffic that passes through the security zones. See [“Example: Configuring a Security Policy to Permit or Deny All Traffic” on page 1074](#).

To configure UAC through a Junos OS security policy, enter the following configuration statement:

```
user@host# set security policies from-zone zone-name to-zone zone-name policy match
then permit application-services uac-policy
```

# Establishing Communications Between Devices

- [Understanding Communications Between the Junos OS Enforcer and the IC Series UAC Appliance on page 5565](#)
- [Understanding Communications Between Junos OS Enforcer and a Cluster of IC Series UAC Appliances on page 5566](#)
- [Configuring Communications Between the Junos OS Enforcer and the IC Series UAC Appliance \(CLI Procedure\) on page 5566](#)

## Understanding Communications Between the Junos OS Enforcer and the IC Series UAC Appliance

---

When you configure an SRX Series device to connect to an IC Series UAC Appliance, the SRX Series device and the IC Series appliance establish secure communications as follows:

1. If more than one IC Series device are configured as Infranet Controllers on the SRX Series device, a round-robin algorithm determines which of the configured IC Series devices is the active Infranet Controller. The others are failover devices. If the active Infranet Controller becomes inoperative, the algorithm is reapplied to the remaining IC Series devices that are configured to establish the new active Infranet Controller.
2. The active IC Series appliance presents its server certificate to the SRX Series device. If configured to do so, the SRX Series device verifies the certificate. (Server certificate verification is not required; however, as an extra security measure you can verify the certificate to implement an additional layer of trust.)
3. The SRX Series device and the IC Series appliance perform mutual authentication using the proprietary challenge-response authentication. For security reasons, the password is not included in the message sent to the IC Series appliance.
4. After successfully authenticating with the SRX Series device, the IC Series appliance sends its user authentication and resource access policy information. The SRX Series device uses this information to act as the Junos OS Enforcer in the UAC network.
5. Thereafter, the IC Series appliance and the Junos OS Enforcer can communicate freely with one another over the SSL connection. The communications are controlled by a proprietary protocol called *Junos UAC Enforcer Protocol (JUEP)*.

- Related Documentation**
- [Understanding UAC in a Junos OS Environment on page 5561](#)
  - [Configuring Communications Between the Junos OS Enforcer and the IC Series UAC Appliance \(CLI Procedure\) on page 5566](#)

## Understanding Communications Between Junos OS Enforcer and a Cluster of IC Series UAC Appliances

---

You can configure a Junos OS Enforcer to work with more than one IC Series UAC Appliance in a high availability configuration known as an IC Series appliance cluster. The Junos OS Enforcer communicates with only one IC Series appliance at a time; the other IC Series appliances are used for failover. If the Junos OS Enforcer cannot connect to the first IC Series appliance you added to a cluster, it tries to connect to the failed IC Series appliance again. Then it fails over to the other IC Series appliances in the cluster. It continues trying to connect to IC Series appliances in the cluster until a connection occurs.

When the Junos OS Enforcer cannot establish a connection to an Infranet Enforcer, it preserves all its existing authentication table entries and Unified Access Control (UAC) policies and takes the timeout action that you specify. Timeout actions include:

- **close**—Close existing sessions and block any further traffic. This is the default option.
- **no-change**—Preserve existing sessions and require authentication for new sessions.
- **open**—Preserve existing sessions and allow new sessions access.

Once the Junos OS Enforcer can reestablish a connection to an IC Series appliance, the IC Series appliance compares the authentication table entries and UAC policies stored on the Junos OS Enforcer with the authentication table entries and policies stored on the IC Series appliance and reconciles the two as required.

**NOTE:** The IC Series appliances configured on a Junos OS Enforcer should all be members of the same IC Series appliance cluster.

---

## Configuring Communications Between the Junos OS Enforcer and the IC Series UAC Appliance (CLI Procedure)

---

To configure an SRX Series device to act as a Junos OS Enforcer in a UAC deployment, and therefore to enforce IC Series UAC Appliance policies, you must specify an IC Series appliance to which the SRX Series device should connect.

Before you begin:

1. Enable UAC through the relevant Junos OS security policies. See [“Enabling UAC in a Junos OS Environment \(CLI Procedure\)” on page 5563](#).
2. (Optional) Create a profile for the certificate authority (CA) that signed the IC Series appliance's server certificate, and import the CA certificate onto the SRX Series device. See [“Example: Loading CA and Local Certificates Manually” on page 6672](#).
3. Configure user authentication and authorization by setting up user roles, authentication and authorization servers, and authentication realms on the IC Series appliance.
4. Configure resource access policies on the IC Series appliance to specify which endpoints are allowed or denied access to protected resources.

To configure an SRX Series device to act as a Junos OS Enforcer:

1. Specify the IC Series appliance(s) to which the SRX Series device should connect.
  - To specify the IC Series appliance hostname:

```
user@host# set services unified-access-control infranet-controller hostname
```

- To specify the IC Series appliance IP address:

```
user@host# set services unified-access-control infranet-controller hostname address ip-address
```

**NOTE:** When configuring access to multiple IC Series appliances, you must define each separately. For example:

```
user@host# set services unified-access-control infranet-controller IC1
user@host# set services unified-access-control infranet-controller IC2
user@host# set services unified-access-control infranet-controller IC3

user@host# set services unified-access-control infranet-controller IC1
address 10.10.10.1
user@host# set services unified-access-control infranet-controller IC2
address 10.10.10.2
user@host# set services unified-access-control infranet-controller IC3
address 10.10.10.3
```

Make sure that all of the IC Series appliances are members of the same cluster.

**NOTE:** By default, the IC Series appliance should select port 11123.

2. Specify the Junos OS interface to which the IC Series appliance should connect:

```
user@host# set services unified-access-control infranet-controller hostname interface interface-name
```

3. Specify the password that the SRX Series device should use to initiate secure communications with the IC Series appliance:

**NOTE:** Any change in the Unified Access Control's (UAC) contact interval and timeout values in the SRX Series device will be effective only after the next reconnection of the SRX Series device with the IC Series appliance.

user@host# **set services unified-access-control infranet-controller *hostname* password *password***

4. (Optional) Specify information about the IC Series appliance's server certificate that the SRX Series device needs to verify the certificate.

- To specify the server certificate subject that the SRX Series device checks:

user@host# **set services unified-access-control infranet-controller *hostname* server-certificate-subject *certificate-name***

- To specify the CA profile associated with the certificate:

user@host# **set services unified-access-control infranet-controller *hostname* ca-profile *ca-profile***

**NOTE:** An IC Series appliance server certificate can be issued by an intermediate CA. There are two types of CAs—root CAs and intermediate CAs. An intermediate CA is secondary to a root CA and issues certificates to other CAs in the public key infrastructure (PKI) hierarchy. Therefore, if a certificate is issued by an intermediate CA, you need to specify the complete list of CA profiles in the certification chain.

# Configuring Policy Enforcement

- [Understanding Junos OS Enforcer Policy Enforcement on page 5569](#)
- [Configuring Junos OS Enforcer Failover Options \(CLI Procedure\) on page 5570](#)
- [Testing Junos OS Enforcer Policy Access Decisions Using Test-Only Mode \(CLI Procedure\) on page 5571](#)
- [Verifying Junos OS Enforcer Policy Enforcement on page 5572](#)

## Understanding Junos OS Enforcer Policy Enforcement

---

Once the SRX Series device has successfully established itself as the Junos OS Enforcer, it secures traffic as follows:

1. First, the Junos OS Enforcer uses the appropriate Junos OS security policy to process the traffic. A *security policy* uses criteria such as the traffic's source IP address or the time of day that the traffic was received to determine whether or not the traffic should be allowed to pass.
2. Once it determines that the traffic may pass based on the Junos OS security policy, the Junos OS Enforcer maps the traffic flow to an authentication table entry. The Junos OS Enforcer uses the source IP address of the first packet in the flow to create the mapping.

An *authentication table entry* contains the source IP address and user role(s) of a user who has already successfully established a UAC session. A *user role* identifies a group of users based on criteria such as type (for instance, "Engineering" or "Marketing") or status (for instance, "Antivirus Running"). The Junos OS Enforcer determines whether to allow or deny the traffic to pass based on the authentication results stored in the appropriate authentication table entry.

The IC Series UAC Appliance pushes authentication table entries to the Junos OS Enforcer when the devices first connect to one another and, as necessary, throughout the session. For example, the IC Series appliance might push updated authentication table entries to the Junos OS Enforcer when the user's computer becomes noncompliant with endpoint security policies, when you change the configuration of a user's role, or when you disable all user accounts on the IC Series appliance in response to a security problem such as a virus on the network.

If the Junos OS Enforcer drops a packet because of a missing authentication table entry, the device sends a message to the IC Series appliance, which in turn may

provision a new authentication table entry and send it to the Junos OS Enforcer. This process is called dynamic authentication table provisioning.

3. Once it determines that the traffic may pass based on the authentication table entries, the Junos OS Enforcer maps the flow to a resource. The Junos OS Enforcer uses the destination IP address specified in the flow to create the mapping. Then the device uses that resource as well as the user role specified in the authentication table entry to map the flow to a resource access policy.

A *resource access policy* specifies a particular resource to which you want to control access based on user role. For instance, you might create a resource access policy that allows only users who are members of the Engineering and Antivirus Running user roles access to the Engineering-Only server. Or you might create a resource access policy that allows members of the No Antivirus Running user role access to the Remediation server on which antivirus software is available for download.

The IC Series appliance pushes resource access policies to the Junos OS Enforcer when the devices first connect to one another and when you modify your resource access policy configurations on the IC Series appliance.

If the Junos OS Enforcer drops the packet because of a “deny” policy, the Junos OS Enforcer sends a message to the IC Series appliance, which in turn sends a message to the endpoint’s Odyssey Access Client (if available). (The IC Series appliance does not send “deny” messages to the agentless client.)

4. Once it determines that the traffic may pass based on the resource access policies, the Junos OS Enforcer processes the traffic using the remaining application services defined in the Junos OS policy. The Junos OS Enforcer runs the remaining services in the following order: Intrusion Detection and Prevention (IDP), URL filtering, and Application Layer Gateways (ALGs).

---

## Configuring Junos OS Enforcer Failover Options (CLI Procedure)

---

To configure IC Series UAC Appliance failover processing, you must configure the Junos OS Enforcer to connect to a cluster of IC Series appliances. The Junos OS Enforcer communicates with one of these IC Series appliances at a time and uses the others for failover processing.

Before you begin:

1. Enable UAC through the relevant Junos OS security policies.
2. Configure the SRX Series device as a Junos OS Enforcer. During the configuration, define a cluster of IC Series appliances to which the Junos OS Enforcer should connect. See [“Enabling UAC in a Junos OS Environment \(CLI Procedure\)” on page 5563](#).

To configure failover processing:

1. Specify how often (in seconds) the Junos OS Enforcer should expect a heartbeat signal from the IC Series appliance indicating an active connection:

**user@host# set services unified-access-control interval *seconds***

- Specify the interval (in seconds) at which the Junos OS Enforcer should consider the current connection timed out:

**NOTE:** Any change in the Unified Access Control's (UAC) contact interval and timeout values in the SRX Series device will be effective only after the next reconnection of the SRX Series device with the IC Series appliance.

```
user@host# set services unified-access-control timeout seconds
```

- Specify how the Junos OS Enforcer should handle all current and subsequent traffic sessions when its connection to an IC Series appliance cluster times out:

```
user@host# set services unified-access-control timeout-action (close | no-change | open)
```

#### Related Documentation

## Testing Junos OS Enforcer Policy Access Decisions Using Test-Only Mode (CLI Procedure)

When configured in test-only mode, the SRX Series device enables all UAC traffic to go through regardless of the UAC policy settings. The device logs the UAC policy's access decisions without enforcing them so you can test the implementation without impeding traffic.

Before you begin:

- Enable UAC through the relevant Junos OS security policies. See [“Enabling UAC in a Junos OS Environment \(CLI Procedure\)” on page 5563](#)
- Configure the SRX Series devices as a Junos OS Enforcer. See [“Configuring Communications Between the Junos OS Enforcer and the IC Series UAC Appliance \(CLI Procedure\)” on page 5566](#).
- If you are connecting to a cluster of IC Series UAC Appliances, enable failover options. See [“Configuring Junos OS Enforcer Failover Options \(CLI Procedure\)” on page 5570](#).

To activate or deactivate test-only mode, enter the following configuration statement:

```
user@host# set services unified-access-control test-only-mode (true | false)
```

## Verifying Junos OS Enforcer Policy Enforcement

### Displaying IC Series UAC Appliance Authentication Table Entries from the Junos OS Enforcer

**Purpose** Display a summary of the authentication table entries configured from the IC Series UAC Appliance.

**Action** Enter the `show services unified-access-control authentication-table` CLI command.

### Displaying IC Series UAC Appliance Resource Access Policies from the Junos OS Enforcer

**Purpose** Display a summary of UAC resource access policies configured from the IC Series UAC Appliance.

**Action** Enter the `show services unified-access-control policies` CLI command.

# Classifying Traffic with User Roles

- [Understanding Unified Access Control on page 5573](#)
- [Acquiring User Role Information from an Active Directory Authentication Server on page 5573](#)

## Understanding Unified Access Control

---

In Junos OS Release 12.1 and later, user role firewall security policies let you classify traffic based on the roles to which a user is assigned. Based on match criteria, which includes the user's role, you create policies to apply services that allow or block access to resources. The user role firewall is similar to the identity-based network access control (NAC) solution available with UAC on the SRX Series device. A user role firewall, however, does not require the Junos Pulse/Odyssey installation, and it supports agentless transparent authentication.

User role information can be collected in several ways: locally on the SRX Series device, from a Junos Pulse Access Control Service device, or by relaying authentication data from a third-party authentication server through a Junos Pulse Access Control Service device to the SRX Series device.

### Related Documentation

- [Acquiring User Role Information from an Active Directory Authentication Server on page 5573](#)

## Acquiring User Role Information from an Active Directory Authentication Server

---

Networks have used the IP address as a way of identifying users and servers. The strategy is based on the assumption that users or groups of users connect to the network from fixed locations and use one device at a time.

Wireless networking and mobile devices require a different strategy. Individuals can connect to the network using multiple devices simultaneously. The way in which devices connect to the network changes rapidly. It is no longer possible to identify a user with a group of statically allocated IP addresses.

In Junos OS Release 12.1 and later, user role firewall security policies let you classify traffic based on the roles to which a user is assigned. Based on match criteria, which includes the user's role, you create policies to apply services that allow or block access to resources. The user role firewall is similar to the identity-based network access control (NAC)

solution available with UAC on the SRX Series device. A user role firewall, however, does not require the Junos Pulse/Odyssey installation, and it supports agentless transparent authentication.

User role information can be collected in several ways: locally on the SRX Series device, from a Junos Pulse Access Control Service device, or by relaying authentication data from a third-party authentication server through a Junos Pulse Access Control Service device to the SRX Series device.

Incorporating a third-party authentication server into a user role firewall configuration can also provide single sign-on (SSO) support. This allows a browser-based user to authenticate once and have that authentication communicated to other trusted servers in the domain as needed.

- [Requirements on page 5574](#)
- [Overview on page 5575](#)
- [Configuration on page 5576](#)

## Requirements

This solution uses the following hardware and software components:

- One MAG Series Junos Pulse Gateway device with software release 4.2 or later
- The MAGx600-UAC-SRX license installed on the MAG Series device
- One SRX Series device with Junos OS Release 12.1 or later
- One Microsoft Active Directory server using version 2008

**NOTE:** Microsoft Windows 2003 is also compatible with this functionality, but terminology, pathways, and settings might differ from what is presented in this document.

Before you begin:

- Ensure that the MAG Series device is configured as an Access Control Service and is accessible to the network. See the *MAG Series Junos Pulse Gateway Hardware Guide* for configuration details.
- Ensure that the MAGx600-UAC-SRX license is installed on the MAG Series device.
- Ensure that the SRX Series device is configured and initialized with Junos OS version 12.1 or later.
- Ensure that the Active Directory authentication server is configured for standard Junos Pulse Access Control Service authentication. See your third-party documentation.
- Ensure that the administrator has the appropriate capabilities for configuring the roles, users, and device interactions.

## Overview

In this solution an SRX Series device obtains user role information dynamically from a Microsoft Active Directory authentication server. Authentication verification and user role information from the Active Directory server is relayed by the Access Control Service on the MAG Series device to the SRX Series device.

Users within the same domain are connected to a LAN segment. They are associated with user role groups, such as developer or manager, depending on their work in the organization. When a user authenticates to the AD authentication server, the user should be able to access protected resources without having to authenticate a second time.

The SRX Series device is configured as an enforcer for the MAG Series device. It receives user role information from the MAG Series device and applies user role firewall policies accordingly to incoming and outgoing traffic.

When the SRX Series device has no user role information for a user, the user's browser is redirected to the MAG Series device. Transparently to the user, the MAG Series device requests verification from the browser. The browser retrieves a token from the Active Directory server confirming authentication and passes it to the MAG Series device. With the information provided by the token, the MAG Series device retrieves user role information for the user from the Active Directory server and creates an authentication table entry consisting of the current IP address and the user role data. The MAG Series device pushes the updated table to the SRX Series device and redirects the browser back to the SRX to request access again. This time, the table does contain user role information which is then retrieved and used as part of the match criteria for applying user role firewall services.

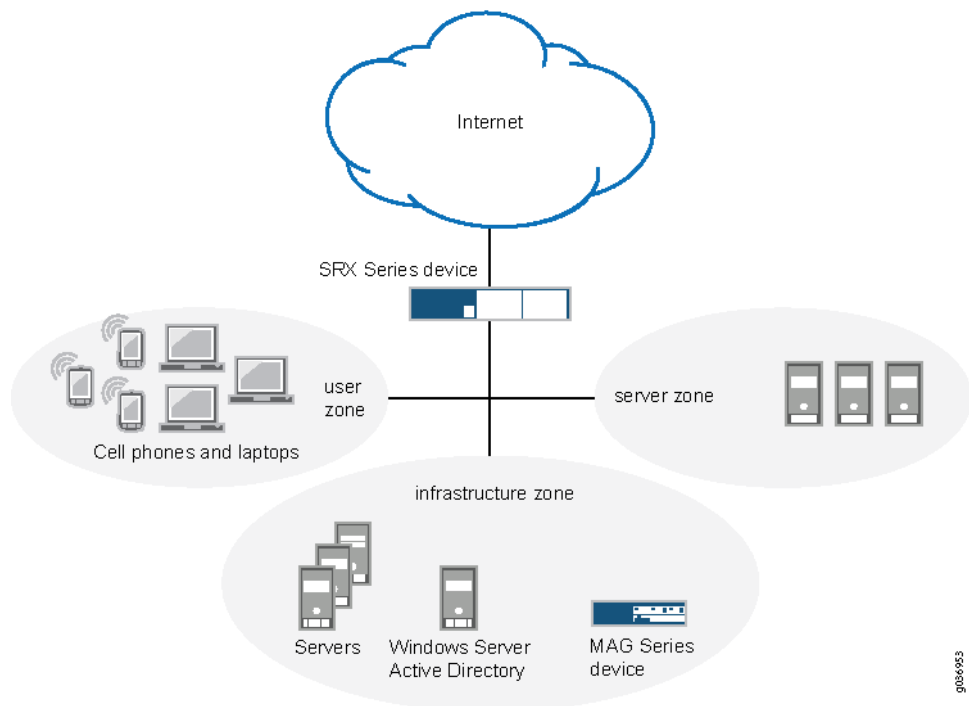

The user is not aware of the process unless the Active Directory (AD) server has no current authentication for the user. When that is the case, the server prompts the user for name and password. Once authentication occurs, the server returns a token to the browser.

The procedure documented here initially configures the MAG Series device as the authenticator. The configuration is later modified to retrieve authentication information from the AD server. This solution uses SPNEGO negotiation and Kerberos authentication to secure communications among the SRX device, the MAG Series device, the browser, and the authentication server.

## Topology

Figure 252 shows the topology for this deployment in which the MAG Series device is used initially as the authentication source. Later, the AD server is used transparently unless the user is not authenticated, in which case he is prompted for a user name and password.

Figure 252: Single Sign-On Support Topology

A user's request to access another resource is controlled by roles and groups associated with the user. For example, a user belonging to a group of developers named Dev might have access to a particular test server. The same user might also be the manager and belong to the Mgr group that can access certain HR resources. A contractor working for this manager might require access to the test server as well but not to the HR resources. In this case, the user would be added to the Dev group and perhaps a Contractor group, but not the Mgr group.

User role firewall policies defined on the SRX Series device control the groups and user roles that can access various resources. In this configuration, if user role data does not exist for a user requesting access, a policy redirects the user's browser to the MAG Series device to authenticate the user and retrieve any associated user role data.

A token exchange among the Access Control Service, the browser, and the Active Directory server remains transparent to the user while it verifies the user's authentication. The exchange uses SPNEGO negotiation and Kerberos authentication for encrypting and decrypting messages among the devices.

With information obtained from the response token, the MAG Series device retrieves the user's roles and groups directly from the Active Directory server. It then creates an authentication table entry and passes it to the SRX Series device.

## Configuration

Configure the devices for this solution by performing the following tasks.

- Connect the SRX Series device and the MAG Series device in an enforcer configuration.
- Configure the Access Control Service on the MAG Series device for local user authentication and verify that authentication information is transferred between the devices.
- Configure a captive portal policy on the SRX Series device to redirect any unauthenticated user to the Access Control Service and verify that redirection is functioning properly.
- Configure the Microsoft Active Directory authentication server to interact with the Access Control Service and the endpoints.
- Reconfigure the Access Control Service for remote authentication by the Active Directory server and redefine Active Directory groups for the SRX Series device.
- Configure endpoint browsers for the SPNEGO protocol

**NOTE:** Configuring the Access Control Service using local authentication is not necessary for this solution. However, by configuring local authentication first you can verify the captive portal interaction between the MAG Series device and the SRX Series device.

The following solution requires you to navigate various levels in the configuration hierarchy on the SRX Series device. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

### Connecting the SRX Series Device to the Access Control Service

#### Step-by-Step Procedure

In an enforcer configuration, the Access Control Service on the MAG Series device and the SRX Series device communicate over a secure channel. When the SRX Series device first connects with the Access Control Service, the devices exchange information to ensure secure communication. Optionally, you can use digital security certificates as an enhanced mechanism for establishing trust.

See the *Unified Access Control Administration Guide* for details about configuring certificate trust between the SRX Series device and the Access Control Service.

To connect the SRX Series device and the Access Control Service on the MAG Series device:

1. Configure the SRX Series device.
  - a. Configure the zones and interfaces of the devices.
 

```
user@host# set security zones security-zone user interfaces ge-0/0/0
user@host# set security zones security-zone infrastructure interfaces ge-0/0/1
user@host# set security zones security-zone untrust interfaces ge-0/0/2
```
  - b. Configure the IP addresses of the interfaces.
 

```
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.12.12.1/24
user@host# set interfaces ge-0/0/1 unit 0 family inet address 10.0.0.20/24
user@host# set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24
```

- c. Identify the Access Control Service as a new Infranet Controller, and configure the interface for the connection to it.

```
[edit]
user@host# set services unified-access-control infranet-controller mag123
address 10.0.0.22
user@host# set services unified-access-control infranet-controller mag123
interface fxp0.0
```

- d. Specify the password for securing interactions between the Access Control Service and the SRX Series device.

```
[edit]
user@host# set services unified-access-control infranet-controller mag123
password "InSub321"
```

**NOTE:** The same password must be configured on both devices.

- e. (Optional) Specify the full name of the Access Control Service certificate that the SRX Series device must match during connection.

```
user@host# set services unified-access-control infranet-controller mag123
ca-profile ca-mag123-enforcer
```

- f. If you are done configuring the SRX Series device, enter commit from configuration mode.

2. Configure the Access Control Service from the administrator console on the MAG Series device.

- a. Navigate to the Infranet Enforcer page, and click **New Enforcer**.
- b. Select **Junos**, enter the password set previously on the SRX Series device (InSub321), and enter the serial number of the SRX Series device.
- c. Click **Save Changes**.

**Results** When both devices are configured, the SRX Series device connects automatically to the Access Control Service.

- From the Access Control Service, select **System>Status>Overview** to view the status of the connection to the SRX Series device. The diode in the display is green if the connection is functioning. To display additional information, click the device name.
- From operational mode on the SRX Series device, confirm your connection by entering the **show services unified-access-control status** command. If the output does not display the intended configuration, repeat the instructions in this section to correct the configuration.

```
user@host> show services unified-access-control status
```

| Host   | Address   | Port  | Interface | State     |
|--------|-----------|-------|-----------|-----------|
| mag123 | 10.0.0.22 | 11123 | fxp0.0    | connected |

### Configuring the Access Control Service for Local User Authentication

#### Step-by-Step Procedure

When a user is authenticated, the Access Control Service on the MAG Series device updates its authentication table with the IP address and associated roles of the user, and pushes the updated table to the SRX Series device. If this user data is deleted or modified, the Access Control Service updates the authentication table with the new information and again pushes it to the SRX Series device.

To test the successful transfer and content of the authentication table, this task configures the Access Control Service on the MAG Series device for local authentication. Within this configuration you can test the user role firewall from the SRX Series device without affecting other network operations. A later task modifies this configuration to provide user role retrieval from the remote Active Directory server.

**NOTE:** It is not a requirement to configure the Access Control Service for local user authentication. It is provided so that you can test each task in the configuration.

To configure the Access Control Service for local authentication:

1. Define roles on the Access Control Service.
  - a. From the administrator console of the Access Control Service, select **Users>User Roles>New User Role**.
  - b. Enter **dev** as the role name.  
In this solution, use the default values for other role settings.
  - c. Click **Save Changes**.

**NOTE:** This solution assumes that the MAGx600-UAC-SRX license is installed on the Access Control Service. If the full-feature license is installed, you will need to disable OAC Install and enable Agentless Access.

2. Configure the default authentication server.
  - a. Select **Authentication>Auth. Servers**.
  - b. Select **System Local**. This establishes the MAG Series device as the default authentication server.
3. Create users.
  - a. Select the **Users** tab, and click **New**.
  - b. Create **user-a** by entering the following details.

- Username
  - User's full name
  - Password
  - Password confirmation
- c. Repeat the previous step to create **user-b**.
- d. Click **Save Changes**.
- 4. Create a realm.
  - a. Select **Users>User Realms>New User Realm**.
  - b. Enter **REALM6** as the realm name.
  - c. Select **System Local** in the Authentication box.
  - d. Click **Save Changes**.
- 5. From the same page, create role mapping rules.
  - a. Select the **Role Mapping** tab, and click **New Rule**.
  - b. Define two rules with the following details.
    - Enter username user-a, and assign it to role dev.
    - Enter username user-b, and assign it to role dev.
  - c. Click **Save Changes**.
- 6. Set up the default sign-in page.
  - a. Select **Authentication>Signing In>Sign-in Policies**.
  - b. Click the default **Sign-in policy (\*/\*)**.
  - c. In the **Sign-in URL** box, enter the IP address of this device.
  - d. In **Authentication realm**, **Available realms**, select REALM6.
  - e. Click **Save Changes**.

**Results** Verify the results of the configuration. If the output does not display the intended configuration, repeat the instructions in this section to correct the configuration.

1. Verify that local authentication on the Access Control Service is functioning properly.
  - Open a browser window from an endpoint in the network.
  - Enter the fully qualified domain name for the Access Control Service.  
The default sign-in page should display.
  - Sign in as user-a, and provide the defined password.

## 2. From operational mode on the SRX Series device:

- a. Confirm that the authentication table on the SRX Series device was updated with **user-a**.

```
user@host> show services unified-access-control authentication-table
```

| Id       | Source IP    | Username | Age | Role identifier     |
|----------|--------------|----------|-----|---------------------|
| 1        | 172.24.72.79 | user-a   | 0   | 0000000001.000005.0 |
| Total: 1 |              |          |     |                     |

- b. Confirm that the correct role has been associated with the role identifier.

```
user@host> show services unified-access-control roles
```

| Name | Identifier          |
|------|---------------------|
| dev  | 0000000001.000005.0 |

- c. List all roles associated with user-a.

```
user@host> show services unified-access-control authentication-table detail
```

```
Identifier: 1
Source IP: 172.24.72.79
Username: user-a
Age: 0
Role identifier Role name
0000000001.000005.0 dev
```

### Configuring Redirection from the SRX Series Device to the Access Control Service

#### Step-by-Step Procedure

Local authentication, as configured in the previous task, requires users to log on to the Access Control Service directly to gain access to network resources. The SRX Series device can be configured to automatically redirect the browser of an unauthenticated user to the Access Control Service if a user requests access to a protected resource directly. You can define a user role firewall policy to redirect an unauthenticated user to a captive portal on the Access Control Service for sign-in.

**NOTE:** Other services, such as IDP, UTM, AppFW, and AppQoS, can be configured as well as the UAC captive portal implementation. The solution focuses on captive portal for authentication for user role implementation only.

To configure redirection from the SRX Series device to the Access Control Service:

1. From configuration mode on the SRX Series device, configure the profile for the captive portal acs-device.

```
[edit]
```

```
user@host# set services unified-access-control captive-portal acs-device
redirect-traffic unauthenticated
```

2. Add either the redirection URL for the Access Control Service or a default URL.

```
[edit]
user@host# set services unified-access-control captive-portal acs-device
redirect-url "https://%ic-url%/?target=%dest-url%&enforcer=%enforcer-id%"
```

This command specifies the default target and enforcer variables so that the browser is returned to the SRX Series device after authentication.

3. Allow traffic to the Active Directory (AD) server, the Access Control Service, and the other infrastructure servers.

```
[edit]
user@host# set security policies from-zone user to-zone infrastructure policy
Allow-AD-UAC match source-address any
user@host# set security policies from-zone user to-zone infrastructure policy
Allow-AD-UAC match destination-address any
user@host# set security policies from-zone user to-zone infrastructure policy
Allow-AD-UAC application any
user@host# set security policies from-zone user to-zone infrastructure policy
Allow-AD-UAC then permit
```

4. Configure a security policy that redirects HTTP traffic from zone user to zone untrust if the source-identity is unauthenticated-user.

```
[edit]
user@host# set security policies from-zone user to-zone untrust policy user-role-fw1
match source-address any
user@host# set security policies from-zone user to-zone untrust policy user-role-fw1
match destination-address any
user@host# set security policies from-zone user to-zone untrust policy user-role-fw1
match application http
user@host# set security policies from-zone user to-zone untrust policy user-role-fw1
match source-identity unauthenticated-user
```

5. Configure the action to be taken when traffic matches the criteria for user-role-fw1.

In this case, traffic meeting the specified criteria is allowed access to the UAC captive portal defined by the acs-device profile.

```
user@host# set security policies from-zone user to-zone untrust policy user-role-fw1
then permit application-services uac-policy captive-portal acs-device
```

6. Configure a security policy allowing access to any HTTP traffic from zone user to zone untrust.

```
[edit]
user@host# set security policies from-zone user to-zone untrust policy user-role-fw2
match source-address any
user@host# set security policies from-zone user to-zone untrust policy user-role-fw2
match destination-address any
user@host# set security policies from-zone user to-zone untrust policy user-role-fw2
match application http
user@host# set security policies from-zone user to-zone untrust policy user-role-fw2
match source-identity any
user@host# set security policies from-zone user to-zone untrust policy user-role-fw2
then permit
```

**NOTE:** It is important to position the redirection policy for unauthenticated users before a policy for “any” user so that UAC authentication is not shadowed by a policy intended for authenticated users.

7. If you are done configuring the policies, commit the changes.

```
[edit]
user@host# commit
```

**Results** Confirm your configuration with the following procedures. If the output does not display the intended configuration, repeat the instructions in this section to correct the configuration.

1. From configuration mode, confirm your captive portal profile configuration by entering the **show services** command.

```
[edit]
user@host# show services

...
unified-access-control {
 captive-portal acs-device {
 redirect-traffic unauthenticated;
 redirect-url "https://%ic-url%/?target=%dest-url%&enforcer=%enforcer-id%"
 }
}
```

2. From configuration mode, confirm your policy configuration by entering the **show security policies** command.

```
user@host# show security policies

...
from-zone user to-zone infrastructure {
 policy Allow-AD-UAC {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit
 }
 }
}
from-zone user to-zone untrust {
 policy user-role-fw1 {
 match {
 source-address any;
 destination-address any;
 application http;
 source-identity unauthenticated-user
 }
 then {
 permit {
 application-services {
```

```

 uac-policy {
 captive-portal acs-device;
 }
 }
}
}
}
}
}
from-zone user to-zone untrust {
 policy user-role-fw2 {
 match {
 source-address any;
 destination-address any;
 application http;
 source-identity any
 }
 then {
 permit
 }
 }
}
}
...

```

3. Verify that the redirection policy is functioning correctly.
  - a. Open a browser window from a second endpoint in the network.
  - b. Enter a third-party URL, such as [www.google.com](http://www.google.com).

The default sign-in page from the Access Control Service prompts for a user and password.

- c. Enter the username **user-b** and its password.

The browser should display the requested URL.

**NOTE:** If a pop-up blocker is set on the endpoint, it could interfere with this functionality.

- d. From operational mode on the SRX Series device, verify that the authentication data and roles from the Access Control Service were pushed to the SRX Series device successfully.

```
user@host> show services unified-access-control authentication-table
```

| Id       | Source IP    | Username | Age | Role identifier     |
|----------|--------------|----------|-----|---------------------|
| 1        | 172.24.72.79 | user-a   | 0   | 0000000001.000005.0 |
| 2        | 172.24.72.87 | user-b   | 0   | 0000000001.000005.0 |
| Total: 2 |              |          |     |                     |

## Configuring Active Directory Settings

### Step-by-Step Procedure

SPNEGO negotiation and Kerberos authentication are transparent to the user and network administrator, but certain configuration options enable the use of these protocols. This section identifies configuration requirements when using Active Directory as the authentication server. To interact in SPNEGO negotiation, the Access Control Service requires a keytab file created by Active Directory. Refer to your third-party documentation for more information about enabling SPNEGO and Kerberos usage.

This section is not intended to be a tutorial for Active Directory. However, there are specific configuration details required for this solution. See your third-party documentation to set up Active Directory as a domain controller.

To configure the Active Directory authentication server:

1. Add a DNS entry as the UAC service account in the **Forward Lookup Zones**. In this way clients can refer to the MAG Series device by name or by IP address.  
  
This UAC service account name will be used in the next section when reconfiguring the UAC service on the MAG Series device.
2. Single sign-on authentication requires that the UAC service account password never expires. To modify user settings:
  - a. From the Active Directory Users and Computers application in DNS, select **Users>New>User** and select the UAC service account created in step 1.
  - b. Select the **Account** tab.
  - c. In user settings, click **Password Never Expires**.
3. On the Domain Controller, open a command line, and enter the **ktpass** command to create the SPNEGO keytab file.

The keytab file created on the Active Directory server contains the full service principal name (SPN) and other encryption information from the server. The keytab file is then uploaded to the Access Control Service on the MAG Series device. This shared information identifies one device to the other whenever encrypted messages and responses are sent.

Use the following syntax.

```
ktpass -out output-file-name -mapuser uac-service-account-name -prn
service://fqdn@REALM
```

**ktpass**—Third-party Kerberos utility that maps an SPN to a user, in this case, to the UAC service account. The executable is available for download. Refer to your third-party documentation for the source for this utility.

**-out *output-file-name***—The name for the SPNEGO keytab file you are creating.

**-mapuser *uac-service-account-name***—The name of the UAC service account created in step 1.

**-prin service://fqdn@REALM**—The service principal name. The Kerberos authentication uses the SPN in its communication. It does not use an IP address.  
**service**—The HTTP service.

**fqdn**—The hostname of the Junos Pulse Access Control Service. The **service://FQDN** portion of the name is provided by the Access Control Service when registering with the Active Directory server.

**REALM**—The realm of the Active Directory authentication server. It is the same as the domain name. The Kerberos realm name is always in uppercase letters following the recommendation in RFC 1510. This affects interoperability with other Kerberos-based environments.

The following command creates an SPNEGO keytab file named `ic.ktpass`.

```
ktpass -out ic.ktpass -mapuser icuser@UCDC.COM -prin
HTTP/mag123.ucdc.com@UCDC.COM -pass Doj73096
```

This file is copied to the Access Control Service on the MAG Series device in the next section when SPNEGO is configured for remote authentication.

### Reconfiguring Remote Authentication on the Access Control Service

#### Step-by-Step Procedure

This section reconfigures the Access Control Service on the MAG Series device to query the remote Active Directory server instead of the local authentication table when authenticating a user. The following steps add services and authentication options to the Access Control Service on the MAG Series device. The configuration of the SRX Series device remains unchanged.

When you reconfigure the realm's authentication server, the Access Control Service displays all roles or groups from the configured domain controller and its trusted domains. Establishing role mapping rules equates the authentication server's roles or groups to those defined on the Access Control Service.

To reconfigure remote authentication on the Access Control Service:

1. From the administrator console of the Access Control Service on the MAG Series device, select **Authentication > Auth. Servers**.
2. Choose the **Active Directory/Windows NT** server type, and click **Add New Server**.
3. Enter the profile of the new authentication server.
  - a. Name the Active Directory server.
  - b. Enter its NetBIOS domain name in the domain box.

**NOTE:** You might receive the following message: "Either the server is not a domain controller of the domain, or the NetBIOS name of the domain is different from the Active Directory (LDAP) name." This message is informational and does not affect the processing of the authentication.

- c. Enter the Kerberos Realm name.

The Kerberos realm name is the FQDN of the Active Directory domain. For example-name, if “example-name” is the domain or NetBIOS name, example-name.net is the Kerberos realm name.

- d. In the Domain Join Configuration section, enter the username and password of the UAC services account which has permission to join computers to the Active Directory domain.

Select the Save credentials box.

- e. Enter the Container name.

This is the name of the container in Active Directory where you created the UAC services account for the Access Control Service.

- f. Enter the Computer Name.

Specify the machine ID that the Access Control Service uses to join the specified Active Directory domain as a computer. This name is derived from the licence hardware ID of the Access Control Service in the following format:  
0161MT2L00K2C0.

- g. Verify that the join operation has succeeded.

The Join Status indicator provides a color-coded status for the domain join operation as follows:

- Gray: Not started
- Yellow: In progress
- Red: Failed to join
- Green: Joined the domain

- h. Select **Kerberos** and **NTLM v2** as the authentication protocols.

- i. In the Trusts section, select the Allow trusted domains box.

- j. Select **Enable SPNEGO**.

- k. Use the Browse button to upload the keytab file that you created in the previous section.

- l. Click **Save Changes** and **Test Configuration**.

4. Ensure that SSO is enabled.

- a. Select **Users>User Realms** and the realm name.

- b. Select the Active Directory server name from the **Auth Server** list.

- c. Select the **Authentication Policy** tab.

- d. Verify that the **SSO** option is selected.
  - e. Click **Save Changes**.
5. Create role-mapping policies for groups acquired from the authentication server.
- Groups from the Active Directory authentication server need to be mapped to roles on the Access Control Service. You first need to create roles, and then map one or more groups to the appropriate role.
- a. Select the Role Mapping tab.
  - b. Click **New Rule**, enter a role name, and click **Save Changes**.  
You do not need to add users to the role. Create as many roles as needed to map the groups from the Active Directory authentication server.
  - c. Click **Groups**, and select **Search** to list the groups defined in the domain controller.
  - d. Select the group names that you want to map to the new role.
  - e. Repeat steps b through d to create and map other groups.
  - f. Click **Save Changes**.

### Configuring Endpoint Browsers for the SPNEGO

**Step-by-Step Procedure** Ensure that endpoint browsers have SPNEGO enabled. For further information, see your third-party documentation.

- Internet Explorer

From **Security>Local Intranet>Sites>Advanced** add the trusted URL.

IE performs SPNEGO without any further endpoint configuration but the user is prompted for a username and password. The username and password can be cached.

To provide single sign-on support, an Internet Explorer configuration can be pushed by configuring a group policy on the Active Directory server. See your third-party documentation for further information.

Integrated Windows Authentication must be enabled. Use the **Tools>Internet Options>Advanced>Security>Enable Integrated Windows Authentication** path to verify that IWA is enabled.

- Firefox (Windows and MacOS)

The configuration is in a hidden location. For the URL, type **about:config** and search for the word **trusted**. The required key is the comma separated parameter named **network.negotiate-auth.trusted-uris**.

**NOTE:** You need to specify the URL of the resource (in this solution, the FQDN or domain controller value UCDC.com).

- Chrome

Use the Internet Explorer setting. From **Security>Local Intranet>Sites>Advanced** add the trusted URL.

An internet Explorer configuration can also be pushed by configuring a group policy on the Active Directory server. This configuration is honored by Chrome.

After successful authentication, the standard agentless page is shown along with a second window with the protected resource (unless a pop-up blocker prevents this).

## Understanding Endpoint Security Using the Infranet Agent with the Junos OS Enforcer

An Infranet agent helps you secure traffic on your network starting with the endpoints that initiate communications as follows:

1. The Infranet agent, which runs directly on the endpoint, checks that the endpoint is compliant with your Unified Access Control (UAC) Host Checker policies. You can use a wide variety of criteria within a UAC Host Checker policy to determine compliance. For example, you can configure the Host Checker policy to confirm that the endpoint is running antivirus software or a firewall or that the endpoint is not running specific types of malware or processes.
2. The Infranet agent transmits the compliance information to the Junos OS Enforcer.
3. The Junos OS Enforcer allows or denies the endpoint access to the resources on your network based on the Host Checker compliance results.

Because the Infranet agent runs directly on the endpoint, you can use the Infranet agent to check the endpoint for security compliance at any time. For instance, when a user tries to sign into the IC Series UAC Appliance, you can require the Infranet agent to send compliance results immediately—the user will not even see the sign-in page until the Infranet agent returns positive compliance results to the IC Series appliance. You can also configure the Infranet agent to check for compliance after the user signs in or periodically during the user session.

If the endpoints running the Infranet agent have appropriate access, they will automatically send their compliance results to the IC Series appliance, and the IC Series appliance will update the authentication table entries accordingly and push them to the Junos OS Enforcer. The Junos OS Enforcer supports connections with the Odyssey Access Client and “agentless” Infranet agents.

## Configuring Endpoint Security Using the Infranet Agent with the Junos OS Enforcer

To integrate the Infranet agent into a Junos OS-UAC deployment, no special configuration is required on the Junos OS Enforcer. You simply need to create security policies enabling access to the appropriate endpoints as you would for any other Junos OS-UAC deployment.

# Configuring IPsec

- [Understanding Junos OS Enforcer Implementations Using IPsec on page 5593](#)
- [Example: Configuring the Device as a Junos OS Enforcer Using IPsec \(CLI\) on page 5594](#)

## Understanding Junos OS Enforcer Implementations Using IPsec

To configure an SRX Series device to act as a Junos OS Enforcer using IPsec, you must:

- Include the identity configured under the security IKE gateway. The identity is a string such as "gateway1.example.net", where gateway1.example.net distinguishes between IKE gateways. (The identities specify which tunnel traffic is intended.)
- Include the preshared seed. This generates the preshared key from the full identity of the remote user for Phase 1 credentials.
- Include the RADIUS shared secret. This allows the IC Series UAC Appliance to accept RADIUS packets for extended authentication (XAuth) from the Junos OS Infranet Enforcer.

When configuring IPsec between the IC Series appliance, the Odyssey Access Client, and the SRX Series device, you should note that the following are IKE (or Phase 1) proposal methods or protocol configurations that are supported from the IC Series appliance to the Odyssey Access Client:

- IKE proposal: **authentication-method pre-shared-keys** (you must specify **pre-shared-keys**)
- IKE policy:
  - **mode aggressive** (you must use aggressive mode)
  - **pre-shared-key ascii-text key** (only ASCII text preshared-keys are supported)
- IKE gateway: dynamic
  - **hostname *identity*** (you must specify a unique identity among gateways)
  - **ike-user-type group-ike-id** (you must specify **group-ike-id**)
  - **xauth access-profile *profile*** (you must specify **xauth**)

The following are IPsec (or Phase 2) proposal methods or protocol configurations that are supported from the IC Series appliance to the Odyssey Access Client.

- IPsec proposal: **protocol esp** (you must specify **esp**)
- IPsec VPN: **establish-tunnels immediately** (you must specify **establish-tunnels immediately**)

NOTE:

- Only one IPsec VPN tunnel is supported per from-zone to to-zone security policy. This is a limitation on the IC Series appliance.
- Junos OS security policies enable you to define multiple policies differentiated by different source addresses, destination addresses, or both. The IC Series appliance, however, cannot differentiate such configurations. If you enable multiple policies in this manner, the IC Series appliance could potentially identify the incorrect IKE gateway.

## Example: Configuring the Device as a Junos OS Enforcer Using IPsec (CLI)

To configure an SRX Series device to act as a Junos OS Enforcer using IPsec:

1. Set system and syslog information using the following configuration statements:

```
system {
 host-name test_host;
 domain-name test.juniper.net;
 host-name test_host;
 root-authentication {
 encrypted-password "1uhqXoD0T$6h26f0xXExOqkPHQLvaTF0";
 }
 services {
 ftp;
 ssh;
 telnet;
 web-management {
 http {
 interface ge-0/0/0.0;
 }
 }
 }
}
syslog {
 user * {
 any emergency;
 }
 file messages {
 any critical;
 authorization info;
 }
 file interactive-commands {
 interactive-commands error;
 }
}
```

```

}
max-configurations-on-flash 5;
max-configuration-rollbacks 5;
license {
autoupdate {
 url https://ae1.juniper.net/junos/key_retrieval;
}
}
ntp {
boot-server 1.2.3.4;
server 1.2.3.4;
}
}

```

**NOTE:** On SRX Series devices, the factory default for the maximum number of backup configurations allowed is five. Therefore, you can have one active configuration and a maximum of five rollback configurations. Increasing this backup configuration number will result in increased memory usage on disk and increased commit time.

To modify the factory defaults, use the following commands:

```

root@host# set system max-configurations-on-flash number
root@host# set system max-configuration-rollbacks number

```

where `max-configurations-on-flash` indicates backup configurations to be stored in the configuration partition and `max-configuration-rollbacks` indicates the maximum number of backup configurations.

2. Configure the interfaces using the following configuration statements:

```

interfaces {
ge-0/0/0 {
 unit 0 {
 family inet {
 address 10.64.75.135/16;
 }
 }
}
ge-0/0/1 {
 unit 0 {
 family inet {
 address 10.100.54.1/16;
 }
 }
}
ge-0/0/2 {
 unit 0 {
 family inet {
 address 10.101.54.1/16;
 }
 }
}
}

```

3. Configure routing options using the following configuration statements:

```
routing-options {
 static {
 route 0.0.0.0/0 next-hop 10.64.0.1;
 route 10.11.0.0/16 next-hop 10.64.0.1;
 route 172.0.0.0/8 next-hop 10.64.0.1;
 route 10.64.0.0/16 next-hop 10.64.0.1;
 }
}
```

4. Configure security options using the following configuration statements:

```
security {
 ike {
 traceoptions {
 file ike;
 flag all;
 }
 proposal prop1 {
 authentication-method pre-shared-keys;
 dh-group group2;
 authentication-algorithm sha1;
 encryption-algorithm 3des-cbc;
 }
 policy pol1 {
 mode aggressive;
 proposals prop1;
 pre-shared-key ascii-text "9YS4ZjmPQ6CuTz6Au0cSvWLxNbiHm";
 }
 gateway gateway1 {
 ike-policy pol1;
 dynamic {
 hostname gateway1.juniper.net;
 connections-limit 1000;
 ike-user-type group-ike-id;
 }
 external-interface ge-0/0/0;
 xauth access-profile infranet;
 }
 gateway gateway2 {
 ike-policy pol1;
 dynamic {
 hostname gateway2.juniper.net;
 connections-limit 1000;
 ike-user-type group-ike-id;
 }
 external-interface ge-0/0/0;
 xauth access-profile infranet;
 }
 }
}
```

5. Configure IPsec parameters using the following configuration statements:

```
ipsec {
 proposal prop1 {
 protocol esp;
 authentication-algorithm hmac-sha1-96;
 encryption-algorithm 3des-cbc;
```

```

lifetime-seconds 86400;
}
policy pol1 {
proposals prop1;
}
vpn vpn1 {
ike {
 gateway gateway1;
 ipsec-policy pol1;
}
}
vpn vpn2 {
ike {
 gateway gateway2;
 ipsec-policy pol1;
}
}
}
}

```

6. Configure screen options using the following configuration statements:

```

screen {
ids-option untrust-screen {
 icmp {
 ping-death;
 }
 ip {
 source-route-option;
 tear-drop;
 }
 tcp {
 syn-flood {
 alarm-threshold 1024;
 attack-threshold 200;
 source-threshold 1024;
 destination-threshold 2048;
 queue-size 2000;
 timeout 20;
 }
 land;
 }
}
}
}

```

7. Configure zones using the following configuration statements:

```

zones {
security-zone trust {
 tcp-rst;
 host-inbound-traffic {
 system-services {
 all;
 }
 protocols {
 all;
 }
 }
}
}

```

```
 interfaces {
 ge-0/0/0.0;
 }
 }
 security-zone untrust {
 host-inbound-traffic {
 system-services {
 all;
 }
 protocols {
 all;
 }
 }
 interfaces {
 ge-0/0/1.0;
 }
 }
 security-zone zone101 {
 host-inbound-traffic {
 system-services {
 all;
 }
 protocols {
 all;
 }
 }
 interfaces {
 ge-0/0/2.0;
 }
 }
}
```

8. Configure policies for UAC using the following configuration statements:

```
policies {
 from-zone trust to-zone trust {
 policy default-permit {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
 }
 from-zone trust to-zone untrust {
 policy default-permit {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
 }
}
```

```

}
}
policy default-deny {
match {
 source-address any;
 destination-address any;
 application any;
}
then {
 permit;
}
}
policy pol1 {
match {
 source-address any;
 destination-address any;
 application any;
}
then {
 permit {
 tunnel {
 ipsec-vpn vpn1;
 }
 application-services {
 uac-policy;
 }
 }
 log {
 session-init;
 session-close;
 }
}
}
}
from-zone untrust to-zone trust {
policy pol1 {
match {
 source-address any;
 destination-address any;
 application any;
}
then {
 permit;
 log {
 session-init;
 session-close;
 }
}
}
}
from-zone trust to-zone zone101 {
policy pol1 {
match {
 source-address any;
 destination-address any;
 application any;
}

```

```

 }
 then {
 permit {
 tunnel {
 ipsec-vpn vpn2;
 }
 application-services {
 uac-policy;
 }
 }
 log {
 session-init;
 session-close;
 }
 }
 }
 policy test {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit;
 }
 }
 }
 default-policy {
 deny-all;
 }
 }
 }

```

9. Configure RADIUS server authentication access using the following configuration statements:

```

access {
 profile infranet {
 authentication-order radius;
 radius-server {
 10.64.160.120 secret "9KBoWX-YgJHqfVwqfTzCAvWL";
 }
 }
}

```

10. Configure services for UAC using the following configuration statements:

```

services {
 unified-access-control {
 infranet-controller IC27 {
 address 3.23.1.2;
 interface ge-0/0/0.0;
 password "9Wjl8X-Vb2GDkev4aGUHkuOB";
 }
 infranet-controller prabaIC {
 address 10.64.160.120;
 interface ge-0/0/0.0;
 }
 }
}

```

```
password "9jdkmT69pRhrz3hrev7Nik.";
}
certificate-verification optional;
traceoptions {
 flag all;
}
}
}
```

# Configuring Captive Portal

## Understanding the Captive Portal on the Junos OS Enforcer

---

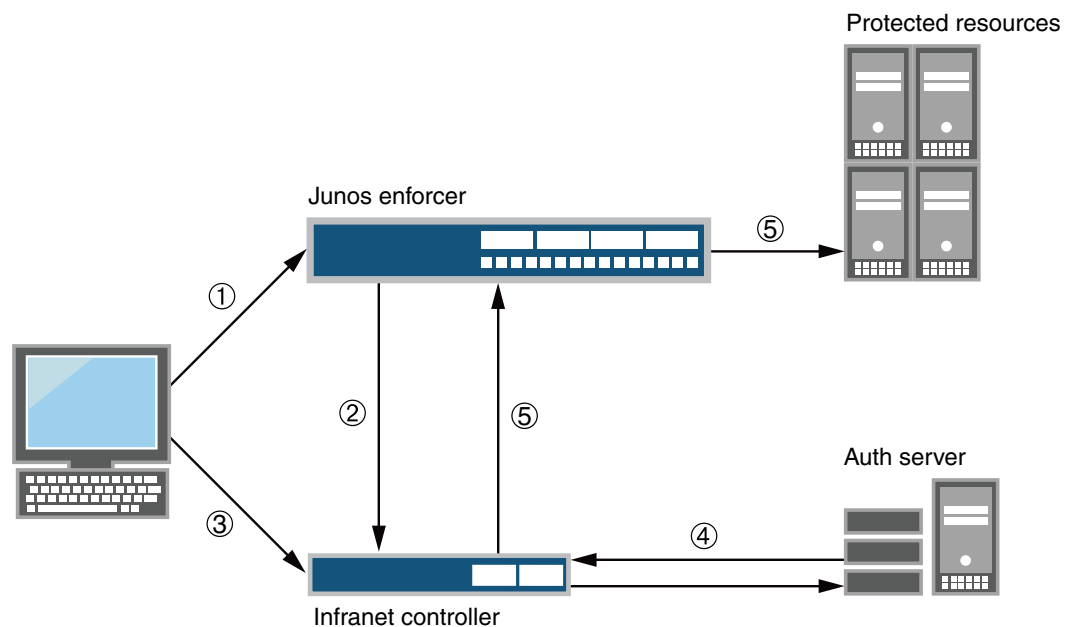

In a Unified Access Control (UAC) deployment, users might not be aware that they must first sign in to the IC Series UAC Appliance for authentication and endpoint security checking before they are allowed to access a protected resource behind the Junos OS Enforcers. To help users sign in to the IC Series appliance, you can configure the captive portal feature. The captive portal feature allows you to configure a policy in the Junos OS Enforcer that automatically redirects HTTP traffic destined for protected resources to the IC Series appliance or to a URL configured in the Junos OS Enforcer.

You can configure a captive portal for deployments that use either source IP enforcement or IPsec enforcement, or a combination of both enforcement methods.

[Figure 253](#) shows the captive portal feature enabled on a Junos OS Enforcer. Users accessing protected resources are automatically redirected to the IC Series appliance:

1. Users point to a protected resource using the browser.
2. The Junos OS Enforcer determines that the user is not authenticated and redirects the request to the IC Series appliance or another server.
3. Users enter their Infranet username and password to log in.
4. The IC Series appliance passes the user credentials to an authentication server.
5. After authentication, the IC Series appliance redirects the users to the protected resource they wanted to access.

Figure 253: Enabling the Captive Portal Feature on a Junos OS Enforcer

By default, the Junos OS Enforcer encodes and forwards to the IC Series appliance the protected resource URL that the user entered. The IC Series appliance uses the protected resource URL to help users navigate to the protected resource. The manner in which the IC Series appliance uses the protected resource URL depends on whether or not the user's endpoint is running the Odyssey Access Client or Junos Pulse. If the user's endpoint is not running the Odyssey Access Client or Junos Pulse (that is, it is in an agentless or Java agent configuration), the IC Series appliance automatically opens a new browser window and uses HTTP to access the protected resource after the user signs in. If the endpoint is using the Odyssey Access Client, the IC Series appliance inserts a hypertext link in the webpage that automatically opens after the user signs in. The user must then click that hypertext link to access the protected resource by means of HTTP in the same browser window.

The Junos OS Enforcer supports the captive portal feature only for HTTP traffic. If you attempt to access a protected resource by using HTTPS or a non-browser application (such as an e-mail application), the Junos OS Enforcer does not redirect the traffic. When using HTTPS or a non-browser application, you must manually sign in to the IC Series appliance first before attempting to access protected resources.

## Understanding Captive Portal Configuration on the Junos OS Enforcer

---

To configure the captive portal feature, you create a security policy on the Junos OS Enforcer and then specify a redirection option for the captive portal security policy. You can choose to redirect traffic to an external server or to the IC Series UAC Appliance. You can also choose to redirect all traffic or unauthenticated traffic only.

- Redirecting traffic to an external webserver—You can configure the Junos OS Enforcer to redirect HTTP traffic to an external webserver instead of the IC Series appliance. For example, you can redirect HTTP traffic to a webpage that explains to users the requirement to sign in to the IC Series appliance before they can access the protected resource. You could also include a link to the IC Series appliance on that webpage to help users sign in.
- Redirecting unauthenticated traffic—Select this option if your deployment uses source IP only or a combination of source IP and IPsec. The Junos OS Enforcer redirects clear-text traffic from unauthenticated users to the currently connected IC Series appliance or to an IP address or domain name that you specify in a redirect URL. After a user signs in to the IC Series appliance and the user's endpoint system meets the requirements of the IC Series appliance security policies, the Junos OS Enforcer allows the user's clear-text traffic to pass through in source IP deployments. For IPsec deployments, the Odyssey Access Client creates a VPN tunnel between the user and the Junos OS Enforcer. The Junos OS Enforcer then applies the VPN policy, allowing the encrypted traffic to pass through.
- Redirecting all traffic—Specify this option if you want to redirect all traffic to the URL that you specify in a redirect URL.
- Redirecting traffic with multiple IC Series appliances—You can configure multiple IC Series appliances on your Junos OS Enforcer, but it is connected to only one IC Series appliance at any given time. If the connection to the IC Series appliance fails, the Junos OS Enforcer tries to connect to next configured IC Series appliance. As a result, you cannot be sure which IC Series appliance is connected to the Junos OS Enforcer at any given time. To ensure that the Junos OS Enforcer redirects traffic to the connected IC Series appliance, configure the default redirect URL or the **%ic-ip%** option in the URL.

### Related Documentation

- [Example: Creating a Captive Portal Policy on the Junos OS Enforcer on page 5606](#)

## Understanding the Captive Portal Redirect URL Options

---

By default, after you configure a captive portal policy, the Junos OS Enforcer redirects HTTP traffic to the currently connected IC Series UAC Appliance by using HTTPS. To perform the redirection, the Junos OS Enforcer uses the IP address or domain name that you specified when you configured the IC Series appliance instance on the Junos OS Enforcer. The format of the URL that the Junos OS Enforcer uses for default redirection is:

```
https://%ic-ip%/?target = %dest-url% &enforcer = %enforcer-id% &policy =
%policy-id% &dest-ip = %dest-ip%
```

If you configured your Junos OS Enforcer to work with multiple IC Series appliances in a cluster, and the current IC Series appliance becomes disconnected, the Junos OS Enforcer automatically redirects HTTP traffic to the next active IC Series appliance in its configuration list. The Junos OS Enforcer redirects traffic to only one IC Series appliance at a time.

Otherwise, the browser displays a certificate warning to users when they sign in. You do not need to override the default redirection destination except in these situations:

- You are using a VIP for a cluster of IC Series appliances, and the Junos OS Enforcer is configured to connect to the IC Series appliance physical IP addresses.
- You want to redirect traffic to a webserver instead of the IC Series appliance.
- If, because of split DNS or IP routing restrictions at your site, the Junos OS Enforcer uses a different address for the IC Series appliance than endpoints, you must specify the domain name or IP address that endpoints must use to access the IC Series appliance.

**NOTE:** If a captive portal policy is configured with the IC Series UAC Appliance URL as the target, then use only HTTPS to redirect traffic.

Table 499 lists different options that you can configure in the redirect URL string.

**Table 499: Redirect URL String Options**

| URL String           | Description                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>%dest-url%</b>    | Specifies the protected resource which the user is trying to access.                                                   |
| <b>%enforcer-id%</b> | Specifies the ID assigned to the Junos OS Enforcer by the IC Series appliance.                                         |
| <b>%policy-id%</b>   | Specifies the encrypted policy ID for the captive portal security policy that redirected the traffic.                  |
| <b>%dest-ip%</b>     | Specifies the IP address or hostname of the protected resource which the user is trying to access.                     |
| <b>%ic-ip%</b>       | Specifies the IP address or hostname of the IC Series appliance to which the Junos OS Enforcer is currently connected. |

### Example: Creating a Captive Portal Policy on the Junos OS Enforcer

This example shows how to create a captive portal policy on the Junos OS Enforcer. In this example, you deploy a Junos OS Enforcer in front of the data center resources you want to protect and configure the captive portal feature on the Junos OS Enforcer. The

Junos OS Enforcer then automatically redirects HTTP traffic destined for the protected resource to the IC Series UAC Appliance for authentication.

- [Requirements on page 5607](#)
- [Overview on page 5607](#)
- [Configuration on page 5607](#)
- [Verification on page 5609](#)

## Requirements

Before you begin:

- Deploy the IC Series appliance in the network so that users can access the device. Use the internal port on the IC Series appliance to connect users, the Junos OS Enforcer (an SRX210 device in this example), and authentication servers. See [“Configuring Communications Between the Junos OS Enforcer and the IC Series UAC Appliance \(CLI Procedure\)” on page 5566](#).
- Set up security zones and interfaces on the Junos OS Enforcer. Make sure that end users are in a different security zone than protected resources. For example, protected resources in the data center are configured in the trusted zone and users in an untrusted zone. See [“Example: Creating Security Zones” on page 1031](#).
- Add individual users to either an external authentication server or the local authentication server. Set up roles and realms for individual users. You can provision access to protected resources based on your network security needs.

## Overview

In this example, you want to protect the trusted zone from users on the LAN by making sure that only compliant and authenticated users are granted access. New users join your network every month. You want to configure the captive portal feature on your system so that unauthenticated users are redirected to the IC Series appliance automatically without requiring new users to remember to log in to the IC Series appliance.

The configuration instructions in this topic describe how to create a security policy called **my-policy**, specify a match condition for this policy, specify the captive portal policy as a part of the UAC policy, and set criteria for redirecting traffic to the IC Series appliance. In this example, the policy **my-policy**:

- Specifies the match condition to include any traffic from a previously configured zone called **trust** to another previously configured zone called **untrust**.
- Specifies the captive portal policy called **my-captive-portal-policy** as part of the UAC policy.
- Specifies the redirect-traffic criteria as **unauthenticated**.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy

and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set security policies from-zone untrust to-zone trust policy my-policy match
 destination-address any source-address any application any
set security policies from-zone untrust to-zone trust policy my-policy then permit
 application-services uac-policy captive-portal my-captive-portal-policy
set services unified-access-control captive-portal my-captive-portal-policy redirect-traffic
 unauthenticated
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To create a captive portal policy on the Junos OS Enforcer:

1. Specify the match condition for the policy.  

```
[edit security policies from-zone untrust to-zone trust policy my-policy]
user@host# set match destination-address any source-address any application
any
```
2. Specify the captive portal policy as part of the UAC policy to be applied on the traffic that matches the conditions specified in the security policy.  

```
[edit security policies from-zone untrust to-zone trust policy my-policy]
user@host# set then permit application-services uac-policy captive-portal
my-captive-portal-policy
```
3. Redirect all unauthenticated traffic to the IC Series appliance.  

```
[edit services unified-access-control]
user@host# set captive-portal my-captive-portal-policy redirect-traffic
unauthenticated
```

**Results** Confirm your configuration by entering the **show services** and **show security policies** command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show services
unified-access-control {
 captive-portal my-captive-portal-policy {
 redirect-traffic unauthenticated;
 }
}

[edit]
user@host# show security policies
...
from-zone untrust to-zone trust {
 policy my-policy {
```

```
match {
 source-address any;
 destination-address any;
 application any;
}
then {
 permit {
 application-services {
 uac-policy {
 captive-portal my-captive-portal-policy;
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying the Captive Portal Policy on page 5609](#)

### Verifying the Captive Portal Policy

---

**Purpose** Verify that the captive portal policy was created.

**Action** From operational mode, enter the **show security policies detail** command.

**Related Documentation** • [Understanding Captive Portal Configuration on the Junos OS Enforcer on page 5605](#)

## Example: Configuring a Redirect URL for Captive Portal

---

This example shows how to redirect traffic to the currently connected IC Series UAC Appliance or to an IP address or domain name that you specify in a redirect URL. We recommend the default configuration that redirects traffic to the IC Series appliance for authentication.

- [Requirements on page 5609](#)
- [Overview on page 5610](#)
- [Configuration on page 5610](#)
- [Verification on page 5610](#)

## Requirements

Before you specify the redirect URL, make sure you configure the captive portal policy. For information about creating the captive portal policy, see [“Example: Creating a Captive Portal Policy on the Junos OS Enforcer” on page 5606](#).

## Overview

In this example, you configure the URL to redirect traffic to the IC Series appliance and after authentication to forward the traffic automatically to the protected resource. The configuration instructions in this topic describe how to set the URL to `https://my-website.com`.

You can redirect traffic to the currently connected IC Series appliance or to an IP address or domain name that you specify in a redirect URL. We recommend the default configuration that redirects traffic to the IC Series appliance for authentication.

If you need to override the default redirection destination, you can specify any combination of redirect options:

- **`https://IP or domain name/URL path/target=%dest-url%`**—Forwards users to the protected resource automatically after authentication with the IC Series appliance or webserver. The Junos OS Enforcer replaces the `%dest-url%` parameter with the protected resource URL and then forwards the protected resource URL in encrypted form to the IC Series appliance.
- **`https://IP or domain name/target=URL path`**—Forwards users to the specified URL automatically after authentication with the IC Series appliance or webserver.
- **`https://IP or domain name/URL path`**—Redirects users to the IC Series appliance authentication page but not be forwarded to the protected resource after authentication. Users must manually open a new browser window and enter the protected resource URL again after signing in.
- **`redirect-all`**—Redirects all traffic to the URL that you specify in a redirect URL.

## Configuration

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the redirect URL for the captive portal feature on the Junos OS Enforcer:

1. Specify the redirect URL for the preconfigured captive portal policy.  

```
[edit services unified-access-control]
user@host# set captive-portal my-captive-portal-policy redirect-url
https://192.168.0.100/target=my-website.com
```
2. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **`show services unified-access-control captive-portal my-captive-portal-policy`** command.

- [How the Integrated User Firewall Works on page 5614](#)
- [Deployment Scenario for User Firewall Integration with Windows Active Directory on page 5615](#)
- [Limitations on page 5615](#)

## Integrated User Firewall and Authentication Sources

The SRX Series device already supports Unified Access Control (UAC) integration with Network Access Control (NAC) and a user firewall that can derive its authentication source from Windows Active Directory via the UAC MAG Series Junos Pulse Gateway. However, many customers want simple user firewall functionality without full NAC, and do not want the additional cost or complexity of user role firewall (which has Active Directory dependencies such as Kerberos, SPNEGO on Browsers, Active Directory DNS/Certs, and UAC configuration).

The integrated user firewall feature fulfills the requirement for simplicity. It retrieves user-to-IP address mappings from the Windows Active Directory to use in firewall policies as match criteria. This feature consists of the SRX Series polling the event log of the Active Directory controller to determine, by username and source IP address, who has logged in to the SRX Series device. Then the username and group information are queried from the LDAP service in the Active Directory controller. Once the SRX Series has the IP address, username, and group relationship information, it generates authentication entries. With the authentication entries, the SRX Series UserFW module enforces user-based and group-based policy control over traffic.

For a comparison of integrated user firewall, user role firewall, and UAC NAC, see [“Understanding the Three-Tiered User Firewall Features” on page 5499](#).

## Benefits of Integrated User Firewall

The integrated user firewall feature introduces an authentication source via integration with Microsoft Active Directory technology.

- It provides visibility into who is accessing the SRX Series and best-effort security for access to the SRX Series.
- It is a single-box solution, requiring only an SRX Series.
- It requires fewer configuration steps than the UAC integration with NAC, which uses the UAC MAG Series.
- It does not require the configuration of a captive portal, although that option is available to enforce on users who do not authenticate.
- It is ideal for small-to-medium businesses and low-scale deployments.
- It supports High Availability (HA).

## How the Integrated User Firewall Works

At a high level, this feature involves the UserID process in the SRX Series Routing Engine, which reads the Windows event log from the Active Directory controller and abstracts IP address-to-user mapping information. The process correlates users to the groups to which they belong, via the LDAP protocol with LDAP service in the Active Directory controller. Thus, the process has gathered enough information to generate authentication entries. The network administrator then references the authentication entries in user firewall security policies to control traffic.

A more detailed explanation of how this feature works is as follows:

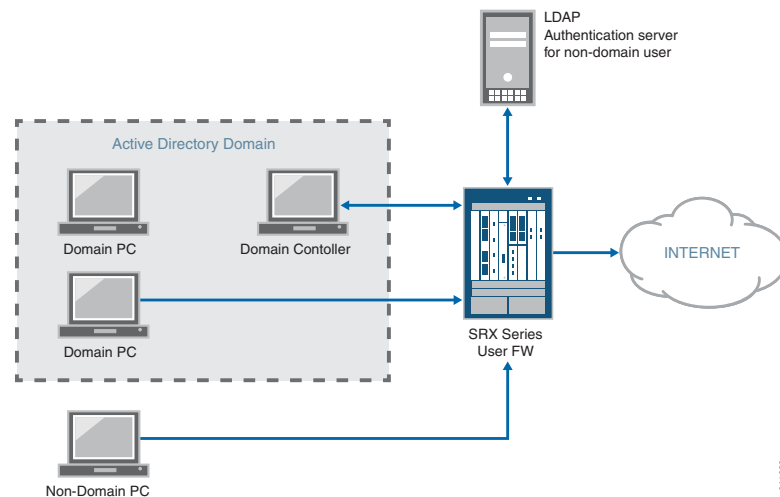

1. The SRX Series reads the Active Directory event log to get source IP address-to-username mapping information. To do so, a process in the SRX Series Routing Engine implements a Windows Management Instrumentation (WMI) client with Microsoft Distributed COM/Microsoft RPC stacks and an authentication mechanism to communicate with a Windows Active Directory controller in an Active Directory domain. Using event log information retrieved from the Active Directory controller, the process knows the IP addresses of active Active Directory users and abstracts IP-to-Active Directory username mapping information. The process monitors Active Directory event log changes via the same WMI DCOM interface to adjust local mapping information to reflect any change in the Active Directory server.
2. The process uses LDAP to query the LDAP service interface of the Active Directory to identify the groups to which users belong. Having the IP address, the Active Directory user, and the groups, the process can generate authentication entries accordingly.
3. The process pushes the authentication entries to the Packet Forwarding Engine authentication table. The Packet Forwarding Engine uses the entries and user policy to apply user firewall access control to traffic.

This feature supports two domains and up to 10 Active Directory controllers in a domain.

## Deployment Scenario for User Firewall Integration with Windows Active Directory

Figure 254 illustrates a typical scenario where the integrated user firewall feature is deployed. Users in the Active Directory domain and users outside the Active Directory domain want access to the Internet through an SRX Series device. The domain controller might also act as the LDAP server.

Figure 254: Scenario for Integrated User Firewall

The SRX Series device reads and analyzes the event log of the domain controller and generates an authentication table as an Active Directory authentication source for this feature. The user firewall is aware of any domain user on an Active Directory domain device via the Active Directory authentication source. The SRX Series device administrator configures a user firewall policy that enforces the desired user-based or group-based access control.

For any non-domain user or domain user on a non-domain machine, the administrator specifies a captive portal to force the user to do firewall authentication (if the SRX Series supports captive portal for the traffic type). After the user enters a name and password and passes firewall authentication, the SRX Series gets firewall authentication user/group information and can enforce user firewall policy to control the user accordingly.

In addition to captive portal, if the IP address or user information is not available from the event log, the user can again log in to the Windows PC to generate an event log entry. Then the system generates the user's authentication entry accordingly.

## Limitations

- Windows Active Directory controllers older than Windows 2003 are not supported.
- Tracking the status of non-Windows Active Directory users is not supported.
- IPv6 addresses are not supported.

- Logical systems are not supported.
- The WMIC does not support multiple users logged onto the same PC.
- Domain controllers and domain PCs must be running Windows OS. The minimum support for a Windows client is Windows XP. The minimum support for a server is Windows Server 2003.
- You cannot use the Primary Group, whether by its default name of Domain Users or any other name (if you happened to have changed it), in integrated user firewall configurations.

When a new user is created in the Active Directory, the user is added to the global security group Primary Group which is by default named Domain Users. The Primary Group is less specific than other groups created in the Active Directory because all users belong to it. Also, it can become very large.

## Understanding Active Directory Authentication Tables

This topic includes the following sections:

- [Active Directory Authentication as an Authentication Source on page 5616](#)
- [Active Directory Authentication Tables on page 5617](#)
- [State Information for Active Directory Authentication Table Entries on page 5618](#)
- [Active Directory Authentication Table Management on page 5619](#)
- [Timeout Interval for Table Entries on page 5620](#)

### Active Directory Authentication as an Authentication Source

On an SRX Series device, user information tables serve as the authentication source for information required by firewall security policies. The SRX Series device supports various user information tables including local, user firewall, and Unified Access Control (UAC) types. The integrated user firewall feature introduces another type of authentication source—Active Directory authentication.

The integrated user firewall feature gathers user and group information for Active Directory authentication by reading domain controller event logs, probing domain PCs, and querying Lightweight Directory Access Protocol (LDAP) services within the configured Windows domain. Up to two Windows domains are supported.

From the user and group information, the integrated user firewall feature generates an Active Directory authentication table on the Routing Engine of the SRX Series device, which then pushes the authentication table to the Packet Forwarding Engine. Security policies use the information in the table to authenticate users and to provide access control for traffic through the firewall.

## Active Directory Authentication Tables

The Active Directory authentication table contains the IP address, username, and group mapping information that serves as the authentication source for the SRX Series integrated user firewall feature. Information in the table is obtained by reading Windows Active Directory domain controller event logs, probing domain PCs, and querying LDAP services within a specified Windows domain.

Reading domain controller event logs generates a list of IP address-to-user mapping information that is used to create entries in the Active Directory authentication table. Once entries have been added in the table, a query is sent to the LDAP server for user-to-group mapping information.

The LDAP server returns all group information; this includes not only information about the groups you directly belong to, but also all the parent (and parent of the parent and so on) groups that you belong to. Group information returned from the LDAP server is compared with the source identity in security policies. If there is a match, Active Directory authentication table entries are updated to include only the group information provided in the security policy. In this way, only relevant group information is listed in the authentication table. Whenever source identity is updated, the authentication table is also updated to reflect the up-to-date relevant group information for all listed users.

When user traffic arrives at the firewall, the Active Directory authentication table is searched for an entry corresponding to the source IP address of the traffic. If an entry exists, policies matching that entry are applied to the traffic and access is allowed or denied.

Table 1 lists Active Directory authentication table support by SRX Series devices:

**Table 500: Active Directory Authentication Table Support by SRX Series Devices**

| SRX Series Devices | Active Directory Authentication Table Entries | Domains | Active Directory Controllers |
|--------------------|-----------------------------------------------|---------|------------------------------|
| SRX550HM           | 5000                                          | 2       | 10                           |
| SRX1500            | 20,000                                        | 2       | 10                           |
| SRX5000 line       | 100,000                                       | 2       | 10                           |
| vSRX               | 5000                                          | 2       | 10                           |

Once the maximum number of authentication table entries is reached, no additional entries are created.

To be compliant with the Active Directory authentication table, entries must adhere to the following parameters:

- Usernames are limited to 64 characters.
- Group names are limited to 64 characters.
- Each entry can be associated with up to 200 relevant groups (configured in the source identity field). For example, if you belong to 1000 groups in LDAP and out of these, no more than 200 groups are configured in the source identity field, you are compliant with the Active Directory authentication table.

The Active Directory Authentication table must be enabled as the authentication source for integrated user firewall information retrieval.

```
user@host# set security user-identification authentication source
active-directory-authentication-table priority priority
```

**NOTE:** The *priority* option specifies the sequence in which user information tables are checked. Using the lowest setting for the Active Directory authentication source specifies the highest priority, meaning that the Active Directory authentication source is searched first.

## State Information for Active Directory Authentication Table Entries

Active Directory authentication table entries can be in one of four states:

**Initial**—Specifies that IP address-to-user mapping information was obtained by reading domain controller event logs and an entry was added to the authentication table. Entries in this state are changed to valid when the table is pushed from the Routing Engine to the Packet Forwarding Engine.

**Valid**—Specifies that a valid entry was obtained by reading domain controller event logs or that a valid response was received from a domain PC probe and the user is a valid domain user.

**Invalid**—Specifies that an invalid response was received from a domain PC probe and the user is an invalid domain user.

**Pending**—Specifies that a probe event generated an entry in the authentication table, but no probe response has been received from the domain PC. If a probe response is not received within 90 seconds, the entry is deleted from the table.

For a list of probe responses, see [“Understanding Integrated User Firewall Domain PC Probing” on page 5636](#).

To display Active Directory authentication entries, along with their state information, use the following command:

```
user@host>show services user-identification active-directory-access
active-directory-authentication-table all
```

```
Domain: www.example1.net
Total count: 2
```

| Source IP    | Username | Groups     | State   |
|--------------|----------|------------|---------|
| 192.168.10.2 | u2       | r1, r3, r4 | initial |
| 192.168.10.3 | u3       | r5, r6, r4 | pending |

Domain: www.example2.net

Total count: 2

| Source IP | Username | Groups     | State   |
|-----------|----------|------------|---------|
| 10.1.1.2  | u4       | r1, r3, r4 | valid   |
| 10.1.1.3  | u5       | r5, r6, r4 | invalid |

Command options allow you to display information by **user** or **group**, and to define additional output levels—**brief**, **domain**, **extensive**, **node**.

## Active Directory Authentication Table Management

Windows domain environments are constantly changing as users log in and out of the network and as network administrators modify user group information. The integrated user firewall feature manages changes in the Windows domain by periodically reading domain controller event logs and querying the LDAP server for user-to-group mapping information. That information is used in updating the Active Directory authentication table as appropriate.

Additionally, a probe function is provided to address changes that occur between reading event logs, or to address the case where event log information is lost. An on-demand probe is triggered when client traffic arrives at the firewall but a source IP address for that client cannot be found in the table. And at any point, manual probing is available to probe a specific IP address.

Changes to the active Directory Authentication table also occur due to source identity changes in the security policy configuration.

[Table 501](#) describes events that trigger an Active Directory authentication table update.

**Table 501: Events Triggering Active Directory Authentication Table Updates**

| Event                                                               | Active Directory Authentication Table Update                                                                                                                                                                                                                  |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A domain controller event log is read at configured intervals.      | <p>New IP address-to-user entries are added in the authentication table in initial state. Group information is retrieved from the LDAP server.</p> <p>When the authentication entry is pushed to Packet Forwarding Engine, the state is changed to valid.</p> |
| An on-demand or manual probe is sent to a domain PC.                | An entry is added in the authentication table in pending state. If a probe response is not returned within 90 seconds, the state of the entry is deleted.                                                                                                     |
| An on-demand or manual probe response is received from a domain PC. | Based on the response, entries in pending state are changed to valid or invalid. For valid responses, the group information is retrieved from the LDAP server. For invalid responses, the entry is marked as invalid.                                         |

Table 501: Events Triggering Active Directory Authentication Table Updates (*continued*)

| Event                                                                            | Active Directory Authentication Table Update                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| An LDAP server query identifies new user-to-group mapping information.           | Entries are updated with the group information.                                                                                                                                                                                                                                                                                                                                                                                         |
| An LDAP server query identifies deleted user information.                        | Entries associated with that user are deleted from the table.                                                                                                                                                                                                                                                                                                                                                                           |
| An LDAP server query identifies deleted group information.                       | <p>The affected group information is updated.</p> <p>For example, user2 belongs to group2, and group2 belongs to group1. And, group1 is listed as a source-identity for group2. For any authentication entry of user2, group1 is listed in its relevant groups. However, if group2 is removed from the LDAP server, user2 loses the connection with group1, and as a result, group1 is removed from the user2 authentication table.</p> |
| An LDAP server query identifies added group information.                         | If the group is referenced in a security policy, entries associated with this group are updated to add the group information.                                                                                                                                                                                                                                                                                                           |
| The source identity information is removed from a security policy configuration. | Entries associated with the source identity are deleted from Active Directory authentication table.                                                                                                                                                                                                                                                                                                                                     |

**NOTE:** If an entry is deleted from the table, any sessions attached to that entry are also deleted. If an entry in the table is updated to add or remove group information, there is no impact to existing sessions for that entry.

To manually delete an entry from the table, use the **request services user-identification active-directory-access active-directory-authentication-table** command. Options exist for deleting a specific IP address, domain, group, or user.

To clear the contents of the Active Directory authentication table, use the **clear services user-identification active-directory-access active-directory-authentication-table** command.

### Timeout Interval for Table Entries

When a user is no longer active, a timer is started for that user's entry in the Active Directory authentication table. When time is up, the user's entry is removed from the table. Entries in the table remain active as long as there are sessions associated with the entry.

To set the timeout value, use the following statement:

```
user@host# set services user-identification active-directory-access
authentication-entry-timeout minutes
```

The default **authentication-entry-timeout** interval is 30 minutes. To disable timeouts, set the interval to 0.

**NOTE:** We recommend that you disable timeouts when disabling on-demand probing in order to prevent someone from accessing the Internet without logging in again.

To view timeout information for Active Directory authentication table entries, use the following command:

```
user@host>show services user-identification active-directory-access
active-directory-authentication-table all extensive
```

```
Domain: www.example1.net
Total entries: 2
Source IP: 192.168.1.2
Username: u2
Groups: r1, r3, r4
State: initial
Access start date: 2014-03-22
Access start time: 10:56:58
Age time: 20 min
```

```
Source IP: 192.168.1.3
Username: u3
Groups: r5, r6, r4
State: pending
Access start date: 2014-03-22
Access start time: 10:46:58
Age time: 10 min
```

This example shows that the timer has started for two entries—the entry for user u2 will time out in 20 minutes, while the entry for user u3 will time out in 10 minutes. When session traffic is associated with an entry, the age time value changes to “infinite.”

## Role of LDAP in Integrated User Firewall

In order to get the user and group information necessary to implement the Integrated User Firewall feature, the SRX Series device uses the Lightweight Directory Access Protocol (LDAP). The SRX Series acts as an LDAP client communicating with an LDAP server. In a common implementation scenario of the integrated user firewall feature, the domain controller acts as the LDAP server. The LDAP module in the SRX Series, by default, queries the Active Directory in the domain controller.

The SRX Series downloads user and group lists from the LDAP server. The device also queries the LDAP server for user and group updates. The SRX Series downloads a first-level, user-to-group mapping relationship and then calculates a full user-to-group mapping.

The use of “LDAP” in this section applies specifically to LDAP functionality within the integrated user firewall feature.

## LDAP Server Configuration and Base Distinguished Name

Most of the LDAP server configuration is optional, leveraging the common implementation scenario where the domain controller acts as the LDAP server. The SRX Series periodically (every two minutes) queries the LDAP server to get the user and group information changed since the last query.

The only required LDAP server configuration is the LDAP base distinguished name (DN), which is the top level of the LDAP directory tree. Microsoft Active Directory follows the convention of deriving the base DN from a company's DNS domain components. An example of a base DN is dc=example, dc=net.

## LDAP's Authentication Method

By default, the LDAP authentication method uses simple authentication. The client's username and password are sent to the LDAP server in plaintext. Keep in mind that the password is clear and can be read from the network.

To avoid exposing the password, you can use simple authentication within an encrypted channel [namely Secure Sockets layer (SSL)], as long as the LDAP server supports LDAP over SSL (LDAPS). After enabling SSL, the data sent from the LDAP server to the SRX Series is encrypted. To enable SSL, see the **user-group-mapping** statement.

## LDAP Server's Username, Password, and Server Address

The LDAP server's username, password, IP address, and port are all optional, but they can be configured.

- If the username and password are not configured, the system uses the configured domain controller's username and password.
- If the LDAP server's IP address is not configured, the system uses the address of one of the configured Active Directory domain controllers.

- If the port is not configured, the system uses port 389 for plaintext or port 636 for encrypted text.

## Caching and Calculation of User-to-Group Mappings

The SRX Series device caches user-to-group mappings in its local database when the **show services user-identification active-directory-access user-group-mapping** operation is performed. This command displays the users who belong to a group or the groups to which a user belongs.

Three events cause a user-to-group mapping to be removed from the cache:

- A source-identity is removed from a referenced firewall policy (because only source-identities referenced in a policy are stored in the authentication table).
- The LDAP configuration is deleted from the customer's configuration, so all cached Active Directory user-to-group mappings for the domain are removed.
- The user-to-group mapping is deleted from the LDAP server.

The SRX periodically queries to get user and group information from the LDAP server in real time. The user list and the group list show only cached users or groups, not all users or groups in the LDAP server. From this information, the SRX Series calculates one-level mapping relationships. The user list, group list, and mapping are cached in the local database.

## Updating Group Information in the Authentication Entry Table

The SRX Series device queries to get the changed users and groups based on the prior query results from the LDAP server. The SRX Series updates the local database and triggers an authentication entry update. Only user/group mappings that are already cached are updated. Other users and groups that are not in the database do not have their mapping relationships cached.

## LDAP Server Status and Statistics

You can verify the LDAP connection status by issuing the **show services user-identification active-directory-access user-group-mapping status** command.

You can see counts of queries made to the LDAP server by issuing the **show services user-identification active-directory-access statistics user-group-mapping** command.

## Active Directory Autodiscovery

The integrated user firewall feature provides the IP address and Active Directory name of the domain. The auto-discovery feature can use the Active Directory's global catalog feature and then query DNS for a list of global catalogs. The global catalogs in the list are typically provided in a weighted order based on criteria such as network location, system-set weights based on global catalog server size, and so on. Once the customer has the list of Active Directories, the customer can configure it for both event log reading and LDAP search.

## Example: Configuring Integrated User Firewall

This example shows how to implement the integrated user firewall feature by configuring a Windows Active Directory domain, an LDAP base, unauthenticated users to be directed to captive portal, and a security policy based on a source identity.

- [Requirements on page 5624](#)
- [Overview on page 5624](#)
- [Configuration on page 5625](#)
- [Verification on page 5630](#)

### Requirements

This example uses the following hardware and software components:

- One SRX Series device
- Junos OS Release 12.1X47-D10 or later for SRX Series devices

No special configuration beyond device initialization is required before configuring this feature.

### Overview

In a typical scenario for the integrated user firewall feature, domain and non-domain users want to access the Internet through an SRX Series device. The SRX Series reads and analyzes the event log of the domain controllers configured in the domain. Thus, the SRX Series detects domain users on an Active Directory domain controller. Active Directory domain generates an authentication table as the Active Directory authentication source for the integrated user firewall. The SRX Series device uses this information to enforce the policy to achieve user-based or group-based access control.

For any non-domain user or domain user on a non-domain device, the network administrator can specify a captive portal to force the user to submit to firewall authentication (if the SRX Series supports captive portal for the traffic type. For example, HTTP). After the user enters his name and password and passes firewall authentication, the SRX Series gets firewall authentication user-to-group mapping information from LDAP server and can enforce user firewall policy control over the user accordingly.

**NOTE:** You cannot use the Primary Group, whether by its default name of Domain Users or any other name, if you changed it, in integrated user firewall configurations.

When a new user is created in Active Directory (AD), the user is added to the global security group Primary Group which is by default Domain Users. The Primary Group is less specific than other groups created in AD because all users belong to it. Also, it can become very large.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands to a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set services user-identification active-directory-access domain example.net
 user-group-mapping ldap base DC=example,DC=net
set services user-identification active-directory-access domain example.net user
 administrator password xxxxx
set services user-identification active-directory-access domain example.net
 domain-controller ad1 address 192.0.2.15
set access profile profile1 authentication-order ldap
set access profile profile1 authentication-order password
set access profile profile1 ldap-options base-distinguished-name
 CN=Users,DC=example,DC=net
set access profile profile1 ldap-options search search-filter sAMAccountName=
set access profile profile1 ldap-options search admin-search distinguished-name
 CN=Administrator,CN=Users,DC=example,DC=net
set access profile profile1 ldap-options search admin-search password
 "$9$8HqL-wJGikmfGU0BEhrI"
set access profile profile1 ldap-server 192.0.2.3
set security policies from-zone trust to-zone untrust policy p1 match source-address any
set security policies from-zone trust to-zone untrust policy p1 match destination-address
 any
set security policies from-zone trust to-zone untrust policy p1 match application any
set security policies from-zone trust to-zone untrust policy p1 match source-identity
 unauthenticated-user
set security policies from-zone trust to-zone untrust policy p1 match source-identity
 unknown-user
set security policies from-zone trust to-zone untrust policy p1 then permit
 firewall-authentication user-firewall access-profile profile1
set security policies from-zone trust to-zone untrust policy p2 match source-address any
set security policies from-zone trust to-zone untrust policy p2 match destination-address
 any
set security policies from-zone trust to-zone untrust policy p2 match application any
set security policies from-zone trust to-zone untrust policy p2 match source-identity
 "example.net\galenrikka"
set security policies from-zone trust to-zone untrust policy p2 match source-identity
 "example.net\domainuser_1_0000001"
set security policies from-zone trust to-zone untrust policy p2 then permit
set security user-identification authentication source active-directory-authentication-table
 priority 125
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To establish a Windows Active Directory domain, to configure captive portal, and to configure another security policy, perform the steps in this section.

Once configured, when traffic arrives, the SRX Series consults the user firewall process, which in turn consults the Active Directory authentication source to determine whether the source is in its authentication table. If user firewall hits an authentication entry, the SRX Series checks the policy configured in Step 4 for further action. If user firewall does not hit any authentication entry, the SRX Series checks the policy configured in Step 3 to force the user to do captive portal.

1. Configure the LDAP base distinguished name.

```
[edit services user-identification]
user@host# set active-directory-access domain example.net user-group-mapping
ldap base DC=example,DC=net
```

2. Configure a domain name, the username and password of the domain, and the name and IP address of the domain controller in the domain.

```
[edit services user-identification]
user@host# set active-directory-access domain example.net user administrator
password xxxxx
user@host# set active-directory-access domain example.net domain-controller
ad1 address 192.0.2.15
```

3. Configure an access profile and set the authentication order and LDAP options.

```
[edit access profile profile1]
user@host# set authentication-order ldap
user@host# set authentication-order password
user@host# set ldap-options base-distinguished-name
CN=Users,DC=example,DC=net
user@host# set ldap-options search search-filter sAMAccountName=
user@host# set ldap-options search admin-search distinguished-name
CN=Administrator,CN=Users,DC=example,DC=net
user@host# set ldap-options search admin-search password pw1593
user@host# set ldap-server 192.0.2.3
```

4. Configure a policy for the source-identity "unauthenticated-user" and "unknown-user" and enable the firewall authentication captive portal. Configuring the source-identity is required in case there is no authentication sources configured, or disconnected.

```
[edit security policies from-zone trust to-zone untrust policy p1]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application any
user@host# set match source-identity unauthenticated-user
user@host# set match source-identity unknown-user
user@host# set then permit firewall-authentication user-firewall access-profile
profile1
user@host# set then permit firewall-authentication user-firewall domain
ad-userfw.net
```

5. Configure a second policy to enable a specific user.

```
[edit security policies from-zone trust to-zone untrust policy p2]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application any
user@host# set match source-identity "example.net\domainuser_1_0000001"
user@host# set match source-identity "example.net\galenrikka"
user@host# set then permit
```

**NOTE:** When you specify a source identity in a policies statement, prepend the domain name and a backslash to the group name or username. Enclose the combination in quotation marks.

6. Set the Active Directory Authentication table as the authentication source for integrated user firewall information retrieval and specify the sequence in which user information tables are checked.

```
[edit security]
user@host# set user-identification authentication source
active-directory-authentication-table priority 125
```

**NOTE:** You must set the Active Directory Authentication table as the authentication source for integrated user firewall information retrieval and specify the sequence in which user information tables are checked using the command `set security user-identification authentication source active-directory-authentication-table priority value`.

The default value of this option is 125. The default priority for all the authentication sources are:

- Local authentication: 100
- Integrated user firewall: 125
- User role firewall: 150

The field `priority` specifies the source(s) for the Active Directory authentication table. The value set determines the sequence for searching among various supported authentication tables to retrieve a user role. Note these are the only currently supported values. You can enter any value from 0 through 65535. The default priority of the Active Directory authentication table is 125. This means that even if you do not specify a priority value, the Active Directory authentication table will be searched starting at sequence of value 125 (Integrated user firewall).

For more details, see [“Understanding Active Directory Authentication Tables” on page 5616](#) and `active-directory-authentication-table`.

### (Optional) Configuration of PKI and SSL Forward Proxy to Authenticate Users

**Step-by-Step Procedure** Optionally, for non-domain users, you can configure Public Key Infrastructure (PKI) to validate integrity, confidentiality, and authenticity of traffic. PKI includes digital certificates issued by the Certificate Authority (CA), certificate validity and expiration dates, details about the certificate owner and issuer, and security policies.

**NOTE:** For any non-domain user or domain user on a non-domain machine, the administrator specifies a captive portal to force the user to complete firewall authentication. In addition to captive portal, if the IP address or user information is not available from the event log, the user can again log in to the Windows PC to generate an event log entry. Then the system generates the user's authentication entry accordingly.

To enable the SRX Series device to authenticate the users through HTTPs, the SSL forward proxy must be configured and enabled. You need to generate local certificate, add SSL termination profile, add SSL proxy profile, and reference the SSL proxy profile in the security policy. If SSL forward proxy is not enabled, SRX Series device cannot authenticate users who are using HTTPS, but for the users who are using HTTP, FTP and Telnet, the authentication can be performed as expected.

To generate public key infrastructure (PKI) and enable SSL forward proxy, perform the following steps:

1. Generate a public key infrastructure (PKI) public/private key pair for a local digital certificate.  

```
user@host# request security pki generate-key-pair certificate-id ssl-inspect-ca size 2048 type rsa
```
2. Manually generate a self-signed certificate for the given distinguished name.  

```
user@host# request security pki local-certificate generate-self-signed certificate-id ssl-inspect-ca domain-name www.example.net subject "CN=www.example.net,OU=IT,O=example Networks,L=Sunnyvale,ST=CA,C=US" email security-admin@example.net
```
3. Define the access profile to be used for SSL termination services. This option is available only on high-end SRX Series devices.  

```
user@host# set services ssl termination profile for_userfw server-certificate ssl-inspect-ca
```
4. Configure the loaded certificate as root-ca in the SSL proxy profile. This option is available only on high-end SRX Series devices.  

```
user@host# set services ssl proxy profile ssl-inspect-profile root-ca ssl-inspect-ca
```
5. Specify the **ignore-server-auth-failure** option if you do not want to import the entire CA list and you do not want dropped sessions. This option is available only on high-end SRX Series devices.

```
user@host# set services ssl proxy profile ssl-inspect-profile actions
ignore-server-auth-failure
```

6. Add SSL termination profile into security policies. This option is available only on high-end SRX Series devices.

```
user@host# set security policies from-zone untrust to-zone trust policy p1 then
permit firewall-authentication user-firewall ssl-termination-profile for_userfw
```

## Results

From configuration mode, confirm your integrated user firewall configuration by entering the **show services user-identification active-directory-access** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show services user-identification active-directory-access
domain example.net {
 user {
 administrator;
 password "$ABC123"; ## SECRET-DATA
 }
 domain-controller ad1 {
 address 192.0.2.15;
 }
 user-group-mapping {
 ldap {
 base DC=example,DC=net;
 }
 }
}
```

From configuration mode, confirm your policy configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show security policies
from-zone trust to-zone untrust {
 policy p1 {
 match {
 source-address any;
 destination-address any;
 application any;
 source-identity unauthenticated-user;
 source-identity unknown-user;
 }
 then {
 permit {
 firewall-authentication {
 user-firewall {
 access-profile profile1;
 }
 }
 }
 }
 }
}
```

```
policy p2 {
 match {
 source-address any;
 destination-address any;
 application any;
 source-identity "example.net\galenrikka";
 source-identity "example.net\domainuser_1_0000001"
 }
 then {
 permit;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying Connectivity to a Domain Controller

|                |                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Verify that at least one domain controller is configured and connected.                                                             |
| <b>Action</b>  | From operational mode, enter the <b>show services user-identification active-directory-access domain-controller status</b> command. |
| <b>Meaning</b> | The domain controller is shown to be connected or disconnected.                                                                     |

### Verifying the LDAP Server

|                |                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Verify that the LDAP server is providing user-to-group mapping information.                                                          |
| <b>Action</b>  | From operational mode, enter the <b>show services user-identification active-directory-access user-group-mapping status</b> command. |
| <b>Meaning</b> | The LDAP server address, port number, and status are displayed.                                                                      |

### Verifying Authentication Table Entries

|                |                                                                                       |
|----------------|---------------------------------------------------------------------------------------|
| <b>Purpose</b> | See which groups users belong to and the users, groups, and IP addresses in a domain. |
|----------------|---------------------------------------------------------------------------------------|

**Action** From operational mode, enter the **show services user-identification active-directory-access active-directory-authentication-table all** command.

**Meaning** The IP addresses, usernames, and groups are displayed for each domain.

---

#### Verifying IP-to-User Mapping

---

**Purpose** Verify that the event log is being scanned.

**Action** From operational mode, enter the **show services user-identification active-directory-access statistics ip-user-mapping** command.

**Meaning** The counts of the queries and failed queries are displayed.

---

#### Verifying IP Probe Counts

---

**Purpose** Verify that IP probes are occurring.

**Action** From operational mode, enter the **show services user-identification active-directory-access statistics ip-user-probe** command.

**Meaning** The counts of the IP probes and failed IP probes are displayed.

---

#### Verifying User-to-Group Mapping Queries

---

**Purpose** Verify that user-to-group mappings are being queried.

**Action** From operational mode, enter the **show services user-identification active-directory-access statistics user-group-mapping** command.

**Meaning** The counts of the queries and failed queries are displayed.

# Managing Event Logs

- [Understanding How the WMIC Reads the Event Log on the Domain Controller on page 5633](#)
- [Using Firewall Authentication as an Alternative to WMIC on page 5635](#)
- [Understanding Integrated User Firewall Domain PC Probing on page 5636](#)

## Understanding How the WMIC Reads the Event Log on the Domain Controller

This topic includes the following sections:

- [Windows Management Instrumentation Client on page 5633](#)
- [WMIC Reads the Event Log on the Domain Controller on page 5634](#)
- [Specifying IP Filters to Limit IP-to-User Mapping on page 5634](#)
- [Event Log Verification and Statistics on page 5634](#)

### Windows Management Instrumentation Client

When you configure the integrated user firewall feature on an SRX Series device, the SRX Series establishes a Windows Management Instrumentation (WMI)/Distributed Component Object Module (DCOM) connection to the domain controller. The SRX Series acts as a WMI client (WMIC). It reads and monitors the security event log on the domain controller. The SRX Series analyzes the event messages to generate IP address-to-user mapping information.

All configuration regarding the WMIC is optional; it will function with default values. After the domain is configured (by the **set services user-identification active-directory-access domain** statement), the WMIC starts to work. The WMIC connection to the domain controller uses the same user credentials as those configured for the domain.

**CAUTION:** Integrated user firewall uses NTLMv2 as the default WMIC authentication protocol for security reasons. NTLMv1 exposes the system to attacks in which authentication hashes could be extracted from NTLMv1 authentication responses.

For compatibility with integrated user firewall, you must apply the latest version of the Microsoft SP2 patch if you are running an older version of Windows OS, including Windows 2000, Windows XP, and Windows 2003.

## WMIC Reads the Event Log on the Domain Controller

The following SRX Series behaviors apply to reading the event log:

- The SRX Series monitors the event log at a configurable interval, which defaults to 10 seconds.
- The SRX Series reads the event log for a certain timespan, which you can configure. The default timespan is one hour. Each time at WMIC startup, the SRX Series checks the last timestamp and the timespan. If the last timestamp is older than the current timespan, then the timespan takes effect. After the WMIC and the UserID process start working, the timespan does not apply; the SRX Series simply reads the latest event log.
- During WMIC startup, the SRX Series has a maximum count of events it will read from the event log, and that maximum is not configurable.
  - On SRX Series branch devices, the maximum count is 100,000.
  - On SRX high-end devices, the maximum count is 200,000.

During WMIC startup, this maximum is used with the timespan setting, so that if either limit is reached, the WMIC stops reading the event log.

- After a failover, the SRX Series reads the event log from the latest event log timestamp.
- In a chassis cluster environment, the WMIC works on the primary node only.

## Specifying IP Filters to Limit IP-to-User Mapping

You can specify IP filters to limit the IP address-to-user mapping information that the SRX Series generates from the event log.

To understand when a filter is useful for such mapping, consider the following scenario. A customer deploys 10 SRX Series devices in one domain, and each SRX Series controls a branch. All 10 SRX Series devices read all 10 branch user login event logs in the domain controller. However, the SRX Series is configured to detect only whether the user is authenticated on the branch it controls. By configuring an IP filter on the SRX Series, the SRX Series reads only the IP event log under its control.

You can configure a filter to include or exclude IP addresses or prefixes. You can specify a maximum of 20 addresses for each filter.

## Event Log Verification and Statistics

You can verify that the authentication table is getting IP address and user information by issuing the **show services user-identification active-directory-access active-directory-authentication-table all** command. A list of IP address-to-user mappings is displayed for each domain. The table contains no group information until LDAP is running.

You can see statistics about reading the event log by issuing the **show services user-identification active-directory-access ip-user-mapping statistics domain** command.

## Using Firewall Authentication as an Alternative to WMIC

This topic includes the following sections:

- [WMIC Limitations on page 5635](#)
- [Firewall Authentication as a Backup Method for IP Address-to-User Mappings on page 5635](#)

### WMIC Limitations

The primary method for the integrated user firewall feature to get IP address-to-user mapping information is for the SRX Series device to act as a WMI client (WMIC). However, the WMIC has limitations, such as the following:

- On Windows XP or Server2003, the Windows firewall does not allow the WMIC request to pass through because of the dynamic port allocation of the Distributed Component Object Model (DCOM). Therefore, for these operating systems when Windows firewall is enabled, the PC does not respond to the WMIC probe.
- Because the event-log-reading and PC probe functions both use WMI, using a global policy to disable the WMI-to-PC probe also affects event log reading.

Because these cases might result in the failure of the PC probe, a backup method for getting IP address-to-user mappings is needed. That method is to use firewall authentication to identify users.

### Firewall Authentication as a Backup Method for IP Address-to-User Mappings

If you want to use firewall authentication to identify users for the integrated user firewall feature, specify a domain name in the **set security policies from-zone trust to-zone untrust policy <policy-name> then permit firewall-authentication user-firewall domain <domain-name>** statement.

If a domain is configured in that statement, fwauth recognizes that the domain is for a domain authentication entry, and will send the domain name to the fwauth process along with the authentication request. After it receives the authentication response, fwauth deletes that domain authentication entry. The fwauth process sends the source IP address, username, domain, and other information to the USERID process, which verifies that it is a valid domain user entry. The subsequent traffic will hit this user firewall entry.

**NOTE:** The Active Directory authentication entry that comes from the fwauth process is not subject to the IP filters.

## Understanding Integrated User Firewall Domain PC Probing

---

This topic includes the following sections:

- [Overview of Domain PC Probing on page 5636](#)
- [Probing Domain PCs for User Information on page 5636](#)
- [Probe Response on page 5637](#)
- [Probe Configuration on page 5638](#)
- [Probe Rate and Statistics on page 5638](#)

### Overview of Domain PC Probing

At a high level, the integrated user firewall feature gathers IP address, user, and group information from Windows Active Directory domain controller event logs and LDAP services. This information is used to generate Active Directory authentication table entries on an SRX Series device. Authentication entries serve as the authentication source for security policies that enforce user-based or group-based access control.

PC probing acts as a supplement of event log reading. When a user logs in to the domain, the event log contains that information. The PC probe is triggered only when there is no IP-to-address mapping from the event log.

Domain information constantly changes as users log in and out of domain PCs. The integrated user firewall probe functionality provides a mechanism for tracking and verifying information in the authentication tables by directly probing domain PCs for IP address-to-user mapping information. New and changed information identified by the probe serves to update Active Directory authentication table entries, which is critical to maintaining firewall integrity.

The IP address filter also impacts the PC probe. Once you configure the IP address filter, only the IP address specified in the filter is probed.

### Probing Domain PCs for User Information

The integrated user firewall feature tracks the online status of users by probing domain PCs. If a user is not online or is not an expected user, the Active Directory authentication table is updated as appropriate. The following probe behaviors apply:

On-demand probing—On-demand probing occurs when a packet is dropped due to a missing entry in the Active Directory authentication table. In this case, an entry is added in pending state to the authentication table, and the domain PC identified by the source IP field of the dropped packet is probed for IP address and user information. The entry remains in pending state until a response is received from the probe.

Manual probing—Manual probing is used to verify and troubleshoot the online status of a user or a range of users, and is at the discretion of the system administrator. To initiate a manual probe, use the **request services user-identification active-directory-access ip-user-probe address ip-address address domain domain-name** command. If a domain name is not specified, the probe looks at the first configured domain for the IP address. To specify a range, use the appropriate network address.

**NOTE:** Manual probing can cause entries to be removed from the Active Directory authentication table. For example, if there is no response from your PC due to a network issue, such as when the PC is too busy, the IP address entry of the PC is marked as *invalid* and your access is blocked.

If the SRX Series device cannot access a domain PC for some reason, such as a network configuration or Windows firewall issue, the probe fails.

## Probe Response

Based on the domain PC probe response, updates are made to the Active Directory authentication table, and associated firewall policies take effect. If no response is received from the probe after 90 seconds, the authentication entry times out. The timed-out authentication entry is the pending state authentication entry, which is generated when you start the PC probe.

If the probe is successful, the state of the authentication entry is updated from pending to valid. If the probe is unsuccessful, the state of the authentication entry is marked as invalid. The invalid entry has the same lifetime as a valid entry and is overwritten by upcoming fwauth (firewall authentication process) authentication results or by the event log. [Table 502](#) lists probe responses and corresponding authentication table actions.

**Table 502: Probe Responses and Associated Active Directory Authentication Table Actions**

| Probe Response from Domain PC                                                    | Active Directory Authentication Table Action |
|----------------------------------------------------------------------------------|----------------------------------------------|
| Valid IP address and username                                                    | Add IP-related entry.                        |
| Logged on user changed                                                           | Update IP-related entry.                     |
| Connection timeout                                                               | Update IP-related entry as invalid.          |
| Access denied                                                                    | Update IP-related entry as invalid.          |
| Connection refused                                                               | Update IP-related entry as invalid.          |
| Authentication failed                                                            | Update IP-related entry as invalid.          |
| (The configured username and password have no privilege to probe the domain PC.) |                                              |

## Probe Configuration

On-demand probing is enabled by default. To disable on-demand probing, use the **set services user-identification active-directory-access no-on-demand-probe** statement. Delete this statement to reenable probing. When on-demand probing is disabled, manual probing is available.

The probe timeout value is configurable. The default timeout is 10 seconds. To configure the timeout value, use the following statement:

```
user@host# set services user-identification active-directory-access wmi-timeout seconds
```

If no response is received from the domain PC within the **wmi-timeout** interval, the probe fails and the system either creates an invalid authentication entry or updates the existing authentication entry as invalid. If an authentication table entry already exists for the probed IP address, and no response is received from the domain PC within the **wmi-timeout** interval, the probe fails and that entry is deleted from the table.

**NOTE:** To probe domain PCs, you must configure the integrated user firewall feature with the username and password credentials. You do not necessarily need a username and password account for each PC; instead you could set up one administrator account with privileges to access information on multiple PCs.

## Probe Rate and Statistics

The maximum probe rate for the integrated user firewall feature is set by default and cannot be changed. For high-end SRX Series devices, the probe rate is 600 times per minute. For branch SRX Series devices, the probe rate is 100 times per minute. Probe functionality supports 5000 users, or up to 10 percent of the total supported authentication entries, whichever is smaller. Supporting 10 percent means that at any time, the number of IP addresses waiting to be probed cannot exceed 10 percent. For more information about the number of supported Active Directory authentication table entries, see [“Understanding Active Directory Authentication Tables” on page 5616](#).

High-level statistics covering probe activity are available for the total number of probes and the number of failed probes. [Table 502](#) describes the reasons for probe failures. To display probe statistics, use the **show services user-identification active-directory-access statistics ip-user-probe** command.

```
user@host> show services user-identification active-directory-access statistics ip-user-probe
Domain: www.example1.net
 Total user probe number : 176116
 Failed user probe number : 916

Domain: www.example2.net
 Total user probe number : 17632
 Failed user probe number : 342
```

## Security Configuration Statement Hierarchy

Use the statements in the **security** configuration hierarchy to configure actions, certificates, dynamic virtual private networks (VPNs), firewall authentication, flow, forwarding options, group VPNs, Intrusion Detection Prevention (IDP), Internet Key Exchange (IKE), Internet Protocol Security (IPsec), logging, Network Address Translation (NAT), public key infrastructure (PKI), policies, resource manager, rules, screens, secure shell known hosts, trace options, user identification, Unified Threat Management (UTM), and zones. Statements that are exclusive to the SRX Series devices running Junos OS are described in this section.

Each of the following topics lists the statements at a sub-hierarchy of the **[edit security]** hierarchy.

## System Configuration Statement Hierarchy

Use the statements in the **system** configuration hierarchy to configure system management functions including addresses of the Domain Name System (DNS) servers; device's hostname, address, and domain name; health monitoring; interface filtering; properties of the device's auxiliary and console ports; security profiles for logical systems; time zones and Network Time Protocol (NTP) properties; trace options; and user login accounts, including user authentication and the root-level user account. Statement descriptions that are exclusive to the SRX Series devices running Junos OS are described in this section.

```

system {
 accounting {
 destination {
 radius {
 server server-address {
 accounting-port port-number;
 max-outstanding-requests number;
 port number;

```

**Hierarchy Level** [edit services user-identification]

**Release Information** Statement introduced in Junos OS Release 12.1X47-D10.

**Description** Identify the domain and domain controllers where the integrated user firewall feature is implemented; configure the IP address-to-user mapping information and the user-to-group mapping information for accessing the LDAP server.

**Options** **domain *domain-name***—Required. Name of the domain; the length of the name ranges from 1 through 64 characters. The SRX Series device can have the integrated user firewall feature configured in a maximum of two domains.

**user *username***—Required. Active Directory account name.

**Range:** 1 through 64 characters.

**password *password***—Required. Password of the Active Directory account.

**Range:** 1 through 128 characters.

**domain-controller** *domain-controller-name*—Required. Name of the domain controller; the length of the name can range from 1 through 64 characters. A maximum of 10 domain controllers can be configured.

**address** *domain-controller-address*—Required. IP address of the domain controller.

The remaining statements are explained separately. See [CLI Explorer](#).

| <b>Description</b>              | An authentication table is generated by polling Active Directory domain controllers for source identity information about active users. Each entry in the table correlates an authenticated user with an IP address and associated user groups. That information is used for matching in IP-based firewall policies. The user information must be retrieved from the table before policy lookup can proceed and traffic is allowed to pass through the firewall.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>                  | <p><b>priority <i>priority</i></b>—Specify the priority of the Active Directory authentication table. The priority determines the sequence for searching among various other authentication tables to retrieve a user role. The priorities of the following tables are considered: local authentication table, firewall authentication table, Active Directory authentication table, and UAC authentication table.</p> <p>Each authentication table is given a unique priority value. The lower the value, the higher the priority. A table with priority 120 is searched before a table with priority 200. Setting the priority value of a table to 0 is equivalent to disabling the table and eliminating it from the search sequence.</p> <p><b>Range:</b> A unique value from 0 through 65535.</p> <p><b>Default:</b> The default priority of the Active Directory authentication table is 125.</p> |
| <b>Required Privilege Level</b> | <p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>              | Specify the certificate authority (CA) of the certificate that the SRX Series device should use in communications with an Infranet Enforcer. The SRX Series device uses the CA to validate the IC Series UAC Appliance server certificate. <p>Use this statement if you have loaded certificates from multiple certificate authorities (CAs) onto your SRX Series device and you need to configure the device to act as a Junos OS Enforcer in a Unified Access Control (UAC) deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series appliance .</p> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>              | <p>This option determines whether server certificate verification is required when initiating a connection between an SRX Series device and a Junos Pulse Access Control Service in a UAC configuration. If no CA profile contains the certificate authority (CA) that signed the configured server certificate for the Access Control Service, this option determines whether the commit check should fail, a warning should be displayed, or the connection should be made without any warning.</p> <p>By default, an administrator is warned if the CA certificate is not configured in the <b>ca-profile</b>.</p>                                                                                    |
|                                 | <div>  <p><b>NOTE:</b> For strict security, this option should be reset to <b>required</b>, and the proper CA certificate should be specified in the CA profile.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Options</b>                  | <ul style="list-style-type: none"> <li>• <b>optional</b>—Certificate verification is not required. If the CA certificate is not specified in the <b>ca-profile</b> option, the commit check passes and no warning is issued.</li> <li>• <b>required</b>—Certificate verification is required. If the CA certificate is not specified in the <b>ca-profile</b> option, an error message is displayed, and the commit check fails. Use this option to ensure strict security.</li> <li>• <b>warning</b>—(Default) Certificate verification is not required, however, a warning message is displayed during commit check if the CA certificate is not specified in the <b>ca-profile</b> option.</li> </ul> |
| <b>Required Privilege Level</b> | <p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## file (System Logging)

**Syntax** file *filename* {  
 allow-duplicates;  
 any (alert | any | critical | emergency | error | info | none | notice | warning);  
 archive {  
 archive-sites {  
 url *password*;  
 }  
 (binary-data | no-binary-data);  
 files *number*;  
 size *size*;  
 start-time *start-time*;  
 transfer-interval *transfer-interval*;  
 (world-readable | no-world-readable);  
 }  
 authorization (alert | any | critical | emergency | error | info | none | notice | warning);  
 change-log (alert | any | critical | emergency | error | info | none | notice | warning);  
 conflict-log (alert | any | critical | emergency | error | info | none | notice | warning);  
 daemon (alert | any | critical | emergency | error | info | none | notice | warning);  
 dfc (alert | any | critical | emergency | error | info | none | notice | warning);  
 explicit-priority;  
 external (alert | any | critical | emergency | error | info | none | notice | warning);  
 firewall (alert | any | critical | emergency | error | info | none | notice | warning);  
 ftp (alert | any | critical | emergency | error | info | none | notice | warning);  
 interactive-commands (alert | any | critical | emergency | error | info | none | notice | warning);  
 kernel (alert | any | critical | emergency | error | info | none | notice | warning);  
 match "*regular-expression*";  
 ntp (alert | any | critical | emergency | error | info | none | notice | warning);  
 pfe (alert | any | critical | emergency | error | info | none | notice | warning);  
 security (alert | any | critical | emergency | error | info | none | notice | warning);  
 structured-data {  
 brief;  
 }  
 user (alert | any | critical | emergency | error | info | none | notice | warning);  
}

**Hierarchy Level** [edit system syslog]

**Release Information** Statement introduced before Junos OS Release 12.1X47 for SRX Series.

**Description** Specify the file in which to log data.

- Options**
- *filename*—Specify the name of the file in which to log data.
  - *allow-duplicates*—Do not suppress the repeated messages.
  - *any*—Specify all facilities information.
    - *alert*—Specify the conditions that should be corrected immediately.
    - *critical*—Specify the critical conditions.
    - *emergency*—Specify the conditions that cause security functions to stop.
    - *error*—Specify the general error conditions.

- *info*—Specify the information about normal security operations.
- *none*—Do not specify any messages.
- *notice*—Specify the conditions that should be handled specifically.
- *warning*—Specify the general warning conditions.
- *archive*—Specify the archive file information.
  - *archive-sites*—Specify a list of destination URLs for the archived log files.
    - *url*—Specify the primary and failover URLs to receive archive files.
  - *binary-data*—Mark file such that it contains binary data.
  - *no-binary-data*—Do not mark the file such that it contains binary data.
  - *files*—Specify the number of files to be archived. Range: 1 through 1000 files.
  - *size*—Specify the size of files to be archived. Range: 65,536 through 1,073,741,824 bytes.
  - *world-readable*—Allow any user to read the log file.
  - *no-world-readable*—Do not allow any user to read the log file.
  - *start-time*—Specify the start time for file transmission. Enter the start time in the yyyy-mm-dd.hh:mm format.
  - *transfer-interval*—Specify the frequency at which to transfer the files to archive sites.
- *authorization*—Specify the authorization system.
- *change-log*—Specify the configuration change log.
- *conflict-log*—Specify the configuration conflict log.
- *daemon*—Specify the various system processes.
- *dfc*—Specify the dynamic flow capture.
- *explicit-priority*—Include the priority and facility in messages.
- *external*—Specify the local external applications.
- *firewall*—Specify the firewall filtering system.
- *ftp*—Specify the FTP process.
- *interactive-commands*—Specify the commands executed by the UI.
- *kernel*—Specify the kernel information.
- *match*—Specify the regular expression for lines to be logged.
- *ntp*—Specify the NTP process.
- *pfe*—Specify the Packet Forwarding Engine.
- *security*—Specify the security-related information.

- *structured-data*—Log the messages in structured log format.
  - *brief*—Omit English language text from the end of the logged message.
- *user*—Specify the user processes.
  - *info*—Specify the informational messages.

## firewall-authentication

```

Syntax firewall-authentication {
 pass-through {
 default-profile profile-name;
 ftp {
 banner {
 fail string;
 login string;
 success string;
 }
 }
 http {
 banner {
 fail string;
 login string;
 success string;
 }
 }
 telnet {
 banner {
 fail string;
 login string;
 success string;
 }
 }
 }
 traceoptions {
 file {
 filename;
 files number;
 flag flag;
 match regular-expression;
 no-remote-trace;
 size maximum-file-size;
 (world-readable | no-world-readable);
 }
 }
 web-authentication {
 banner {
 success string;
 }
 default-profile profile-name;
 }
 }

```

**Hierarchy Level** [edit access]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Configure default firewall authentication settings used by firewall authentication policies that restrict and permit access of firewall users to protected resources behind a firewall.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** access—To view this statement in the configuration.  
access-control—To add this statement to the configuration.

## firewall-authentication (Security)

---

**Syntax**

```
firewall-authentication {
 traceoptions {
 flag flag;
 }
}
```

**Hierarchy Level** [edit security]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Define data-plane firewall authentication tracing options.

- Options**
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple flag statements.
    - **all**—Enable all tracing operations.
    - **authentication**—Trace data-plane firewall authentication events.
    - **proxy**—Trace data-plane firewall authentication proxy events.
  - **detail**—Display moderate amount of data.
  - **extensive**—Display extensive amount of data.
  - **terse**—Display minimum amount of data.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1X45-D10. Support for <b>disable</b> option dropped in Junos OS Release 12.1X47-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>              | Enables the firewall authentication table as an authentication source. The priority of this table among other authentication tables establishes the search sequence used to identify user and role values.                                                                                                                                                                                                                                                                                                                                                             |
| <b>Options</b>                  | <p><b>priority <i>priority</i></b>—A unique value between 0 and 65535 that determines the sequence for searching multiple tables to retrieve a user role. Each table is given a unique priority value. The lower the value, the higher the priority. A table with priority 120 is searched before a table with priority 200. The default priority value of the firewall authentication table is 150.</p> <p>Setting the priority value of the firewall authentication table to 0 is equivalent to disabling the table and eliminating it from the search sequence.</p> |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## group-profile (Access)

**Syntax** `group-profile profile-name {`  
     `ppp {`  
         `cell-overhead;`  
         `encapsulated-overhead encapsulated-overhead-value;`  
         `framed-pool address-pool-name;`  
         `idle-timeout seconds;`  
         `interface-id interface-identifier;`  
         `keepalive seconds;`  
         `ppp-options {`  
             `chap;`  
             `pap;`  
         `}`  
         `primary-dns name;`  
         `primary-wins name;`  
         `secondary-dns name;`  
         `secondary-wins name;`  
     `}`  
`}`

**Hierarchy Level** [edit access]

**Release Information** Statement introduced in Junos OS Release 10.4.

**Description** Configure a group profile to define Point-to-Point Protocol (PPP) attributes. Any client referencing the configured group profile inherits all the group profile attributes.

- Options**
- **ppp**—Configure Point-to-Point Protocol (PPP) attributes.
    - **cell-overhead**—Configure the session to use Asynchronous Transfer Mode (ATM)-aware egress shaping.
    - **encapsulated-overhead *encapsulated-overhead-value***—Configure the encapsulation overhead for class-of-service calculations.
    - **framed-pool *pool-name***—Configure a framed-pool.
    - **idle-timeout**—Configure the idle timeout for a user.
    - **interface-id**—Configure the interface identifier.
    - **keep-alive**—Configure the keepalive interval for an L2TP tunnel.
  - **ppp-options**—Configure PPP authentication.
    - **pap**—Specify Password Authentication Protocol.
    - **chap**—Specify Challenge Handshake Authentication Protocol.
  - **primary-dns**—Specify the primary-dns IP address.
  - **secondary-dns**—Specify the secondary-dns IP address.
  - **primary-wins**—Specify the primary-wins IP address.
  - **secondary-wins**—Specify the secondary-wins IP address.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | <p>To configure an Infranet Controller, specify the hostname of the IC Series device with which the SRX Series device should communicate. Possible values for this statement range from 1 to 31 characters.</p> <p>This statement is required when you are configuring the SRX Series device to act as a Junos OS Enforcer in a Unified Access Control (UAC) deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series device.</p> <p>One or more IC Series devices can be configured as Infranet Controllers on the SRX Series device. There is no maximum number of IC Series devices that can be configured. However, only one IC Series device can be active at any time. The others are failover devices. A round-robin algorithm determines which of the configured IC Series devices is the active Infranet Controller. If the active Infranet Controller becomes inoperative, the algorithm is reapplied to the remaining IC Series devices that are configured to establish the new active Infranet Controller.</p> |
| <b>Options</b>                  | The remaining statements are explained separately. See <a href="#">CLI Explorer</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b>              | <p>Specify the value in seconds that the SRX Series device should expect to receive a heartbeat signal from the IC Series device (default 30). This configuration statement is used in conjunction with the <b>timeout</b> statement to test active communications with the IC Series device. The value of the <b>interval</b> statement must be smaller than the value of <b>timeout</b> statement.</p> <p>Use this statement when you are configuring the SRX Series device to act as a Junos OS Enforcer in a Unified Access Control (UAC) deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series device.</p> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1X47-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | <p>Control how the SRX Series device accesses a domain controller in order to monitor and scan security event logs on the domain controller. By parsing the event log, the SRX Series gets IP address-to-user mappings. This process is part of the integrated user firewall feature. The <b>ip-user-mapping</b> statement is optional because WMI is the default discovery method and its properties have default values.</p> <p>The other available method the SRX Series uses to retrieve address-to-user mapping information is manual (on-demand) probing of a domain PC.</p>                                                                                                                                                                                                                                                        |
| <b>Options</b>                  | <p><b>discovery-method</b>—Method of discover IP address-to-user mappings.</p> <p><b>wmi</b>—Windows Management Instrumentation (WMI) is the discovery method used to access the domain controller.</p> <p><b>event-log-scanning-interval <i>seconds</i></b>—Optional. Interval at which the SRX Series scans the event log on the domain controller.</p> <p><b>Range:</b> 5 through 60 seconds</p> <p><b>Default:</b> 10 seconds</p> <p><b>initial-event-log-timespan <i>hours</i></b>—Optional. Time of the earliest event log on the domain controller that the SRX Series will initially scan. This argument applies to the initial deployment only. After WMIC and the user identification start working, the SRX Series scans only the latest event log.</p> <p><b>Range:</b> 1 through 168 hours</p> <p><b>Default:</b> 1 hour</p> |
| <b>Required Privilege Level</b> | <p><b>security</b>—To view this statement in the configuration.</p> <p><b>security-control</b>—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Release Information</b>      | Statement introduced in Release 12.1 of Junos OS. Support for <b>disable</b> option dropped in Junos OS Release 12.1X47-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | An authentication table created on the SRX Series device using the <b>request security user-identification local-authentication-table add</b> command.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <p><b>priority <i>priority</i></b>—A unique value between 0 and 65535 that determines the sequence for searching multiple tables to retrieve a user role. Each table is given a unique priority value. The lower the value, the higher the priority. A table with priority 120 is searched before a table with priority 200. The default priority value of the local authentication table is 100.</p> <p>Setting the priority value of the local authentication table to 0 is equivalent to disabling the table and eliminating it from the search sequence.</p> |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

 banner {
 fail string;
 login string;
 success string;
 }
 }
 http {
 banner {
 fail string;
 login string;
 success string;
 }
 }
 telnet {
 banner {
 fail string;
 login string;
 success string;
 }
 }
 }
```

**Hierarchy Level** [edit access firewall-authentication]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Configure pass-through firewall user authentication, when a host or user from one zone needs to access a protected resource in another zone. A user must use an FTP, Telnet, or HTTP client to access the IP address of the protected resource and get authenticated by the firewall. The device uses FTP, Telnet, and HTTP to collect username and password information. Subsequent traffic from the user or host is allowed or denied based on the result of this authentication. After the user is authenticated, the firewall proxies the connection.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** access—To view this statement in the configuration.  
access-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5. Support for the <b>tcp-options</b> added in Junos OS Release 10.4. Support for the <b>services-offload</b> option added in Junos OS Release 11.4. Support for the <b>ssl-termination-profile</b> and <b>web-redirect-to-https</b> options added in Junos OS Release 12.1X44-D10. Support for the <b>user-firewall</b> option added in Junos OS Release 12.1X45-D10. |
| <b>Description</b>              | Specify the policy action to perform when packets match the defined criteria.                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>                  | The remaining statements are explained separately. See <a href="#">CLI Explorer</a> .                                                                                                                                                                                                                                                                                                                             |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                             |

| <b>Description</b>              | <p>Specify to redirect traffic destined for protected sources to a specified URL.</p> <p>You can configure the following options in the redirect URL string:</p> <ul style="list-style-type: none"> <li>• <b>%dest-url%</b>—Specifies the protected resource which the user is trying to access.</li> <li>• <b>%enforcer-id%</b>—Specifies the ID assigned to the Junos OS Enforcer by the IC Series device.</li> <li>• <b>%policy-id%</b>—Specifies the encrypted policy ID for the security policy that redirected the traffic.</li> <li>• <b>%dest-ip%</b>—Specifies the IP address or hostname of the protected resource that the user is trying to access.</li> <li>• <b>%ic-ip%</b>—Specifies the IP address or hostname of the IC Series device to which the Junos OS Enforcer is currently connected.</li> </ul> <p>If you do not specify the redirect URL, the Junos OS Enforcer uses the following default configuration:</p> <pre>https://%ic-ip%/?target = %dest-url% &amp;enforcer = %enforcer-id% &amp;policy = %policy-id% &amp;dest-ip = %dest-ip%</pre> <div>  <p><b>NOTE:</b> The maximum size of a redirect payload is 1450 bytes. The size of the redirect URL is restricted to 1407 bytes (excluding a few HTTP headers). If a user accesses a destination URL that is larger than 1407 bytes, the Infranet Controller authenticates the payload, calculates the exact length of the redirect URL, and trims the destination URL so that it can fit into the redirect URL. The destination URL can be fewer than 1407 bytes based on what else is present in the redirect URL (for example, policy ID). The destination URL in the default redirect URL is trimmed so that the redirect packet payload size is limited to 1450 bytes. If the length of the payload is larger than 1450 bytes, the excess length is trimmed and the user is directed to the destination URL that has been resized to 1450 bytes.</p> </div> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | <p>Specify a character to identify where stripping of characters occurs in a client name. Stripping removes characters to the right of each instance of the specified character, plus the character itself. The stripping begins with the rightmost separator character.</p> <p>Use the <b>separator</b> statement with the <b>count</b> statement to determine which characters in a client name are stripped. If the specified number of separator characters (count) exceeds the actual number of separator characters in the client name, stripping stops at the last available separator character.</p> |
| <b>Options</b>                  | <i>special-character</i> —Character used to identify where to start the stripping of characters in a client name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Hierarchy Level** [edit security policies from-zone *zone-name* to-zone *zone-name* policy *policy-name*]

**Release Information** Statement introduced in Junos OS Release 8.5. Support for the **services-offload** option added in Junos OS Release 11.4. Support for the **ssl-termination-profile** and **web-redirect-to-https** options added in Junos OS Release 12.1X44-D10. Support for the **user-firewall** option added in Junos OS Release 12.1X45-D10. Support for the **initial-tcp-mss** and **reverse-tcp-mss** options added in Junos OS Release 12.3X48-D20.

**Description** Specify the policy action to be performed when packets match the defined criteria.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>              | <p>Specify the value, in seconds, that the SRX Series device should wait to get a heartbeat response from an IC Series UAC Appliance (default is 300). If the SRX Series device does not receive it in the specified time, it takes the action specified by the <b>timeout-action</b> configuration statement. It also tries again to make a connection to the IC Series appliance. After the second failed attempt, the SRX Series device fails over to the next IC Series appliance in the cluster. The SRX Series device continues trying to reach IC Series appliances in the cluster until a connection is established.</p> <p>Use this statement when you are configuring the SRX Series device to act as a Junos OS Enforcer in a Unified Access Control (UAC) deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series appliance. When working with a cluster of IC Series appliances, the Junos OS Enforcer connects to one at a time, failing over to other IC Series appliances in the cluster as required.</p> |

```

**Hierarchy Level** [edit security policies from-zone *zone-name*]

**Release Information** Statement introduced in Junos OS Release 8.5. Support for the **services-offload** and **junos-host** options added in Junos OS Release 11.4. Support for the **source-identity** option added in Junos OS Release 12.1. Support for the **ssl-termination-profile** and **web-redirect-to-https** options added in Junos OS Release 12.1X44-D10.

**Description** Specify a destination zone to be associated with the security policy.

- Options**
- **zone-name**—Name of the destination zone object.
  - **junos-host**—Default security zone for self-traffic of the device.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege** security—To view this statement in the configuration.  
**Level** security-control—To add this statement to the configuration.

## traceoptions (Access)

**Syntax** traceoptions {  
     file *filename* {  
         files *number*;  
         match *regular-expression*;  
         size *maximum-file-size*;  
         <world-readable | no-world-readable>;  
     }  
     flag *flag*;  
 }

**Hierarchy Level** [edit access firewall-authentication]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Define Routing Engine firewall authentication tracing options.

- Options**
- file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**.
  - files *number*—(Optional) Maximum number of trace files. When a trace file named *trace-file* reaches its maximum size, it is renamed to *trace-file.0*, then *trace-file.1*, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.
  - If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.

**Range:** 2 through 1000 files

**Default:** 10 files

- match *regular-expression*—(Optional) Refine the output to include lines that contain the regular expression.
- size *maximum-file-size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the file again reaches its maximum size, **trace-file.0** is renamed **trace-file.1**, and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.
- If you specify a maximum file size, you also must specify a maximum number of trace files with the files option and filename.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB.

**Range:** 10 KB through 1 GB

**Default:** 128 KB

- **world-readable | no-world-readable**—(Optional) By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option

enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.

- **flag *flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags.
- **all**—All tracing operations
- **authentication**—Trace authentication events
- **configuration**—Trace configuration events
- **setup**—Trace setup of firewall authentication service

**Required Privilege Level**    trace—To view this statement in the configuration.  
                                     trace-control—To add this statement to the configuration.

## traceoptions (Active Directory Access)

```
Syntax traceoptions {
 file filename ;
 flag {
 active-directory-authentication;
 all;
 configuration;
 db;
 ip-user-mapping;
 ip-user-probe;
 ipc;
 user-group-mapping;
 wmic;
 }
 level {
 all
 error
 info
 notice
 verbose
 warning
 }
 no-remote-trace;
 }
```

**Hierarchy Level** [edit services user-identification active-directory-access]

**Release Information** Statement introduced in Junos OS Release 12.1X47-D10.

**Description** Define Active Directory trace options for the integrated user firewall feature.

**Options** **file *filename***—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**.

**flag**—Trace the operation or operations to perform on the integrated user firewall. To specify more than one trace operation, include multiple flag statements.

**active-directory-authentication**—Trace the building of and modifications to the Active Directory authentication table.

**all**—Trace everything.

**configuration**—Trace configuration events.

**db**—Trace the database.

**ip-user-mapping**—Trace the ip-user-mapping module.

**ip-user-probe**—Trace PC client probing.

**ipc**—Trace communication events with the Packet Forwarding Engine.

**user-group-mapping**—Trace the process of getting user-to-group-mapping.

**wmic**—Trace the Windows Management Instrumentation Client process.

**level**—Level of trace operation to perform.

**all**—Match all levels.

**error**—Match error conditions.

**info**—Match informational messages.

**notice**—Match conditions that should be handled specially.

**verbose**—Match verbose messages.

**warning**—Match warning messages.

**no-remote-trace**—Disallow tracing from a remote device.

| <b>Release Information</b>      | Statement modified in Junos OS Release 9.4.                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | Enable Unified Access Control (UAC) for the security policy. This statement is required when you are configuring the SRX Series device to act as a Junos OS Enforcer in a UAC deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series UAC Appliance . |
| <b>Options</b>                  | The remaining statements are explained separately. | <b>Release Information</b>      | Statement introduced in Release 12.1 of Junos OS. Support for <b>disable</b> option dropped in Junos OS Release 12.1X47-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | An authentication table pushed from a configured authentication device, such as the Junos Pulse Access Control Service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <p><b>priority <i>priority</i></b>—A unique value between 0 and 65535 that determines the sequence for searching multiple tables to retrieve a user role. Each authentication table is given a unique priority value. The lower the value, the higher the priority. A table with priority 120 is searched before a table with priority 200. The default priority value of the unified-access-control authentication table is 200.</p> <p>Setting the priority value of the unified-access-control authentication table to 0 is equivalent to disabling the table and eliminating it from the search sequence.</p> |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Use this statement to configure the SRX Series device to act as a Junos OS Enforcer in a Unified Access Control (UAC) deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Required Privilege Level</b> | services—To view this statement in the configuration.<br>services-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## user-group-mapping

**Syntax**

```

user-group-mapping {
 ldap {
 address ip-address {
 port port;
 }
 authentication-algorithm {
 simple;
 }
 base base;
 ssl;
 user username {
 password password;
 }
 }
}

```

**Hierarchy Level** [edit services user-identification active-directory-access domain]

**Release Information** Statement introduced in Junos OS Release 12.1X47-D10.

**Description** Configure the SRX Series device to connect to an LDAP server, so that the server can provide the SRX Series with user-to-group mappings. These mappings are used to implement the integrated user firewall feature. The domain controller acts as the LDAP server in typical customer scenarios.

Most of this statement is optional, because the default communication method is LDAP and most arguments have default values. Only the LDAP keyword and the base are required.

**Options**

- ldap**—Required. LDAP is the protocol used to access the LDAP server to get user-to-group mappings.
- address *ip-address***—Optional. Specify the IP address of the LDAP server. If no address is specified, the system uses one of the configured Active Directory domain controllers.
- port *port***—Optional. Specify the port number of the LDAP server. If no port number is specified, the system uses port 389 for plaintext or port 636 for encrypted text.
- authentication-algorithm**—Optional. Specify the algorithm used while the SRX Series communicates with the LDAP server. The default method is Kerberos.
- simple**—Configure simple (plaintext) authentication method.
- base *base***—Required. LDAP base distinguished name (DN).
- ssl**—Optional. Enable Secure Sockets Layer (SSL) to ensure secure transmission with the LDAP server. Disabled by default, which means that the password is sent in plaintext.

**user *username***—Optional. Username of the LDAP account. If no username is specified, the system will use the configured domain controller's username.

**password *password***—Optional. Specify the password for the account. If no password is specified, the system uses the configured domain controller's password.

**Required Privilege** security—To view this statement in the configuration.  
**Level** security-control—To add this statement to the configuration.

 verbose;
 warning;
 }
 no-remote-trace;
 }
}

```

**Hierarchy Level** [edit services]

**Release Information** Statement introduced in Junos OS Release 12.1X47-D10.

**Description** Configure the integrated user firewall feature, including access to the Active Directory domain and domain controller, IP address-to-user mapping, and user-to-group mapping. One or two Active Directories are allowed under one domain. The IP address-to-user mapping and user-to-group mapping are configured per domain.

**Options** **authentication-entry-timeout *minutes***—Timeout interval starting from the Active Directory/domain controller login time, the last active session, or the last successful probe. A setting of 0 means the authentication does not need a timeout. We recommend that you configure a setting of 0 when you disable on-demand-probe to prevent someone from accessing the Internet without logging in again.  
**Range:** 10 through 1440 minutes  
**Default:** 30 minutes

**filter**—Optional. Range of IP addresses that needs to be monitored or not monitored.

**include *address***—Include IP address or range. Maximum of 20 addresses.

**exclude *address***—Exclude IP address or range. Maximum of 20 addresses.

**no-on-demand-probe**—Do not use traffic to discover user. Default is disabled.

**wmi-timeout *seconds***—Optional. Configures the number of seconds that the domain PC has to respond to the SRX Series device's query through WMI/DCOM.

- If the PC responds within that timeframe to the WMI query, the SRX creates an authentication entry for this PC.
- If the PC does not respond within that timeframe, the WMI query failed. In the case of a failed query, if the SRX had an authentication entry about the queried PC before the WMI query, that authentication entry is deleted. If the SRX had no authentication entry before the WMI query, the SRX does not create an authentication entry.

**Range:** 3 through 120 seconds

**Default:** 10 seconds

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## web-authentication (Access)

**Syntax**

```
web-authentication {
 banner {
 success string;
 }
 default-profile profile-name;
}
```

**Hierarchy Level** [edit access firewall-authentication]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Specify that users go through the Web authentication process. Users use HTTP to access an IP address on the device that is enabled for Web authentication. Users do not use HTTP to access the IP address of the protected resource in this case. Users are prompted for their username and password, which are verified by the device. Subsequent traffic from the user/host to the protected resource is allowed or denied based on the result of this authentication. This method of authentication differs from pass-through authentication in that users need to access the protected resource directly after accessing the Web authentication IP address and being authenticated.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** access—To view this statement in the configuration.  
access-control—To add this statement to the configuration.

## web-management (System Services)

```
Syntax web-management {
 http {
 interfaces interface-names ;
 port port;
 }
 https {
 interfaces interface-names;
 system-generated-certificate name;
 port port;
 }
 management url management url;
 session {
 idle-timeout minutes;
 session-limit number;
 }
 traceoptions {
 file {
 filename;
 files number;
 match regular-expression;
 size maximum-file-size;
 (no-world-readable | world-readable);
 }
 flag flag;
 level level;
 no-remote-trace;
 }
 }
```

**Hierarchy Level** [edit system services]

**Release Information** Statement introduced in Junos OS Release 9.0.

**Description** Configure settings for HTTP or HTTPS access. HTTP access allows management of the device using the J-Web interface. HTTPS access allows secure management of the device using the J-Web interface. With HTTPS access, communication is encrypted between your browser and the webserver for your device.

**Options** **control**—Disable the SBC process.

- **max-threads**—Maximum simultaneous threads to handle requests.

**Range:** 0 through 16

**http**—Configure HTTP.

- **interface** [*value*]**—**Interface value that accept HTTP access.
- **port** *number***—**TCP port for incoming HTTP connections.

**Range:** 1 through 65,535

**https**—Configure HTTPS.

- **interface** *[value]*—Interface value that accept HTTP access.
- **port** *number*—TCP port for incoming HTTP connections.  
**Range:** 1 through 65,535
- **local-certificate**—X.509 certificate to use from configuration.
- **pki-local-certificate**—X.509 certificate to use from PKI local store.
- **system-generated-certificate**—X.509 certificate generated automatically by system.

**management url** *management url*—URL Path for Web management access.

**session**—Configure web management session.

- **idle-timeout** *minutes*—Default timeout of web-management sessions in minutes.
- **session-limit** *number*—Maximum number of web-management sessions to allow.

**traceoptions**—Set the trace options.

- **file**—Configure the trace file information.
  - *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. By default, the name of the file is the name of the process being traced.
  - **files number**—Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the **size maximum file-size** option.

**Range:** 2 through 1000 files

**Default:** 10 files

- **match regular-expression**—Refine the output to include lines that contain the regular expression.
- **size maximum-file-size**—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).

**Range:** 10 KB through 1 GB

**Default:** 128 KB

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files number** option.

- **(world-readable | no-world-readable)**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag flag**—Specify which tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements. You can include the following flags.
  - **all**—Trace all areas.
  - **configuration**—Trace configuration.
  - **dynamic-vpn**—Trace dynamic-vpn events.
  - **init**—Trace daemon init process.
  - **mgd**—Trace MGD requests.
  - **webauth**—Trace webauth requests.
- **level level**—Specify the level of debugging output.
  - **all**—Match all levels.
  - **error**—Match error conditions.

- **info**—Match informational messages.
- **notice**—Match conditions that should be handled specially.
- **verbose**—Match verbose messages.
- **warning**—Match warning messages.
- **no-remote-trace**—Disable the remote tracing.

## Sample Output

The following example displays the network access requests that are pending, clears the requests, and displays the results of the clear operation:

### clear network-access requests pending

```

user@host> show network-access requests pending
Information about pending authentication entries
 Total pending authentication requests: 2
Index User Status
1 Sun Processing
2 Sam Processed

user@host> clear network-access requests pending
user@host> show network-access requests pending
Information about pending authentication entries
 Total pending authentication requests: 2
Index User Status
1 Sun Cancelled by Admin
2 Sam Cancelled by Admin

```

## clear network-access requests statistics

---

### Sample Output

The following example clears all entries in the Active Directory authentication table:

[clear services user-identification active-directory-access active-directory-authentication-table](#)

```
user@host> clear services user-identification active-directory-access
active-directory-authentication-table
```

## request services user-identification active-directory-access active-directory-authentication-table delete

| <b>Description</b>              | Delete entries from the active directory authentication table by domain, address, group, or user. This command provides the network administrator with flexibility and control over the table entries beyond what is automatically added to or deleted from the table. For example, if a person leaves the company, the corresponding username can be deleted; after a department reorganization, a group can be deleted.                                                                                                                                                                                                                                                                                                                                                               |

| <b>Output Fields</b>            | This command produces no output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Sample Output

The following example clears all entries in the Active Directory authentication table for the specified user:

**request services user-identification active-directory-access active-directory-authentication-table delete user jsmith**

```
user@host> request services user-identification active-directory-access
active-directory-authentication-table delete user jsmith
```

## request services user-identification active-directory-access domain-controller

|                                 |                                                                                                                                                                                                                                                                                                            |

| Field Name     | Field Description                                                                                                                                                                                                                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Profile</b> | <p>The profile determines how the user is authenticated.</p> <p>Local clients defined with the statement <b>access profile client</b> are authenticated with the password authentication. Clients configured external to the device, on a RADIUS or LDAP server are authenticated with RADIUS or LDAP authentication.</p> |

## Sample Output

### show network-access requests pending

```

user@host> show network-access requests pending
Information about pending authentication entries
 Total pending authentication requests: 2
Index User Status
1 Sun Processing
2 Sam Processed

```

## Sample Output

### show network-access requests pending detail

```

user@host> show network-access requests pending detail
Information about pending authentication entries
 Total pending authentication requests: 2
Index: 1 User: Sun
 Status: Processing
 Profile: Sunnyvale-firewall-users
Index: 2 User: Sam
 Status: Processed
 Profile: Westford-profile

```

## Sample Output

### show network-access requests pending index 1

```

user@host> show network-access requests pending index 1
Index: 1 User: Sun
 Status: Processing
 Profile: Sunnyvale-firewall-users

```

| <b>Output Fields</b>            | <a href="#">Table 505</a> lists the output fields for the network-access securid-node-secret-file command. Output fields are listed in the approximate order in which they appear. |

**Table 505: show network-access securid-node-secret-file Output Fields**

| Field Name       | Field Description                          |
|------------------|--------------------------------------------|
| SecurID Server   | Name of the SecurID authentication server. |
| Node Secret File | Path to the node secret file.              |

## Sample Output

### show network-access securid-node-secret-file

```

user@host> show network-access securid-node-secret-file
SecurID server node secret file:
SecurID Server Node Secret File
ace-server1 /var/db/securid/ace-server1/node-secret

```

## show security firewall-authentication history

**Table 506: show security firewall-authentication history Output Fields**

| Field Name      | Field Description                         |
|-----------------|-------------------------------------------|
| Authentications | Number of authentications.                |
| Id              | Identification number.                    |
| Source IP       | IP address of the authentication source.  |
| Date            | Authentication date.                      |
| Time            | Authentication time.                      |
| Duration        | Authentication duration.                  |
| Status          | Authentication status success or failure. |

Table 506: show security firewall-authentication history Output Fields (*continued*)

| Field Name | Field Description |
|------------|-------------------|
| User       | Name of the user. |

## Sample Output

### show security firewall-authentication history

```

user@host> show security firewall-authentication history
History of firewall authentication data:
Authentications: 1
 Id Source Ip Date Time Duration Status User
 1 211.0.0.6 2007-04-03 11:43:06 00:00:45 Success hello

```

## Sample Output

### show security firewall-authentication history node all

```

user@host> show security firewall-authentication history node all
node0:

History of firewall authentication data:
Authentications: 2
 Id Source Ip Date Time Duration Status User
 1 100.0.0.1 2008-01-04 12:00:10 0:05:49 Success local1
 2 100.0.0.1 2008-01-04 14:36:52 0:01:03 Success local1
node1:

History of firewall authentication data:
Authentications: 1
 Id Source Ip Date Time Duration Status User
 1 100.0.0.1 2008-01-04 14:59:43 1193046:06: Success local1

```

## show security firewall-authentication history address

| <b>Output Fields</b>            | <a href="#">Table 507</a> lists the output fields for the <b>show security firewall-authentication history address</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 507: show security firewall-authentication history address Output Fields**

| Field Name            | Field Description                              |
|-----------------------|------------------------------------------------|
| Username              | User ID.                                       |
| Source IP             | IP address of the authentication source.       |
| Authentication state  | Status of authentication (success or failure). |
| Authentication method | Path chosen for authentication.                |
| Access start date     | Date when user authenticated.                  |
| Access start time     | Time when user authenticated.                  |

Table 507: show security firewall-authentication history address Output Fields (*continued*)

| Field Name                  | Field Description                        |
|-----------------------------|------------------------------------------|
| Duration of user access     | Time duration of the accessing firewall. |
| Policy name                 | Name of the policy.                      |
| Source zone                 | User traffic received from the zone.     |
| Destination zone            | User traffic destined to the zone.       |
| Access profile              | Name of profile used for authentication. |
| Bytes sent by this user     | Number of bytes sent by the user.        |
| Bytes received by this user | Number of bytes received by the user.    |

## Sample Output

### show security firewall-authentication history address 4.4.4.2

```

user@host> show security firewall-authentication history address 4.4.4.2
Username: u1
Source IP: 4.4.4.2
Authentication state: Success
Authentication method: Pass-through using HTTP
Access start date: 2007-09-12
Access start time: 15:33:29
Duration of user access: 0:00:48
Policy name: Z1-Z2
Source zone: Z1
Destination zone: Z2
Access profile: profile-local
Bytes sent by this user: 0
Bytes received by this user: 449

```

## Sample Output

### show security firewall-authentication history address 100.0.0.1 node local

```

user@host> show security firewall-authentication history address 100.0.0.1 node local
node0:

Username: local1
Source IP: 100.0.0.1
Authentication state: Success
Authentication method: Pass-through using Telnet
Access start date: 2008-01-04
Access start time: 12:00:10
Duration of user access: 0:05:49
Policy name: POL1
Source zone: z1
Destination zone: z2
Access profile: p1
Bytes sent by this user: 0
Bytes received by this user: 0

```

Username: local1  
Source IP: 100.0.0.1  
Authentication state: Success  
Authentication method: Pass-through using Telnet  
Access start date: 2008-01-04  
Access start time: 14:36:52  
Duration of user access: 0:01:03  
Policy name: POL1  
Source zone: z1  
Destination zone: z2  
Access profile: p1  
Bytes sent by this user: 2178  
Bytes received by this user: 4172

## show security firewall-authentication history identifier

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Output Fields</b>            | <a href="#">Table 508</a> lists the output fields for the <b>show security firewall-authentication history identifier</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 508: show security firewall-authentication history identifier Output Fields**

| Field Name            | Field Description                              |
|-----------------------|------------------------------------------------|
| Username              | User ID.                                       |
| Source IP             | IP address of the authentication source.       |
| Authentication state  | Status of authentication (success or failure). |
| Authentication method | Path chosen for authentication.                |
| Access start date     | Date when user authenticated.                  |

Table 508: show security firewall-authentication history identifier Output Fields (*continued*)

| Field Name                  | Field Description                        |
|-----------------------------|------------------------------------------|
| Access start time           | Time when user authenticated.            |
| Duration of user access     | Time duration of the accessing firewall. |
| Policy index                | Identification number of the policy.     |
| Policy name                 | Name of the policy.                      |
| Source zone                 | User traffic received from the zone.     |
| Destination zone            | User traffic destined to the zone.       |
| Access profile              | Name of profile used for authentication. |
| Bytes sent by this user     | Number of bytes sent by the user.        |
| Bytes received by this user | Number of bytes received by the user.    |
| Client-groups               | Name of the client group.                |

## Sample Output

### show security firewall-authentication history identifier 1

```

user@host> show security firewall-authentication history identifier 1
Username: hello
Source IP: 211.0.0.6
Authentication state: Success
Authentication method: Pass-through using Telnet
Access start date: 2007-04-03
Access start time: 11:43:06
Duration of user access: 00:00:45
Policy index: 4
Source zone: z2
Destination zone: z1
Access profile: profile1
Bytes sent by this user: 0
Bytes received by this user: 1050
Client-groups: Sunnyvale Bangalore

```

## Sample Output

### show security firewall-authentication identifier 1 node primary

```

user@host> show security firewall-authentication history identifier 1 node primary
node0:

Username: local1
Source IP: 100.0.0.1
Authentication state: Success
Authentication method: Pass-through using Telnet

```

Access start date: 2008-01-04  
Access start time: 12:00:10  
Duration of user access: 0:05:49  
Policy name: POL1  
Source zone: z1  
Destination zone: z2  
Access profile: p1  
Bytes sent by this user: 0  
Bytes received by this user: 0

## show security firewall-authentication users

| <b>Output Fields</b>            | <a href="#">Table 394</a> lists the output fields for the <b>show security firewall-authentication users</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 509: show security firewall-authentication users Output Fields**

| Field Name                  | Field Description                                               |
|-----------------------------|-----------------------------------------------------------------|
| <b>Total users in table</b> | Gives count of how many entries/users the command will display. |
| <b>Id</b>                   | Identification number.                                          |
| <b>Source IP</b>            | IP address of the authentication source.                        |
| <b>Src zone</b>             | User traffic received from the zone.                            |
| <b>Dst zone</b>             | User traffic destined to the zone.                              |
| <b>Profile</b>              | Name of profile used for authentication.                        |
| <b>Age</b>                  | Idle timeout for the user.                                      |

Table 509: show security firewall-authentication users Output Fields (*continued*)

| Field Name | Field Description                         |
|------------|-------------------------------------------|
| Status     | Authentication status success or failure. |
| User       | Name of the user.                         |

## Sample Output

### show security firewall-authentication users

```

user@host> show security firewall-authentication users
Firewall authentication data:
Total users in table: 1
 Id Source Ip Src zone Dst zone Profile Age Status User
 1 1111:1212/64 z1 z2 p1 0 Success local1

```

## Sample Output

### show security firewall-authentication users node 0

```

user@host> show security firewall-authentication users node 0
node0:

Firewall authentication data:
Total users in table: 1
 Id Source Ip Src zone Dst zone Profile Age Status User
 3 100.0.0.1 z1 z2 p1 1 Success local1

```

## Sample Output

### show security firewall-authentication users node all

```

user@host> show security firewall-authentication users node all
node0:

Firewall authentication data:
Total users in table: 1
 Id Source Ip Src zone Dst zone Profile Age Status User
 3 100.0.0.1 z1 z2 p1 1 Success local1

node1:

Firewall authentication data:
Total users in table: 1
 Id Source Ip Src zone Dst zone Profile Age Status User
 2 100.0.0.1 z1 z2 p1 1 Success local1

```

## show security firewall-authentication users address

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 510: show security firewall-authentication users address Output Fields**

| Field Name            | Field Description                              |
|-----------------------|------------------------------------------------|
| Username              | User ID.                                       |
| Source IP             | IP address of the authentication source.       |
| Authentication state  | Status of authentication (success or failure). |
| Authentication method | Path chosen for authentication.                |
| Access time remaining | Duration for which the connection exists.      |

Table 510: show security firewall-authentication users address Output Fields (*continued*)

| Field Name                  | Field Description                                  |
|-----------------------------|----------------------------------------------------|
| Lsys                        | The logical system where the traffic was received. |
| Source zone                 | User traffic received from the zone.               |
| Destination zone            | User traffic destined to the zone.                 |
| Policy index                | Identification number of the policy.               |
| Policy name                 | Name of the policy.                                |
| Access profile              | Name of profile used for authentication.           |
| Interface Name              | Name of the interface.                             |
| Bytes sent by this user     | Number of bytes sent by the user.                  |
| Bytes received by this user | Number of bytes received by the user.              |
| Client-groups               | Name of the client group.                          |

## Sample Output

### show security firewall-authentication users address 211.0.0.6

```

user@host>show security firewall-authentication users address 211.0.0.6
Username: hello
Source IP: 211.0.0.6
Authentication state: Success
Authentication method: Pass-through using Telnet
Access time remaining: 0
Source zone: z2
Destination zone: z1
Policy index: 5
Access profile: profile1
Interface Name: ge-0/0/2.0
Bytes sent by this user: 0
Bytes received by this user: 0
Client-groups: Sunnyvale Bangalore

```

## Sample Output

### show security firewall-authentication users address 100.0.0.1 node local

```

user@host> show security firewall-authentication users address 100.0.0.1 node local
node0:

Username: local1
Source IP: 100.0.0.1
Authentication state: Success
Authentication method: Pass-through using Telnet
Age: 2

```

```
Access time remaining: 4
Source zone: z1
Destination zone: z2
Policy name: POL1
Access profile: p1
Interface Name: reth1.0
Bytes sent by this user: 614
Bytes received by this user: 1880
```

#### **show security firewall-authentication users address 10.208.16.1**

```
user@host> show security firewall-authentication users address 10.208.16.1
Username: abc-user
Source IP: 10.208.16.1
Authentication state: Success
Authentication method: User-firewall
Age: 0
Access time remaining: 10
Lsys: root-logical-system
Source zone: N/A
Destination zone: N/A
Access profile: test
```

## show security firewall-authentication users identifier

| <b>Username</b>              | User ID.                                       |
| <b>Source IP</b>             | IP address of the authentication source.       |
| <b>Authentication state</b>  | Status of authentication (success or failure). |
| <b>Authentication method</b> | Path chosen for authentication.                |
| <b>Age</b>                   | Idle timeout for the user.                     |
| <b>Access time remaining</b> | Duration for which the connection exists.      |

Table 511: show security firewall-authentication users identifier Output Fields (*continued*)

| Field Name                  | Field Description                        |
|-----------------------------|------------------------------------------|
| Source zone                 | User traffic received from the zone.     |
| Destination Zone            | User traffic destined to the zone.       |
| Policy Name                 | Name of the policy.                      |
| Access profile              | Name of profile used for authentication. |
| Interface Name              | Name of the interface                    |
| Bytes sent by this user     | Number of bytes sent by the user.        |
| Bytes received by this user | Number of bytes received by the user.    |

## Sample Output

### show security firewall-authentication users identifier 3

```

user@host> show security firewall-authentication users identifier 3
Username: u1
Source IP: 4.4.4.2
Authentication state: Success
Authentication method: Pass-through using HTTP
Age: 1
Access time remaining: 254
Source zone: Z1
Destination zone: Z2
Policy name: Z1-Z2
Access profile: profile-local
Interface Name: ge-0/0/1.0
Bytes sent by this user: 0
Bytes received by this user: 449

```

## Sample Output

### show security firewall-authentication users identifier 3 node primary

```

user@host> show security firewall-authentication users identifier 3 node primary
node0:

Username: local1
Source IP: 100.0.0.1
Authentication state: Success
Authentication method: Pass-through using Telnet
Age: 1
Access time remaining: 5
Source zone: z1
Destination zone: z2
Policy name: POL1
Access profile: p1
Interface Name: reth1.0
Bytes sent by this user: 614
Bytes received by this user: 1880

```

| <b>Release Information</b>      | <p>Command modified in Junos OS Release 9.2. Support for IPv6 addresses added in Junos OS Release 10.2. Support for IPv6 addresses in active/active chassis cluster configurations in addition to the existing support of active/passive chassis cluster configurations added in Junos OS Release 10.4. Support for wildcard addresses added in Junos OS Release 11.1. Support for global policy added in Junos OS Release 11.4. Support for services offloading added in Junos OS Release 11.4. Support for source-identities added in Junos OS Release 12.1. The <b>Description</b> output field added in Junos OS Release 12.1. Support for negated address added in Junos OS Release 12.1X45-D10. The output fields for Policy Statistics expanded, and the output fields for the <b>global</b> and <b>policy-name</b> options expanded to include from-zone and to-zone global match criteria in Junos OS Release 12.1X47-D10. Support for the <b>initial-tcp-mss</b> and <b>reverse-tcp-mss</b> options added in Junos OS Release 12.3X48-D20.</p> |
| <b>Description</b>              | <p>Display a summary of all security policies configured on the device. If a particular policy is specified, display information particular to that policy.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Output Fields** Table 51 lists the output fields for the **show security policies** command. Output fields are listed in the approximate order in which they appear.

**Table 512: show security policies Output Fields**

| Field Name                              | Field Description                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>From zone</b>                        | Name of the source zone.                                                                                                                                                                                                                                                                                                                                                   |
| <b>To zone</b>                          | Name of the destination zone.                                                                                                                                                                                                                                                                                                                                              |
| <b>Policy</b>                           | Name of the applicable policy.                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>                      | Description of the applicable policy.                                                                                                                                                                                                                                                                                                                                      |
| <b>State</b>                            | Status of the policy: <ul style="list-style-type: none"> <li>• <b>enabled:</b> The policy can be used in the policy lookup process, which determines access rights for a packet and the action taken in regard to it.</li> <li>• <b>disabled:</b> The policy cannot be used in the policy lookup process, and therefore it is not available for access control.</li> </ul> |
| <b>Index</b>                            | Internal number associated with the policy.                                                                                                                                                                                                                                                                                                                                |
| <b>Sequence number</b>                  | Number of the policy within a given context. For example, three policies that are applicable in a from-zoneA-to-zoneB context might be ordered with sequence numbers 1, 2, 3. Also, in a from-zoneC-to-zoneD context, four policies might have sequence numbers 1, 2, 3, 4.                                                                                                |
| <b>Source addresses</b>                 | For standard display mode, the names of the source addresses for a policy. Address sets are resolved to their individual names.<br><br>For detail display mode, the names and corresponding IP addresses of the source addresses for a policy. Address sets are resolved to their individual address name-IP address pairs.                                                |
| <b>Destination addresses</b>            | Name of the destination address (or address set) as it was entered in the destination zone's address book. A packet's destination address must match this value for the policy to apply to it.                                                                                                                                                                             |
| <b>Source addresses (excluded)</b>      | Name of the source address excluded from the policy.                                                                                                                                                                                                                                                                                                                       |
| <b>Destination addresses (excluded)</b> | Name of the destination address excluded from the policy.                                                                                                                                                                                                                                                                                                                  |
| <b>Source identities</b>                | One or more user roles specified for a policy.                                                                                                                                                                                                                                                                                                                             |

| <b>Release Information</b>      | Command introduced in Junos OS Release 9.4. Options updated in Junos OS Release 12.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b>              | <p>Display a summary of the authentication table entries configured from the IC Series UAC Appliance. Authentication tables store mappings between traffic sessions and Unified Access Control (UAC) roles. The IC Series appliance uses the roles specified in the mappings to help determine which UAC policies to apply to a session.</p> <p>Use this command when you have configured the SRX Series device to act as a Junos OS Enforcer in a UAC deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series appliance.</p> <p>You can also use this command to display the content of the authentication table in a user role firewall implementation. The table, pushed from a supporting UAC device, provides the user roles associated with incoming traffic.</p> |
| <b>Options</b>                  | <ul style="list-style-type: none"> <li>• <b>detail</b>—Display a detailed view of all authentication table entries.</li> <li>• <b>extended</b>—Display a view of all authentication table entries with the user roles listed.</li> <li>• <b>identifier <i>id</i></b>—Display all authentication table entries with the specified identifier number.</li> <li>• <b>ip <i>source-ip-address</i></b>—Display any authentication table entry for the specified IP address.</li> <li>• <b>role <i>role-name</i></b>—Display all authentication table entries for the specified role name.</li> <li>• <b>user <i>username</i></b>—Display all authentication table entries for the specified user.</li> </ul>                                                                                                                                               |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Syntax</b>                   | show services unified-access-control counters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Release Information</b>      | Command introduced in Junos OS Release 12.1X44-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | <p>Display the number of sessions allowed, denied, and terminated by the Unified Access Control (UAC) service when invoked by a firewall policy with the uac-policy action. Counts are reported for each action taken by UAC. Sessions that were allowed, denied, or terminated by other firewall policy actions are not included in these statistics.</p> <p>On high-end SRX Series devices, UAC counts are grouped and displayed for each PIC on the device. On branch SRX Series devices, UAC counts are accumulated by device only. There is no PIC specification on these devices.</p> |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Output Fields</b>            | <a href="#">Table 513</a> lists the output fields for the <b>show services unified-access-control counters</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 513: show services unified-access-control counters Output Fields**

| Field Name          | Field Description                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------|
| PIC                 | If applicable, the number of each PIC implementing UAC. UAC statistics are grouped by PIC.                     |
| Sessions allowed    | The sessions permitted by UAC when invoked by a user role firewall policy.                                     |
| Policy action       | Number of sessions permitted by UAC based on the UAC policy action.                                            |
| Timeout action      | Number of sessions permitted by the timeout action while the SRX was disconnected from the UAC device.         |
| Sessions denied     | The sessions denied by UAC when invoked by a user role firewall policy.                                        |
| Unauthenticated     | Number of sessions denied by UAC because the user was not authenticated.                                       |
| Policy action       | Number of sessions denied by UAC based on the UAC policy action.                                               |
| Policy not matched  | Number of sessions denied because no UAC policy match was found.                                               |
| Timeout action      | Number of sessions denied by the timeout action while the SRX was disconnected from the access control device. |
| Sessions terminated | The sessions originally permitted that were later terminated.                                                  |

Table 513: show services unified-access-control counters Output Fields (*continued*)

| Field Name   | Field Description                                                                                |
|--------------|--------------------------------------------------------------------------------------------------|
| Reevaluation | Number of sessions terminated due to a change in the UAC user roles associated with the session. |
| Signout      | Number of sessions terminated due to the user signing out.                                       |

## Sample Output

### show services unified-access-control counters

```

user@host> show services unified-access-control counters
PIC: fpc2.pic0
 Sessions allowed
 Policy action: 0
 Timeout action: 0
 Sessions denied
 Unauthenticated: 0
 Policy action: 0
 Policy not matched: 0
 Timeout action: 0
 Sessions terminated
 Reevaluation: 0
 Signout: 0

```

Statistics on branch devices are accumulated by device only. There is no PIC specification on these devices.

```

user@host> show services unified-access-control counters
Sessions allowed
 Policy action: 0
 Timeout action: 0
Sessions denied
 Unauthenticated: 0
 Policy action: 0
 Policy not matched: 0
 Timeout action: 0
Sessions terminated
 Reevaluation: 0
 Signout: 0

```

## show services unified-access-control status

---

**Syntax**    show services unified-access-control status

**Release Information**    Command introduced in Junos OS Release 9.4.

**Description**    Display the status of the connection between the SRX Series device and the IC Series UAC Appliance as well as statistics to help debug connections to the IC Series appliance.

Use this command when you have configured the SRX Series device to act as a Junos OS Enforcer in a Unified Access Control (UAC) deployment. When deployed as a Junos OS Enforcer, the SRX Series device enforces the policies that are defined on the UAC's IC Series appliance.

[show services user-identification active-directory-access  
active-directory-authentication-table all extensive on page 5863](#)

**Output Fields** [Table 515](#) lists the output fields for the **show services user-identification  
active-directory-access active-directory-authentication-table all extensive** command.

**Table 515: show services user-identification active-directory-access  
active-directory-authentication-table all extensive Output Fields**

| Field Name        | Field Description                                                                                                                                                                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source IP         | IP address for user who is logged in through the domain controller.                                                                                                                                                                                                                                                           |
| Username          | ID of the user who is logged in through the domain controller.                                                                                                                                                                                                                                                                |
| Groups            | Groups to which the user is associated in the domain controller.                                                                                                                                                                                                                                                              |
| State             | States include the following:<br><br>Pending—This IP address is being probed.<br><br>Initial—The authentication entry is only received from the WMIC daemon, not pushed to the Packet Forwarding Engine.<br><br>Valid—The authentication entry is pushed to the Packet Forwarding Engine.<br><br>Invalid—The PC probe failed. |
| Access start date | Date that the authentication entry was created.                                                                                                                                                                                                                                                                               |
| Access start time | Time that the authentication entry was created.                                                                                                                                                                                                                                                                               |
| Age time          | Number of minutes after which the authentication entry will time out.                                                                                                                                                                                                                                                         |

## Sample Output

**show services user-identification active-directory-access active-directory-authentication-table ip-address  
<ip-address>**

```
user@host> show services user-identification active-directory-access
active-directory-authentication-table ip-address 192.0.2.3
Domain: ad02.net
Source-ip: 192.0.2.3
Username: lesjay
Groups:group1
State: Valid

**Table 516: show services user-identification active-directory-access domain-controller Output Fields**

| Field Name        | Field Description                    |
|-------------------|--------------------------------------|
| Domain controller | Domain controller name.              |
| Address           | IP address of the domain controller. |

Table 516: show services user-identification active-directory-access domain-controller Output Fields (*continued*)

| Field Name | Field Description                                                                            |
|------------|----------------------------------------------------------------------------------------------|
| Status     | Connection status of the domain controller: connected or disconnected.                       |
| Reason     | Reason for a disconnected status: network issue, authentication failed, or host unreachable. |

## Sample Output

### show services user-identification active-directory-access domain-controller status

Displays brief information for domain controllers in all configured domains.

```
user@host> show services user-identification active-directory-access domain-controller status
Domain: ad02.net
 Domain controller Address Status
 DC1 172.16.164.51 Connected
 DC2 172.16.211.12 Connected
 DC3 172.16.5.6 Connected
 DC4 192.168.10.11 Disconnected
 DC5 192.168.211.7 Disconnected

Domain: Mars
 Domain controller Address Status
 Mars10 10.1.1.1 Disconnected
 Mars20 10.2.2.2 Disconnected
 Mars30 10.3.3.3 Disconnected
```

## Sample Output

### show services user-identification active-directory-access domain-controller status brief domain

```
user@host> show services user-identification active-directory-access domain-controller status
brief domain ad02.net
Domain: ad02.net
 Domain controller Address Status
 DC1 172.16.164.51 Connected
 DC2 172.16.211.12 Connected
 DC3 172.16.5.6 Connected
 DC4 192.168.10.11 Disconnected
 DC5 192.168.211.7 Disconnected
```

## Sample Output

### show services user-identification active-directory-access domain-controller status extensive domain

```
user@host> show services user-identification active-directory-access domain-controller status
extensive domain Mars
Domain: Mars
 Domain controller: Mars10
 Address: 10.1.1.1
 Status: Disconnected
 Reason: Network issue
 Domain controller: Mars20
```

Address: 10.2.2.2  
Status: Disconnected  
Reason: Authentication failed  
Domain controller: Mars30  
Address: 10.3.3.3  
Status: Disconnected  
Reason: Host unreachable

## show services user-identification active-directory-access statistics

**Table 517: show services user-identification active-directory-access statistics ip-user-mapping Output Fields**

| Field Name                 | Field Description                                                                                                                                                              |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host                       | IP address of the domain controller.                                                                                                                                           |
| Initial event log timespan | When the feature is first deployed, the number of previous hours for which the event log on the domain controller is read. A one means the last hour of the event log is read. |

**Table 517: show services user-identification active-directory-access statistics ip-user-mapping Output Fields (continued)**

| Field Name              | Field Description                                                                |
|-------------------------|----------------------------------------------------------------------------------|
| Eventlog scan interval  | Number of seconds between event log scans.                                       |
| Total log query number  | Count of the queries on the event log.                                           |
| Failed log query number | Count of the failed queries on the event log.                                    |
| Log read number         | Count of the times the event log was read.                                       |
| Latest timestamp        | Year:month:date:hours:minutes:seconds is the timestamp taken from the event log. |

Table 518 lists the output fields for the **show services user-identification active-directory-access statistics ip-user-probe** command.

**Table 518: show services user-identification active-directory-access statistics ip-user-probe Output Fields**

| Field Name               | Field Description                                                       |
|--------------------------|-------------------------------------------------------------------------|
| Total user probe number  | Count of the probes of IP addresses to get IP address-to-user mappings. |
| Failed user probe number | Count of failed probe attempts.                                         |

Table 519 lists the output fields for the **show services user-identification active-directory-access statistics user-group-mapping** command.

**Table 519: show services user-identification active-directory-access statistics user-group-mapping Output Fields**

| Field Name          | Field Description                  |
|---------------------|------------------------------------|
| Host                | IP address and port being queried. |
| Total query number  | Count of queries.                  |
| Failed query number | Count of failed query attempts.    |

## Sample Output

### show services user-identification active-directory-access statistics ip-user-mapping

```

user@host> show services user-identification active-directory-access statistics ip-user-mapping
Domain: ad03.net
Host: 192.0.2.192
Initial event log timespan : 1
Eventlog scan interval : 60
Total log query number : 240
Failed log query number : 0

```

```
Log read number : 838
Latest timestamp :2013-10-11:15:11:54
Host: 192.0.2.50
Initial event log timespan : 1
Eventlog scan interval : 60
Total log query number : 273
Failed log query number : 0
Log read number : 2012
Latest timestamp :2013-10-11:15:11:23
Domain: acme.net
Host: 192.0.2.39
Initial event log timespan : 1
Eventlog scan interval : 10
Total log query number : 1596
Failed log query number : 0
Log read number : 6691
Latest timestamp :2013-10-11:15:25:03
Host: 192.0.2.1
Initial event log timespan : 1
Eventlog scan interval : 10
Total log query number : 2628
Failed log query number : 0
Log read number : 114953
Latest timestamp :2013-10-11:15:24:01
```

## Sample Output

### show services user-identification active-directory-access statistics ip-user-probe

```
user@host> show services user-identification active-directory-access statistics ip-user-probe
Domain: www.apac-acme.net
Total user probe number : 176116
Failed user probe number : 916
Domain: www.usa-acme.net
Total user probe number : 17632
Failed user probe number : 342
```

## Sample Output

### show services user-identification active-directory-access statistics user-group-mapping

```
user@host> show services user-identification active-directory-access statistics
user-group-mapping
Domain: www.apac-acme.net
Host: 192.0.2.1 Port 389
Total query number : 176116
Failed query number : 916
Domain: www.usa-acme.net
Host: 192.0.2.5 Port 389
Total query number : 8965
```

## show services user-identification active-directory-access user-group-mapping

## Unified Threat Management Overview

---

Unified Threat Management (UTM) is a term used to describe the consolidation of several security features into one device, protecting against multiple threat types. The advantage of UTM is streamlined installation and management of these multiple security capabilities.

The security features provided as part of the UTM solution are:

- **Antispam Filtering**—E-mail spam consists of unwanted e-mail messages, usually sent by commercial, malicious, or fraudulent entities. The antispam feature examines transmitted e-mail messages to identify e-mail spam. When the device detects an e-mail message deemed to be spam, it either drops the message or tags the message header or subject field with a preprogrammed string. The antispam feature uses a constantly updated spam block list (SBL). Sophos updates and maintains the IP-based SBL. The antispam feature is a separately licensed subscription service.
- **Content Filtering**—Content filtering blocks or permits certain types of traffic based on the MIME type, file extension, protocol command, and embedded object type. Content filtering does not require a separate license.
- **Web Filtering**—Web filtering lets you manage Internet usage by preventing access to inappropriate Web content. There are three types of Web filtering solutions. In the case of the integrated Web filtering solution, the decision-making for blocking or permitting Web access is done on the device after it identifies the category for a URL either from user-defined categories or from a category server (Websense provides the CPA Server). The integrated Web filtering feature is a separately licensed subscription service. The redirect Web filtering solution intercepts HTTP requests and forwards the server URL to an external URL filtering server provided by Websense to determine whether to block or permit the requested Web access. Redirect Web filtering does not require a separate license. With Juniper Local Web Filtering, the decision-making for blocking or permitting Web access is done on the device after it identifies the category for a URL from user-defined categories stored on the device. With Local filtering, there is no additional Juniper license or remote category server required.

- **Full File-Based Antivirus**—A virus is executable code that infects or attaches itself to other executable code to reproduce itself. Some malicious viruses erase files or lock up systems. Other viruses merely infect files and overwhelm the target host or network with bogus data. The full file-based antivirus feature provides file-based scanning on specific Application Layer traffic checking for viruses against a virus signature database. It collects the received data packets until it has reconstructed the original application content, such as an e-mail file attachment, and then scans this content. Kaspersky Lab provides the internal scan engine. The full file-based antivirus scanning feature is a separately licensed subscription service.
- **Express Antivirus**—Express antivirus scanning is offered as a less CPU intensive alternative to the full file-based antivirus feature. The express antivirus feature, like the full antivirus feature, scans specific Application Layer traffic for viruses against a virus signature database. However, unlike full antivirus, express antivirus does not reconstruct the original application content. Rather, it just sends (streams) the received data packets, as is, to the scan engine. With express antivirus, the virus scanning is executed by a hardware pattern matching engine. This improves performance while scanning is occurring, but the level of security provided is lessened. Juniper Networks provides the scan engine. The express antivirus scanning feature is a separately licensed subscription service.
- **Sophos Antivirus**—Sophos antivirus scanning is offered as a less CPU-intensive alternative to the full file-based antivirus feature. Sophos supports the same protocols as full antivirus and functions in much the same manner; however, it has a smaller memory footprint and is compatible with lower end devices that have less memory. Sophos antivirus is as an in-the-cloud antivirus solution. The virus pattern and malware database is located on external servers maintained by Sophos (Sophos Extensible List) servers, thus there is no need to download and maintain large pattern databases on the Juniper device. The Sophos antivirus scanner also uses a local internal cache to maintain query responses from the external list server to improve lookup performance.

**NOTE:** The `sessions-per-client limit` CLI command, which imposes a session throttle to prevent a malicious user from generating large amounts of traffic simultaneously, supports the antispam, content filtering, and antivirus UTM features. It does not support Web filtering.

## Understanding UTM Custom Objects

---

Before you can configure most UTM features, you must first configure the custom objects for the feature in question. Custom objects are global parameters for UTM features. This means that configured custom objects can be applied to all UTM policies where applicable, rather than only to individual policies.

The following UTM features make use of certain custom objects:

- Anti-Virus (see [“Full Antivirus Pattern Update Configuration Overview” on page 5949](#))
- Web Filtering (see [“Example: Configuring Integrated Web Filtering” on page 6080](#))
- Anti-Spam (see [“Server-Based Antispam Filtering Configuration Overview” on page 5900](#))
- Content Filtering (see [“Content Filtering Configuration Overview” on page 6040](#))

## Understanding UTM Licensing

The majority of UTM features function as a subscription service requiring a license. You can redeem this license once you have purchased your subscription license SKUs. You redeem your license by entering your authorization code and chassis serial number into the Customer Service License Management System (LMS) interface. Once your entitlement is generated, you can use the CLI from your device to send a license update request to the LMS server. The LMS server then sends your subscription license directly to the device.

NOTE: UTM requires 1 GB of memory.

Table 523: UTM Feature Subscription Service License Requirements

| UTM Feature               | Requires License |
|---------------------------|------------------|
| Antispam                  | Yes              |
| Antivirus: full           | Yes              |
| Antivirus: express        | Yes              |
| Antivirus: sophos         | Yes              |
| Content Filtering         | No               |
| Web Filtering: integrated | Yes              |
| Web Filtering: redirect   | No               |
| Web Filtering: local      | No               |
| Web Filtering: enhanced   | Yes              |

**NOTE:** License enforcement is supported on all high-end SRX Series devices. Licensed features including anti-virus or Enhanced Web Filtering will not function until a license has been installed. The license must be installed after installing or upgrading to a new Junos OS Release version. Unlicensed features such as UTM blacklists and whitelists will continue to function without a license.

---

## Updating UTM Licenses (CLI Procedure)

---

To apply your UTM subscription license to the device, use the following CLI command:

```
user@host> request system license update
```

After you install the license and reboot the device, the device reserves more memory for UTM features, and hence decreases the session capacity. Use the **set security forwarding-process application-services enable-utm-memory** command to manually reallocate the memory for UTM features. You must reboot the device for the configuration to take effect.

## Understanding WELF Logging for UTM Features

---

UTM features support the WELF standard. The WELF Reference defines the WebTrends industry standard log file exchange format. Any system logging to this format is compatible with Firewall Suite 2.0 and later, Firewall Reporting Center 1.0 and later, and Security Reporting Center 2.0 and later.

A WELF log file is composed of records. Each record is a single line in the file. Records are always in chronological order. The earliest record is the first record in the file; the most recent record is the last record in the file. WELF places no restrictions on log filenames or log file rotation policies.

**NOTE:** Each WELF record is composed of fields. The record identifier field (**id=**) must be the first field in a record. All other fields can appear in any order.

The following is a sample WELF record:

```
id=firewall time="2000-2-4 12:01:01" fw=192.168.0.238 pri=6 rule=3 proto=http
src=192.168.0.23 dst=6.1.0.36 rg=www.webtrends.com/index.html op=GET result=0
rcvd=1426
```

The fields from the example WELF record include the following required elements (all other fields are optional):

- **id** (Record identifier)
- **time** (Date/time)
- **fw** (Firewall IP address or name)
- **pri** (Priority of the record)

## Example: Configuring WELF Logging for UTM Features

---

This example shows how to configure WELF logging for UTM features.

- [Requirements on page 5886](#)
- [Overview on page 5886](#)
- [Configuration on page 5886](#)
- [Verification on page 5887](#)

### Requirements

Before you begin, review the fields used to create a WELF log file and record. See [“Understanding WELF Logging for UTM Features” on page 5885](#).

### Overview

A WELF log file is composed of records. Each record is a single line in the file. Records are always in chronological order. The earliest record is the first record in the file; the most recent record is the last record in the file. WELF places no restrictions on log filenames or log file rotation policies. In this example, the severity level is emergency and the name of the security log stream is **utm-welf**.

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security log source-address 1.2.3.4 stream utm-welf
set security log source-address 1.2.3.4 stream utm-welf format welf
set security log source-address 1.2.3.4 stream utm-welf format welf category
content-security
set security log source-address 1.2.3.4 stream utm-welf format welf category
content-security severity emergency
set security log source-address 1.2.3.4 stream utm-welf format welf category
content-security severity emergency host 5.6.7.8
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure WELF logging for UTM features:

1. Set the security log source IP address.  
**[edit security log]**

```
user@host# set source-address 1.2.3.4
```

**NOTE:** You must save the WELF logging messages to a dedicated WebTrends server.

2. Name the security log stream.  

```
[edit security log]
user@host# set source-address 1.2.3.4 stream utm-welf
```
3. Set the format for the log messages.  

```
[edit security log]
user@host# set source-address 1.2.3.4 stream utm-welf format welf
```
4. Set the category of log messages that are sent.  

```
[edit security log]
user@host# set source-address 1.2.3.4 stream utm-welf format welf category
content-security
```
5. Set the severity level of log messages that are sent.  

```
[edit security log]
user@host# set source-address 1.2.3.4 stream utm-welf format welf category
content-security severity emergency
```
6. Enter the host address of the dedicated WebTrends server to which the log messages are to be sent.  

```
[edit security log]
user@host# set source-address 1.2.3.4 stream utm-welf format welf category
content-security severity emergency host 5.6.7.8
```

**Results** From configuration mode, confirm your configuration by entering the **show security log** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security log
stream utm-welf {
 severity emergency;
 format welf;
 category content-security;
 host {
 5.6.7.8;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying the Security Log on page 5888](#)

### Verifying the Security Log

---

**Purpose** Verify that the WELF log for UTM features is complete.

**Action** From operational mode, enter the **show security utm status** command to verify if the UTM service is running or not.

# Configuring UTM for Chassis Cluster

- [Understanding UTM Support for Active/Active Chassis Cluster on page 5889](#)
- [Understanding Chassis Cluster Support for UTM Modules on page 5891](#)

## Understanding UTM Support for Active/Active Chassis Cluster

---

A chassis cluster environment supports UTM with:

- Packet Forwarding Engine in active/backup chassis cluster configurations with the Packet Forwarding Engine and the Routing Engine being active in the same node (On SRX Series devices).
- On SRX100, SRX210, SRX220, SRX240, SRX550, and SRX650 devices, the UTM functionality is supported in both active/active and active/backup chassis cluster configurations where the Packet Forwarding Engine can be active on both the cluster nodes and the Routing Engine and the Packet Forwarding Engine can be active in different nodes.

**NOTE:** UTM does not require a separate license for chassis cluster mode. The usual UTM license is sufficient and should be available on both of the nodes in the chassis cluster.

UTM supports stateless (that is, no state regarding UTM is synchronized between the cluster nodes) the Packet Forwarding Engine active/active chassis cluster configurations. All the UTM sessions anchored on the redundancy group being failed over will be aborted and new sessions are set up with the new primary redundancy group.

Stateful active/active cluster mode is not supported. Stateful objects like UTM sessions will not be synchronized; that is, no UTM module runtime objects (RTOs) are synchronized between the cluster nodes. You need to install UTM licenses in both the nodes independently.

UTM is supported in the following chassis cluster modes:

- **Active/active mode**—In this mode, the redundancy groups can be active on both of the cluster nodes. The transit traffic can be processed by both nodes. Any traffic between nodes transits through the fabric link.

The transit traffic includes:

- Traffic forwarded between interfaces for redundancy groups 1 and up across nodes
- Traffic forwarded between interfaces for redundancy groups 1 and up that are part of the same node but have one or more redundancy groups active on both of the nodes
- Traffic forwarded between RGO-controlled interfaces across devices (traffic from the secondary RGO is sent to the primary RGO over the fabric link for routing decisions)
- **Active/backup mode**—In this mode, all the redundancy groups are active in one cluster node. All the transit traffic is processed by this single node.

The transit traffic includes:

- Traffic forwarded between interfaces for redundancy groups 1 and up that are part of the same node
- Traffic forwarded between RGO-controlled interfaces for redundancy groups 1 and up that are in the same node

UTM is supported for the following chassis cluster failover types:

- **Manual failover**—Supports manual failover through the **set chassis cluster failover** command. Both RGO and redundancy groups 1 and up can fail over using this command.
- **RGO automatic failover**—This failover is supported through control link failure, monitoring objects (IP address, interface monitoring), or preempt/priority configuration.
- **Redundancy groups 1 and up automatic failover**—This failover is supported through monitoring objects (IP address, interface monitoring) or preempt/priority configuration. This failover leads to active link changes and can result in active/active mode.
- **Failover through reboot**—A primary node can be changed to a secondary node by rebooting the node. All redundancy groups in the node that's is rebooted will no longer be primary nodes.
- **Failover through flowd restart**—Redundancy groups 1 and up will be changed to secondary nodes when the flowd restarts.

The following UTM features are supported in chassis cluster:

- Content filtering
- URL (Web) filtering
- Antispam filtering
- Express antivirus scanning
- Full file-based antivirus scanning
- Sophos antivirus scanning

All the UTM configurations are either maintained in the Routing Engine or pushed to the Packet Forwarding Engine from the Routing Engine. The configuration synchronization

between the two nodes is taken care of by the chassis cluster infrastructure. This holds true for all the UTM modules too. You can configure UTM either from the primary or secondary node, and the same configuration will be reflected in the other node once you commit the first configuration.

There is a dependency on ACL support on control links. The time taken to spawn the processes depends on the device. There will be a small delay for the Unified Threat Management daemon (utmd) to come up operationally, even though utmd daemon is running in the secondary Routing Engine, because there can be a startup delay for all the dependant daemons.

## Understanding Chassis Cluster Support for UTM Modules

- **Content filtering**—Content filtering blocks or permits certain types of traffic based on the MIME type, file extension, and protocol command. The content filter controls file transfers across the gateway by checking traffic against configured filter lists.

In content filtering, the user configuration (mime-pattern/filename-extension/protocol-command/content-type) is pushed from the Routing Engine to the Packet Forwarding Engine real-time (PFE-RT). The filtering decision is entirely based on the user configuration and is done on the Packet Forwarding Engine real-time (PFE-RT) side. For the transit traffic, the configuration lookup (for the block/permit decision) and the entire UTM processing occurs in the Packet Forwarding Engine itself and does not go to the Routing Engine (that is the complete UTM session resides in the Packet Forwarding Engine).

- **URL (Web) filtering**—Web filtering lookups takes place in the primary Routing Engine and both the Packet Forwarding Engines send the lookup request to the primary Routing Engine.

Four kinds of Web filtering mechanisms supported on SRX100, SRX210, SRX220, SRX240, and SRX650 devices are described in [Table 524](#).

**Table 524: Web Filtering Mechanisms for Chassis Cluster Support**

| Web Filtering Type     | Description                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Redirect Web filtering | <ul style="list-style-type: none"> <li>• Decision (allow/deny) is always made by an external Websense server</li> <li>• TCP connections are set up from the utmd daemon to the Websense server</li> <li>• Any request to the Websense server is sent using one of these TCP connections.</li> </ul> |

Table 524: Web Filtering Mechanisms for Chassis Cluster Support (*continued*)

| Web Filtering Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Integrated Web filtering    | <ul style="list-style-type: none"> <li>The local URL Filtering cache maintained on the RT side is updated with the URL to category mappings received from the SurfControl content portal authority (SC-CPA) server for URL lookup requests sent to it.</li> <li>RT side also maintains a list of categories received from the SC-CPA server.</li> <li>You can configure actions for various categories received from the SC-CPA server. This configuration is maintained in RT side.</li> <li>You can define your own categories that contain a list of URLs and IP addresses. A predefined profile (ns-profile) can be used too. This configuration is also maintained on the RT side.</li> <li>URL lookups are made against the URL Filtering cache and the user-defined categories.</li> <li>If the category for the URL is not found in the local URL Filtering cache, categorization requests are sent to the utmd daemon and subsequently forwarded to the external SC-CPA Server for response.</li> </ul> |
| Enhanced Web Filtering      | Enhanced Web Filtering is similar to integrated Web filtering. It maintains the URL Filtering cache, a list of categories from the server, and a list of user-defined categories. It performs the lookup and categorization similar to integrated Web filtering. It is similar in mechanism but differs in the server functionality to determine URL categories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Juniper local URL filtering | You can configure URL whitelists or blacklists for the URL lookups. This configuration is maintained on the real-time side of the Packet Forwarding Engine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

- **Antispam filtering**—Antispam filtering pushes the user configuration (whitelist and blacklist) from the Routing Engine to the PFE-RT.
- **Express antivirus scanning**—In express antivirus scanning, the antivirus detection functionality is performed by the Pattern Matching Engine (PME) in the Packet Forwarding Engine of the node where the UTM traffic is anchored. The signature database is downloaded by the primary Routing Engine and synchronized to the secondary Routing Engine to be loaded in its local PME. If configured, the primary Routing Engine does the periodic signature database updates and synchronizes them to the secondary Routing Engine.
- **Full file-based antivirus scanning**—In full antivirus scanning, the Kaspersky Lab engine is responsible for scanning all the data it receives. The signature database is downloaded from external Kaspersky Lab servers and used by the scan engine in the Routing Engine. Full AV antivirus scanning is done in the Routing Engine of each node where the UTM traffic is anchored. The signature database files are downloaded by the primary Routing Engine and synchronized to the secondary Routing Engine. If configured, the primary Routing Engine performs the periodic signature database update and synchronizes it to the secondary Routing Engine.

Apart from the signature database lookup, full antivirus scanning uses the following configuration that is maintained in the RT side to determine if full antivirus scanning needs to be performed:

- Mime whitelist—A hit bypasses antivirus scanning
- Mime exception list—An exception to the whitelist

- URL whitelist—a hit bypasses antivirus scanning
- Filename extension—Only these extensions are sent for antivirus scanning

The packet processing in full antivirus scanning might occur within RT side based on the result of the user-configured lists. Otherwise, the UTM session spans across RT and RE side if full virus scanning needs to be performed.

## Antispam Filtering Overview

---

Spam consists of unwanted e-mail messages, usually sent by commercial, malicious, or fraudulent entities. The antispam feature examines transmitted e-mail messages to identify spam. When the device detects a message deemed to be spam, it blocks the e-mail message or tags the e-mail message header or subject with a preprogrammed string.

Antispam filtering allows you to use both a third-party server-based spam block list (SBL) and to optionally create your own local whitelists (benign) and blacklists (malicious) for filtering against e-mail messages. The antispam feature is not meant to replace your antispam server, but to complement it.

## Handling Spam Messages

---

There are two possible actions the device can take when spam is detected. It can perform a drop action or a tag action.

- [Blocking Detected Spam on page 5897](#)
- [Tagging Detected Spam on page 5898](#)

### Blocking Detected Spam

The device can block and drop detected spam at either the connection level or the e-mail level:

- Blocking spam at the connection level

When the SMTP sender is identified as a spam sender based on its IP address, the SMTP connection is rejected and dropped. An error message with a proper error code from the firewall is sent out on behalf of the SMTP server. An example of such an error message is:

554 Transaction failed due to anti spam setting

- Blocking spam at the e-mail level

When a particular e-mail sender is identified as spam sender based on its sender address, the e-mail is rejected and dropped. An error message with a proper error code from the firewall is sent back to the sender on behalf of the server. An example of such an error message is:

550 Requested action not taken: mailbox unavailable

## Tagging Detected Spam

The device can allow and tag the e-mail if the message sender is detected as a spammer. This tagging can occur at the connection level so that all the e-mails for the connection in question are tagged. Otherwise, you can tag only an individual e-mail. Two tagging methods are supported:

- Tag the subject: A user-defined string is added at the beginning of the subject of the e-mail.
- Tag the header: A user-defined string is added to the e-mail header.

## Understanding Server-Based Antispam Filtering

---

Server-based antispam filtering requires Internet connectivity with the spam block list (SBL) server. Domain Name Service (DNS) is required to access the SBL server. The firewall performs SBL lookups through the DNS protocol. The lookups are against the IP address of the sender (or relaying agent) of the e-mail, adding the name of the SBL server as the authoritative domain. The DNS server then forwards each request to the SBL server, which returns a DNS response to the device. The device then interprets the DNS response to determine if the e-mail sender is a spammer.

IP addresses that are included in the block lists are generally considered to be invalid addresses for mail servers or easily compromised addresses. Criteria for listing an IP address as a spammer on the SBL can include:

- Running an SMTP open relay service
- Running open proxy servers (of various kinds)
- Being a zombie host possibly compromised by a virus, worm, Trojan, or spyware
- Using a dynamic IP range
- Being a confirmed spam source with a known IP address

By default, the device first checks incoming e-mail against local whitelists and blacklists. If there are no local lists, or if the sender is not found on local lists, the device proceeds to query the SBL server over the Internet. When both server-based spam filtering and local list spam filtering are enabled, checks are done in the following order:

1. The local whitelist is checked. If there is a match, no further checking is done. If there is no match...
2. The local blacklist is checked. If there is a match, no further checking is done. If there is no match...

3. The SBL server list is checked.

**NOTE:**

- SBL server matching stops when the antispam license key is expired.
- Server-based spam filtering supports only IP-based spam block list blacklist lookup. Sophos updates and maintains the IP-based spam block list. Server-based antispam filtering is a separately licensed subscription service. When your antispam license key expires, you can continue to use locally defined blacklists and whitelists.

## Server-Based Antispam Filtering Configuration Overview

For each UTM feature, configure feature parameters in the following order:

1. Configure UTM custom objects for the feature:

```
user@host# set security utm custom-objects
```

2. Configure the main feature parameters, using feature profiles.

```
user@host# set security utm feature-profile anti-spam
```

3. Configure a UTM policy for each protocol, and attach this policy to a profile.

```
user@host# set security utm utm-policy utmp1 anti-spam smtp-profile smtp1
```

**NOTE:** Antispam filtering is only supported for the SMTP protocol.

4. Attach the UTM policy to a security policy.

```
user@host# set security policies from-zone trust to-zone untrust policy p1 then permit
application-services utm-policy utmp1
```

## Example: Configuring Server-Based Antispam Filtering

This example shows how to configure server-based antispam filtering.

- [Requirements on page 5901](#)
- [Overview on page 5901](#)
- [Configuration on page 5901](#)
- [Verification on page 5906](#)

### Requirements

Before you begin, review how to configure the feature parameters for each UTM feature. See “[Server-Based Antispam Filtering Configuration Overview](#)” on page 5900.

### Overview

Server-based antispam filtering requires Internet connectivity with the spam block list (SBL) server. Domain Name Service (DNS) is required to access the SBL server.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile anti-spam sbl profile sblprofile1 sbl-default-server
set security utm feature-profile anti-spam sbl profile sblprofile1 sbl-default-server
spam-action block
set security utm feature-profile anti-spam sbl profile sblprofile1 sbl-default-server
custom-tag-string ***spam***
set security utm utm-policy spampolicy1 anti-spam smtp-profile sblprofile1
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy1 match
source-address any
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy1 match
destination-address any
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy1 match
application junos-smtp
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy1 then permit
application-services utm-policy spampolicy1
```

**GUI Step-by-Step  
Procedure**

To configure server-based antispam filtering:

1. Configure a profile and enable/disable the SBL server lookup. Select **Configure>Security>UTM>Anti-Spam**.
  - a. In the Anti-Spam profiles configuration window, click **Add** to configure a profile for the SBL server, or click **Edit** to modify an existing item.
  - b. In the Profile name box, enter a unique name for the antispam profile that you are creating.
  - c. If you are using the default server, select **Yes** next to Default SBL server. If you are not using the default server, select **No**.

**NOTE:** The SBL server is predefined on the device. The device comes preconfigured with the name and address of the SBL server. If you do not select Yes, you are disabling server-based spam filtering. You should disable it only if you are using only local lists or if you do not have a license for server-based spam filtering.

- d. In the Custom tag string box, enter a custom string for identifying a message as spam. By default, the devices uses **\*\*\*SPAM\*\*\***.
  - e. From the antispam action list, select the action that the device should take when it detects spam. Options include Tag subject, Block email, and Tag header.
2. Configure a UTM policy for SMTP to which you attach the antispam profile.
  - a. Select **Configure>Security>Policy>UTM Policies**.
  - b. In the UTM policy configuration window, click **Add**.
  - c. In the policy configuration window, select the **Main** tab.
  - d. In the Policy name box, type a unique name for the UTM policy.
  - e. In the Session per client limit box, type a session per client limit. Valid values range from 0 to 2000.
  - f. From the Session per client over limit list, select the action that the device should take when the session per client limit for this UTM policy is exceeded. Options include Log and permit and Block.
  - g. Select the **Anti-Spam profiles** tab in the pop-up window.
  - h. From the SMTP profile list, select an antispam profile to attach to this UTM policy.

3. Attach the UTM policy to a security policy.
  - a. Select **Configure>Security>Policy>FW Policies**.
  - b. In the Security Policy window, click **Add** to configure a security policy with UTM or click **Edit** to modify an existing policy.
  - c. In the Policy tab, type a name in the **Policy Name** box.
  - d. Next to From Zone, select a zone from the list.
  - e. Next to To Zone, select a zone from the list.
  - f. Choose a source address.
  - g. Choose a destination address.
  - h. Choose an application by selecting **junos-smtp** (for antispam) in the Application Sets box and move it to the Matched box.
  - i. Next to Policy Action, select one of the following: **Permit**, **Deny**, or **Reject**.

**NOTE:** When you select Permit for Policy Action, several additional fields become available in the Applications Services tab, including UTM Policy.

- j. Select the **Application Services** tab.
  - k. Next to UTM Policy, select the appropriate policy from the list. This attaches your UTM policy to the security policy.
  - l. Click **OK** to check your configuration and save it as a candidate configuration.
  - m. If the policy is saved successfully, you receive a confirmation, and you must click **OK** again. If the profile is not saved successfully, click **Details** in the pop-up window to discover why.

**NOTE:**

- You must activate your new policy to apply it.
- In SRX Series devices the confirmation window that notifies you that the policy is saved successfully disappears automatically.

- n. If you are done configuring the device, click **Commit Options>Commit**.

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure server-based antispam filtering:

1. Create a profile.

```
[edit security]
user@host# set utm feature-profile anti-spam sbl profile sblprofile1
```

2. Enable or disable the default SBL server lookup.

```
[edit security]
user@host# set utm feature-profile anti-spam sbl profile sblprofile1
sbl-default-server
```

**NOTE:** If you are using server-based antispam filtering, you should type `sbl-default-server` to enable the default SBL server. (The SBL server is predefined on the device. The device comes preconfigured with the name and address of the SBL server.) You should disable server-based antispam filtering using the `no-sbl-default-server` option only if you are using only local lists or if you do not have a license for server-based spam filtering.

3. Configure the action to be taken by the device when spam is detected (block, tag-header, or tag-subject).

```
[edit security]
user@host# set utm feature-profile anti-spam sbl profile sblprofile1sbl-default-server
spam-action block
```

4. Configure a custom string for identifying a message as spam.

```
[edit security]
user@host# set utm feature-profile anti-spam sbl profile sblprofile1
sbl-default-server custom-tag-string ***spam***
```

5. Attach the spam feature profile to the UTM policy.

```
[edit security]
user@host# set utm utm-policy spampolicy1 anti-spam smtp-profile sblprofile1
```

6. Configure a security policy for UTM to which to attach the UTM policy.

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy1 match source-address any
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy1 match destination-address any
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy1 match application junos-smtp
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy1 then permit application-services utm-policy spampolicy1
```

**NOTE:** The device comes preconfigured with a default antispam policy. The policy is called `junos-as-defaults`. It contains the following configuration parameters:

```
anti-spam {
 sbl {
 profile junos-as-defaults {
 sbl-default-server;
 spam-action block;
 custom-tag-string "****SPAM****";
 }
 }
}
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security utm
feature-profile {
 anti-spam {
 sbl {
 profile sblprofile1 {
 sbl-default-server;
 spam-action block;
 custom-tag-string ***spam***;
 }
 }
 }
}
utm-policy spampolicy1 {
 anti-spam {
 smtp-profile sblprofile1;
 }
}
```

```
[edit]
user@host# show security policies
from-zone trust to-zone untrust {
 policy utmsecuritypolicy1 {
 match {
 source-address any;
 destination-address any;
 application junos-smtp;
 }
 then {
 permit {
 application-services {
 utm-policy spampolicy1;
 }
 }
 }
 }
}
```

```
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Antispam Statistics on page 5906](#)

---

### Verifying Antispam Statistics

**Purpose** Verify the antispam statistics.

**Action** From operational mode, enter the **show security utm anti-spam status** and **show security utm anti-spam statistics** commands.

The following information appears:

```
SBL Whitelist Server:
SBL Blacklist Server:
msgsecurity.example.net
DNS Server:
Primary : 1.2.3.4, Src Interface: ge-0/0/0
Secondary: 2.3.4.5, Src Interface: ge-0/0/1
Ternary : 0.0.0.0, Src Interface: fe-0/0/2

Total connections: #
Denied connections: #
Total greetings: #

## Understanding Local List Antispam Filtering

---

When creating your own local whitelist and blacklist for antispam filtering, you can filter against domain names, e-mail addresses, and/or IP addresses. Pattern matching works a bit differently depending upon the type of matching in question. For example, pattern matching for domain names uses a longest suffix match algorithm. If the sender e-mail address has a domain name of aaa.bbb.ccc, the device tries to match "aaa.bbb.ccc" in the list. If no match is found, it tries to match "bbb.ccc", and then "ccc". IP address matching, however, does not allow for partial matches.

Antispam filtering uses local lists for matching in the following manner:

1. **Sender IP:** The sender IP is checked against the local whitelist, then the local blacklist, and then the SBL IP-based server (if enabled).
2. **Sender Domain:** The domain name is checked against the local whitelist and then against the local blacklist.
3. **Sender E-mail Address:** The sender e-mail address is checked against the local whitelist and then against the local blacklist.

By default, the device first checks incoming e-mail against the local whitelist and blacklist. If the sender is not found on either list, the device proceeds to query the SBL server over the Internet. When both server-based antispam filtering and local list antispam filtering are enabled, checks are done in the following order:

1. The local whitelist is checked. If there is a match, no further checking is done. If there is no match...
2. The local blacklist is checked. If there is a match, no further checking is done. If there is no match...
3. The SBL server list is checked.

**NOTE:** Local blacklist and whitelist matching continues after the antispam license key is expired.

## Local List Antispam Filtering Configuration Overview

For each UTM feature, configure feature parameters in the following order:

1. Configure UTM custom objects for the feature:

```
user@host# set security utm custom-objects url-pattern url-pattern-name
```

2. Configure the main feature parameters, using feature profiles.

```
user@host# set security utm feature-profile anti-spam as-profile-name
```

3. Configure a UTM policy for each protocol, and attach this policy to a profile.

```
user@host# set security utm utm-policy utmp1 anti-spam smtp-profile smtp1
```

4. Attach the UTM policy to a security policy.

```
user@host# set security policies from-zone trust to-zone untrust policy p1 then permit
application-services utm-policy utmp1
```

## Example: Configuring Local List Antispam Filtering

This example shows how to configure local list antispam filtering.

- [Requirements on page 5911](#)
- [Overview on page 5911](#)
- [Configuration on page 5911](#)
- [Verification on page 5916](#)

## Requirements

Before you begin, review how to configure the feature parameters for each UTM feature. See [“Local List Antispam Filtering Configuration Overview” on page 5910](#).

## Overview

Antispam filtering uses local lists for matching. When creating your own local whitelist and blacklist for antispam filtering, you can filter against domain names, e-mail addresses, and/or IP addresses.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm custom-objects url-pattern as-black value [150.61.8.134]
set security utm custom-objects url-pattern as-white value [150.1.2.3]
set security utm feature-profile anti-spam address-whitelist as-white
set security utm feature-profile anti-spam sbl profile localprofile1
set security utm feature-profile anti-spam sbl profile localprofile1 spam-action block
set security utm feature-profile anti-spam sbl profile localprofile1 custom-tag-string
 spam
set security utm utm-policy spampolicy2 anti-spam smtp-profile localprofile1
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy2 match
 source-address any
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy2 match
 destination-address any
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy2 match
 application junos-smtp
set security policies from-zone trust to-zone untrust policy utmsecuritypolicy2 then permit
 application-services utm-policy spampolicy2
```

### GUI Step-by-Step Procedure

To configure local list antispam filtering:

1. Create local whitelist and blacklist custom objects by configuring a URL pattern list.
  - a. Select **Configure>Security>UTM>Custom Objects**.
  - b. In the UTM custom objects configuration window, select the **URL Pattern List** tab.
  - c. Click **Add** to create URL pattern lists.
  - d. Next to URL Pattern Name, type a unique name.

**NOTE:** If you are creating a whitelist, it is helpful to indicate this in the list name. The same applies to a blacklist. The name you enter here becomes available in the Address Whitelist and Address Blacklist fields when you are configuring your antispam profiles.

- e. Next to URL Pattern Value, type the URL pattern for whitelist or blacklist antispam filtering.
2. Configure antispam filtering to use the whitelist and blacklist custom objects.
  - a. Select **Configure>Security>UTM>Global options**.
  - b. In the right pane, select the **Anti-Spam** tab.
  - c. Under Anti-Spam, select an Address Whitelist and/or an Address Blacklist from the list for local lists for spam filtering. (These lists are configured as custom objects.)
  - d. Click **OK**.
  - e. If the configuration item is saved successfully, you receive a confirmation, and you must click **OK** again. If it is not saved successfully, click **Details** in the pop-up window to discover why.
  - f. In the left pane under Security, select the **Anti-Spam** tab.
  - g. Click **Add** to configure an anti-spam profile. The profile configuration pop-up window appears.
  - h. In the Profile name box, enter a unique name.
  - i. If you are using the default server, select **Yes** beside Default SBL server. If you are not using the default server, select **No**.

**NOTE:** If you select No, you are disabling server-based spam filtering. You disable it only if you are using local lists or if you do not have a license for server-based spam filtering.

- j. In the Custom tag string box, type a custom string for identifying a message as spam. By default, the device uses **\*\*\*SPAM\*\*\***.
  - k. In the Actions list, select the action that the device should take when it detects spam. Options include Tag subject, Block email, and Tag header.
3. Configure a UTM policy for SMTP to which you attach the antispam profile.
    - a. Select **Configure>Security>Policy>UTM Policies**.
    - b. In the UTM policy configuration window, click **Add** to configure a UTM policy. The policy configuration pop-up window appears.
    - c. Select the **Main** tab.
    - d. In the Policy name box, type a unique name.
    - e. In the Session per client limit box, type a session per client limit. Valid values range from 0 through 2000.
    - f. From the Session per client over limit list, select the action that the device should take when the session per client limit for this UTM policy is exceeded. Options include Log and permit and Block.
    - g. Select the **Anti-Spam profiles** tab.
    - h. From the SMTP profile list, select the antispam profile that you are attaching to this UTM policy.
  4. Attach the UTM policy to a security policy.
    - a. Select **Configure>Security>Policy>FW Policies**.
    - b. In the Security Policy window, click **Add** to configure a security policy with UTM. The policy configuration pop-up window appears.
    - c. In the Policy tab, type a name in the Policy Name box.
    - d. Next to From Zone, select a zone from the list.
    - e. Next to To Zone, select a zone from the list.
    - f. Choose a source address.
    - g. Choose a destination address.
    - h. Choose an application by selecting **junos-smtp** (for antispam) in the Application Sets box and move it to the Matched box.
    - i. Next to Policy Action, select one of the following: **Permit, Deny, or Reject**.

**NOTE:** When you select Permit for policy action, several additional fields become available in the Applications Services tab, including UTM Policy.

- j. Select the **Application Services** tab.
- k. Next to UTM Policy, select the appropriate policy from the list. This attaches your UTM policy to the security policy.
- l. Click **OK** to check your configuration and save it as a candidate configuration.
- m. If the policy is saved successfully, you receive a confirmation, and you must click **OK** again. If the profile is not saved successfully, click **Details** in the pop-up window to discover why.

**NOTE:** You must activate your new policy to apply it.

- n. If you are done configuring the device, click **Commit Options>Commit**.

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure local list antispam filtering:

1. Configure the local list spam blocking by first creating your global local spam lists.

```
[edit security]
user@host# set utm custom-objects url-pattern as-black value [150.61.8.134]
user@host# set utm custom-objects url-pattern as-white value [150.1.2.3]
```

2. Configure the local list antispam feature profile by first attaching your custom-object blacklist or whitelist or both.

```
[edit security]
user@host# set utm feature-profile anti-spam address-whitelist as-white
```

**NOTE:** When both the whitelist and the blacklist are in use, the whitelist is checked first. If there is no match, then the blacklist is checked.

3. Configure a profile for your local list spam blocking.

```
[edit security]
user@host# set utm feature-profile anti-spam sbl profile localprofile1
```

**NOTE:** Although you are not using the SBL for local list spam blocking, you configure your profile from within that command similar to the server-based spam blocking procedure.

4. Configure the action to be taken by the device when spam is detected (block, tag-header, tag-subject).

```
[edit security]
user@host# set utm feature-profile anti-spam sbl profile localprofile1 spam-action
block
```

5. Configure a custom string for identifying a message as spam.

```
[edit security]
user@host# set utm feature-profile anti-spam sbl profile localprofile1
custom-tag-string ***spam***
```

6. Attach the spam feature profile to the UTM policy.

```
[edit security]
user@host# set utm utm-policy spampolicy2 anti-spam smtp-profile localprofile1
```

7. Configure a security policy for UTM, and attach the UTM policy to the security policy.

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy2 match source-address any
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy2 match destination-address any
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy2 match application junos-smtp
user@host# set security policies from-zone trust to-zone untrust policy
utmsecuritypolicy2 then permit application-services utm-policy spampolicy2
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security utm
custom-objects {
 anti-spam {
 url-pattern patternwhite;
 address-whitelist as-white;
 sbl {
 profile localprofile1 {
 spam-action block;
 custom-tag-string ***spam***;
 }
 }
 }
}
utm-policy spampolicy2 {
 anti-spam {
 smtp-profile localprofile1;
 }
}
```

```
[edit]
user@host# show security policies
from-zone trust to-zone untrust {
 policy utmsecuritypolicy2 {
 match {
 source-address any;
 destination-address any;
 application junos-smtp;
```

```
 }
 then {
 permit {
 application-services {
 utm-policy spampolicy2;
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Antispam Statistics on page 5916](#)

---

### Verifying Antispam Statistics

**Purpose** Verify the antispam statistics.

**Action** From operational mode, enter the **show security utm anti-spam status** and **show security utm anti-spam statistics** commands.

The following information appears:

```
SBL Whitelist Server:
SBL Blacklist Server:
msgsecurity.juniper.net
DNS Server:
Primary : 1.2.3.4, Src Interface: ge-0/0/0
Secondary: 2.3.4.5, Src Interface: ge-0/0/1
Ternary : 0.0.0.0, Src Interface: fe-0/0/2
```

```
Total connections: #
Denied connections: #
Total greetings: #
Denied greetings: #
Total e-mail scanned: #
White list hit: #
Black list hit: #
Spam total: #
Spam tagged: #
Spam dropped: #
DNS errors: #
Timeout errors: #
Return errors: #
Invalid parameter errors: #
Statistics start time:
Statistics for the last 10 days.
```

## Express Antivirus Protection Overview

---

Express antivirus scanning is offered as a less CPU intensive alternative to the full file-based antivirus feature. Express antivirus supports the same protocols as full antivirus and functions in much the same manner, however, it has a smaller memory footprint, compatible with the smaller system memory present on lower end devices.

This topic includes the following sections:

- [Express Antivirus Packet-Based Scanning Versus File-Based Scanning on page 5921](#)
- [Express Antivirus Expanded MIME Decoding Support on page 5922](#)
- [Express Antivirus Scan Result Handling on page 5922](#)
- [Express Antivirus Intelligent Prescreening on page 5922](#)
- [Express Antivirus Limitations on page 5922](#)

## Express Antivirus Packet-Based Scanning Versus File-Based Scanning

Express antivirus uses a different antivirus scan engine than the full file-based antivirus feature and a different back-end hardware engine to accelerate pattern matching for higher data throughput.

The packet-based scanning done by express antivirus provides virus scanning data buffers without waiting for entire file to be received by the firewall, whereas the file-based scanning done by full antivirus can only start virus scanning when entire file is received.

### Express Antivirus Expanded MIME Decoding Support

Express antivirus offers MIME decoding support for HTTP, POP3, SMTP, and IMAP. MIME decoding support includes the following for each supported protocol:

- Multi-part and nested header decoding
- Base64 decoding, printed quote decoding, and encoded word decoding (in the subject field)

### Express Antivirus Scan Result Handling

With express antivirus, the TCP traffic is closed gracefully when a virus is found and the data content is dropped.

**NOTE:** Express antivirus supports the following fail mode options: default, engine-not-ready, out-of-resource, and too-many-requests. Fail mode handling of supported options with express antivirus is much the same as with full antivirus.

### Express Antivirus Intelligent Prescreening

Intelligent prescreening functionality is identical in both express antivirus and full antivirus.

### Express Antivirus Limitations

Express antivirus has the following limitations when compared to full antivirus functionality:

- Express antivirus provides limited support for the scanning of file archives and compressed file formats. Express antivirus can only support gzip, deflate and compressed compressing formats.
- Express antivirus provides limited support for decompression. Decompression is only supported with HTTP (supports only gzip, deflate, and compress for HTTP and only supports one layer of compression) and POP3 (supports only gzip for POP3 and only supports one layer of compression).
- Express antivirus does not support scanning by extension.
- Express antivirus scanning is interrupted when the scanning database is loading.
- Express antivirus may truncate a warning message if a virus has been detected and the replacement warning message that is sent is longer than the original content it is replacing.
- If you switch from express antivirus protection to full file-based antivirus protection, you must reboot the device in order for full file-based antivirus to begin working.

**NOTE:** Because express antivirus does only packet-based string matching, if you use the standard EICAR file to test express antivirus, you will see false positives. To avoid these false positives, Juniper Networks has disabled scanning on the standard EICAR file to create a modified EICAR file for testing express antivirus. You can download this modified EICAR file from the following links:

<http://www.juniper.net/security/avtest/ss-eicar.txt>

<http://www.juniper.net/security/avtest/ss-eicar.com>

<http://www.juniper.net/security/avtest/ss-eicar.zip>

**NOTE:** The modified EICAR file must be tested with express antivirus only. The Kaspersky antivirus and Sophos antivirus do not detect this file.

**NOTE:** The express antivirus feature provides better performance but lower security. Note that if you switch from full file-based antivirus protection to express antivirus protection, you must reboot the device in order for express antivirus to begin working.

- [Example: Automatically Updating Express Antivirus Patterns on page 5942](#)

## Express Antivirus Configuration Overview

For each UTM feature, you should configure feature parameters in the following order:

1. Configure UTM custom objects for the UTM features. The following example enables the mime-pattern, url-pattern, and custom-url-category custom objects:

```
user@host# set security utm custom-objects mime-pattern
user@host# set security utm custom-objects url-pattern
user@host# set security utm custom-objects custom-url-category
```

2. Configure main feature parameters using feature profiles. The following examples enables the anti-virus feature profile:

```
user@host# set security utm feature-profile anti-virus juniper-express-engine
```

3. Configure a UTM policy for each protocol and attach this policy to a profile. The following example creates the utmp3 UTM policy for the HTTP protocol:

```
user@host# set security utm utm-policy utmp3 anti-virus http-profile http1
```

4. Attach the UTM policy to a security policy. The following example attaches the utmp3 UTM policy to the p3 security policy:

```
user@host# set security policies from-zone trust to-zone untrust policy p3 then permit
application-services utm-policy utmp3
```

- [Configuring Express Antivirus UTM Policies \(J-Web Procedure\) on page 5937](#)

## Example: Configuring Express Antivirus Custom Objects

---

This example shows how to configure express antivirus custom objects.

- [Requirements on page 5924](#)
- [Overview on page 5924](#)
- [Configuration on page 5925](#)
- [Verification on page 5926](#)

### Requirements

Before you begin:

- Decide the type of express antivirus protection you require. See [“Express Antivirus Protection Overview” on page 5921](#).
- Understand the order in which express antivirus parameters are configured. See [“Express Antivirus Configuration Overview” on page 5923](#).

### Overview

In this example, you define custom objects that are used to create express antivirus feature profiles. You perform the following tasks to define custom objects:

- Create two MIME lists called avmime2 and ex-avmime2, and add patterns to the list.
- Configure a URL pattern list called urlist2.

When entering the URL pattern, note the following wildcard character support:

- The `\*\.[]\?` wildcard characters are supported.
- You must precede all wildcard URLs with `http://`.
- You can use the asterisk `*` wildcard character only if it is at the beginning of the URL and is followed by a period.
- You can use the question mark `?` wildcard character only at the end of the URL.

- The following wildcard syntax is supported: `http://*example.net`, `http://www.example.ne?`, `http://www.example.n??`.
- The following wildcard syntax is not supported: `*example.net`, `www.example.ne?`, `http://*example.net`, `http://*`.
- Configure a custom URL category list called `custurl2`, using the `urllist2` URL pattern list.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm custom-objects mime-pattern avmime2 value [video/quicktime
image/x-portable-anymap x-world/x-vrml]
set security utm custom-objects mime-pattern ex-avmime2 value
[video/quicktime-inappropriate]
set security utm custom-objects url-pattern urllist2 value [http://www.example.net
1.2.3.4]
set security utm custom-objects custom-url-category custurl2 value urllist2
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure express antivirus filtering custom objects:

1. Create MIME lists, and add MIME patterns to the lists.

```
[edit security utm]
user@host# set custom-objects mime-pattern avmime2 value [video/quicktime
image/x-portable-anymap x-world/x-vrml]
user@host# set custom-objects mime-pattern ex-avmime2 value
[video/quicktime-inappropriate]
```

**NOTE:** Because you use URL pattern lists to create custom URL category lists, you must configure URL pattern list custom objects before you configure custom URL category list.

2. Configure a URL pattern list custom object.

```
[edit security utm]
user@host# set custom-objects url-pattern urllist2 value [http://www.example.net
1.2.3.4]
```

3. Configure a custom URL category list.

```
[edit security utm]
user@host# set custom-objects custom-url-category custurl2 value urllist2
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security utm
custom-objects {
 mime-pattern {
 avmime2 {
 value [video/quicktime image/x-portable-anymap x-world/x-vrml];
 }
 ex-avmime2 {
 value video/quicktime-inappropriate;
 }
 }
 url-pattern {
 urllist2 {
 value [http://www.example.net 1.2.3.4];
 }
 }
 custom-url-category {
 custurl2 {
 value urllist2;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Express Antivirus Custom Objects on page 5926](#)

### [Verifying Express Antivirus Custom Objects](#)

---

**Purpose** Verify the express antivirus custom objects.

**Action** From operational mode, enter the **show configuration security utm** command.

**Related Documentation**

- [Configuring Express Antivirus Custom Objects \(J-Web Procedure\) on page 5926](#)
- [Attaching Express Antivirus UTM Policies to Security Policies \(J-Web Procedure\) on page 5939](#)
- [Configuring Express Antivirus Feature Profiles \(J-Web Procedure\) on page 5934](#)

## [Configuring Express Antivirus Custom Objects \(J-Web Procedure\)](#)

---

To configure express antivirus protection using the J-Web configuration editor, you must first create your custom objects (MIME pattern list, URL pattern list, and custom URL category list).

Configure a MIME pattern list custom object as follows:

1. Select **Configure>Security>UTM Custom Objects**.
2. From the MIME Pattern List tab, click **Add** to create MIME pattern lists.
3. In the Add MIME Pattern pop-up window, next to **MIME Pattern Name**, enter a unique name.

**NOTE:** Keep in mind that you are creating a MIME whitelist and a MIME exception list (if necessary). Both MIME lists appear in the MIME Whitelist and Exception MIME Whitelist fields when you configure antivirus. Therefore, the MIME list names you create should be as descriptive as possible.

4. Next to MIME Pattern Value, enter the MIME pattern.
5. Click **Add** to add your MIME pattern to the Values list box. Within this box, you can also select an entry and use the Delete button to delete it from the list. Continue to add MIME patterns in this manner.
6. Optionally, create a new MIME list to act as an exception list. The exception list is generally a subset of the main MIME list.
7. Click **OK** to check your configuration and save the selected values as part of the MIME list, then click **Commit Options>Commit**.
8. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

Configure a URL pattern list custom object as follows:

**NOTE:** Because you use URL pattern lists to create custom URL category lists, you must configure URL pattern list custom objects before you configure a custom URL category list.

1. Select **Configure>Security>UTM>Custom Objects**.
2. From the URL Pattern List tab, click **Add** to create URL pattern lists.
3. Next to URL Pattern Name, enter a unique name. This name appears in the Custom URL Category List Custom Object page for selection.
4. Next to URL Pattern Value, enter the URL or IP address you want added to list for bypassing scanning.

When entering the URL pattern, note the following wildcard character support:

- The `\*\.[]\?` wildcard characters are supported.
- You must precede all wildcard URLs with `http://`.

- You can only use the asterisk **\*** wildcard character if it is at the beginning of the URL and is followed by a period.
  - You can only use the question mark **?** wildcard character at the end of the URL.
  - The following wildcard syntax IS supported: **http://\*.juniper.net**, **http://www.juniper.ne?**, **http://www.juniper.n??**.
  - The following wildcard syntax is NOT supported: **\*juniper.net**, **www.juniper.ne?**, **http://\*juniper.net**, **http://\***.
5. Click **Add** to add your URL pattern to the Values list box. The list can contain up to 8192 items. You can also select an entry and use the Delete button to delete it from the list. Continue to add URLs or IP addresses in this manner.
  6. Click **OK** to check your configuration and save the selected values as part of the URL pattern list, then click **Commit Options>Commit**.
  7. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

Configure a custom URL category list custom object using the URL pattern list that you created:

1. Select **Configure>Security>UTM>Custom Objects**.
2. From the URL Category List tab, click **Add** to create URL category lists.
3. Next to URL Category Name, enter a unique name. This name appears in the URL Whitelist list when you configure antivirus global options.
4. In the Available Values box, select a **URL Pattern List** name from the list for bypassing scanning and click the right arrow button to move it to the Selected Values box.
5. Click **OK** to check your configuration and save the selected values as part of the URL list, then click **Commit Options>Commit**.
6. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

**Related  
Documentation**

- [Express Antivirus Protection Overview on page 5921](#)
- [Express Antivirus Configuration Overview on page 5923](#)
- [Configuring Express Antivirus Feature Profiles \(J-Web Procedure\) on page 5934](#)
- [Configuring Express Antivirus UTM Policies \(J-Web Procedure\) on page 5937](#)

## Example: Configuring Express Antivirus Feature Profiles

This example shows how to configure an express antivirus feature profile.

- [Requirements on page 5929](#)
- [Overview on page 5929](#)
- [Configuration on page 5930](#)
- [Verification on page 5933](#)

### Requirements

Before you begin:

- Decide the type of express antivirus protection you require. See [“Express Antivirus Protection Overview” on page 5921](#).
- Understand the order in which express antivirus parameters are configured. See [“Express Antivirus Configuration Overview” on page 5923](#).
- MIME patterns must be defined for lists and exception lists. See [“Example: Configuring MIME Whitelists to Bypass Antivirus Scanning” on page 6006](#).
- Custom objects must be defined. See [“Example: Configuring Express Antivirus Custom Objects” on page 5924](#).
- SMTP must be configured on the device. See [“Understanding SMTP Antivirus Scanning” on page 5998](#).

### Overview

In this example, you configure a feature profile called `junexprof1` and specify custom objects to be used for filtering content.

- Select and configure the Juniper Express Engine as the engine type.
- Select 120 as the time interval for updating the pattern database. The default antivirus pattern-update interval is once a day.

**NOTE:** The command for changing the URL for the pattern database is:

[edit]

```
user@host# set security utm feature-profile anti-virus juniper-express-engine
pattern-update url http://...
```

Under most circumstances, you should not need to change the default URL.

- Enable an e-mail notification with a custom message as pattern file was updated and a custom subject line as AV pattern file updated.
- Configure a list of fallback options as block.

- Configure the notification options for fallback blocking for virus detection. Configure a custom message for the fallback blocking action, and send a notification.
- Configure a notification for protocol-only virus detection, and send a notification as Antivirus Alert.
- Configure content size parameters as 20000.

**NOTE:** For SRX100, SRX110, SRX210, SRX220, and SRX240 devices, the maximum value for content size is 20,000. For SRX650 devices, the maximum value for content size is 40,000.

- Enable intelligent prescreening and set its timeout setting to 1800 seconds and trickling setting (applicable only to HTTP) to 600 seconds. This means that if the device receives a packet within a 600-second period during a file transfer or while performing an antivirus scan, it should not time out.

**NOTE:** Intelligent prescreening is intended only for use with non-encoded traffic. It is not applicable to mail protocols (SMTP, POP3, IMAP) or HTTP POST.

- Configure the antivirus scanner to use MIME bypass lists and exception lists. You can use your own custom object lists, or you can use the default list, called `junos-default-bypass-mime`, which ships with the device. The following example enables the `avmime2` and `ex-avmime2` lists.
- Configure the antivirus module to use URL bypass lists. If you are using a URL whitelist (valid only for HTTP traffic), this is a custom URL category that you previously configured as a custom object. For this example, you enable the `custurl1` bypass list.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile anti-virus juniper-express-engine pattern-update interval 120
set security utm feature-profile anti-virus juniper-express-engine pattern-update email-notify admin-email administrator@example.net custom-message "pattern file was updated" custom-message-subject "AV pattern file updated"
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1 fallback-options content-size block
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1 fallback-options default block
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1 fallback-options engine-not-ready block
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1 fallback-options out-of-resources block
```

```

set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 fallback-options timeout block
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 fallback-options too-many-requests block
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 notification-options fallback-block custom-message "Dropped due to fallback condition"
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 notification-options virus-detection type protocol-only
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 notification-options virus-detection custom-message ***virus-found***
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 scan-options content-size-limit 20000
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 scan-options intelligent-prescreening
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1
 scan-options timeout 1800
set security utm feature-profile anti-virus juniper-express-engine profile junexprof1 trickling
 timeout 600
set security utm feature-profile anti-virus mime-whitelist list avmime2
set security utm feature-profile anti-virus mime-whitelist list avmime2 exception
 ex-avmime2
set security utm feature-profile anti-virus url-whitelist custurl2

```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure express antivirus feature profiles:

1. Select and configure the engine type.  

```

[edit]
user@host# set security utm feature-profile anti-virus type juniper-express-engine

```
2. Select a time interval for updating the pattern database.  

```

[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set pattern-update interval 120

```
3. Configure the device to notify a specified administrator when patterns are updated.  

```

[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set pattern-update email-notify admin-email
 administrator@example.net custom-message "pattern file was updated"
 custom-message-subject "AV pattern file updated"

```
4. Create a profile for the Juniper Express Engine, and configure fallback options as block.  

```

[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set profile junexprof1 fallback-options content-size block
user@host# set profile junexprof1 fallback-options default block
user@host# set profile junexprof1 fallback-options engine-not-ready block
user@host# set profile junexprof1 fallback-options out-of-resources block
user@host# set profile junexprof1 fallback-options timeout block
user@host# set profile junexprof1 fallback-options too-many-requests block

```

5. Configure a custom notification for the fallback blocking action, and send a notification.

```
[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set profile junexprof1 notification-options fallback-block
custom-message "Dropped due to fallback condition"
```

6. Configure a notification for protocol-only virus detection, and send a notification.

```
[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set profile junexprof1 notification-options virus-detection type
protocol-only
```

7. Configure a custom notification for virus detection.

```
[edit security utm feature-profile anti-virus juniper-express-engine]
set profile junexprof1 notification-options virus-detection custom-message
virus-found
```

8. Configure content size parameter.

```
[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set profile junexprof1 scan-options content-size-limit 20000
```

9. Configure intelligent prescreening.

```
[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set profile junexprof1 scan-options intelligent-prescreening
```

10. Configure the timeout setting.

```
[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set profile junexprof1 scan-options timeout 1800
```

11. Configure trickling setting.

```
[edit security utm feature-profile anti-virus juniper-express-engine]
user@host# set profile junexprof1 trickling timeout 600
```

12. Configure the antivirus scanner to use MIME bypass lists and exception lists.

```
[edit security utm feature-profile anti-virus]
user@host# set mime-whitelist list avmime2
user@host# set mime-whitelist list avmime2 exception ex-avmime2
```

13. Configure the antivirus module to use URL bypass lists.

```
[edit security utm feature-profile anti-virus]
user@host# set url-whitelist custurl2
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm feature-profile anti-virus** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security utm feature-profile anti-virus
mime-whitelist {
 list avmime2;
 exception ex-avmime2;
}
url-whitelist custurl2;
```

```

juniper-express-engine {
 pattern-update {
 email-notify {
 admin-email "administrator@example.net";
 custom-message "pattern file was updated";
 custom-message-subject "AV pattern file updated";
 }
 interval 120;
 }
 profile junexprof1 {
 fallback-options {
 default block;
 content-size block;
 engine-not-ready block;
 timeout block;
 out-of-resources block;
 too-many-requests block;
 }
 scan-options {
 intelligent-prescreening;
 content-size-limit 20000;
 timeout 1800;
 }
 trickling timeout 600;
 notification-options {
 virus-detection {
 type protocol-only;
 custom-message ***virus-found***;
 }
 fallback-block {
 custom-message "Dropped due to fallback condition";
 }
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task.

- [Verifying the Configuration of Express Antivirus Feature Profile on page 5933](#)

### Verifying the Configuration of Express Antivirus Feature Profile

**Purpose** Verify the express antivirus feature profile.

**Action** From operational mode, enter any of the following commands:

- **show configuration security utm**
- **show security utm anti-virus status**
- **show security utm anti-virus statistics**

**Related Documentation**

- [Configuring Express Antivirus UTM Policies \(J-Web Procedure\) on page 5937](#)
- [Example: Configuring Express Antivirus UTM Policies on page 5936](#)
- [Example: Attaching Express Antivirus UTM Policies to Security Policies on page 5938](#)

## Configuring Express Antivirus Feature Profiles (J-Web Procedure)

---

After you create your custom objects, configure the antivirus feature profile:

1. Select **Configure>Security>UTM>Global options**.
2. In the **Anti-Virus** tab, next to **MIME whitelist**, select the custom object you created from the list.
3. Next to **Exception MIME whitelist**, select the custom object you created from the list.
4. Next to **URL Whitelist**, select the custom object you created from the list.
5. In the **Engine Type** section, select the type of engine you are using. For express antivirus protection, you should select **Juniper Express**.
6. Next to **Pattern update URL**, enter the URL for the pattern database in the box. Note that the URL is `http://update.juniper-updates.net/EAV/<device version>` and you should not change it.
7. Next to **Pattern update interval**, enter the time interval for automatically updating the pattern database in the box. The default for express antivirus checking is once per day.
8. Select whether you want the pattern file to update automatically (**Auto update**) or not (**No Auto update**).
9. Click **OK** to save the selected values.
10. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.
11. Under **Security**, in the left pane, select **Anti-Virus**.
12. Click **Add** in the right window to create a profile for the antivirus Juniper Express Engine. To edit an existing item, select it and click **Edit**.
13. In the **Main** tab, next to **Profile name**, enter a unique name for this antivirus profile.
14. Select the **Profile Type**. In this case, select **Juniper Express**.
15. Next to **Trickling timeout**, enter timeout parameters.

**NOTE:** Trickling applies only to HTTP. HTTP trickling is a mechanism used to prevent the HTTP client or server from timing out during a file transfer or during antivirus scanning.

16. Next to **Intelligent prescreening**, select **Yes** or **No**.

**NOTE:** Intelligent prescreening is only intended for use with non-encoded traffic. It is not applicable for mail protocols (SMTP, POP3, IMAP, and HTTP POST).

17. Next to Content Size Limit, enter content size parameters. The content size check occurs before the scan request is sent. The content size refers to accumulated TCP payload size.
18. Next to Scan engine timeout, enter scanning timeout parameters.
19. Select the Fallback settings tab.
20. Next to Default (fallback option), select Log and permit or Block from the list. In most cases, Block is the default fallback option.
21. Next to Decompress Layer (fallback option), select Log and permit or Block from the list.
22. Next to Content Size (fallback option), select Log and permit or Block from the list.
23. Next to Engine Not Ready (fallback option), select Log and permit or Block from the list.
24. Next to Timeout (fallback option), select Log and permit or Block from the list.
25. Next to Out of Resource (fallback option), select Log and permit or Block from the list.
26. Next to Too Many Requests (fallback option), select Log and permit or Block from the list.
27. Select the Notification options tab.
28. In the Fallback block section, next to Notification type, select Protocol Only or Message to select the type of notification that is sent when a fallback option of block is triggered.
29. Next to Notify mail sender, select Yes or No.
30. If you selected Yes, next to Custom Message, enter text for the message body of your custom message for this notification (if you are using a custom message).
31. Next to Custom message subject, enter text to appear in the subject line of your custom message for this notification (if you are using a custom message).
32. In the Fallback non block section, next to Notify mail recipient, select Yes or No.
33. If you selected Yes, next to Custom Message, enter text for the message body of your custom message for this notification (if you are using a custom message).
34. Next to Custom message subject, enter text to appear in the subject line of your custom message for this notification (if you are using a custom message).
35. Select the Notification options cont tab.
36. In the Virus detection section, next to Notification type, select Protocol Only or Message to select the type of notification that is sent when a fallback option of block is triggered.
37. Next to Notify mail sender, select Yes or No.

38. If you selected Yes, next to Custom Message, enter text for the message body of your custom message for this notification (if you are using a custom message).
39. Next to Custom message subject, enter text to appear in the subject line of your custom message for this notification (if you are using a custom message). The limit is 255 characters.
40. Click OK to check your configuration and save it as a candidate configuration, then click Commit Options>Commit.
41. If the configuration item is saved successfully, you receive a confirmation and you must click OK again. If it is not saved successfully, you can click Details in the pop-up that appears window to discover why.

**NOTE:** You create a separate antivirus profile for each antivirus protocol. These profiles may basically contain the same configuration information, but when you are creating your UTM policy for antivirus, the UTM policy configuration page provides separate antivirus profile selection fields for each supported protocol.

## Example: Configuring Express Antivirus UTM Policies

This example shows how to create an express antivirus UTM policy to attach to your feature profile.

- [Requirements on page 5936](#)
- [Overview on page 5936](#)
- [Configuration on page 5937](#)
- [Verification on page 5937](#)

### Requirements

Before you begin, create an antivirus feature profile. See [“Example: Configuring Express Antivirus Feature Profiles” on page 5929](#).

### Overview

In this example, you configure an express antivirus UTM policy called utmp3 and attach the policy to the antivirus profile called junexprofl.

## Configuration

### Step-by-Step Procedure

To configure an express antivirus UTM policy:

1. Create a UTM policy for HTTP antivirus scanning and attach the policy to the profile.  

```
[edit]
user@host# set security utm utm-policy utmp3 anti-virus http-profile junexprof1
```
2. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security utm** command.

### Related Documentation

- [Example: Attaching Express Antivirus UTM Policies to Security Policies on page 5938](#)

## Configuring Express Antivirus UTM Policies (J-Web Procedure)

After you have created an antivirus feature profile, configure a UTM policy to which you can attach the feature profile:

1. Select **Configure>Security>Policy>UTM Policies**.
2. From the UTM policy configuration window, click **Add** to configure a UTM policy. The policy configuration pop-up window appears.
3. Select the **Main** tab.
4. In the **Policy name** box, enter a unique name.
5. In the **Session per client limit** box, enter a session per client limit from 0 to 20000 for this UTM policy.
6. In the Session per client over limit list, select the action that the device should take when the session per client limit for this UTM policy is exceeded. Options include **Log and permit** and **Block**.
7. Select the **Anti-Virus profiles** tab.
8. Select the appropriate profile you have configured from the list for the corresponding protocol listed.
9. Click **OK**.
10. If the policy is saved successfully, you receive a confirmation and you must click **OK** again. If the profile is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

## Example: Attaching Express Antivirus UTM Policies to Security Policies

---

This example shows how to attach an express antivirus UTM policy to a security policy.

- [Requirements on page 5938](#)
- [Overview on page 5938](#)
- [Configuration on page 5938](#)
- [Verification on page 5939](#)

### Requirements

Before you begin, create a UTM policy. See “[Example: Configuring Express Antivirus UTM Policies](#)” on page 5936.

### Overview

In this example, you attach the express antivirus UTM policy called utmp3 to the security policy called p3.

### Configuration

#### Step-by-Step Procedure

To attach an express antivirus UTM policy to a security policy:

1. Enable and configure the security policy.  

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy p3 match
source-address any
user@host# set security policies from-zone trust to-zone untrust policy p3 match
destination-address any
user@host# set security policies from-zone trust to-zone untrust policy p3 match
application junos-http
```
2. Attach the UTM policy to the security policy.  

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy p3 then
permit application-services utm-policy utmp3
```
3. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter **show security policies detail** from operational mode.

### Related Documentation

- [Express Antivirus Configuration Overview on page 5923](#)
- [Example: Configuring Express Antivirus Feature Profiles on page 5929](#)
- [Attaching Express Antivirus UTM Policies to Security Policies \(J-Web Procedure\) on page 5939](#)

## Attaching Express Antivirus UTM Policies to Security Policies (J-Web Procedure)

After you create a UTM policy, create a security policy and attach the UTM policy to the security policy:

1. Select **Configure>Security>Policy>FW Policies**.
2. From the Security Policy window, click **Add** to configure a security policy with UTM. The policy configuration pop-up window appears.
3. In the Policy tab, enter a name in the **Policy Name** box.
4. Next to Default Policy Action, select one of the following: **Deny-All** or **Permit-All**.
5. Next to **From Zone**, select a zone from the list.
6. Next to **To Zone**, select a zone from the list.
7. Under Zone Direction, click **Add a Policy**.
8. Choose a **Source Address**.
9. Choose a **Destination Address**.
10. Choose an application by selecting **junos-protocol** (for all protocols that support antivirus scanning) in the Application Sets box and clicking the —> button to move it to the Matched box.
11. Next to Policy Action, select **Permit**.

**NOTE:** When you select Permit for Policy Action, several additional fields become available in the Applications Services tab, including UTM Policy.

12. Select the **Application Services** tab.
13. Next to **UTM Policy**, select the appropriate policy from the list. This action attaches your UTM policy to the security policy.
14. Click **OK**.

15. Click **OK** to check your configuration and save it as a candidate configuration, then click **Commit Options>Commit**.
16. If the policy is saved successfully, you receive a confirmation and you must click **OK** again. If the profile is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

You must activate your new policy to apply it.

## Understanding Express Antivirus Scanner Pattern Updates

Express antivirus uses a different signature database than the full antivirus signature database. The express antivirus signature database is called Juniper Express antivirus database and it is compatible with the hardware engine. The express signature database targets only critical viruses and malware, including worms, Trojans, and spyware. This is a smaller sized database, providing less coverage than the full antivirus signature database.

The express antivirus pattern database is updated over HTTP or HTTPS and can occur automatically or manually. This is similar functionality to that found in full antivirus with some minor differences:

- With express antivirus, the signature database auto-update interval, is once a day.
- With express antivirus, there is no support for the downloading of multiple database types.
- With express antivirus, during database loading, all scan operations are interrupted. Scan operations for existing traffic flows are stopped and no new scan operations are initiated for newly established traffic flows. You can specify the desired action for this interruption period using the fall-back parameter for engine-busy-loading-database. The available actions are block or log-and-permit.
- By default, the URL for express antivirus is <http://update.juniper-updates.net/EAV/SRX210>. "SRX210" in the URL is the platform name. This part of the URL is different and platform specific for each platform. (Other than the platform name, you should not change this URL unless you are experiencing problems with it and have called for support.)

**NOTE:** Once your subscription expires, you have a 30 day grace period during which you can continue to update the antivirus pattern file. Once that grace period expires, the update server no longer permits antivirus pattern file updates.

The express Antivirus scanning feature is a separately licensed subscription service. When your antivirus license key expires, you can continue to use locally stored antivirus signatures. But in that case, if the local database is deleted, antivirus scanning is disabled.

#### Related Documentation

---

## Example: Automatically Updating Express Antivirus Patterns

This example shows how to update the pattern file automatically on a security device.

- [Requirements on page 5942](#)
- [Overview on page 5942](#)
- [Configuration on page 5942](#)
- [Verification on page 5943](#)

### Requirements

Before you begin:

- Obtain a valid antivirus scanner license. See [“Full Antivirus Protection Overview” on page 5947](#).
- Get network connectivity and access to the pattern database server. See [“Understanding Full Antivirus Pattern Updates” on page 5969](#).
- Configure your DNS settings and port settings (port 80) correctly. See *DNS Overview*.

### Overview

In this example, you configure the security device to update the pattern file automatically every 120 minutes. (The default antivirus pattern-update interval is once a day.)

### Configuration

#### Step-by-Step Procedure

To configure the security device to update the pattern file automatically:

1. Set the interval.

```
[edit]
user@host# set security utm feature-profile anti-virus juniper-express-engine
pattern-update interval 120
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security utm** command.

### Related Documentation

- [Express Antivirus Protection Overview on page 5921](#)

## Example: Automatically Updating Express Antivirus Patterns (J-Web)

In this example, you configure the security device to update the pattern file automatically every 120 minutes. (The default antivirus pattern-update interval is once a day.)

To automatically update antivirus patterns:

1. Select **Configure>Security>UTM>Anti-Virus**.
2. Next to Interval, in the Juniper Express Engine section, enter **120** in the box.
3. Click **OK** to check your configuration and save it as a candidate configuration, then click **Commit Options>Commit**.

## Manually Updating, Reloading, and Deleting Express Antivirus Patterns (CLI Procedure)

To manually update antivirus patterns, enter the following CLI statement:

```
user@host> request security utm anti-virus juniper-express-engine pattern-update
```

To manually reload antivirus patterns, enter the following CLI statement:

```
user@host> request security utm anti-virus juniper-express-engine pattern-reload
```

To manually delete antivirus patterns, enter the following CLI statement:

```
user@host> request security utm anti-virus juniper-express-engine pattern-delete
```

## Full Antivirus Protection Overview

---

A virus is executable code that infects or attaches itself to other executable code in order to reproduce itself. Some malicious viruses erase files or lock up systems, while other viruses merely infect files and can overwhelm the target host or network with bogus data. The full file-based antivirus feature provides file-based scanning on specific Application Layer traffic checking for viruses against a virus signature database. It collects the received data packets until it has reconstructed the original application content, such as an e-mail file attachment, and then scans this content.

The full file-based antivirus scanning feature is a separately licensed subscription service. Kaspersky Lab provides the scan engine for full file-based antivirus. When your antivirus license key expires, you can continue to use locally stored antivirus signatures without any updates. But in that case, if the local database is deleted, antivirus scanning is disabled.

**NOTE:** The express antivirus feature provides better performance but lower security. Note that if you switch from full file-based antivirus protection to express antivirus protection, you must reboot the device in order for express antivirus to begin working.

The Kaspersky scan engine is provided as a downloadable UTM module. To download the Kaspersky scan engine, your SRX Series device must have an active UTM license. When you install the KAV license, the system automatically downloads the Kaspersky module from the Juniper Networks server and runs it.

When you set the antivirus type to KAV, and if the SRX Series device had a preinstalled Kaspersky engine, then the downloaded module replaces the original module on the device. Regardless of the UTM license status, when the KAV license is deleted from the device, the Kaspersky engine and all files associated with KAV are removed from the system immediately.

Use the **set security utm feature-profile anti-virus type kaspersky-lab-engine** command to set the antivirus type to KAV. If Kaspersky engine is not available on the device, and if the Kaspersky engine cannot be downloaded from the predefined URL, then use the **set security utm feature-profile anti-virus kaspersky-lab-engine pattern-update url url** command to configure the downloading application URL.

- [Understanding the Full Antivirus Internal Scan Engine on page 5975](#)
- [Full Antivirus Configuration Overview on page 5948](#)

---

## Full Antivirus Configuration Overview

When configuring antivirus protection, you must first create the antivirus custom objects you are using. Those custom objects may include the MIME pattern list, MIME exception list, and the filename extension list. Once you have created your custom objects, you can configure full antivirus protection, including intelligent prescreening, and content size limits.

To configure full file-based antivirus protection:

1. Configure UTM custom objects for the UTM feature. The following example enables the mime-pattern, filename-extension, url-pattern, and custom-url-category custom-objects:

```
user@host# set security utm custom-objects mime-pattern
user@host# set security utm custom-objects filename-extension
user@host# set security utm custom-objects url-pattern
user@host# set security utm custom-objects custom-url-category
```

2. Configure the main feature parameters using feature profiles. The following example enables options using the anti virus feature profile:

```
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine
pattern-update
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile
fallback-options
```

```

user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile
notification-options
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile
scan-options
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile
trickling
user@host# set security utm feature-profile anti-virus mime-whitelist
user@host# set security utm feature-profile anti-virus url-whitelist

```

3. Configure a UTM policy for each protocol and attach this policy to a profile. The following example configure the utmp2 UTM policy for the HTTP protocol:

```

user@host# set security utm utm-policy utmp2 anti-virus http-profile http1

```

4. Attach the UTM policy to a security policy. The following example attaches the utmp2 UTM policy to the p2 security policy:

```

user@host# set security policies from-zone trust to-zone untrust policy p2 then permit
application-services utm-policy utmp2

```

**Related Documentation**

- [Full Antivirus Protection Overview on page 5947](#)

## Full Antivirus Pattern Update Configuration Overview

Before you begin, there are several prerequisites that must be met in order to perform a successful pattern database update:

- You must have a valid antivirus scanner license.
- You must have network connectivity and access to the pattern database server.
- Your DNS settings and port settings (port 80) must be correct.

To update the patterns for the antivirus signature database:

1. On the security device, specify the URL address of the pattern-update server.
2. (Optional) Specify how often the device should automatically check for pattern-server updates.

After the security device downloads the server-initialization file, the device checks that the pattern file is valid. The device then parses the file to obtain information about it, including the file version, size, and location of the pattern file server.

If the pattern file on the security device is out-of-date (or nonexistent because this is the first time you are loading it), and, if the antivirus pattern-update service subscription is still valid, the device automatically retrieves an updated pattern file from the pattern file server.

The following is an example of the CLI for configuring the database update feature:

```

utm {
 feature-profile {
 anti-virus {
 type

```

```
kaspersky-lab-engine {
 pattern-update
 url url
 interval minutes
}
}
}
```

## Example: Configuring Full Antivirus Custom Objects

This example shows how to configure full antivirus custom objects.

- [Requirements on page 5950](#)
- [Overview on page 5950](#)
- [Configuration on page 5951](#)
- [Verification on page 5953](#)

### Requirements

Before you begin:

- Decide the type of full antivirus protection you require. See [“Full Antivirus Protection Overview” on page 5947](#).
- Understand the order in which full antivirus parameters are configured. See [“Full Antivirus Pattern Update Configuration Overview” on page 5949](#).

### Overview

In this example, you define custom objects that are used to create full antivirus feature profiles. You perform the following tasks to define custom objects:

1. Configure a filename extension list called `extlist1` and add extensions such as `.zip`, `.js`, and `.vbs` to the list.
2. Create two MIME lists called `avmime1` and `ex-avmime1` and add patterns to the list.
3. Configure a URL pattern list called `urllist1`.
4. Configure a custom URL category list called `custurl1` using the `urllist1` URL pattern list.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm custom-objects filename-extension extlist1 value [zip js vbs]
set security utm custom-objects mime-pattern avmime1 value [video/quicktime
image/x-portable-anymap x-world/x-vrml]
set security utm custom-objects mime-pattern ex-avmime1 value
[video/quicktime-inappropriate]
set security utm custom-objects url-pattern urlist1 value [http://www.url.com 5.6.7.8]
set security utm custom-objects custom-url-category custurl1 value urlist1
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure full antivirus filtering custom objects:

1. Configure the filename extension list and add extensions to it.

```
[edit security utm]
user@host# set custom-objects filename-extension extlist1 value [zip js vbs]
```

**NOTE:** The Kaspersky scan engine ships with a read-only default extension list that you can use.

2. Create MIME lists and add MIME patterns to the lists.

```
[edit security utm]
user@host# set custom-objects mime-pattern avmime1 value [video/quicktime
image/x-portable-anymap x-world/x-vrml]
user@host# set custom-objects mime-pattern ex-avmime1 value
[video/quicktime-inappropriate]
```

3. Configure a URL pattern list.

```
[edit security utm]
user@host# set custom-objects url-pattern urlist1 value [http://www.url.com
5.6.7.8]
```

When entering the URL pattern, note the following wildcard character support:

- The `\*\.[]\?*` wildcard characters are supported.
- You must precede all wildcard URLs with `http://`.
- You can only use the asterisk `*` wildcard character if it is at the beginning of the URL and is followed by a period.
- You can only use the question mark `?` wildcard character at the end of the URL.

- The following wildcard syntax is supported: `http://*example.net`, `http://www.example.ne?`, `http://www.example.n??`.
- The following wildcard syntax is not supported: `*example.net`, `www.example.ne?`, `http://*example.net`, `http://*`.

**NOTE:** Because you use URL pattern lists to create custom URL category lists, you must configure URL pattern list custom objects before you configure custom URL category lists.

4. Configure a custom URL category list.

```
[edit security utm]
user@host# set custom-objects custom-url-category custurl1 value urllist1
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
userhost# show security utm
custom-objects {
 mime-pattern {
 avmime1 {
 value [video/quicktime image/x-portable-anymap x-world/x-vrml];
 }
 ex-avmime1 {
 value video/quicktime-inappropriate;
 }
 }
 filename-extension {
 extlist1 {
 value [zip js vbs];
 }
 }
 url-pattern {
 urllist1 {
 value [http://www.url.com 5.6.7.8];
 }
 }
 custom-url-category {
 custurl1 {
 value urllist1;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Full Antivirus Custom Objects on page 5953](#)

### Verifying Full Antivirus Custom Objects

|                              |                                                                                                                                                                                                                                             |

## Configuring Full Antivirus Custom Objects (J-Web Procedure)

To configure antivirus protection, you must first create your custom objects (MIME Pattern List, Filename Extension List, URL Pattern List, and Custom URL Category List).

Configure a MIME pattern list custom object:

1. Select **Configure>Security>UTM>Custom Objects**.
2. From the MIME Pattern List tab, click the **Add** button to create MIME pattern lists.
3. In the Add MIME Pattern pop-up window, next to **MIME Pattern Name**, enter a unique name.

**NOTE:** Keep in mind that you are creating a MIME whitelist and a MIME exception list (if necessary). Both MIME lists appear in the MIME Whitelist and Exception MIME Whitelist fields when you configure antivirus. Therefore, the MIME list names you create should be as descriptive as possible.

4. Next to **MIME Pattern Value**, enter the MIME pattern.
5. Click **Add** to add your MIME pattern to the Values list box. Within this box, you can also select an entry and use the Delete button to delete it from the list. Continue to add MIME patterns in this manner.
6. Optionally, create a new MIME list to act as an exception list. The exception list is generally a subset of the main MIME list.
7. Click **OK** to check your configuration and save the selected values as part of the MIME list, then click **Commit Options>Commit**.
8. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

Configure a filename extension list custom object:

1. Select **Configure>Security>UTM>Custom Objects**.
2. From the Filename Extension List tab, click the **Add** button to create filename extension lists.
3. Next to **File Extension Name**, enter a unique name. This name appears in the Scan Option By Extension list when you configure an antivirus profile.
4. In the **Available Values** box, select one or more default values (press Shift to select multiple concurrent items or press Ctrl to select multiple separate items) and click the right arrow button to move the value or values to the Selected Values box.
5. Click **OK** to check your configuration and save it as a candidate configuration, then click **Commit Options>Commit**.
6. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If the profile is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

Configure a URL pattern list custom object:

**NOTE:** Because you use URL pattern lists to create custom URL category lists, you must configure URL pattern list custom objects before you configure a custom URL category list.

1. Select **Configure>Security>UTM>Custom Objects**.
2. From the URL Pattern List tab, click the **Add** button to create URL pattern lists.
3. Next to URL Pattern Name, enter a unique name. This name appears in the Custom URL Category List Custom Object page for selection.
4. Next to **URL Pattern Value**, enter the URL or IP address you want added to the list for bypassing scanning.

When entering the URL pattern, note the following wildcard character support:

- The `\*\.[ ]\?` wildcard characters are supported.
- You must precede all wildcard URLs with `http://`.
- You can only use the asterisk `*` wildcard character if it is at the beginning of the URL and is followed by a period.
- You can only use the question mark `?` wildcard character at the end of the URL.
- The following wildcard syntax IS supported: `http://*.example.net`, `http://www.example.ne?`, `http://www.example.n??`.
- The following wildcard syntax is NOT supported: `*example.net`, `www.example.ne?`, `http://*example.net`, `http://*`.

5. Click **Add** to add your URL pattern to the Values list box. The list can contain up to 8192 items. You can also select an entry and use the Delete button to delete it from the list. Continue to add URLs or IP addresses in this manner.
6. Click **OK** to check your configuration and save the selected values as part of the URL pattern list you have created, then click **Commit Options>Commit**.
7. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

Configure a custom URL category list custom object:

**NOTE:** Because you use URL Pattern Lists to create custom URL category lists, you must configure URL pattern list custom objects before you configure a custom URL category list.

1. Select **Configure>Security>UTM>Custom Objects**.
2. In the URL Category List tab, click **Add** to create URL category lists.
3. Next to **URL Category Name**, enter a unique name. This name appears in the URL Whitelist list when you configure antivirus global options.
4. In the **Available Values** box, select a URL Pattern List name from the list for bypassing scanning and click the right arrow button to move it to the Selected Values box.
5. Click **OK** to check your configuration and save the selected values as part of the URL list that you have created, then click **Commit Options>Commit**.  
Click **OK** to save the selected values as part of the custom URL list you have created.
6. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

## Example: Configuring Full Antivirus Feature Profiles

This example shows how to configure a full antivirus feature profile.

- [Requirements on page 5956](#)
- [Overview on page 5956](#)
- [Configuration on page 5957](#)
- [Verification on page 5961](#)

## Requirements

Before you begin:

- Decide the type of full antivirus protection you require. See [“Full Antivirus Protection Overview” on page 5947](#).
- Understand the order in which full antivirus parameters are configured. See [“Full Antivirus Configuration Overview” on page 5948](#).
- MIME patterns must be defined for lists and exception lists. See [“Example: Configuring MIME Whitelists to Bypass Antivirus Scanning” on page 6006](#).

## Overview

In this example, you configure a feature profile called `kasprof1` and specify custom objects to be used for filtering content:

- Select and configure the engine type as Kaspersky Lab Engine.
- Select 120 as the time interval for updating the pattern database. The default full file-based antivirus pattern-update interval is 60 minutes.

**NOTE:** The command for changing the URL for the pattern database is:

[edit]

```
user@host# edit security utm feature-profile anti-virus kaspersky-lab-engine
[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set pattern-update url http://.
```

The default URL is `http://update.juniper-updates.net/AV/<device-version>`. You should not change this URL unless you are experiencing problems with it and have called for support.

- Enable an e-mail notification with a custom message as pattern file was updated and a custom subject line as AV pattern file updated.
- Configure a list of fallback options as block.
- Configure the notification options for fallback blocking for virus detection. Configure a custom message for the fallback blocking action.
- Configure a notification for protocol-only virus detection.
- Configure scan options. For this example, configure the device to perform a TCP payload content size check before the scan request is sent.
- Configure the decompression layer limit. For this example configure the device to decompress three layers of nested compressed files before it executes the virus scan.
- Configure content size parameters as 20000.

**NOTE:** For SRX100, SRX110, SRX210, SRX220, and SRX240 devices the content size is 20000. For SRX650 devices the content size is 40,000.

- Configure scan extension settings. The default list is `junos-default-extension`. For this example, you select `extlist1`, which you created as a custom object.
- Configure the scan mode setting to configure the device to use a custom extension list. Although you can choose to scan all files, for this example you select only files with the extensions that you specify.
- Enable intelligent prescreening and set its timeout setting to 1800 seconds and trickling setting (applicable only to HTTP) to 600 seconds. This means that if the device receives a packet within a 600-second period during a file transfer or while performing an antivirus scan, it should not time out.

**NOTE:** Intelligent prescreening is only intended for use with non-encoded traffic. It is not applicable for mail protocols (SMTP, POP3, IMAP) and HTTP POST.

The following example disables intelligent prescreening for the `kasprof1` profile:

```
[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 scan-options no-intelligent-prescreening
```

- Configure the antivirus scanner to use MIME bypass lists and exception lists. You can use your own custom object lists, or you can use the default list that ships with the device called `junos-default-bypass-mime`. For this example, you use the `avmime1` and `ex-avmime1` lists.
- Configure the antivirus module to use URL bypass lists. If you are using a URL whitelist (valid only for HTTP traffic), this is a custom URL category that you have previously configured as a custom object. For this example, you enable the `custurl1` bypass list.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile anti-virus type kaspersky-lab-engine
set security utm feature-profile anti-virus kaspersky-lab-engine pattern-update interval
 120
set security utm feature-profile anti-virus kaspersky-lab-engine pattern-update
 email-notify admin-email administrator@example.net custom-message
 patternfilewasupdated custom-message-subject AVpatternfileupdated
set security utm feature-profile anti-virus type kaspersky-lab-engine
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options content-size block
```

```

set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options corrupt-file block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options decompress-layer block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options default block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options engine-not-ready block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options out-of-resources block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options password-file block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options timeout block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options too-many-requests block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 notification-options fallback-block custom-message "Dropped due to fallback settings"
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 notification-options virus-detection type protocol-only
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 scan-options content-size-limit 20000
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 scan-options decompress-layer-limit 3
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 scan-options intelligent-prescreening
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 scan-options scan-extension extlist1
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 scan-options scan-mode by-extension
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 scan-options timeout 1800
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1 trickling
 timeout 600
set security utm feature-profile anti-virus mime-whitelist list avmime1
set security utm feature-profile anti-virus mime-whitelist list avmime1 exception
 ex-avmime1
set security utm feature-profile anti-virus url-whitelist custurl1

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure full antivirus feature profiles:

1. Select and configure the engine type.  

```

[edit]
user@host# set security utm feature-profile anti-virus type kaspersky-lab-engine
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine
 pattern-update interval 120

```
2. Configure the device to notify a specified administrator when patterns are updated.  

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]

```

```

user@host# set pattern-update email-notify admin-email
administrator@example.net custom-message patternfilewasupdated
custom-message-subject AVpatternfileupdated

```

3. Create a profile for the Kaspersky Lab engine and configure fallback options as block.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 fallback-options content-size block
user@host# set profile kasprof1 fallback-options corrupt-file block
user@host# set profile kasprof1 fallback-options decompress-layer block
user@host# set profile kasprof1 fallback-options default block
user@host# set profile kasprof1 fallback-options engine-not-ready block
user@host# set profile kasprof1 fallback-options out-of-resources block
user@host# set profile kasprof1 fallback-options password-file block
user@host# set profile kasprof1 fallback-options timeout block
user@host# set profile kasprof1 fallback-options too-many-requests block

```

4. Configure a custom notification for the fallback blocking action and send a notification.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 notification-options fallback-block custom-message
"Dropped due to fallback settings"

```

5. Configure a notification for protocol-only virus detection.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 notification-options virus-detection type
protocol-only

```

6. Configure content size parameter.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 scan-options content-size-limit 20000

```

7. Configure the decompression layer limit.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 scan-options decompress-layer-limit 3

```

8. Configure intelligent prescreening.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 scan-options intelligent-prescreening

```

9. Configure scan extension setting.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 scan-options scan-extension extlist1

```

10. Configure the scan mode setting.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 scan-options scan-mode by-extension

```

11. Configure the timeout setting.

```

[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 scan-options timeout 1800

```

12. Configure trickling setting.

```
[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 trickling timeout 600
```

13. Configure the antivirus scanner to use MIME bypass lists and exception lists.

```
[edit security utm feature-profile anti-virus]
user@host# set mime-whitelist list avmime1
user@host# set mime-whitelist list avmime1 exception ex-avmime1
```

14. Configure the antivirus module to use URL bypass lists.

```
[edit security utm feature-profile anti-virus]
user@host# set url-whitelist custurl1
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm feature-profile anti-virus** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security utm feature-profile anti-virus
mime-whitelist {
 list avmime1;
 exception ex-avmime1;
}
url-whitelist custurl1;
kaspersky-lab-engine {
 pattern-update {
 email-notify {
 admin-email "administrator@example.net";
 custom-message patternfilewasupdated;
 custom-message-subject AVpatternfileupdated;
 }
 interval 120;
 }
 profile kasprof1 {
 fallback-options {
 default block;
 corrupt-file block;
 password-file block;
 decompress-layer block;
 content-size block;
 engine-not-ready block;
 timeout block;
 out-of-resources block;
 too-many-requests block;
 }
 scan-options {
 intelligent-prescreening;
 scan-mode by-extension;
 scan-extension extlist1;
 content-size-limit 20000;
 timeout 1800;
 decompress-layer-limit 3;
 }
 }
 trickling timeout 600;
 notification-options {
```

```

virus-detection {
 type protocol-only;
 custom-message ***virus-found***;
}
fallback-block {
 custom-message "Dropped due to fallback settings";
}
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying the Configuration of Full Antivirus Feature Profile on page 5961](#)

### Verifying the Configuration of Full Antivirus Feature Profile

**Purpose** Verify the full antivirus feature profile.

**Action** From operational mode, enter the **show configuration security utm** command.

- Related Documentation**
- [Full Antivirus Configuration Overview on page 5948](#)
  - [Example: Configuring Full Antivirus UTM Policies on page 5964](#)
  - [Example: Attaching Full Antivirus UTM Policies to Security Policies on page 5966](#)

## Configuring Full Antivirus Feature Profiles (J-Web Procedure)

After you have created your custom object, configure an antivirus feature profile:

1. Select **Configure>Security>UTM>Global options**.
2. In the Anti-Virus tab, next to **MIME whitelist**, select the custom object you created from the list.
3. Next to **Exception MIME whitelist**, select the custom object you created from the list.
4. Next to **URL Whitelist**, select the custom object you created from the list.
5. In the **Engine Type** section, select the type of engine you are using. For full antivirus protection, you should select **Kaspersky Lab**.
6. In the Kaspersky Lab Engine Option section, in the **Pattern update URL** box, enter the URL for the pattern database.

**NOTE:** The URL is `http://update.juniper-updates.net/AV/<device version>` and you should not change it.

7. Next to **Pattern update interval**, enter the time interval, in seconds, for automatically updating the pattern database in the box. The default interval is 60.
8. Select whether you want the pattern file to update automatically (**Auto update**) or not (**No Auto update**).
9. Click **OK** to save the selected values.
10. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in a pop-up window that appears to discover why.
11. Under Security, in the left pane, select **Anti-Virus**.
12. In the right window, click **Add** to create a profile for the antivirus Kaspersky Lab Engine. (To edit an existing item, select it and click the **Edit** button.)
13. Next to **Profile name**, enter a unique name for this antivirus profile.
14. Select the **Profile Type**. In this case, select **Kaspersky**.
15. Next to **Trickling timeout**, enter timeout parameters.

**NOTE:** Trickling applies only to HTTP. HTTP trickling is a mechanism used to prevent the HTTP client or server from timing out during a file transfer or during antivirus scanning.

16. Next to Intelligent prescreening, select **Yes** or **No**.

**NOTE:** Intelligent prescreening is only intended for use with non-encoded traffic. It is not applicable for mail protocols (SMTP, POP3, IMAP, and HTTP POST).

17. In the Scan Options section, next to Intelligent prescreening, select **Yes** if you are using it.

**NOTE:** Intelligent prescreening is only intended for use with non-encoded traffic. It is not applicable for mail protocols (SMTP, POP3, IMAP, and HTTP POST).

18. Next to **Content Size Limit**, enter content size parameters. The content size check occurs before the scan request is sent. The content size refers to accumulated TCP payload size.
19. Next to **Scan engine timeout**, enter scanning timeout parameters.
20. Next to **Decompress Layer Limit**, enter decompression layer limit parameters.
21. In the Scan mode section, select either **Scan all files**, if you are scanning all content, or **Scan files with specified extension**, if you are scanning by file extensions.

**NOTE:** If you select Scan files with specified extension, you must select a filename extension list custom object from the Scan engine filename extension list that appears.

22. Select the **Fallback settings** tab.
23. Next to Default (fallback option), select **Log and permit** or **Block** from the list. In most cases, Block is the default fallback option.
24. Next to Corrupt File (fallback option), select **Log and permit** or **Block** from the list.
25. Next to Password File (fallback option), select **Log and permit** or **Block** from the list.
26. Next to Decompress Layer (fallback option), select **Log and permit** or **Block** from the list.
27. Next to Content Size (fallback option), select **Log and permit** or **Block** from the list.
28. Next to Engine Not Ready (fallback option), select **Log and permit** or **Block** from the list.
29. Next to Timeout (fallback option), select **Log and permit** or **Block** from the list.
30. Next to Out Of Resources (fallback option), select **Log and permit** or **Block** from the list.
31. Next to Too Many Request (fallback option), select **Log and permit** or **Block** from the list.
32. Select the **Notification options** tab.
33. In the Fallback block section, next to Notification type, select **Protocol Only** or **Message** to select the type of notification that is sent when a fallback option of block is triggered.
34. Next to Notify mail sender, select **Yes** or **No**.
35. If you selected Yes, next to **Custom Message**, enter text for the message body of your custom message for this notification (if you are using a custom message).
36. Next to **Custom message subject**, enter text to appear in the subject line of your custom message for this notification (if you are using a custom message).
37. In the Fallback non block section, next to Notify mail recipient, select **Yes** or **No**.
38. If you selected Yes, next to **Custom Message**, enter text for the message body of your custom message for this notification (if you are using a custom message).
39. Next to **Custom message subject**, enter text to appear in the subject line of your custom message for this notification (if you are using a custom message).
40. Select the **Notification options cont** tab.
41. In the Virus detection section, next to Notification type, select **Protocol Only** or **Message** to select the type of notification that is sent when a fallback option of block is triggered.
42. Next to Notify mail sender, select **Yes** or **No**.

43. If you selected Yes, next to **Custom Message**, enter text for the message body of your custom message for this notification (if you are using a custom message).
44. Next to **Custom message subject**, enter text to appear in the subject line of your custom message for this notification (if you are using a custom message). The limit is 255 characters.
45. Click **OK** to check your configuration and save it as a candidate configuration, then click **Commit Options>Commit**.
46. If the configuration item is saved successfully, you receive a confirmation and you must click **OK** again. If it is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

**NOTE:** You create a separate antivirus profile for each antivirus protocol. These profiles may basically contain the same configuration information, but when you are creating your UTM policy for an antivirus profile, the UTM policy configuration page provides separate antivirus profile selection fields for each supported protocol.

## Example: Configuring Full Antivirus UTM Policies

This example shows how to create a UTM policy to attach to a feature profile.

- [Requirements on page 5964](#)
- [Overview on page 5964](#)
- [Configuration on page 5964](#)
- [Verification on page 5965](#)

### Requirements

Before you begin, create an antivirus feature profile. See [“Example: Configuring Full Antivirus Feature Profiles” on page 5955](#).

### Overview

In this example, you configure a full antivirus UTM policy called utmp2 and attach the policy to an HTTP profile called kasprofile1 HTTP.

### Configuration

#### Step-by-Step Procedure

To configure a full antivirus UTM policy:

1. Create a UTM policy for HTTP antivirus scanning and attach the policy to the profile.  

```
[edit]
user@host# set security utm utm-policy utmp2 anti-virus http-profile kasprofile1
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security utm** command.

### Related Documentation

- [Example: Configuring Full Antivirus Feature Profiles on page 5955](#)
- [Example: Attaching Full Antivirus UTM Policies to Security Policies on page 5966](#)

## Configuring Full Antivirus UTM Policies (J-Web Procedure)

After you have created an antivirus feature profile, configure a UTM policy to which you can attach the feature profile:

1. Select **Configure>Security>Policy>UTM Policies**.
2. From the UTM policy configuration window, click **Add** to configure a UTM policy. This action takes you to the policy configuration pop-up window.
3. Select the **Main** tab in pop-up window.
4. In the **Policy name** box, enter a unique name for the UTM policy.
5. In the **Session per client limit** box, enter a session per client limit from 0 to 20000 for this UTM policy.
6. In the **Session per client over limit** list, select the action that the device should take when the session per client limit for this UTM policy is exceeded. Options include **Log and permit** and **Block**.
7. Select the **Anti-Virus profiles** tab in the pop-up window.
8. Select the appropriate profile you have configured from the list for the corresponding protocol listed.
9. Click **OK** to check your configuration and save it as a candidate configuration, then click **Commit Options>Commit**.
10. If the policy is saved successfully, you receive a confirmation and you must click **OK** again. If the profile is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

## Example: Attaching Full Antivirus UTM Policies to Security Policies

---

This example shows how to attach a UTM policy to a security policy.

- [Requirements on page 5966](#)
- [Overview on page 5966](#)
- [Configuration on page 5966](#)
- [Verification on page 5966](#)

### Requirements

Before you begin, create a UTM policy. See [“Example: Configuring Full Antivirus UTM Policies” on page 5964](#).

### Overview

In this example, you attach the UTM policy called utmp2 to the security policy called p2.

### Configuration

#### Step-by-Step Procedure

To attach a full antivirus UTM policy to a security policy:

1. Enable and configure the security policy.  
  
[edit]  
user@host# set security policies from-zone trust to-zone untrust policy p2 match source-address any  
user@host# set security policies from-zone trust to-zone untrust policy p2 match destination-address any  
user@host# set security policies from-zone trust to-zone untrust policy p2 match application junos-http
2. Attach the UTM policy to the security policy.  
  
[edit]  
user@host# set security policies from-zone trust to-zone untrust policy p2 then permit application-services utm-policy utmp2
3. If you are done configuring the device, commit the configuration.  
  
[edit]  
user@host# commit

### Verification

To verify the configuration is working properly, enter the **show security policies** command.

#### Related Documentation

- [Full Antivirus Configuration Overview on page 5948](#)
- [Example: Configuring Full Antivirus UTM Policies on page 5964](#)

## Attaching Full Antivirus UTM Policies to Security Policies (J-Web Procedure)

After you create a UTM policy, create a security policy and attach the UTM policy to the security policy:

1. Select **Configure>Security>Policy>FW Policies**.
2. From the Security Policy window, click **Add** to configure a security policy with UTM. This action takes you to the policy configuration pop-up window.
3. In the Policy tab, enter a name in the **Policy Name** box.
4. Next to **From Zone**, select a zone from the list.
5. Next to **To Zone**, select a zone from the list.
6. Choose a **Source Address**.
7. Choose a **Destination Address**.
8. Choose an application by selecting **junos-protocol** (for all protocols that support antivirus scanning) in the Application Sets box and clicking the —> button to move it to the Matched box.
9. Next to Policy Action, select **Permit**.

**NOTE:** When you select Permit for Policy Action, several additional fields become available in the Applications Services tab, including UTM Policy.

10. Select the **Application Services** tab in the pop-up window.
11. Next to **UTM Policy**, select the appropriate policy from the list. This action attaches your UTM policy to the security policy.
12. Click **OK** to check your configuration and save it as a candidate configuration, then click **Commit Options>Commit**.
13. If the policy is saved successfully, you receive a confirmation and you must click **OK** again. If the profile is not saved successfully, you can click **Details** in the pop-up window that appears to discover why.

You must activate your new policy to apply it.

## Understanding Full Antivirus Pattern Updates

---

The full file-based antivirus protection signature database is called the Juniper Full antivirus database (downloaded by the pattern-update command). This database is different from the database used by express antivirus. It detects all destructive malicious code, including viruses (polymorphic and other advanced virus types), worms, Trojans, and malware.

Updates to the pattern file are added as new viruses are discovered. When Kaspersky Lab updates the signatures in its pattern database, the security device downloads these updates so that the antivirus scanner is using the latest, most up-to-date signatures when scanning traffic. The security device can perform these updates automatically (the default), or you can perform pattern update downloads manually.

The database pattern server is accessible through HTTP or HTTPS. By default, the antivirus module checks for database updates automatically every 60 minutes. You can change this interval and you can trigger updates manually, as well. The number of files that are downloaded during an update and the duration of the download process can vary.

A local copy of the pattern database is saved in persistent data storage (that is, the flash disk). If the device is rebooted, the local copy remains available for the antivirus scan engine to use during the antivirus scan engine initialization time, without the need for network access to the pattern database server.

**NOTE:** If the auto-update fails, the updater automatically retries to update three more times. If the database download continues to fail, the updater stops trying and waits for the next periodic update before trying again.

**NOTE:** Once your subscription expires, you have a 30 day grace period during which you can continue to update the antivirus pattern file. Once that grace period expires, the update server no longer permits antivirus pattern file updates.

---

## Example: Configuring the Full Antivirus Pattern Update Server

This example shows how to configure the pattern-update server on the security device.

- [Requirements on page 5970](#)
- [Overview on page 5970](#)
- [Configuration on page 5971](#)
- [Verification on page 5971](#)

### Requirements

Before you begin:

- Obtain a valid antivirus scanner license. See [“Full Antivirus Protection Overview” on page 5947](#).
- Get network connectivity and access to the pattern database server. See [“Understanding Full Antivirus Pattern Updates” on page 5969](#).
- Configure your DNS settings and port settings (port 80) correctly. See [DNS Overview](#).

### Overview

To configure the pattern-update server on the security device, enter the URL address of the pattern-update server. In this example, you update the URL for an SRX210 Services Gateway.

By default, the Juniper-Kaspersky URL for full antivirus protection is `http://update.juniper-updates.net/AV/device-name`, where *device-name* is the name of your device, for example, SRX210.

## Configuration

### Step-by-Step Procedure

To configure the pattern-update server on a security device:

1. Specify the URL of the pattern-update server.

[edit]

```
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine
pattern-update url http://update.juniper-updates.net/AV/SRX210
```

**NOTE:** Other than the platform name, you should not change this URL unless you are experiencing problems with it and have called for support.

2. If you are done configuring the device, commit the configuration.

[edit]

```
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security utm** command.

- [Manually Updating, Reloading, and Deleting Full Antivirus Patterns \(CLI Procedure\) on page 5973](#)

## Example: Automatically Updating Full Antivirus Patterns (J-Web)

In this example, you configure the security device to update the pattern file automatically every 120 minutes. (The default antivirus pattern-update interval is 60 minutes.)

To automatically update antivirus patterns:

1. Select **Configure>UTM>Anti-Virus**.
2. Next to Interval, in the Kaspersky Lab Engine section, enter **120** in the box.
3. Click **OK** to check your configuration and save it as a candidate configuration, then click **Commit Options>Commit**.

---

## Example: Automatically Updating Full Antivirus Patterns

This example shows how to update the pattern file automatically on a security device.

- [Requirements on page 5972](#)
- [Overview on page 5972](#)
- [Configuration on page 5972](#)
- [Verification on page 5972](#)

### Requirements

Before you begin:

- Obtain a valid antivirus scanner license. See [“Full Antivirus Protection Overview” on page 5947](#).
- Get network connectivity and access to the pattern database server. See [“Understanding Full Antivirus Pattern Updates” on page 5969](#).
- Configure your DNS settings and port settings (port 80) correctly. See *DNS Overview*.

### Overview

In this example, you configure the security device to update the pattern file automatically every 120 minutes. (The default antivirus pattern-update interval is 60 minutes.)

### Configuration

#### Step-by-Step Procedure

To configure the security device to update the pattern file automatically:

1. Set the interval.  
  
[edit]  
user@host# **set security utm feature-profile anti-virus kaspersky-lab-engine pattern-update interval 120**
2. If you are done configuring the device, commit the configuration.  
  
[edit]  
user@host# **commit**

### Verification

To verify the configuration is working properly, enter the **show security utm** command.

#### Related Documentation

- [Full Antivirus Pattern Update Configuration Overview on page 5949](#)
- [Example: Configuring the Full Antivirus Pattern Update Server on page 5970](#)

- [Example: Automatically Updating Full Antivirus Patterns \(J-Web\)](#) on page 5971
- [Manually Updating, Reloading, and Deleting Full Antivirus Patterns \(CLI Procedure\)](#) on page 5973

## **Manually Updating, Reloading, and Deleting Full Antivirus Patterns (CLI Procedure)**

---

To manually update antivirus patterns, enter the following CLI command:

```
user@host> request security utm anti-virus kaspersky-lab-engine pattern-update
```

To manually reload antivirus patterns, enter the following CLI command:

```
user@host> request security utm anti-virus kaspersky-lab-engine pattern-reload
```

To manually delete antivirus patterns, enter the following CLI command:

```
user@host> request security utm anti-virus kaspersky-lab-engine pattern-delete
```

You can update the Kaspersky antivirus signature database offline without using a direct Internet connection. This is required in some security installations and for sites that access the Internet through a proxy server.

To update the Kaspersky antivirus signature database offline, you must configure a local webserver.

To configure a webserver, use the following CLI statement.

```
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine pattern-update
url <http_server>
```

```
user@host# commit
```

To update the Kaspersky antivirus signature database, perform the following tasks:

1. Based on your hardware platform, enter any of the following URLs in your computer browser.
  - SRX100—<http://update.juniper-updates.net/AV/SRX100>
  - SRX210—<http://update.juniper-updates.net/AV/SRX210>
  - SRX240—<http://update.juniper-updates.net/AV/SRX240>
  - SRX650—<http://update.juniper-updates.net/AV/SRX650>
2. Copy all the files to a directory on your local webserver. You might want to use a download manager for your browser to get all the files more quickly.
3. Download the Kaspersky Lab engine from [http://update.juniper-updates.net/KAV\\_engine/](http://update.juniper-updates.net/KAV_engine/).
  - For JSR, the URL is [http://update.juniper-updates.net/KAV\\_engine/i386/](http://update.juniper-updates.net/KAV_engine/i386/).
  - For branch SRX Series devices, the URL is [http://update.juniper-updates.net/KAV\\_engine/octeon32/](http://update.juniper-updates.net/KAV_engine/octeon32/).
4. Copy all the files to the same directory on your local server.

**NOTE:** The Kaspersky Lab engine is automatically loadable. For updating the Kaspersky antivirus signature database offline, both pattern update files and Kaspersky Lab engine files must be placed in the same folder on the local webserver.

5. Set the directory as a sharepoint that can be accessed through HTTP from the SRX Series device.
6. Run the update command in the CLI.

```
user@host>request security utm anti-virus kaspersky-lab-engine pattern-update
```

## Understanding the Full Antivirus Internal Scan Engine

---

The full file-based antivirus module is the software subsystem on the gateway device that scans specific Application Layer traffic to protect users from virus attacks and to prevent viruses from spreading. The antivirus software subsystem consists of a virus signature database, an application proxy, the scan manager, and the scan engine.

Kaspersky Lab provides the scan engine and it works in the following manner:

1. A client establishes a TCP connection with a server and then starts a transaction.
2. If the application protocol in question is marked for antivirus scanning, the traffic is forwarded to an application proxy for parsing.
3. When the scan request is sent, the scan engine scans the data by querying a virus pattern database.

4. The scan manager monitors antivirus scanning sessions, checking the properties of the data content against the existing antivirus settings.
5. After scanning has occurred, the result is then handled by the scan manager.

The Kaspersky Lab scan engine supports regular file scanning and script file scanning. With regular file scanning, the input object is a regular file. The engine matches the input content with all possible signatures. With script file scanning, the input object is a script file. It can be JavaScript, VBScript, mIRC script, bat scripts (DOS bat files), and other text scripts. The engine matches the input content only with signatures for script files. Script scanning is only applicable for HTML content over the HTTP protocol. There are two criteria for this scan type. First, the content-type field of this HTML document must be text or HTML. Second, there is no content encoding in the HTTP header. If those two criteria are met, an HTML parser is used to parse the HTML document for scripts.

**Related  
Documentation**

---

## Understanding Full Antivirus Scan Mode Support

---

The Kaspersky Lab scan engine supports two modes of scanning:

- scan-all—This option tells the scan engine to scan all the data it receives.
- scan-by-extension—This option bases all scanning decisions on the file extensions found in the traffic in question.

When scanning content, you can use a file extension list to define a set of file extensions that are used in file extension scan mode (scan-by-extension). The antivirus module can then scan files with extensions on the scan-extension list. If an extension is not defined in an extension list, the file with that extension is not scanned in scan-by-extension mode. If there is no extension present, the file in question is scanned.

When using a file extension list to scan content, please note the following requirements:

- File extension entries are case-insensitive.
- The maximum length of the file extension list name is 29 bytes.
- The maximum length of each file extension entry is 15 bytes.
- The maximum entry number in a file extension list is 255.

## Configuring Full Antivirus File Extension Scanning (CLI Procedure)

To configure file-extension scanning, use the following CLI configuration statements:

```
security utm {
 custom-objects {
 filename-extension { ; set of list
 name extension-list-name; #mandatory
 value windows-extension-string;
 }
 }
}

security utm feature-profile anti-virus kaspersky-lab-engine profile name {
 scan-options {
 scan-extension ext-list
 }
}
```

- [Understanding Full Antivirus Scan Mode Support on page 5976](#)

## Example: Configuring Full Antivirus File Extension Scanning

This example shows how to configure full antivirus file extension scanning.

- [Requirements on page 5977](#)
- [Overview on page 5977](#)
- [Configuration on page 5978](#)
- [Verification on page 5978](#)

### Requirements

Before you begin, decide the mode of scanning you require. See “[Understanding Full Antivirus Scan Mode Support](#)” on page 5976.

### Overview

In this example, you perform the following tasks:

1. Create a file called `extlist1` for the `kasprof1` profile, and add extensions such as `.zip`, `.js`, and `.vbs` to the `extlist1`.
2. Configure the scan mode setting. You can choose to scan all files or to scan only the files that have the extensions that you specify. This example uses the scan by-extension option to configure the device to use the `extlist1` file.

## Configuration

### Step-by-Step Procedure

To configure full antivirus file extension scanning:

1. Create a extension for the list and add extensions to the filename extension list.  

```
[edit]
user@host# set security utm custom-objects filename-extension extlist1 value [zip
js vbs]
```
2. Configure scan extension settings.  

```
[edit]
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile
kasprof1 scan-options scan-extension extlist1
```
3. Configure the scan mode setting.  

```
[edit]
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile
kasprof1 scan-options scan-mode by-extension
```
4. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security utm** command.

---

## Understanding Full Antivirus Scan Level Settings

The antivirus module allows you to configure scanning options on a global level, on a UTM profile level, or on a firewall policy level. Each configuration level has the following implications:

- Global antivirus settings—Settings are applied to all antivirus sessions. Global settings are general overall configurations for the antivirus module or settings that are not specific for profiles.
- Profile-based settings—Antivirus settings are different for different protocols within the same policy.
- Policy-based settings—Antivirus settings are different for different policies. Policy-based antivirus settings are applied to all scan-specified traffic defined in a firewall policy.

The majority of antivirus settings are configured within an antivirus profile, bound to specified protocols, and used by designated policies. These UTM policies are then applied to the traffic according to firewall policies. If a firewall policy with an antivirus setting matches the properties of a traffic flow, the antivirus setting is applied to the traffic

session. Therefore, you can apply different antivirus settings for different protocols and for different traffic sessions.

**Related Documentation**

- [Full Antivirus Protection Overview on page 5947](#)
- [Understanding the Full Antivirus Internal Scan Engine on page 5975](#)
- [Example: Configuring Full Antivirus Scan Settings at Different Levels on page 5979](#)
- [Understanding Full Antivirus Scan Mode Support on page 5976](#)

## Example: Configuring Full Antivirus Scan Settings at Different Levels

This example shows how to configure full antivirus scan settings at different levels.

- [Requirements on page 5979](#)
- [Overview on page 5979](#)
- [Configuration on page 5979](#)
- [Verification on page 5980](#)

### Requirements

Before you begin, decide the type of scanning option you require. See “[Understanding Full Antivirus Scan Level Settings](#)” on page 5978.

### Overview

In this example, you define antivirus scanning options on any of the following levels:

- Global level
- UTM profile level using the kasprof1 UTM profile
- Firewall policy level using the p1 UTM policy

### Configuration

**CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile anti-virus kaspersky-lab-engine pattern-update interval 20
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options default block
set utm-policy p1 anti-virus http-profile av-profile
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure antivirus scanning options at different levels:

1. Configure scanning options at the global level.

```
[edit security utm]
user@host# set feature-profile anti-virus kaspersky-lab-engine pattern-update
interval 20
```

2. Configure scanning options at the UTM profile level.

```
[edit security utm]
user@host# set feature-profile anti-virus kaspersky-lab-engine profile kasprof1
fallback-options default block
```

3. Configure scanning options at the UTM policy level.

```
[edit security utm]
user@host# set utm-policy p1 anti-virus http-profile av-profile
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show security utm
...
 utm-policy p1 {
 anti-virus {
 http-profile av-profile
 ftp {
 upload-profile av-profile
 download-profile av-profile
 }
 }
 }
 ...
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Scan Settings at Different Levels on page 5980](#)

### Verifying Scan Settings at Different Levels

**Purpose** Verify the scan settings at different levels.

**Action** From operational mode, enter the **show configuration security utm** command.

## Understanding Full Antivirus Intelligent Prescreening

By default, intelligent prescreening is enabled to improve antivirus scanning performance. The antivirus module generally begins to scan data after the gateway device has received all the packets of a file. Intelligent prescreening tells the antivirus module to begin scanning a file much earlier. In this case, the scan engine uses the first packet or the first several packets to determine if a file could possibly contain malicious code. The scan engine does a quick check on these first packets and if it finds that it is unlikely that the file is infected, it then decides that it is safe to bypass the normal scanning procedure.

**NOTE:** Intelligent prescreening is only intended for use with non-encoded traffic. It is not applicable for MIME encoded traffic, mail protocols (SMTP, POP3, IMAP) and HTTP POST.

- Related Documentation**

  - [Example: Configuring Full Antivirus Intelligent Prescreening on page 5981](#)
  - [Understanding Full Antivirus Scan Mode Support on page 5976](#)

## Example: Configuring Full Antivirus Intelligent Prescreening

This example shows how to configure full antivirus intelligent prescreening. By default, intelligent prescreening is enabled to improve antivirus scanning performance.

- [Requirements on page 5981](#)
- [Overview on page 5981](#)
- [Configuration on page 5982](#)
- [Verification on page 5982](#)

### Requirements

Before you begin, understand how intelligent prescreening enables the improvement of antivirus scanning performance. See [“Understanding Full Antivirus Intelligent Prescreening” on page 5981](#).

### Overview

In this example, you perform the following tasks:

- Enable intelligent prescreening for the kasprof1 profile.
- Disable intelligent prescreening for the kasprof1 profile.

## Configuration

### Step-by-Step Procedure

To enable or disable full antivirus intelligent prescreening:

1. Enable intelligent prescreening for the kasprof1 profile.

[edit]

```
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1 scan-options intelligent-prescreening
```

2. Disable intelligent prescreening for the kasprof1 profile.

[edit]

```
user@host# set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1 scan-options no-intelligent-prescreening
```

**NOTE:** Intelligent prescreening is intended only for use with non-encoded traffic. It is not applicable to mail protocols (SMTP, POP3, IMAP) or HTTP POST.

3. If you are done configuring the device, commit the configuration.

[edit]

```
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security utm** command.

## Understanding Full Antivirus Content Size Limits

Due to resource constraints, there is a default, device-dependent limit on maximum content size for the database. The content size value is configurable. There is also a lower and upper limit for maximum content size. (This range is device dependent and is not configurable.)

The content size check occurs before the scan request is sent. The exact timing of this is protocol dependent. If the protocol header contains an accurate content length field, the content size check takes place when the content length field is extracted during header parsing. The content size usually refers to file size. If there is no content length field, the size is checked while the antivirus module is receiving packets. The content size, in this case, refers to accumulated TCP payload size.

**NOTE:** This setting can be used in all protocols.

**Related  
Documentation**

- [Full Antivirus Protection Overview on page 5947](#)
- [Configuring Full Antivirus Content Size Limits \(CLI Procedure\) on page 5983](#)

## Configuring Full Antivirus Content Size Limits (CLI Procedure)

To configure content size limits, use the following CLI configuration statements:

```
security utm feature-profile anti-virus kaspersky-lab-engine profile name {
 scan-options {
 content-size-limit KB;
 }
}
```

**Related  
Documentation**

- [Full Antivirus Protection Overview on page 5947](#)
- [Understanding Full Antivirus Content Size Limits on page 5982](#)

## Understanding Full Antivirus Decompression Layer Limits

The decompression layer limit specifies how many layers of nested compressed files and files with internal extractable objects, such as archive files (tar), MS Word and PowerPoint files, the internal antivirus scanner can decompress before it executes the virus scan. For example, if a message contains a compressed .zip file that contains another compressed .zip file, there are two compression layers. Decompressing both files requires a decompress layer setting of 2.

It is worth noting that during the transfer of data, some protocols use content encoding. The antivirus scan engine must decode this layer, which is considered a decompression level, before it scans for viruses.

There are three kinds of compressed data:

- compressed file (zip, rar, gzip)
- encoded data (MIME)
- packaged data (OLE, .CAP, .MSI, .TAR, .EML)

A decompression layer could be a layer of a zipped file or an embedded object in packaged data. The antivirus engine scans each layer before unpacking the next layer, until it either reaches the user-configured decompress limit, reaches the device decompress layer limit, finds a virus or other malware, or decompresses the data completely, whichever comes first.

As the virus signature database becomes larger and the scan algorithms become more sophisticated, the scan engine has the ability to look deeper into the data for embedded malware. As a result, it can uncover more layers of compressed data. The Juniper Networks

device's level of security is limited by decompress limit, which is based on the memory allocated to the security service. If a virus is not found within the decompress limit, the user has an option to either pass or drop the data.

**NOTE:** This setting can be used in all protocols.

## Understanding Full Antivirus Scanning Timeouts

The scanning timeout value includes the time frame from when the scan request is generated to when the scan result is returned by the scan engine. The time range can be 1 to 1800 seconds. By default, it is 180 seconds.

**NOTE:** This timeout parameter is used by all supported protocols. Each protocol can have a different timeout value.

**Related  
Documentation**

- [Full Antivirus Protection Overview on page 5947](#)
- [Configuring Full Antivirus Scanning Timeouts \(CLI Procedure\) on page 5984](#)

## Configuring Full Antivirus Scanning Timeouts (CLI Procedure)

To configure scanning timeouts, use the following CLI configuration statements:

```
security utm feature-profile anti-virus kaspersky-lab-engine profile name {
 scan-options {
 timeout-value seconds {
 }
 }
}
```

---

## Understanding Full Antivirus Scan Session Throttling

In an attempt to consume all available resources and hinder the ability of the scan engine to scan other traffic, a malicious user might generate a large amount of traffic all at once. To prevent such activity from succeeding, a session throttle is imposed for antivirus resources, thereby restricting the amount of traffic a single source can consume at one time. The limit is an integer with 100 as the default setting. This integer refers to the maximum allowed sessions from a single source. You may change this default limit, but understand that if this limit is set high, that is comparable to no limit.

Over-limit is a fallback setting for the connection-per-client limit. The default behavior of over-limit is to block sessions. This is a per-policy setting. You can specify different settings for different UTM policies.

- Related Documentation**
- [Full Antivirus Protection Overview on page 5947](#)
  - [Configuring Full Antivirus Scan Session Throttling \(CLI Procedure\) on page 5985](#)

---

## Configuring Full Antivirus Scan Session Throttling (CLI Procedure)

To configure scan session throttling, use the following CLI configuration statements:

```
security utm utm-policy name
 traffic-options {
 sessions-per-client {
 limit number;
 over-limit { log-and-permit | block }
 }
 }
```

## Understanding Full Antivirus Scan Result Handling

---

Different antivirus scan results are handled in different manners. For example, if a scan result is clean, the traffic is forwarded to the receiver. If the scan result is infected, the traffic is dropped. If the scan results in an error, the result handling depends on the cause of the failure and the configuration (fallback settings).

The following is a list of actions based on scan results:

- Scan Result = Pass

The scan result handling action is to pass the message. In this case, no virus is detected and no error code is returned. Or, an error code is returned, but the fallback option for this error code is set to log-and-permit.

- Scan Result = Block

The scan result handling action is to block the message. In this case, either a virus is detected or an error code is returned and the fallback option for this error code is BLOCK.

## Monitoring Antivirus Scan Engine Status

---

**Purpose** Using the CLI, you can view the following scan engine status items:

#### Antivirus license key status

- View license expiration dates.

#### Scan engine status and settings

- View last action result.
- View default file extension list.

#### Antivirus pattern update server settings

- View update URL (HTTP or HTTPS-based).
- View update interval.

#### Antivirus pattern database status

- View auto update status.
- View last result of database loading.
- If the download completes, view database version timestamp virus record number.
- If the download fails, view failure reason.

**Action** In the CLI, enter the `user@host> show security utm anti-virus status` command.

Example status result:

```
AV Key Expire Date: 03/01/2010 00:00:00
Update Server: http://update.juniper-updates.net/AV/SRX210
interval: 60 minutes
auto update status: next update in 12 minutes
last result: new database loaded
AV signature version: 12/21/2008 00:35 GMT, virus records: 154018
Scan Engine Info: last action result: No error(0x00000000)
```

## Monitoring Antivirus Session Status

**Purpose** Using the CLI, you can view the following session status items:

Antivirus session status displays a snapshot of current antivirus sessions. It includes

- Maximum supported antivirus session numbers.
- Total allocated antivirus session numbers.
- Total freed antivirus session numbers.
- Current active antivirus session numbers.

**Action** In the CLI, enter the `user@host> show security utm session status` command.

---

## Monitoring Antivirus Scan Results

---

**Purpose** View statistics for antivirus requests, scan results, and fallback counters.

Scan requests provide

- The total number of scan request forwarded to the engine.
- The number of scan request being pre-windowed.
- The number of scan requests using scan-all mode.
- The number of scan requests using scan-by-extension mode.

Scan code counters provide

- Number of clean files.
- Number of infected files.
- Number of password protected files.
- Number of decompress layers.
- Number of corrupt files.
- When the engine is out of resources.
- When there is an internal error.

Fallback applied status provides either a log-and-permit or block result when the following has occurred

- Scan engine not ready.
- Maximum content size reached.
- Too many requests.
- Password protected file found.
- Decompress layer too large.
- Corrupt file found.
- Timeout occurred.
- Out of resources.
- Other.

**Action** To view antivirus scan results using the CLI editor, enter the **user@host> show security utm anti-virus statistics status** command.

To view antivirus scan results using J-Web:

1. Select **Monitor>Security>UTM>Anti-Virus**.

The following information becomes viewable in the right pane.

Antivirus license key status

- View license expiration dates.

Antivirus pattern update server settings

- View update URL (HTTP or HTTPS-based).
- View update interval.

Antivirus pattern database status

- View auto update status.
- View last result of database loading.
- If the download completes, view database version timestamp virus record number.
- If the download fails, view failure reason.

Antivirus statistics provide

- The number of scan request being pre-windowed.
- The total number of scan request forwarded to the engine.
- The number of scan requests using scan-all mode.
- The number of scan requests using scan-by-extension mode.

Scan code counters provide

- Number of clean files.
- Number of infected files.
- Number of password protected files.
- Number of decompress layers.
- Number of corrupt files.
- When the engine is out of resources.
- When there is an internal error.

Fallback applied status provides either a log-and-permit or block result when the following has occurred

- Scan engine not ready.
- Password protected file found.

- Decompress layer too large.
  - Corrupt file found.
  - Out of resources.
  - Timeout occurred.
  - Maximum content size reached.
  - Too many requests.
  - Other.
2. You can click the **Clear Anti-Virus Statistics** button to clear all current viewable statistics and begin collecting new statistics.

**Related  
Documentation**

- [Monitoring Antivirus Session Status on page 5988](#)

## Understanding Antivirus Scanning Fallback Options

Fallback options tell the system how to handle the errors returned by either the scan engine or the scan manager. The following is a list of possible errors:

- Scan engine is not ready (engine-not-ready)

The scan engine is initializing itself, for example, loading the signature database. During this phase, it is not ready to scan a file. A file could either pass or be blocked according to this setting.

- Corrupt file (corrupt-file)

Corrupt file is the error returned by the scan engine when engine detects a corrupted file.

- Decompression layer (decompress-layer)

Decompress layer error is the error returned by the scan engine when the scanned file has too many compression layers.

- Password protected file (password-file)

Password protected file is the error returned by the scan engine when the scanned file is protected by a password.

- Max content size (content-size)

If the content size exceeds a set limit, the content is passed or blocked depending on the max-content-size fallback option.

- Too many requests (too-many-requests)

If the total number of messages received concurrently exceeds the device limits, the content is passed or blocked depending on the too-many-request fallback option. (The allowed request limit is not configurable.)

- Timeout

Scanning a complex file could consume resources and time. If the time it is taking to scan exceeds the timeout setting in the antivirus profile, the processing is aborted and the content is passed or blocked without completing the virus checking. The decision is made based on the timeout fallback option.

- Out of resources (out-of-resources)

Virus scanning requires a great deal of memory and CPU resources. Due to resource constraints, memory allocation requests can be denied by the system. This failure could be returned by either scan engine (as a scan-code) or scan manager. When out-of-resources occurs, scanning is aborted.

- Default

All the errors other than those in the above list fall into this category. This could include either unhandled system exceptions (internal errors) or other unknown errors.

The default fallback action for all the error types is log-and-permit.

**Related  
Documentation**

- [Full Antivirus Protection Overview on page 5947](#)
- [Example: Configuring Antivirus Scanning Fallback Options on page 5992](#)

---

## Example: Configuring Antivirus Scanning Fallback Options

---

This example shows how to configure antivirus scanning fallback options.

- [Requirements on page 5992](#)
- [Overview on page 5992](#)
- [Configuration on page 5993](#)
- [Verification on page 5994](#)

### Requirements

Before you begin, understand the possible error types and the default fallback actions for those error types. See [“Understanding Antivirus Scanning Fallback Options” on page 5991](#).

### Overview

In this example, you configure a feature profile called kasprof, and set the fallback scanning options for default, content-size, corrupt-file, decompress-layer, engine-not-ready, out-of-resources, password-file, timeout, too-many-requests, as block.

**NOTE:** The command for changing the URL for the pattern database is:

```
[edit]
user@host# edit security utm feature-profile anti-virus kaspersky-lab-engine
[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set pattern-update url http://..
```

The default URL is `http://update.juniper-updates.net/AV/<device-version>`. You should not change this URL unless you are experiencing problems with it and have called for support.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile anti-virus type kaspersky-lab-engine
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options content-size block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options corrupt-file block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options decompress-layer block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options default block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options engine-not-ready block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options out-of-resources block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options password-file block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options timeout block
set security utm feature-profile anti-virus kaspersky-lab-engine profile kasprof1
 fallback-options too-many-requests block
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure scanning fallback options:

1. Select and configure the engine type.

```
[edit]
user@host# set security utm feature-profile anti-virus type kaspersky-lab-engine
```

2. Create a profile for the Kaspersky Lab engine and configure a list of fallback options as block or log-and-permit.

```
[edit security utm feature-profile anti-virus kaspersky-lab-engine]
user@host# set profile kasprof1 fallback-options content-size block
```

```
user@host# set profile kasprof1 fallback-options corrupt-file block
user@host# set profile kasprof1 fallback-options decompress-layer block
user@host# set profile kasprof1 fallback-options default block
user@host# set profile kasprof1 fallback-options engine-not-ready block
user@host# set profile kasprof1 fallback-options out-of-resources block
user@host# set profile kasprof1 fallback-options password-file block
user@host# set profile kasprof1 fallback-options timeout block
user@host# set profile kasprof1 fallback-options too-many-requests block
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm feature-profile anti-virus** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host#show security utm feature-profile anti-virus
kaspersky-lab-engine {
 profile kasprof1 {
 fallback-options {
 default block;
 corrupt-file block;
 password-file block;
 decompress-layer block;
 content-size block;
 engine-not-ready block;
 timeout block;
 out-of-resources block;
 too-many-requests block;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying the Antivirus Scanning Fallback Options on page 5994](#)

### Verifying the Antivirus Scanning Fallback Options

**Purpose** Verify the antivirus scanning fallback options.

**Action** From operational mode, enter the **show configuration security utm** command.

## Understanding Full Antivirus Application Protocol Scanning

You can turn antivirus scanning on and off on a per protocol basis. If scanning for a protocol is disabled in an antivirus profile, there is no application intelligence for this protocol. Therefore, in most cases, traffic using this protocol is not scanned. But if the protocol in question is based on another protocol for which scanning is enabled in an antivirus profile, then the traffic is scanned as that enabled protocol.

The internal antivirus scan engine supports scanning for specific Application Layer transactions allowing you to select the content (HTTP, FTP, SMTP, POP3, or IMAP traffic) to scan. For each content type that you are scanning, you have different configuration options.

Profile-based settings, including enable/disable, scan-mode, and scan result handling settings, may not be applicable to all supported protocols. The following table lists profile-based settings and their protocol support.

Table 525: Supported Profile-based Settings By Protocol

| Profile Setting                                  | Protocol Support                   |
|--------------------------------------------------|------------------------------------|
| Enable or disable scanning on per protocol basis | All protocols support this feature |

**Table 525: Supported Profile-based Settings By Protocol** (*continued*)

## Understanding HTTP Scanning

If antivirus scanning is enabled for Hypertext Transfer Protocol (HTTP) traffic in a content security profile, TCP traffic to defined HTTP service ports (generally port 80) is monitored. For HTTP traffic, the security device scans both HTTP responses and requests (get, post, and put commands).

**NOTE:** For HTTP antivirus scanning, both HTTP 1.0 and 1.1 are supported. If the protocol version is HTTP 0.x, the antivirus scanner attempts to scan the traffic. Unknown protocols are bypassed. For example, some application protocols use HTTP as the transport but do not comply with HTTP 1.0 or 1.1. These are considered unknown protocols and are not scanned.

This is a general description of how HTTP traffic is intercepted, scanned, and acted upon by the antivirus scanner:

1. An HTTP client sends an HTTP request to a webserver or a webserver responds to an HTTP request.

2. The security device intercepts the request and passes the data to the antivirus scanner, which scans it for viruses.
3. After completing the scan, the device follows one of two courses:
  - If there is no virus, the device forwards the request to the webserver.
  - If there is a virus, the device drops the request and sends an HTTP message reporting the infection to the client.

With script-only scanning, the input object is a script file. It can be JavaScript, VBScript, mIRC script, bat scripts (DOS bat files) and other text scripts. The engine matches the input content only with signatures for script files. Script scanning is applicable only for HTML content over the HTTP protocol. There are two criteria for this scan-type. First, the content-type field of this HTML document must be text or HTML. Second, there is no content encoding in the HTTP header. If those two criteria are met, an HTML parser is used to parse the HTML document.

## Understanding FTP Antivirus Scanning

If antivirus scanning is enabled for File Transfer Protocol (FTP) traffic in a content security profile, the security device monitors the control channel and, when it detects one of the FTP commands for transferring data, it scans the data sent over the data channel.

This is a general description of how FTP traffic is intercepted, scanned, and acted upon by the antivirus scanner:

1. A local FTP client opens an FTP control channel to an FTP server and requests the transfer of some data.
2. The FTP client and server negotiate a data channel over which the server sends the requested data. The security device intercepts the data and passes it to the antivirus scan engine, which scans it for viruses.
3. After completing the scan, the device follows one of two courses:

- If there is no virus, the device forwards the data to the client.
- If there is a virus, the device replaces the data with a drop message in the data channel and sends a message reporting the infection in the control channel.

**Related  
Documentation**

- [Full Antivirus Protection Overview on page 5947](#)
- [Enabling FTP Antivirus Scanning \(CLI Procedure\) on page 5998](#)

---

## Enabling FTP Antivirus Scanning (CLI Procedure)

To enable antivirus scanning for File Transfer Protocol (FTP) traffic, enter the following CLI configuration statement:

```
user@host# security utm utm-policy policy-name anti-virus ftp
```

**NOTE:** In order to scan FTP traffic, the FTP ALG must be enabled.

---

## Understanding SMTP Antivirus Scanning

If SMTP (Simple Mail Transfer Protocol) antivirus scanning is enabled in a content security profile, the security device redirects traffic from local SMTP clients to the antivirus scanner before sending it to the local mail server.

**NOTE:** Chunking is an alternative to the data command. It provides a mechanism to transmit a large message in small chunks. It is not supported. Messages using chunking are bypassed and are not scanned.

This is a general description of how SMTP traffic is intercepted, scanned, and acted upon by the antivirus scanner:

1. An SMTP client sends an e-mail message to a local mail server or a remote mail server forwards an e-mail message via SMTP to the local mail server.
2. The security device intercepts the e-mail message and passes the data to the antivirus scanner, which scans it for viruses.
3. After completing the scan, the device follows one of two courses:
  - If there is no virus, the device forwards the message to the local server.
  - If there is a virus, the device sends a replacement message to the client.

This topic includes the following sections:

- [Understanding SMTP Antivirus Mail Message Replacement on page 5999](#)
- [Understanding SMTP Antivirus Sender Notification on page 5999](#)
- [Understanding SMTP Antivirus Subject Tagging on page 6000](#)

## Understanding SMTP Antivirus Mail Message Replacement

If the antivirus scanner finds a virus in an e-mail message, the original message is dropped, the message body is truncated, and the content is replaced by a message that may appear as follows:

```
nContent-Type: text/plain
Your mail <src_ip> : <src_port> — <dst_port>: <dst_port> contains contaminated file
<filename> with virus <virusname>, so it is dropped.
```

If a scan error is returned and the fail mode is set to drop, the original message is dropped and the entire message body is truncated. The content is replaced by a message that may appear as follows:

```
nContent-Type: text/plain
Your mail <src_ip> : <src_port> — <dst_port>: <dst_port> is dropped for <reason>.
```

## Understanding SMTP Antivirus Sender Notification

If **notify-sender-on-virus** is set and the message is dropped due to a detected virus, an e-mail is sent to the mail sender. The content of the notification may appear as follows:

```
From: <admin>@<gateway_ip>
To: <sender_e-mail>
Subject: Mail Delivery Failure
This message is created automatically by mail delivery software. A message that you sent
could not be delivered to one or more of its recipients for the reason:
<src_ip> : <src_port> — <dst_port>: <dst_port> <ENVID> contaminated file <filename>
with virus <virusname>.
e-mail Header is:
<header of scanned e-mail>
```

If **notify-sender-on-error-drop** is set and the message is dropped due to a scan error, an e-mail is sent to the mail sender of the scanned message. The content of the e-mail may appear as follows:

```
From: <admin>@<gateway_ip>
To: <sender_e-mail>
Subject: Mail Delivery Failure
This message is created automatically by mail delivery software. A message that you sent
could not be delivered to one or more of its recipients for the reason:
<src_ip> : <src_port> — <dst_port>: <dst_port> <ENVID> <reason>.
e-mail Header is:
<header of scanned e-mail>
```

**NOTE:** For information on the ENVID parameter, refer to RFC 3461.

## Understanding SMTP Antivirus Subject Tagging

If a scan error is returned and the fail mode is set to **pass**, the antivirus module passes the message through to the server. If **notify-recipient-on-error-pass** is set, the following string is appended to the end of the subject field:

(No virus check: <reason>)

## Understanding POP3 Antivirus Scanning

If Post Office Protocol 3 (POP3) antivirus scanning is enabled in a content security profile, the security device redirects traffic from a local mail server to antivirus scanner before sending it to the local POP3 client.

This is a general description of how POP3 traffic is intercepted, scanned, and acted upon by the antivirus scanner.

1. The POP3 client downloads an e-mail message from the local mail server.
2. The security device intercepts the e-mail message and passes the data to the antivirus scanner, which scans it for viruses.
3. After completing the scan, the security device follows one of two courses:
  - If there is no virus, the device forwards the message to the client.
  - If there is a virus, the device sends a message reporting the infection to the client.

**NOTE:** See “[Understanding Protocol-Only Virus-Detected Notifications](#)” on page 6011 for information on protocol-only notifications for IMAP.

---

This topic includes the following sections:

- [Understanding POP3 Antivirus Mail Message Replacement on page 6001](#)
- [Understanding POP3 Antivirus Sender Notification on page 6001](#)
- [Understanding POP3 Antivirus Subject Tagging on page 6001](#)

## Understanding POP3 Antivirus Mail Message Replacement

If the antivirus scanner finds a virus in an e-mail message, the original message is dropped, the message body is truncated, and the content is replaced by a message that may appear as follows:

```
nContent-Type: text/plain
Your mail <src_ip> : <src_port> — <dst_port>: <dst_port> contains contaminated file
<filename> with virus <virusname>, so it is dropped.
```

## Understanding POP3 Antivirus Sender Notification

If **notify-sender-on-virus** is set and the message is dropped due to a detected virus, an e-mail is sent to the mail sender.

```
From: <admin>@<gateway_ip>
To: <sender_e-mail>
Subject: Mail Delivery Failure
This message is created automatically by mail delivery software. A message that you sent
could not be delivered to one or more of its recipients for the reason:
<src_ip> : <src_port> — <dst_port>: <dst_port> contaminated file <filename> with virus
<virusname>.
e-mail Header is:
<header of scanned e-mail>
```

If **notify-sender-on-error-drop** is set and the message is dropped due to a scan error, an e-mail is sent to the mail sender of the scanned message. The content of the e-mail may appear as follows:

```
From: <admin>@<gateway_ip>
To: <sender_e-mail>
Subject: Mail Delivery Failure
This message is created automatically by mail delivery software. A message that you sent
could not be delivered to one or more of its recipients for the reason:
<src_ip> : <src_port> — <dst_port>: <dst_port> <reason>.
e-mail Header is:
<header of scanned e-mail>
```

## Understanding POP3 Antivirus Subject Tagging

If a scan error is returned and the fail mode is set to **pass**, the antivirus module passes the message through to the server. If **notify-recipient-on-error-pass** is set, the following string is appended to the end of subject field:

```
(No virus check: <reason>)
```

## Understanding IMAP Antivirus Scanning

If IMAP (Internet Message Access Protocol) antivirus scanning is enabled in a content security profile, the security device redirects traffic from a local mail server to the internal antivirus scanner before sending it to the local IMAP client.

This is a general description of how IMAP traffic is intercepted, scanned, and acted upon by the antivirus scanner.

1. The IMAP client downloads an e-mail message from the local mail server.
2. The security device intercepts the e-mail message and passes the data to the antivirus scanner, which scans it for viruses.
3. After completing the scan, the security device follows one of two courses:
  - If there is no virus, the device forwards the message to the client.
  - If there is a virus, the device sends a message reporting the infection to the client.

**NOTE:** See “[Understanding Protocol-Only Virus-Detected Notifications](#)” on page 6011 for information on protocol-only notifications for IMAP.

This topic includes the following sections:

- [Understanding IMAP Antivirus Mail Message Replacement on page 6002](#)
- [Understanding IMAP Antivirus Sender Notification on page 6003](#)
- [Understanding IMAP Antivirus Subject Tagging on page 6003](#)
- [Understanding IMAP Antivirus Scanning Limitations on page 6003](#)

## Understanding IMAP Antivirus Mail Message Replacement

If the antivirus scanner finds a virus in an e-mail message, the original message is dropped, the message body is truncated, and the content is replaced by a message that may appear as follows:

nContent-Type: text/plain

Your mail <src\_ip> : <src\_port> — <dst\_port>: <dst\_port> contains contaminated file <filename> with virus <virusname>, so it is dropped.

## Understanding IMAP Antivirus Sender Notification

If **notify-sender-on-virus** is set and the message is dropped due to a detected virus, an e-mail is sent to the mail sender.

```
From: <admin>@<gateway_ip>
To: <sender_e-mail>
Subject: Mail Delivery Failure
This message is created automatically by mail delivery software. A message that you sent
could not be delivered to one or more of its recipients for the reason:
<src_ip> : <src_port> — <dst_port>: <dst_port> contaminated file <filename> with virus
<virusname>.
e-mail Header is:
<header of scanned e-mail>
```

If **notify-sender-on-error-drop** is set and the message is dropped due to a scan error, an e-mail is sent to the mail sender of the scanned message. The content of the e-mail may appear as follows:

```
From: <admin>@<gateway_ip>
To: <sender_e-mail>
Subject: Mail Delivery Failure
This message is created automatically by mail delivery software. A message that you sent
could not be delivered to one or more of its recipients for the reason:
<src_ip> : <src_port> — <dst_port>: <dst_port> <reason>.
e-mail Header is:
<header of scanned e-mail>
```

## Understanding IMAP Antivirus Subject Tagging

If a scan error is returned and the fail mode is set to **pass**, the antivirus module passes the message through to the server. If **notify-recipient-on-error-pass** is set, the following string is appended to the end of subject field:

```
(No virus check: <reason>)
```

## Understanding IMAP Antivirus Scanning Limitations

**Mail Fragments** — It is possible to chop one e-mail into multiple parts and to send each part through a different response. This is called mail fragmenting and most popular mail clients support it in order to send and receive large e-mails. Scanning of mail fragments is not supported by the antivirus scanner and in such cases, the message body is not scanned.

**Partial Content** — Some mail clients treat e-mail of different sizes differently. For example, small e-mails (less than 10 KB) are downloaded as a whole. Large e-mails (for example, less than 1 MB) are chopped into 10 KB pieces upon request from the IMAP server. Scanning of any partial content requests is not supported by the antivirus scanner.

**IMAP Uploads** — Only antivirus scanning of IMAP downloads is supported. IMAP upload traffic is not scanned.

# Configuring Whitelists

- [Understanding MIME Whitelists on page 6005](#)
- [Example: Configuring MIME Whitelists to Bypass Antivirus Scanning on page 6006](#)
- [Understanding URL Whitelists on page 6006](#)
- [Configuring URL Whitelists to Bypass Antivirus Scanning \(CLI Procedure\) on page 6007](#)

## Understanding MIME Whitelists

---

The gateway device uses MIME (Multipurpose Internet Mail Extension) types to decide which traffic may bypass antivirus scanning. The MIME whitelist defines a list of MIME types and can contain one or many MIME entries.

A MIME entry is case-insensitive. An empty MIME is an invalid entry and should never appear in the MIME list. If the MIME entry ends with a / character, prefix matching takes place. Otherwise, exact matching occurs.

There are two types of MIME lists used to configure MIME type antivirus scan bypassing:

- **mime-whitelist list**—This is the comprehensive list for those MIME types that can bypass antivirus scanning.
- **exception list**—The exception list is a list for excluding some MIME types from the mime-whitelist list. This list is a subset of MIME types found in the mime-whitelist.

For example, if the mime-whitelist includes the entry, **video/** and the exception list includes the entry **video/x-shockwave-flash**, by using these two lists, you can bypass objects with “video/” MIME type but not bypass “video/x-shockwave-flash” MIME type.

You should note that there are limits for mime-whitelist entries as follows:

- The maximum number of MIME items in a MIME list is 50.
- The maximum length of each MIME entry is restricted to 40 bytes.
- The maximum length of a MIME list name string is restricted to 40 bytes.

### Related Documentation

## Example: Configuring MIME Whitelists to Bypass Antivirus Scanning

---

This example shows how to configure MIME whitelists to bypass antivirus scanning.

- [Requirements on page 6006](#)
- [Overview on page 6006](#)
- [Configuration on page 6006](#)
- [Verification on page 6006](#)

### Requirements

Before you begin, decide the type of MIME lists used to configure MIME type antivirus scan bypassing. See “[Understanding MIME Whitelists](#)” on page 6005.

### Overview

In this example, you create MIME lists called avmime2 and ex-avmime2 and add patterns to them.

### Configuration

#### Step-by-Step Procedure

To configure MIME whitelists to bypass antivirus scanning:

1. Create MIME lists and add patterns to the lists.  

```
[edit]
user@host# set security utm custom-objects mime-pattern avmime2 value
[video/quicktime image/x-portable-anymap x-world/x-vrml]
user@host# set security utm custom-objects mime-pattern ex-avmime2 value
[video/quicktime-inappropriate]
```
2. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

### Verification

To verify the configuration is working properly, enter the **show security utm** command.

#### Related Documentation

- [Understanding URL Whitelists on page 6006](#)
- [Configuring URL Whitelists to Bypass Antivirus Scanning \(CLI Procedure\) on page 6007](#)

## Understanding URL Whitelists

---

A URL whitelist is a unique custom list that you define in which all the URLs or IP addresses in that list for a specified category are always bypassed for scanning. Because antivirus

scanning is CPU and memory intensive action, if there are URLs or IP addresses that you are sure do not require scanning, you might want to create this custom list and add them to it.

# Configuring HTTP Trickling

- [Understanding HTTP Trickling on page 6009](#)
- [Configuring HTTP Trickling to Prevent Timeouts During Antivirus Scanning \(CLI Procedure\) on page 6009](#)

## Understanding HTTP Trickling

---

HTTP trickling is a mechanism used to prevent the HTTP client or server from timing-out during a file transfer or during antivirus scanning. On some slow link transferring, a large file could timeout if too much time is taken for the antivirus scanner to scan a complex file.

HTTP trickling is the forwarding of specified amounts of unscanned HTTP traffic to the requesting HTTP client to prevent the browser window from timing out while the scan manager examines downloaded HTTP files. (The security device forwards small amounts of data in advance of transferring an entire scanned file.)

HTTP Trickling is time-based and there is only one parameter, the time-out interval, to configure for this feature. By default, trickling is disabled.

**NOTE:** The timeout based trickling is packet driven. This means, if no packet is received within a certain time frame, HTTP trickling is discontinued. This setting is only supported for HTTP connections.

---

- [Configuring Custom Message Virus-Detected Notifications \(CLI Procedure\) on page 6013](#)

## Understanding Protocol-Only Virus-Detected Notifications

---

When content is blocked because a virus is found or a scan error occurs, the client generally still receives a successful response code but with modified content (file replacement) containing a warning message. But with protocol-only notifications, a protocol-specific error code may be returned to the client. This way, the client determines that a virus was detected rather than interpreting that a file transfer succeeded.

### Related Documentation

- [Full Antivirus Protection Overview on page 5947](#)
- [Configuring Protocol-Only Virus-Detected Notifications \(CLI Procedure\) on page 6011](#)

## Configuring Protocol-Only Virus-Detected Notifications (CLI Procedure)

---

To configure protocol-only virus-detected notifications, use the following CLI configuration statements:

```
security utm feature-profile anti-virus kaspersky-lab-engine profile name {
 notification-options {
 virus-detection {
 type { protocol-only | message }
 }
 fallback-block {
 type { protocol-only | message }
 }
 }
}
```

- [Full Antivirus Protection Overview on page 5947](#)
  - [Understanding Protocol-Only Virus-Detected Notifications on page 6011](#)

---

## Understanding E-Mail Virus-Detected Notifications

For mail protocols (SMTP, POP3, IMAP), e-mail notification is used to notify the sender or the recipient about the detected viruses or the scanning errors. There are three settings for e-mail notifications:

- **virus-detection/notify-mail-sender** — This setting is used when a virus is detected. If it is enabled, an e-mail is sent to the sender upon virus detection.
- **fallback-block/notify-mail-sender** — This setting is used when other scan codes or scanning errors are returned and the message is dropped. If it is enabled, an e-mail is sent to the sender when an error code is returned.
- **fallback-non-block/notify-mail-recipient** — This setting is used when other scan codes or scanning errors are returned and the message is passed. If it is enabled, the e-mail sent to the recipient is tagged when an error code is returned.

- Related Documentation**
- [Full Antivirus Protection Overview on page 5947](#)
  - [Configuring E-Mail Virus-Detected Notifications \(CLI Procedure\) on page 6012](#)

---

## Configuring E-Mail Virus-Detected Notifications (CLI Procedure)

To configure the system to send e-mail notifications when viruses are detected, use the following CLI configuration statements:

```
security utm feature-profile anti-virus kaspersky-lab-engine profile name {
 notification-options {
 virus-detection {
 notify-mail-sender
 }
 fallback-block {
 notify-mail-sender
 }
 fallback-non-block {
 notify-mail-recipient
 }
 }
}
```

- Related Documentation**
- [Full Antivirus Protection Overview on page 5947](#)
  - [Understanding E-Mail Virus-Detected Notifications on page 6012](#)

## Understanding Custom Message Virus-Detected Notifications

Custom message notifications are mainly used in file replacement or in a response message when the antivirus scan result is to drop the file. When using custom messages, you can provide a customized message in the message content you can define customized subject tags.

**NOTE:** Custom-message in fallback-nonblock is used only by mail protocols.

## Sophos Antivirus Protection Overview

---

Sophos antivirus scanning is offered as a less CPU-intensive alternative to the full file-based antivirus feature. Sophos supports the same protocols as full antivirus and functions in much the same manner; however, it has a smaller memory footprint and is compatible with lower end devices that have less memory.

Sophos antivirus is as an in-the-cloud antivirus solution. The virus pattern and malware database is located on external servers maintained by Sophos (Sophos Extensible List) servers, thus there is no need to download and maintain large pattern databases on the Juniper device. The Sophos antivirus scanner also uses a local internal cache to maintain query responses from the external list server to improve lookup performance.

Because a significant amount of traffic processed by Juniper Unified Threat Management (UTM) is HTTP based, Uniform Resource Identifier (URI) checking is used to effectively prevent malicious content from reaching the endpoint client or server. The following checks are performed for HTTP traffic: URI lookup, true file type detection, and file checksum lookup. The following application layer protocols are supported: HTTP, FTP, SMTP, POP3 and IMAP.

### Related Documentation

- [Sophos Antivirus Features on page 6018](#)
- [Sophos Antivirus Configuration Overview on page 6020](#)

## Sophos Antivirus Features

Sophos Antivirus has the following main features:

- **Sophos Antivirus Expanded MIME Decoding Support**—Sophos antivirus offers decoding support for HTTP, POP3, SMTP, and IMAP. MIME decoding support includes the following for each supported protocol:
  - Multipart and nested header decoding
  - Base64 decoding, printed quote decoding, and encoded word decoding in the subject field
- **Sophos Antivirus Scan Result Handling**—With Sophos antivirus, the TCP traffic is closed gracefully when a virus is found and the data content is dropped.

The following fail mode options are supported: content-size, default, engine-not-ready, out-of-resource, timeout, and too-many-requests. You can set the following actions: block, log-and-permit, and permit. Fail mode handling of supported options with Sophos is much the same as with full antivirus.

- **Sophos Uniform Resource Identifier Checking**—Sophos provides Uniform Resource Identifier (URI) checking, which is similar to anti-spam realtime blackhole list (RBL) lookups. URI checking is a way of analyzing URI content in HTTP traffic against the Sophos database to identify malware or malicious content. Because malware is predominantly static, a checksum mechanism is used to identify malware to improve performance. Files that are capable of using a checksum include: .exe, .zip, .rar, .swf, .pdf, and .ole2 (doc and xls).

**NOTE:** If you have a Juniper device protecting an internal network that has no HTTP traffic, or has Web servers that are not accessible to the outside world, you may want to turn off URI checking. If the Web servers are not accessible to the outside world, it is unlikely that they contain URI information that is in the Sophos URI database. URI checking is on by default.

### Related Documentation

- [Sophos Antivirus Configuration Overview on page 6020](#)
- [Example: Configuring Sophos Antivirus Feature Profile on page 6024](#)

## Understanding Sophos Antivirus Data File Update

Sophos antivirus uses a small set of data files that need to be updated periodically. These data files only contain information on guiding scanning logic and do not contain the full pattern database. The main pattern database, which includes protection against critical viruses, URI checks, malware, worms, Trojans, and spyware, is located on remote Sophos Extensible List servers maintained by Sophos.

The Sophos data files are updated over HTTP or HTTPS and can be updated manually or scheduled to update automatically. This is similar functionality to that found in the Full Antivirus solution, but with some minor differences:

- With Sophos antivirus, the signature database auto-update interval is once a day by default. This interval can be changed.
- With Sophos, there is no interruption in virus scanning capability during the data file update. If the update fails, the existing data files will continue to be used.
- By default, the URL for Sophos antivirus data file update is <http://update.juniper-updates.net/SAV/>.

**NOTE:** The Sophos antivirus scanning feature is a separately licensed subscription service. When your antivirus license key expires, functionality will no longer work because the pattern lookup database is located on remote Sophos servers. You have a 30-day grace period in which to update your license.

#### Related Documentation

- [Managing Sophos Antivirus Data Files on page 6033](#)
- [Sophos Antivirus Configuration Overview on page 6020](#)

## Comparison of Sophos Antivirus to Kaspersky Antivirus

Sophos Antivirus is much like Juniper Express Antivirus and also has similarities to the Full Antivirus feature:

- Unlike the Juniper Express and Full Antivirus solutions, the antivirus and malware database for Sophos is stored on a group of remote Sophos Extensible List servers. Queries are performed using the DNS protocol. Sophos maintains these servers, so there is no need to download and maintain large pattern databases on the Juniper device. Because the database is remote, there is no size limitation and there is a quicker response to new virus outbreaks.

**NOTE:** Sophos antivirus uses a set of data files that need to be updated on a regular basis. These are not typical virus pattern files; they are a set of small files that help guide virus scanning logic. You can manually download the data files or set up automatic download.

- Sophos does not provide the same prescreening detection as Kaspersky Antivirus. Sophos does provide a similar solution that is part of the Sophos engine and cannot be turned on and off.
- The Sophos antivirus scanning feature is a separately licensed subscription service. Also, the pattern lookup database is located on remote servers maintained by Sophos,

so when your antivirus license key expires, functionality will no longer work. You have a 30-day grace period in which to update your license.

## Sophos Antivirus Configuration Overview

Sophos antivirus is part of the Unified Threat Management (UTM) feature set, so you first configure UTM options (custom objects), configure the Sophos Feature, then create a UTM policy and a security policy. The security policy controls all traffic that is forwarded by the device, and the UTM policy specifies which parameters to use to scan traffic. The UTM policy is also used to bind a set of protocols to one or more UTM feature profiles, including Sophos antivirus in this case.

You must complete the following tasks to configure Sophos antivirus:

1. Configure UTM custom objects and MIME lists. See [“Example: Configuring Sophos Antivirus Custom Objects” on page 6020](#),
2. Configure the Sophos antivirus feature profile. See [“Example: Configuring Sophos Antivirus Feature Profile” on page 6024](#).
3. Configure a UTM policy. See [“Example: Configuring Sophos Antivirus UTM Policies” on page 6030](#)
4. Configure a security policy. See [“Example: Configuring Sophos Antivirus Firewall Security Policies” on page 6031](#).

- Related Documentation**
- [Sophos Antivirus Protection Overview on page 6017](#)

---

## Example: Configuring Sophos Antivirus Custom Objects

This example shows you how to create UTM global custom objects to be used with Sophos antivirus.

- [Requirements on page 6020](#)
- [Overview on page 6021](#)
- [Configuration on page 6021](#)
- [Verification on page 6023](#)

### Requirements

Before you begin, read about UTM custom objects. See [“Understanding UTM Custom Objects” on page 5881](#).

## Overview

Configure MIME lists. This includes creating a MIME whitelist and a MIME exception list for antivirus scanning. In this example, you bypass scanning of QuickTime videos, unless if they contain the MIME type quicktime-inappropriate.

**WARNING:** When you configure the MIME whitelist feature, be aware that, because header information in HTTP traffic can be spoofed, you cannot always trust HTTP headers to be legitimate. When a Web browser is determining the appropriate action for a given file type, it detects the file type without checking the MIME header contents. However, the MIME whitelist feature does refer to the MIME encoding in the HTTP header. For these reasons, it is possible in certain cases for a malicious website to provide an invalid HTTP header. For example, a network administrator might inadvertently add a malicious website to a MIME whitelist, and, because the site is in the whitelist, it will not be blocked by Sophos even though Sophos has identified the site as malicious in its database. Internal hosts would then be able to reach this site and could become infected.

## Configuration

### GUI Step-by-Step Procedure

To configure a MIME list:

1. Click the **Configure** tab from the taskbar, and then select **Security>UTM>Custom Objects**.
2. Click the **MIME Pattern List** tab and then click **Add**.
3. In the MIME Pattern Name box, type **avmime2**.
4. In the MIME Pattern Value box, type **video/quicktime**, and click **Add**.
5. In the MIME Pattern Value box, type **image/x-portable-anympa**, and click **Add**.
6. In the MIME Pattern Value box, type **x-world/x-vrml**, and click **Add**.

To configure a MIME exception list:

1. Click the **Configure** tab from the taskbar, and then select **Security>UTM>Custom Objects**.
2. Click the **MIME Pattern List** tab and then select **Add**.
3. In the MIME Pattern Name box, type **exception-avmime2**.
4. In the MIME Pattern Value box, type **video/quicktime-inappropriate** and click **Add**.

Configure a URL pattern list (whitelist) of URLs or addresses that will be bypassed by antivirus scanning. After you create the URL pattern list, you will create a custom URL category list and add the pattern list to it.

**NOTE:** Because you use URL pattern lists to create custom URL category lists, you must configure URL pattern list custom objects before you configure custom URL category lists.

To configure a URL pattern whitelist:

1. Click the **Configure** tab from the taskbar, and then select **Security>UTM>Custom Objects**.
2. Click the **URL Pattern List** tab, and then click **Add**.
3. In the URL Pattern Name box, enter **urlist2**.
4. In the URL Pattern Value box, enter **http://example.net**. (You can also use the IP address of the server instead of the URL.)

Save your configuration:

1. Click **OK** to check your configuration and save it as a candidate configuration.
2. If you are done configuring the device, click **Actions>Commit**.

**NOTE:** URL pattern wildcard support—The wildcard rule is as follows: `\*\.[]\?*` and you must precede all wildcard URLs with `http://`. You can use “\*” only if it is at the beginning of the URL and is followed by a “.”. You can only use “?” at the end of the URL.

The following wildcard syntax is supported: `http://*.example.net`, `http://www.example.ne?`, `http://www.example.n??`. The following wildcard syntax is not supported: `*example.net`, `www.example.ne?`, `http://*example.net`, `http://*`.

#### Step-by-Step Procedure

To configure antivirus protection using the CLI, you must create your custom objects in the following order:

1. Create the MIME whitelist.

```
[edit security utm]
user@host# set custom-objects mime-pattern avmime2 value [video/quicktime
image/x-portable-anymap x-world/x-vrml]
```

Create the MIME exception list.

```
[edit security utm]
```

```
user@host# set custom-objects mime-pattern exception-avmime2 value
[video/quicktime-inappropriate]
```

2. Configure a URL pattern list (whitelist) of URLs or addresses that you want to bypass. After you create the URL pattern list, you create a custom URL category list and add the pattern list to it. Configure a URL pattern list custom object by creating the list name and adding values to it as follows.

**NOTE:** Because you use URL pattern lists to create custom URL category lists, you must configure URL pattern list custom objects before you configure custom URL category lists.

```
[edit security utm]
user@host# set custom-objects url-pattern urllist2 value [http://www.example.net
192.168.1.5]
```

**NOTE:** URL pattern wildcard support—The wildcard rule is as follows: `\*\.[]\?*` and you must precede all wildcard URLs with `http://`. You can only use “\*” if it is at the beginning of the URL and is followed by a “.”. You can only use “?” at the end of the URL.

The following wildcard syntax is supported: `http://*.example.net`, `http://www.example.ne?`, `http://www.example.n??`. The following wildcard syntax is not supported: `*example.net`, `www.example.ne?`, `http://*example.net`, `http://*`.

3. Configure a custom URL category list custom object by using the URL pattern list `urllist2` that you created earlier:

```
[edit security utm]
user@host# set custom-objects custom-url-category custurl2 value urllist2
```

## Verification

To verify the configuration, enter the **show security utm custom-objects** command.

### Related Documentation

- [Sophos Antivirus Protection Overview on page 6017](#)
- [Sophos Antivirus Configuration Overview on page 6020](#)
- [Example: Configuring Sophos Antivirus Feature Profile on page 6024](#)
- [Understanding UTM Custom Objects on page 5881](#)

## Example: Configuring Sophos Antivirus Feature Profile

---

This example shows you how to configure a Sophos antivirus profile that defines the parameters that will be used for virus scanning.

- [Requirements on page 6024](#)
- [Overview on page 6024](#)
- [Configuration on page 6024](#)
- [Verification on page 6029](#)

### Requirements

Before you begin:

- Install a Sophos antivirus license. See the *Installation and Upgrade Guide for Security Devices*.
- Configure custom objects for UTM. See “[Example: Configuring Sophos Antivirus Custom Objects](#)” on page 6020.

### Overview

The following configuration defines Sophos as the antivirus engine and sets parameters, such as the data file update interval, notification options for administrators, fallback options, and file size limits.

### Configuration

#### GUI Step-by-Step Procedure

**NOTE:** The following example shows you how to create a custom Sophos profile. If you want to use the Juniper Networks preconfigured profile, use the profile named `junos-sophos-av-defaults` in your UTM policy. See “[Example: Configuring Sophos Antivirus UTM Policies](#)” on page 6030.

1. Select and configure the engine type. Because you are configuring Sophos antivirus, you configure `sophos-engine`:
  - a. Click the **Configure** tab from the taskbar, and then select **Security>UTM>Anti-Virus**.
  - b. Click the **Global Options** tab and then click **Sophos**.

- c. Click **OK** and commit your changes.
  - d. Restart the device to enable Sophos as the antivirus engine.
2. Return to the antivirus Global Options screen as you did in step 1, and set the following parameters:
  - a. In the MIME whitelist list, select **exception-avmime2**.
  - b. In the URL whitelist list, select **custurl2**.
  - c. In the Pattern update interval (sec) box, type **2880**.
  - d. In the box, type the e-mail address that will receive SophosAdmin e-mail data file update notifications. For example - admin@example.net.
  - e. In the Custom Message box, type **The Sophos data file update on the SRX240 has been completed**. In the Custom message subject box, type **Sophos Data File Updated**.
  - f. Click **OK** to check your configuration and save it as a candidate configuration.
3. Configure a profile for the sophos-engine and set parameters.
  - a. Click the **Configure** tab from the taskbar and then select **Security>UTM>Anti-Virus**. Click **Add**.
  - b. In the Add profile box, click the **Main** tab.
  - c. In the Profile name box, type **sophos-profl**.
  - d. In the Trickling timeout box, type **180**.

**WARNING:** When enabling the trickling option, it's important to understand that trickling may send part of the file to the client during the antivirus scan. It is possible that some of the content could be received by the client and the client may become infected before the file is fully scanned.

- e. URI checking is on by default. To turn it off, clear **yes** in the URI check box.
  - f. In the Content size Limit box, type **20000**.
  - g. In the Scan engine timeout box, type **1800**.
4. Configure fallback settings by clicking the **Fallback settings** tab. In this example, all fallback options are set to log and permit. Click **Log and permit** for the following items: Default action, Content size, Engine not ready, Timeout, Out of resource, Too many requests.

5. Configure notification options by clicking the **Notification options** tab. You can configure notifications for both fallback blocking and fallback nonblocking actions and for virus detection.

To configure notifications for Fallback settings:

- a. For Notification type, click **Protocol**.
  - b. For Notify mail sender, click **yes**.
  - c. In the Custom message box, type **Fallback block action occurred**.
  - d. In the Custom message subject box, type **\*\*\*Antivirus fallback Alert\*\*\***.
6. To configure notification options for virus detection, click the **Notification options cont...** tab.
    - a. For the Notification type option button, select **Protocol**.
    - b. For the Notify mail sender option button, select **yes**.
    - c. In the Custom message box, type **Virus has been detected**.
    - d. In the Custom message subject box, type **\*\*\*Virus detected\*\*\***.
  7. Click **OK** to check your configuration and save it as a candidate configuration.
  8. If you are done configuring the device, click **Actions>Commit**.

#### Step-by-Step Procedure

To configure the Sophos antivirus feature profile using the CLI:

**NOTE:** The following example shows you how to create a custom Sophos profile. If you want to use the Juniper Networks preconfigured profile, use the profile named `junos-sophos-av-defaults` in your UTM policy. See [“Example: Configuring Sophos Antivirus UTM Policies”](#) on page 6030.

1. Select and configure the engine type. Because you are configuring Sophos antivirus, you configure `sophos-engine`.

[edit]

```
user@host# set security utm feature-profile anti-virus type sophos-engine
```

2. Commit the configuration, and restart the device. After the device restarts, enter configuration mode again.
3. Select a time interval for updating the data files. The default antivirus pattern-update interval is 1440 minutes (every 24 hours). You can choose to leave this default, or you can change it. You can also force a manual update, if needed. To change the default from every 24 hours to every 48 hours:

[edit security utm feature-profile anti-virus]

```
user@host# set sophos-engine pattern-update interval 2880
```

4. Configure the network device with the proxy server details, to download the pattern update from a remote server:

```
[edit security utm feature-profile anti-virus]
user@host# set sophos-engine pattern-update proxy
```

5. In most circumstances, you will not need to change the URL to update the pattern database. If you do need to change this option, use the following command:

```
[edit security utm feature-profile anti-virus]
user@host# set sophos-engine pattern-update url
http://www.example.net/test-download
```

6. You can configure the device to notify a specified administrator when data files are updated. This is an e-mail notification with a custom message and a custom subject line.

```
[edit security utm feature-profile anti-virus]
user@host# set sophos-engine pattern-update email-notify admin-email
admin@example.net custom-message "Sophos antivirus data file was updated"
custom-message-subject "AV data file updated"
```

7. Configure a list of fallback options as block, log and permit, or permit. The default setting is log-and-permit. You can use the default settings, or you can change them.

Configure the content size action. In this example, if the content size is exceeded, the action taken is block.

First create the profile named sophos-profl.

```
[edit security utm feature-profile anti-virus]
user@host# edit sophos-engine profile sophos-profl
```

Configure the content size fallback-option to block.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set fallback-options content-size block
```

Configure the default fallback option to log-and-permit.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set fallback-options default log-and-permit
```

Configure log-and-permit if the antivirus engine is not ready.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set fallback-options engine-not-ready log-and-permit
```

Configure log-and-permit if the device is out of resources.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set fallback-options out-of-resources log-and-permit
```

Configure log-and-permit if a virus scan timeout occurs.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set fallback-options timeout log-and-permit
```

Configure log-and-permit if there are too many requests for the virus engine to handle.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
```

```
user@host# set fallback-options too-many-requests log-and-permit
```

8. Configure notification options. You can configure notifications for fallback blocking, fallback nonblocking actions, and virus detection.

In this step, configure a custom message for the fallback blocking action and send a notification for protocol-only actions to the administrator and the sender.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set notification-options fallback-block custom-message ***Fallback
block action occurred*** custom-message-subject Antivirus Fallback Alert
notify-mail-sender type protocol-only allow email administrator-email
admin@example.net
```

9. Configure a notification for protocol-only virus detection, and send a notification.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set notification-options virus-detection type protocol-only
notify-mail-sender custom-message-subject ***Virus detected***
custom-message Virus has been detected
```

10. Configure content size parameters.

**NOTE:** When you configure the content-size value, keep in mind that in certain cases, content size is available in the protocol headers, so the max-content-size fallback is applied before a scan request is sent. However, in many cases, content size is not provided in the protocol headers. In these cases, the TCP payload is sent to the antivirus scanner and accumulates until the end of the payload. If the accumulated payload exceeds the maximum content size value, then max-content-size fallback is applied. The default fallback action is log and permit, so you may want to change this option to block, in which case such a packet is dropped and a block message is sent to the client.

In this example, if the content size exceeds 20 MB, the packet is dropped.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set scan-options content-size-limit 20000
```

11. URI checking is on by default. To turn off URI checking:

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set scan-options no-uri-check
```

12. Configure the timeout setting for the scanning operation to 1800 seconds.

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set scan-options timeout 1800
```

13. The Sophos Extensible List servers contain the virus and malware database for scanning operations. Set the response timeout for these servers to 3 seconds (the default is 2 seconds).

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-profl]
user@host# set scan-options sxl-timeout 3
```

14. Configure the Sophos Extensible List server retry option to 2 retries (the default is 1).  

```
[edit security utm feature-profile anti-virus sophos-engine profile sophos-prof1]
user@host# set scan-options sxl-retry 2
```
15. Configure the trickling setting to 180 seconds. If you use trickling, you can also set timeout parameters. Trickling applies only to HTTP. HTTP trickling is a mechanism used to prevent the HTTP client or server from timing out during a file transfer or during antivirus scanning.

**WARNING:** When you enable the trickling option, keep in mind that trickling might send part of a file to the client during its antivirus scan. It is therefore possible that some of the content could be received by the client before the file has been fully scanned.

```
[edit security utm feature-profile anti-virus]
user@host# set sophos-engine profile sophos-prof1 trickling timeout 180
```

16. Configure the antivirus module to use MIME bypass lists and exception lists. You can use your own custom object lists, or you can use the default list that ships with the device called junos-default-bypass-mime. In this example, you use the lists that you set up earlier.  

```
[edit security utm feature-profile anti-virus]
user@host# set mime-whitelist list avmime2
[edit security utm feature-profile anti-virus]
user@host# set mime-whitelist list exception-avmime2
```
17. Configure the antivirus module to use URL bypass lists. If you are using a URL whitelist, this is a custom URL category you have previously configured as a custom object. URL whitelists are valid only for HTTP traffic. In this example you use the lists that you set up earlier.  

```
[edit security utm feature-profile anti-virus]
user@host# set url-whitelist custurl2
```

## Verification

To verify your feature profile configuration, run the **show security utm feature-profile anti-virus** command.

### Obtaining Information About the Current Antivirus Status

**Action** From operational mode, enter the **show security utm anti-virus status** command to view the antivirus status.

```
user@host>show security utm anti-virus status
```

**Meaning**

- Antivirus key expire date—The license key expiration date.
- Update server—URL for the data file update server.

- Interval—The time period, in minutes, when the device will update the data file from the update server.
- Pattern update status—When the data file will be updated next, displayed in minutes.
- Last result—Result of the last update. If you already have the latest version, this will display **already have latest database**.
- Antivirus signature version—Version of the current data file.
- Scan engine type—The antivirus engine type that is currently running.
- Scan engine information—Result of the last action that occurred with the current scan engine.

---

## Example: Configuring Sophos Antivirus UTM Policies

This example shows how to create a UTM policy for Sophos antivirus.

- [Requirements on page 6030](#)
- [Overview on page 6030](#)
- [Configuration on page 6031](#)
- [Verification on page 6031](#)

### Requirements

Before you create the UTM policy, create custom objects and the Sophos feature profile.

1. Configure UTM custom objects and MIME lists. See [“Example: Configuring Sophos Antivirus Custom Objects” on page 6020](#).
2. Configure the Sophos antivirus feature profile. See [“Example: Configuring Sophos Antivirus Feature Profile” on page 6024](#).

### Overview

After you have created an antivirus feature profile, you configure a UTM policy for an antivirus scanning protocol and attach this policy to a feature profile. In this example, HTTP will be scanned for viruses, as indicated by the **http-profile** statement. You can scan other protocols as well by creating different profiles or adding other protocols to the profile, such as: imap-profile, pop3-profile, and smtp-profile.

## Configuration

### GUI Step-by-Step Procedure

To configure a UTM policy for Sophos antivirus:

1. Click the **Configure** tab from the taskbar, and then select **Security>Policy>UTM Policies**. Then click **Add**.
2. Click the **Main** tab. In the Policy name box, type **utmp3**.
3. Click the **Anti-Virus profiles** tab. In the HTTP profile list, select **sophos-profl**.
4. Click **OK** to check your configuration and save it as a candidate configuration.
5. If you are done configuring the device, select **Actions>Commit**.

### Step-by-Step Procedure

To configure a UTM policy for Sophos antivirus:

1. Go to the edit security utm hierarchy.  

```
[edit]
user@host# edit security utm
```
2. Create the UTM policy utmp3 and attach it to the http-profile sophos-profl.  

```
[edit security utm]
user@host# set utm-policy utmp3 anti-virus http-profile sophos-profl
```

**NOTE:** You can use the default Sophos feature profile settings by replacing **sophos-profl** in the above statement with **junos-sophos-av-defaults**.

## Verification

To verify the configuration, enter the **show security utm utm-policy utmp3** command.

### Related Documentation

- [Example: Configuring Sophos Antivirus Feature Profile on page 6024](#)

## Example: Configuring Sophos Antivirus Firewall Security Policies

This example shows how to create a security policy for Sophos antivirus.

- [Requirements on page 6032](#)
- [Overview on page 6032](#)
- [Configuration on page 6032](#)
- [Verification on page 6033](#)

## Requirements

Before you create the security policy, create custom objects, the Sophos feature profile, and the UTM policy.

1. Configure UTM custom objects and MIME lists. See [“Example: Configuring Sophos Antivirus Custom Objects” on page 6020](#).
2. Configure the Sophos antivirus feature profile. See [“Example: Configuring Sophos Antivirus Feature Profile” on page 6024](#).
3. Configure a UTM policy. See [“Example: Configuring Sophos Antivirus UTM Policies” on page 6030](#).

## Overview

Create a firewall security policy that will cause traffic from the untrust zone to the trust zone to be scanned by Sophos antivirus using the feature profile settings defined in [“Example: Configuring Sophos Antivirus Feature Profile” on page 6024](#). Because the match application configuration is set to any, all application types will be scanned.

## Configuration

### GUI Step-by-Step Procedure

To configure a security policy for Sophos antivirus:

1. Configure the untrust to trust policy to match any source address or destination address, and select the applications to be scanned to **any**.
  - a. Click the **Configure** tab from the taskbar, and then select **Security>Policy>FW Policies**. Then select **Add**.
  - b. In the Policy Name box, type **p3**.
  - c. In the Policy Action box, select **permit**.
  - d. In the From Zone list, select **untrust**.
  - e. In the To Zone list, select **trust**.
  - f. In the Source Address and Destination Address boxes, make sure that Matched is set to **any**.
  - g. In the Applications boxes, select **any** from the Application/Sets list, and move it to the Matched list.
2. Attach the UTM policy named utmp3 to the firewall security policy. This will cause matched traffic to be scanned by the Sophos antivirus feature.
  - a. From the Edit Policy box, click the **Application Services** tab.
  - b. In the UTM Policy list, select **utmp3**.
3. Click **OK** to check your configuration and save it as a candidate configuration.
4. If you are done configuring the device, select **Actions>Commit**.

**Step-by-Step Procedure**

To configure a security policy for Sophos antivirus:

1. Configure the untrust to trust policy to match any source-address.  

```
[edit security]
user@host# set policies from-zone untrust to-zone trust policy p3 match
source-address any
```
2. Configure the untrust to trust policy to match any destination-address.  

```
[edit security]
user@host# set policies from-zone untrust to-zone trust policy p3 match
destination-address any
```
3. Configure the untrust to trust policy to match any application type.  

```
[edit security]
user@host# set policies from-zone untrust to-zone trust policy p3 match application
any
```
4. Attach the UTM policy named utmp3 to the firewall security policy. This will cause matched traffic to be scanned by the Sophos antivirus feature.  

```
[edit security]
user@host# set policies from-zone untrust to-zone trust policy p3 then permit
application-services utm-policy utmp3
```

**Verification**

To verify the configuration, enter the **show security policies** command.

**Related Documentation**

- [Sophos Antivirus Protection Overview on page 6017](#)
- [Sophos Antivirus Configuration Overview on page 6020](#)
- [Example: Configuring Sophos Antivirus Feature Profile on page 6024](#)

**Managing Sophos Antivirus Data Files**

Before you begin:

- Install a Sophos antivirus license. See the *Installation and Upgrade Guide for Security Devices*.
- Configure Sophos as the antivirus feature for the device. See “[Example: Configuring Sophos Antivirus Feature Profile](#)” on [page 6024](#). To set the antivirus engine type, you run the **set security utm feature-profile anti-virus type sophos-engine** statement.

In this example, you configure the security device to update the data files automatically every 4320 minutes (every 3 days). The default data file update interval is 1440 minutes (every 24 hours).

To automatically update Sophos data files:

```
[edit security utm feature-profile anti-virus]
user@host# set sophos-engine pattern-update interval 4320
```

**NOTE:** The following commands are performed from CLI operational mode.

To manually update data files:

```
user@host> request security utm anti-virus sophos-engine pattern-update
```

To manually reload data files:

```
user@host> request security utm anti-virus sophos-engine pattern-reload
```

To manually delete data files:

```
user@host> request security utm anti-virus sophos-engine pattern-delete
```

To check the status of antivirus, which also shows the data files version:

```
user@host> show security utm anti-virus status
```

To check the status of the proxy server:

```
user@host> show security utm anti-virus status
```

## Content Filtering Overview

---

Content filtering blocks or permits certain types of traffic based on the MIME type, file extension, and protocol command. The content filter controls file transfers across the gateway by checking traffic against configured filter lists.

The content filter module evaluates traffic before all other UTM modules, except Web Filtering. Therefore, if traffic meets criteria configured in the content-filter, the content-filter acts first upon this traffic.

You can configure the following types of content filters:

- **MIME Pattern Filter** — MIME patterns are used to identify the type of traffic in HTTP and MAIL protocols. There are two lists of MIME patterns that are used by the content filter to determine the action to be taken. The block MIME list contains a list of MIME type traffic that is to be blocked by the content filter. The MIME exception list contains MIME patterns that are not to be blocked by the content filter and are generally subsets of items on the block list. Note that the exception list has a higher priority than the block list. If you have MIME entries that appear on both lists, those MIME types are not blocked by the content filter because the exception list takes priority. Therefore, when adding items to the exception list, it is to your advantage to be specific.
- **Block Extension List** — Because the name of a file is available during file transfers, using file extensions is a highly practical way to block or allow file transfers. The content filter list contains a list of file extensions to be blocked. All protocols support the use of the block extension list.

- Protocol Command Block and Permit Lists — Different protocols use different commands to communicate between servers and clients. By blocking or allowing certain commands, traffic can be controlled on the protocol command level.

The block and permit command lists are intended to be used in combination, with the permit list acting as an exception list to the block list.

**NOTE:** If a protocol command appears on both the permit list and the block list, that command is permitted.

Because not all harmful files or components can be controlled by the MIME type or by the file extension, you can also use the content filter module to block ActiveX, Java Applets, and other types of content. The following types of content blocking are supported only for HTTP:

- Block ActiveX
- Block Java applets
- Block cookies
- Block EXE files
- Block ZIP files

---

## Understanding Content Filtering Protocol Support

---

Each supported protocol may implement available content filters differently. Not all filtering capabilities are supported for each protocol.

This topic contains the following sections:

- [HTTP Support on page 6038](#)
- [FTP Support on page 6039](#)
- [E-Mail Support on page 6039](#)

### HTTP Support

The HTTP protocol supports all content filtering features. With HTTP, the content filter remains in the gateway, checking every request and response between the HTTP client and server.

If an HTTP request is dropped due to content filtering, the client receives a response such as:

```
<custom drop message/user-configured drop
message>.<src_port><dst_ip>:<dst_port>Download request was dropped due to
<reason>
```

Therefore, a message may appear as follows:

```
Juniper Networks Firewall Content Filtering blocked request. 5.5.5.1:80->4.4.4.1:55247
Download request was dropped due to file extension block list
```

## FTP Support

The FTP protocol does not support all content filtering features. It supports only the following: Block Extension List and Protocol Command Block List.

When content filtering blocks an FTP request, the following response is sent through the control channel:

```
550 <src_ip>:<src_port>-<dst_ip>:<dst_port><custom drop message/user-configured
drop message> for Content Filtering file extension block list.>
```

Therefore, a message may appear as follows:

```
550 5.5.5.1:21->4.4.4.1:45237 Requested action not taken and the request is dropped for
Content Filtering file extension block list
```

## E-Mail Support

E-mail protocols (SMTP, IMAP, POP3) have limited content filtering support for the following features: Block Extension List, Protocol Command Block List, and MIME Pattern Filtering. Support is limited for e-mail protocols for the following reasons:

- The content filter scans only one level of an e-mail header. Therefore recursive e-mail headers and encrypted attachments are not scanned.
- If an entire e-mail is MIME encoded, the content filter can only scan for the MIME type.
- If any part of an e-mail is blocked due to content filtering, the original e-mail is dropped and replaced by a text file with an explanation for why the e-mail was blocked.

## Specifying Content Filtering Protocols (CLI Procedure)

To configure content filtering protocols, use the following CLI configuration statements:

```
content-filtering {
 profile name {
 permit-command cmd-list
```

```
 block-command cmd-list
 block-extension file-ext-list
 block-mime {
 list mime-list
 exception ex-mime-list
 }
 block-content-type {
 activex
 java-applet
 exe
 zip
 http-cookie
 }
 notification-options {
 type { message }
 notify-mail-sender
 custom-message msg
 }
}
traceoptions {
 flag {
 all
 basic
 detail
 }
}
}
```

---

## Content Filtering Configuration Overview

A content security filter blocks or allows certain type of traffic base on the mime type, file extension, protocol commands and embedded object type. The content filter controls file transfers across the gateway by checking traffic against configured filter lists. The content filtering module evaluates traffic before all other UTM modules, if traffic meets the criteria configured in the content filter, the content filter acts first upon this traffic. The following procedure lists the recommended order in which you should configure content filters:

1. Configure UTM custom objects for the feature. See [“Example: Configuring Content Filtering Custom Objects” on page 6041](#).
2. Configure the main feature parameters using feature profiles. See [“Example: Configuring Content Filtering Feature Profiles” on page 6043](#).
3. Configure a UTM policy for each protocol and attach this policy to a profile. See [“Example: Configuring Content Filtering UTM Policies” on page 6047](#).

4. Attach the UTM policy to a security policy. See [“Example: Attaching Content Filtering UTM Policies to Security Policies”](#) on page 6048.

**Related  
Documentation**

- [Unified Threat Management Overview](#) on page 5879

## Example: Configuring Content Filtering Custom Objects

This example shows how to configure content filtering custom objects.

- [Requirements](#) on page 6041
- [Overview](#) on page 6041
- [Configuration](#) on page 6041
- [Verification](#) on page 6043

### Requirements

Before you begin:

1. Decide on the type of content filter you require. See [“Content Filtering Overview”](#) on page 6037.
2. Understand the order in which content filtering parameters are configured. See [“Content Filtering Configuration Overview”](#) on page 6040.

### Overview

In this example, you define custom objects that are used to create content filtering profiles. You perform the following tasks to define custom objects:

1. Create two protocol command lists called `ftpprotocol1` and `ftpprotocol2`, and add `user`, `pass`, `port`, and `type` commands to it.
2. Create a filename extension list called `extlist2`, and add the `.zip`, `.js`, and `.vbs` extensions to it.
3. Define block-mime list call `cfmime1` and add patterns to the list.

### Configuration

**CLI Quick  
Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm custom-objects protocol-command ftpprotocol1 value [user pass port type]
set security utm custom-objects protocol-command ftpprotocol2 value [user pass port type]
set security utm custom-objects filename-extension extlist2 value [zip js vbs]
set security utm custom-objects mime-pattern cfmime1 value [video/quicktime image/x-portable-anymap x-world/x-vmrml]
```

```
set security utm custom-objects mime-pattern ex-cfmime1 value
[video/quicktime-inappropriate]
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure content filtering custom objects:

1. Create two protocol command lists.

```
[edit security utm]
user@host# set custom-objects protocol-command ftpprotocom1
[edit security utm]
user@host# set custom-objects protocol-command ftpprotocom2
```

2. Add protocol commands to the list.

```
[edit security utm]
user@host# set custom-objects protocol-command ftpprotocom1 value [user pass
port type]
[edit security utm]
user@host# set custom-objects protocol-command ftpprotocom2 value [user pass
port type]
```

3. Create a filename extension list.

```
[edit security utm]
user@host# set custom-objects filename-extension extlist2
```

4. Add extensions to the list.

```
[edit security utm]
user@host# set custom-objects filename-extension extlist2 value [zip js vbs]
```

5. Create antivirus scanning lists.

```
[edit security utm]
user@host# set custom-objects mime-pattern cfmime1
user@host# set custom-objects mime-pattern ex-cfmime1
```

6. Add patterns to the lists.

```
[edit security utm]
user@host# set custom-objects mime-pattern cfmime1 value [video/quicktime
image/x-portable-anymap x-world/x-vrml]
user@host# set custom-objects mime-pattern ex-cfmime1 value
[video/quicktime-inappropriate]
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
userhost#show security utm
custom-objects {
 mime-pattern {
 cfmime1 {
 value [video/quicktime image/x-portable-anymap x-world/x-vrml];
```

```

 }
 ex-cfmime1 {
 value video/quicktime-inappropriate;
 }
}
filename-extension {
 extlist2 {
 value [zip js vbs];
 }
}
protocol-command {
 ftpprotocom1 {
 value [user pass port type];
 }
}
protocol-command {
 ftpprotocom2 {
 value [user pass port type];
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Content Filtering Custom Objects on page 6043](#)

### Verifying Content Filtering Custom Objects

<b>Purpose</b>	Verify the content filtering custom objects.
<b>Action</b>	From operational mode, enter the <b>show configuration security utm</b> command.
<b>Related Documentation</b>	<ul style="list-style-type: none"> <li>• <a href="#">Unified Threat Management Overview on page 5879</a></li> <li>• <a href="#">Content Filtering Overview on page 6037</a></li> <li>• <a href="#">Content Filtering Configuration Overview on page 6040</a></li> <li>• <a href="#">Example: Configuring Content Filtering Feature Profiles on page 6043</a></li> <li>• <a href="#">Example: Configuring Content Filtering UTM Policies on page 6047</a></li> <li>• <a href="#">Example: Attaching Content Filtering UTM Policies to Security Policies on page 6048</a></li> </ul>

## Example: Configuring Content Filtering Feature Profiles

This example describes how to configure the content filtering feature profiles.

- [Requirements on page 6044](#)
- [Overview on page 6044](#)

- [Configuration on page 6044](#)
- [Verification on page 6046](#)

## Requirements

Before you begin:

1. Decide on the type of content filter you require. See “[Content Filtering Overview](#)” on [page 6037](#).
2. Create custom objects. See “[Content Filtering Configuration Overview](#)” on [page 6040](#).

## Overview

In this example, you configure a feature profile called `confilter1` and specify the following custom objects to be used for filtering content:

1. Apply the `ftpprotocom1` protocol command list custom object to `confilter1`.
2. Apply blocks to Java applets, executable files, and HTTP cookies.
3. Apply the extension list `extlist2` custom object to `confilter1` for blocking extensions.
4. Apply the MIME pattern list custom objects `cfmime1` and `ex-cfmime1` to the `confilter1` for blocking MIME types.
5. Apply the protocol permit command custom object `ftpprotocom2` to `confilter1`. (The permit protocol command list acts as an exception list for the block protocol command list.)

**NOTE:** Protocol command lists, both permit and block, are created by using the same custom object.

6. Configure a custom message to send a notification.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile content-filtering profile confilter1
set security utm feature-profile content-filtering profile confilter1 block-command
 ftpprotocom1
set security utm feature-profile content-filtering profile confilter1 block-content-type
 java-applet exe http-cookie
set security utm feature-profile content-filtering profile confilter1 block-extension extlist2
set security utm feature-profile content-filtering profile confilter1 block-mime list cfmime1
 exception ex-cfmime1
set security utm feature-profile content-filtering profile confilter1 permit-command
 ftpprotocom2
```

```
set security utm feature-profile content-filtering profile confilter1 notification-options
custom-message "the action is not taken" notify-mail-sender type message
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a content filtering feature profiles:

1. Create a content filtering profile.

```
[edit security utm]
user@host# set feature-profile content-filtering profile confilter1
```

2. Apply a protocol command list custom object to the profile.

```
[edit security utm]
user@host# set feature-profile content-filtering profile confilter1 block-command
ftpprotocol1
```

3. Apply blocks to available content.

```
[edit security utm]
user@host# set feature-profile content-filtering profile confilter1 block-content-type
java-applet exe http-cookie
```

4. Apply an extension list custom object to the profile.

```
[edit security utm]
user@host# set feature-profile content-filtering profile confilter1 block-extension
extlist2
```

5. Apply pattern list custom objects to the profile.

```
[edit security utm]
user@host# set feature-profile content-filtering profile confilter1 block-mime list
cfmime1 exception ex-cfmime1
```

6. Apply the protocol permit command custom object to the profile.

```
[edit security utm]
user@host# set feature-profile content-filtering profile confilter1 permit-command
ftpprotocol2
```

7. Configure the notification options.

```
[edit security utm]
user@host# set feature-profile content-filtering profile confilter1m
notification-options custom-message "the action is not taken" notify-mail-sender
type message
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security utm
feature-profile {
 content-filtering {
 profile contentfilter1;
```

```
profile confilter1 {
 permit-command ftpprotocom2;
 block-command ftpprotocom1;
 block-extension extlist2;
 block-mime {
 list cfmime1;
 exception ex-cfmime1;
 }
 block-content-type {
 java-applet;
 exe;
 http-cookie;
 }
 notification-options {
 type message;
 notify-mail-sender;
 custom-message " the action is not taken";
 }
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying the Configuration of Content Filtering Feature Profile on page 6046](#)

---

### Verifying the Configuration of Content Filtering Feature Profile

<b>Purpose</b>	Verify the content filtering feature profile.
<b>Action</b>	From operational mode, enter the <b>show configuration security utm</b> command.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">Unified Threat Management Overview on page 5879</a></li><li>• <a href="#">Content Filtering Overview on page 6037</a></li><li>• <a href="#">Content Filtering Configuration Overview on page 6040</a></li><li>• <a href="#">Example: Configuring Content Filtering Custom Objects on page 6041</a></li><li>• <a href="#">Example: Configuring Content Filtering UTM Policies on page 6047</a></li><li>• <a href="#">Example: Attaching Content Filtering UTM Policies to Security Policies on page 6048</a></li></ul>

## Example: Configuring Content Filtering UTM Policies

This example describes how to create a content filtering UTM policy to attach to your feature profile.

- [Requirements on page 6047](#)
- [Overview on page 6047](#)
- [Configuration on page 6047](#)
- [Verification on page 6048](#)

### Requirements

Before you begin:

1. Decide on the type of content filter you require. See [“Content Filtering Overview” on page 6037](#).
2. Configure UTM custom objects for each feature and define the content-filtering profile. See [“Content Filtering Configuration Overview” on page 6040](#).

### Overview

You configure UTM policies to selectively enforce various UTM solutions on network traffic passing through a UTM-enabled device. Through feature profiles you associate custom objects to these policies and specify blocking or permitting certain types of traffic.

In this example, you configure a UTM policy called `utmp4`, and then assign the preconfigured feature profile `confilter1` to this policy.

### Configuration

#### Step-by-Step Procedure

To configure a content filtering UTM policy:

You can configure different protocol applications in the UTM policy. The example only shows HTTP and not other protocols. Earlier you configured custom objects for FTP (`ftpprotocol1` and `ftpprotocol2`). Next you should add a content filter policy for FTP, for example:

```
set security utm utm-policy utmp4 content-filtering ftp upload-profile confilter1
```

```
set security utm utm-policy utmp4 content-filtering ftp download-profile confilter1
```

1. Create a UTM policy.

```
[edit security utm]
user@host# set utm-policy utmp4
```

2. Attach the UTM policy to the profile.

```
[edit security utm]
user@host# set utm-policy utmp4 content-filtering http-profile contentfilter1
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security utm** command.

### Related Documentation

- [Unified Threat Management Overview on page 5879](#)
- [Content Filtering Overview on page 6037](#)
- [Content Filtering Configuration Overview on page 6040](#)
- [Example: Configuring Content Filtering Custom Objects on page 6041](#)
- [Example: Configuring Content Filtering Feature Profiles on page 6043](#)
- [Example: Attaching Content Filtering UTM Policies to Security Policies on page 6048](#)

---

## Example: Attaching Content Filtering UTM Policies to Security Policies

This example shows how to create a security policy and attach the UTM policy to the security policy.

- [Requirements on page 6048](#)
- [Overview on page 6048](#)
- [Configuration on page 6048](#)
- [Verification on page 6050](#)

## Requirements

Before you begin:

1. Configure UTM custom objects, define the content filtering profile, and create a UTM policy. See "[Content Filtering Configuration Overview](#)" on page 6040.
2. Enable and configure a security policy. See "[Example: Configuring a Security Policy to Permit or Deny All Traffic](#)" on page 1074.

## Overview

By attaching content filtering UTM policies to security policies, you can filter traffic transiting from one security zone to another.

In this example, you create a security policy called p4 and specify that traffic from any source address to any destination address with an HTTP application matches the criteria. You then assign a UTM policy called utmp4 to the security policy p4. This UTM policy applies to any traffic that matches the criteria specified in the security policy p4.

## Configuration

### CLI Quick Configuration

To quickly attach a content filtering UTM policy to a security policy, copy the following commands and paste them into the CLI.

```
[edit]
set security policies from-zone trust to-zone untrust policy p4 match source-address any
set security policies from-zone trust to-zone untrust policy p4 match destination-address
 any
set security policies from-zone trust to-zone untrust policy p4 match application
 junos-http
set security from-zone trust to-zone untrust policy p4 then permit application-services
 utm-policy utmp4
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To attach a UTM policy to a security policy:

1. Create a security policy.

```
[edit]
user@host# edit security policies from-zone trust to-zone untrust policy p4
```

2. Specify the match conditions for the policy.

```
[edit security policies from-zone trust to-zone untrust policy p4]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application junos-http
```

3. Attach the UTM policy to the security policy.

```
[edit security policies from-zone trust to-zone untrust policy p4]
user@host# set then permit application-services utm-policy utmp4
```

**Results** From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security policies
from-zone trust to-zone untrust {
 policy p4 {
 match {
 source-address any;
 destination-address any;
 application junos-http;
 }
 then {
 permit {
 application-services {
 utm-policy utmp4;
 }
 }
 }
 }
}
default-policy {
 permit-all;
```

```
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying Attaching Content Filtering UTM Policies to Security Policies on page 6050](#)

---

### Verifying Attaching Content Filtering UTM Policies to Security Policies

**Purpose** Verify the attachment of the content filtering UTM policy to the security policy.

**Action** From operational mode, enter the **show security policy** command.

**Related Documentation**

- [Unified Threat Management Overview on page 5879](#)
- [Content Filtering Overview on page 6037](#)
- [Content Filtering Configuration Overview on page 6040](#)

---

## Monitoring Content Filtering Configurations

**Purpose** View content filtering statistics.

**Action** To view content filtering statistics in the CLI, enter the **user@host > show security utm content-filtering statistics** command.

The content filtering **show statistics** command displays the following information:

```
Base on command list: # Blocked
Base on mime list: # Blocked
Base on extension list: # Blocked
ActiveX plugin: # Blocked
Java applet: # Blocked
EXE files: # Blocked
ZIP files: # Blocked
HTTP cookie: # Blocked
```

To view content filtering statistics using J-Web:

1. Select **Clear Content filtering statisticsMonitor>Security>UTM>Content FilteringMonitor>Security>UTM>Content Filtering**.

The following statistics become viewable in the right pane.

```
Base on command list: # Passed # Blocked
Base on mime list: # Passed # Blocked
Base on extension list: # Passed # Blocked
```

ActiveX plugin: # Passed # Blocked  
Java applet: # Passed # Blocked  
EXE files: # Passed # Blocked  
ZIP files: # Passed # Blocked  
HTTP cookie: # Passed # Blocked

2. You can click **Clear Content filtering statistics** to clear all current viewable statistics and begin collecting new statistics.

## Web Filtering Overview

Web filtering lets you manage Internet usage by preventing access to inappropriate Web content. There are four types of Web filtering solutions:

- **Integrated Web filtering**—The integrated Web filtering solution intercepts every HTTP request in a TCP connection. In this case, the decision making is done on the device after it identifies the category for a URL either from user-defined categories or from a category server (SurfControl Content Portal Authority provided by Websense).

**NOTE:** The integrated Web filtering feature is a separately licensed subscription service. When the license key for Web filtering has expired, no URLs are sent to the category server for checking, only local user-defined categories are checked.

**NOTE:** Integrated Web filtering solution is supported only on branch SRX Series devices.

- **Redirect Web filtering**—The redirect Web filtering solution intercepts HTTP requests and sends them to an external URL filtering server, provided by Websense, to determine whether to block the requests.

**NOTE:** Redirect Web filtering does not require a license.

- **Local Web filtering**—The local Web filtering solution intercepts every HTTP request in a TCP connection. In this case, the decision making is done on the device after it looks up a URL to determine if it is in the whitelist or blacklist based on its user-defined category.

**NOTE:** Local Web filtering does not require a license or a remote category server.

- **Enhanced Web filtering**—The enhanced Web filtering solution intercepts the HTTP and the HTTPS requests and sends the HTTP URL or the HTTPS source IP to the Websense ThreatSeeker Cloud (TSC). The TSC categorizes the URL into one of the 151 or more categories that are predefined and also provides site reputation information. The TSC further returns the URL category and the site reputation information to the device. The device determines if it can permit or block the request based on the information provided by the TSC.

You can bind either Web filtering profiles or antivirus profiles, or both, to a firewall policy. When both are bound to a firewall policy, Web filtering is applied first, then antivirus is applied. If a URL is blocked by Web filtering, the TCP connection is closed and no antivirus

scanning is necessary. If a URL is permitted, the content of the transaction is then passed to the antivirus scanning process.

**NOTE:** Web filtering is applied by TCP port number.

UTM Web filtering supports HTTPS protocol. UTM Web filtering solution uses the IP address of the HTTPS packet to make blacklist, whitelist, permit, or block decisions.

During a block decision, the UTM Web filtering solution does not generate a block page because the clear text is not available for a HTTPS session. However, the solution terminates the session and sends resets to the client and the server for the blocked HTTPS sessions.

UTM Web filtering configuration for HTTP is also applicable for the HTTPS sessions.

**NOTE:** The `sessions-per-client limit` CLI command, which imposes a session throttle to prevent a malicious user from generating large amounts of traffic simultaneously, does not support Web filtering.

## Enhanced Web Filtering Overview

Enhanced Web Filtering (EWF) with Websense is an integrated URL filtering solution. When you enable the solution on the device, it intercepts the HTTP and the HTTPS requests and sends the HTTP URL or the HTTPS source IP to the Websense ThreatSeeker Cloud (TSC). The TSC categorizes the URL into one of the 95 or more categories that are predefined and also provides site reputation information. The TSC further returns the URL category and the site reputation information to the device. The device determines if it can permit or block the request based on the information provided by the TSC.

You can consider the EWF solution as the next-generation URL filtering solution, building upon the existing SurfControl solution.

Enhanced Web Filtering supports the following HTTP methods:

- GET
- POST

- OPTIONS
- HEAD
- PUT
- DELETE
- TRACE
- CONNECT

## Understanding Enhanced Web Filtering Process

---

Web filtering enables you to manage Internet access and prevent access to inappropriate Web content. This topic describes how the Enhanced Web filtering feature intercepts, scans, and acts upon HTTP or HTTPS traffic.

1. The device creates TCP socket connections to the Threat Seeker Cloud(TSC).
2. The device intercepts an HTTP or an HTTPS connection and extracts each URL( in the HTTP request) or IP (in the HTTPS request). For HTTPS connection, EWF is supported through SSL forward proxy (SSL-FP).
3. The device looks for the URL in the user-configured blacklist or whitelist.

**NOTE:** A blacklist or a whitelist action type is a user-defined category in which all the URLs or IP addresses are always blocked or permitted and optionally logged.

- If the URL is in the user-configured blacklist, the device blocks the URL.
  - If the URL is in the user-configured whitelist, the device permits the URL.
4. The device checks the user-defined categories and blocks or permits the URL based on the user-specified action for the category.
  5. The device looks for the URL in the URL filtering cache.
    - If the URL is not available in the URL filtering cache, the device sends the URL in HTTP format to the TSC with a request for categorization. The device uses one of the connections made available to the TSC to send the request.

- The TSC responds to the device with the categorization and a reputation score.
6. The device performs the following actions based on the identified category:
- If the URL is permitted, the device forwards the HTTP request to the HTTP server.
  - If the URL is blocked, the device sends a deny page to the HTTP client and also sends a reset message to the HTTP server to close the connection
  - If the URL is quarantined, the device sends a redirect response to the HTTP client and the URL is redirected to the HTTP server.
  - If the category is not available, the device permits or blocks the URL based on the configured action for the reputation score.
  - If an action for the site reputation score is not configured, the device permits or blocks the URL based on the default action configured in the Web filtering profile.

## Functional Requirements for Enhanced Web Filtering

- **License key**—The enhanced Web filtering solution builds upon the SurfControl integrated feature on the device. Two different valid license keys are required for the Surf Control integrated solution and for enhanced Web filtering. You need to install a new license to upgrade to the enhanced Web filtering solution.

**NOTE:** You can ignore the warning message "requires 'wf\_key\_websense\_ewf' license" because it is generated by routine EWF license validation check.

A grace period of 30 days, consistent with other UTM features, is provided for the Enhanced Web filtering feature after the license key expires.

**NOTE:** The device will continue to support the SurfControl integrated solution after the upgrade.

When the grace period for the Enhanced Web filtering feature has passed (or if the feature has not been installed), Web filtering is disabled, all HTTP requests bypass Web filtering, and any connections to the TSC are disabled. When you install a valid license, the connections to the server are established again.

- A **debug** command provides the following information to each TCP connection available on the device:
  - Number of processed requests
  - Number of pending requests
  - Number of errors (dropped or timed-out requests)
- **TCP connection between a Web client and a Web server**—An App-ID module is used to identify an HTTP connection. The enhanced Web filtering solution identifies an HTTP connection after the device receives the first SYN packet. If an HTTP request has to

be blocked, enhanced Web filtering sends a block message from the device to the Web client. Enhanced Web filtering further sends a TCP FIN request to the client and a TCP reset (RST) to the server to disable the connection. The device sends all the messages through the flow session. The messages follow the entire service chain.

- **HTTP request interception**—Enhanced Web filtering intercepts the first HTTP request on the device and performs URL filtering on all methods defined in HTTP 1.0 and HTTP 1.1. The device holds the original request while waiting for a response from the TSC. If the first packet in the HTTP URL is fragmented or if the device cannot extract the URL for some reason, then the destination IP address is used for the categorization.

**NOTE:** For HTTP 1.1 persistent connections, the subsequent requests on that session are ignored by the enhanced Web filtering module.

If the device holds the original request for a long time, then the client will retransmit the request. The URL filtering code will detect the retransmitted packets. If the original HTTP request has already been forwarded, then enhanced Web filtering forwards the retransmitted packet to the server. However, if enhanced Web filtering is in the middle of first-packet processing or makes the calculation to block the session, then the solution drops the retransmitted packet. A counter tracks the number of retransmitted packets received by the device.

If the TSC does not respond in time to the categorization request from the device, then the original client request is blocked or permitted as per the timeout fallback setting.

Enhanced Web filtering and Redirect Web filtering supports HTTPS requests through SSL forward proxy (SSL-FP); however, the destination IP is used for Web filtering instead of actual plain text URLs. You cannot decrypt HTTPS requests to obtain the URL; however, you can extract the source IP from the IP header. This IP is passed to the TSC and a category corresponding to the TSC is returned if possible.

- **Blocking message**—The blocking message sent to the WebClient is user-configurable and is of the following types:
  - The Juniper Networks blocking message is the default message defined in the device that can be modified by the user. The default blocking message contains the reason why the request is blocked and the category name (if it is blocked because of a category).
  - Syslog message.

For example, if you have set the action for Enhanced\_Search\_Engines\_and\_Portals to block, and you try to access www.example.com, the blocking message is of the following form: **Juniper Web Filtering:Juniper Web Filtering has been set to block this site.**

**CATEGORY: Enhanced\_Search\_Engines\_and\_Portals REASON: BY\_PRE\_DEFINED .**

However, the corresponding syslog message on the DUT is:

**WEBFILTER\_URL\_BLOCKED: WebFilter: ACTION="URL Blocked"**

**56.56.56.2(59418)->74.125.224.48(80)**

**CATEGORY="Enhanced\_Search\_Engines\_and\_Portals" REASON="by predefined category" PROFILE="web-ewf" URL=www.example.com OBJ=/ .**

- **Monitoring the Websense server**—The URL filtering module uses two methods to determine if the TSC is active: socket connections and heartbeat. Enhanced Web filtering maintains persistent TCP sockets to the TSC. The server responds with a TCP ACK if it is enabled. Enhanced Web filtering sends an application layer NOOP keepalive to the TSC. If the device does not receive responses to three consecutive NOOP keepalives in a specific period, it determines the socket to be inactive. Enhanced Web filtering module attempts to open a new connection to the TSC. If all sockets are inactive, the TSC is considered to be inactive. Therefore an error occurs. The error is displayed and logged. Subsequent requests and pending requests are either blocked or passed according to the server connectivity fallback setting until new connections to the TSC are opened again.
- **HTTP protocol communication with TSC**—Enhanced Web filtering uses the HTTP 1.1 protocol to communicate with the TSC. This ensures a persistent connection and transmission of multiple HTTP requests through the same connection. A single HTTP request or response is used for client or server communication. The TSC can handle queued requests; for optimal performance, an asynchronous request or response mechanism is used. The requests are sent over TCP, so TCP retransmission is used to ensure request or response delivery. TCP also ensures valid in-order, non-retransmitted HTTP stream data is sent to the HTTP client on the device.
- **Responses**—The responses adhere to the basic HTTP conventions. Successful responses include a 20x response code (typically 200). An error response include a 4xx or 5xx code. Error responses in the 4xx series indicate issues in the custom code. Error responses in the 5xx series indicate issues with the service.

Error codes and meanings are as follows:

- 400—Bad request
- 403—Forbidden
- 404—Not found
- 408—Request canceled or null response
- 500—Internal server error

Errors in the 400 series indicate issues with the request. Errors in the 500 series indicate issues with the TSC service. Websense is notified of these errors automatically and responds accordingly.

You can configure the default fallback-setting to determine whether to pass or block the request: `set security utm feature-profile web-filtering juniper-enhanced profile juniper-enhanced fallback-settings default ?`

The response also contains the site categorization and site reputation information.

- **Categories**—A category list is available on the device. This list consists of categories, each containing a category code, a name, and a parent ID. Categories can also be user-defined. Each category consists of a list of URLs or IP addresses. Categories are not updated dynamically and are tied to the Junos OS release because they have to be compiled into the Junos OS image. Any update in categories needs to be synchronized with the Junos OS release cycle.

- **Caching**—Successfully categorized responses are cached on the device. Uncategorized URLs are not cached. The size of the cache can be configured by the user.
- **Safe search (HTTP support only, not HTTPS)**—A safe-search solution is used to ensure that the embedded objects such as images on the URLs received from the search engines are safe and that no undesirable content is returned to the client.

A URL is provided to the TSC to provide categorization information. If it is a search URL, the TSC also returns a safe-search string. For instance, the safe-search string for example is **safe=active**. This safe-search string is appended to the URL, and a redirect response for redirecting the client's query with safe search is turned on. This ensures that no unsafe content is returned to the client. If the TSC indicates that it needs to be safe-searched, then you can perform the safe-search redirect.

For example, the client makes a request to the URL

[http://images.example.com/images?hl=en&source=imghp&biw=1183&bih=626&q=adult+movies&gbv=2&aq=f&aqi=&aql=&oq=&gs\\_rfai=No+category](http://images.example.com/images?hl=en&source=imghp&biw=1183&bih=626&q=adult+movies&gbv=2&aq=f&aqi=&aql=&oq=&gs_rfai=No+category)

action is defined for this URL. TSC returns safe-search string **safe=active**. The enhanced Web filtering code on the DUT generates a HTTP 302 response, with the redirect URL:

[http://images.example.com/images?hl=en&source=imghp&biw=1183&bih=626&q=adult+movies&gbv=2&aq=f&aqi=&aql=&oq=&gs\\_rfai=&safe=active](http://images.example.com/images?hl=en&source=imghp&biw=1183&bih=626&q=adult+movies&gbv=2&aq=f&aqi=&aql=&oq=&gs_rfai=&safe=active). This response is returned to the client. The client now sends out a safe redirect request to this URL.

**NOTE:** Safe-search redirect supports HTTP only. You cannot extract the URL for HTTPS. Therefore it is not possible to generate a redirect response for HTTPS search URLs. Safe-search redirects can be disabled by using the CLI option **no-safe-search**.

- **Site reputation**—The TSC provides site reputation information. Based on these reputations, you can choose a block or a permit action. If the URL is not handled by a whitelist or a blacklist and does not fall in a user or predefined category, then the reputation can be used to perform URL filtering decision.

The reputation scores are as follows:

- 100-90—Site is considered very safe.
- 80-89—Site is considered moderately safe.
- 70-79—Site is considered fairly safe.
- 60-69—Site is considered suspicious.
- 0-59—Site is considered harmful.

The device maintains a log for URLs that are blocked or permitted based on site reputation scores.

- **Profiles**—A URL filtering profile is defined as a list of categories, with each profile having an action type (permit, log-and-permit, block, quarantine) associated with it. A predefined profile, *junos-wf-enhanced-default*, is provided to users if they choose not to define their own profile.

You can also define an action based on site reputations in a profile to specify the action when the incoming URL does not belong to any of the categories defined in the profile. If you do not configure the site reputation handling information, then you can define a default action. All URLs that do not have a defined category or defined reputation action in their profile will be blocked, permitted, logged-and-permitted, or quarantined depending on the block or permit handling for the default action explicitly defined in the profile. If you do not specify a default action, then the URLs will be permitted. For search engine requests, if there is no explicit user-defined configuration, and the URL request is without the safe search option, then enhanced Web filtering generates a redirect response and sends it to the client. The client will generate a new search request with the safe-search option enabled.

**NOTE:**

A URL filtering profile can contain the following items:

- Multiple user-defined and predefined categories, each with a permit or block action
- Multiple site reputation handling categories, each with a permit or block action
- One default action with a permit or block action

The order of search is blacklist, whitelist, user-defined category, predefined category, safe-search, site reputation, and default action.

## Example: Configuring Enhanced Web Filtering

- [Requirements on page 6063](#)
- [Overview on page 6064](#)
- [Configuration on page 6065](#)
- [Verification on page 6070](#)

### Requirements

Before you begin, you should be familiar with Web Filtering and Enhanced Web Filtering. See “[Web Filtering Overview](#)” on page 6056 and “[Understanding Enhanced Web Filtering Process](#)” on page 6058.

## Overview

In this example, you configure custom objects and feature profiles.

In the first example configuration, you create a custom object called `urllist3` that contains the pattern `http://www.example.net 1.2.3.4`. The `urllist3` custom object is then added to the custom URL category `custurl3`.

In the second example configuration, you configure the Web filtering feature profile. You set the URL blacklist filtering category to `custblacklist`, set the whitelist filtering category to `custwhitelist`, and set the type of Web filtering engine to `juniper-enhanced`. Then you set the cache size parameters for Web filtering to 500 KB and the cache timeout parameters to 1800.

You name the Enhanced Web Filtering server as `rp.cloud.example.com` and enter 80 as the port number for communicating with it. (Default port is 80.) Then you create a Enhanced Web Filtering profile name called `junos-wf-enhanced-default`.

Next you select a category from the included whitelist and blacklist categories or select a custom URL category list you created for filtering against. Then you enter an action (permit, log and permit, block, or quarantine) to go with the filter. You do this as many times as necessary to compile your whitelists and blacklists and their accompanying actions. This example blocks URLs in the `Enhanced_Hacking` category. You also specify the action to be taken depending on the site reputation returned for the URL if there is no category match found.

Then you enter a custom message to be sent when HTTP requests are blocked. This example configures the device to send an `***access denied***` message. You select a default action (permit, log and permit, block, or quarantine) for this profile for requests that does not match to any explicitly configured action. This example sets the default action to block. You select fallback settings (block or log and permit) for this profile, in case errors occur in each configured category. This example sets fallback settings to block.

You can also define a redirect URL server so that instead of the device sending a block page with plain text html, the device will send a HTTP 302 redirect to this redirect server with some special variables embedded in the HTTP redirect location field. These special variables can be parsed by the redirect server and serve a special block page to the client with rich images and formatting. The cli command hierarchy is as follows:

```
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default block-message type custom-redirect-url
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default block-message url http://10.10.121.18
```

**NOTE:** If you configure the `security utm feature-profile web-filtering juniper-enhanced profile junos-wf-enhanced-default block-message`, then the default block message configuration takes precedence over the `security utm feature-profile web-filtering juniper-enhanced profile junos-wf-enhanced-default custom-block-message` configuration.

Finally, you enter a timeout value in seconds. Once this limit is reached, fail mode settings are applied. The default is 15 seconds, and you can enter a value from 0 to 1800 seconds. This example sets the timeout value to 10. You also disable the safe search functionality. By default, search requests have safe-search strings attached to them, and redirect response is sent to ensure that all search requests are safe or strict.

## Configuration

- [Configuring Enhanced Web Filtering Custom Objects on page 6065](#)
- [Configuring the Enhanced Web Filtering Feature Profiles on page 6067](#)

### Configuring Enhanced Web Filtering Custom Objects

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm custom-objects url-pattern urllist3 value http://www.example.net
set security utm custom-objects url-pattern urllist3 value 1.2.3.4
set security utm custom-objects url-pattern urllistblack value http://www.untrusted.com
set security utm custom-objects url-pattern urllistblack value 13.13.13.13
set security utm custom-objects url-pattern urllistwhite value http://www.trusted.com
set security utm custom-objects url-pattern urllistwhite value 7.7.7.7
set security utm custom-objects custom-url-category custurl3 value urllist3
set security utm custom-objects custom-url-category custblacklist value urllistblack
set security utm custom-objects custom-url-category custwhitelist value urllistwhite
```

**WARNING:** A Custom category does not take precedence over a predefined category when it has the same name as one of the predefined categories. Do not use the same name for a custom category that you have used for a predefined category.

#### Step-by-Step Procedure

To configure integrated Web filtering:

1. Create custom objects and create the URL pattern list.  

```
[edit security utm]
user@host# set custom-objects url-pattern urllist3 value [http://www.example.net 1.2.3.4]
```
2. Configure the custom URL category list custom object using the URL pattern list.  

```
[edit security utm]
user@host# set custom-objects custom-url-category custurl3 value urllist3
```
3. Create a list of untrusted sites.  

```
[edit security utm]
user@host# set custom-objects url-pattern urllistblack value [http://www.untrusted.com 13.13.13.13]
```

4. Configure the custom URL category list custom object using the URL pattern list of untrusted sites.

```
[edit security utm]
user@host# set custom-objects custom-url-category custblacklist value urllistblack
```

5. Create a list of trusted sites.

```
[edit security utm]
user@host# set custom-objects url-pattern urllistwhite value
[http://www.trusted.com 7.7.7.7]
```

6. Configure the custom URL category list custom object using the URL pattern list of trusted sites.

```
[edit security utm]
user@host# set custom-objects custom-url-category custwhitelist value urllistwhite
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm custom-objects** command. If the output does not display the intended configuration, repeat the instructions in this example to correct.

For brevity, this show command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
userhost#show security utm custom-objects
url-pattern {
 urllist3 {
 value [http://www.example.net];
 }
 urllistblack {
 value [http://www.untrusted.com 13.13.13.13];
 }
 urllistwhite {
 value [http://www.trusted.com 7.7.7.7];
 }
}
custom-url-category {
 custurl3 {
 value urllist3;
 }
 custblacklist {
 value urllistblack;
 }
 custwhitelist {
 value urllistwhite;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring the Enhanced Web Filtering Feature Profiles

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile web-filtering url-whitelist custwhitelist
set security utm feature-profile web-filtering url-blacklist custblacklist
set security utm feature-profile web-filtering juniper-enhanced cache size 500
set security utm feature-profile web-filtering juniper-enhanced cache timeout 1800
set security utm feature-profile web-filtering juniper-enhanced server host
 rp.cloud.example.com
set security utm feature-profile web-filtering juniper-enhanced server port 80
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default category Enhanced_Hacking action log-and-permit
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default site-reputation-action very-safe permit
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default site-reputation-action moderately-safe log-and-permit
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default site-reputation-action fairly-safe log-and-permit
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default site-reputation-action harmful block
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default site-reputation-action suspicious block
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default default block
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default custom-block-message "****access denied ****"
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default default block
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default fallback-settings server-connectivity block
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default fallback-settings timeout block
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default fallback-settings too-many-requests block
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default timeout 10
set security utm feature-profile web-filtering juniper-enhanced profile
 junos-wf-enhanced-default no-safe-search
set security utm utm-policy mypolicy web-filtering http-profile my_ewfprofile01
set security policies from-zone utm_clients to-zone mgmt policy 1 then permit
 application-services utm-policy mypolicy
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
 quarantine-custom-message "***The requested webpage is blocked by your
 organization's access policy***".
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
 quarantine-message type custom-redirect-url
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
 quarantine-message url besgas.spglab.example.net
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the Enhanced Web Filtering feature profiles:

1. Configure the Web filtering URL blacklist.  

```
[edit security utm feature-profile web-filtering]
user@host# set url-blacklist custblacklist
```
2. Configure the Web filtering URL whitelist.  

```
[edit security utm feature-profile web-filtering]
user@host# set url-whitelist custwhitelist
```
3. Specify the Enhanced Web Filtering engine, and set the cache size parameters.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced cache size 500
```
4. Set the cache timeout parameters.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced cache timeout 1800
```
5. Set the server name or IP address.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced server host rp.cloud.example.com
```
6. Enter the port number for communicating with the server.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced server port 80
```
7. Create a profile name, and select a category from the included whitelist and blacklist categories.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile junos-wf-enhanced-default category
Enhanced_Hacking action log-and-permit
```
8. Specify the action to be taken depending on the site reputation returned for the URL if there is no category match found.  

```
[edit security utm feature-profile web-filtering]
user@host#set juniper-enhanced profile junos-wf-enhanced-default
site-reputation-action very-safe permit
user@host#set juniper-enhanced profile junos-wf-enhanced-default
site-reputation-action moderately-safe log-and-permit
user@host#set juniper-enhanced profile junos-wf-enhanced-default
site-reputation-action fairly-safe log-and-permit
user@host#set juniper-enhanced profile junos-wf-enhanced-default
site-reputation-action harmful block
user@host#set juniper-enhanced profile junos-wf-enhanced-default
site-reputation-action suspicious block
```
9. Enter a custom message to be sent when HTTP requests are blocked.  

```
[edit security utm feature-profile web-filtering]
```

```
user@host# set juniper-enhanced profile junos-wf-enhanced-default
custom-block-message "***access denied ***"
```

10. Select a default action (permit, log and permit, block, or quarantine) for the profile, when no other explicitly configured action (blacklist, whitelist, custom category, predefined category actions or site reputation actions.) is matched .

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile junos-wf-enhanced-default default block
```

11. Select fallback settings (block or log and permit) for this profile.

```
[edit security utm feature-profile web-filtering]
set juniper-enhanced profile junos-wf-enhanced-default fallback-settings default
block
user@host# set juniper-enhanced profile junos-wf-enhanced-default
fallback-settings server-connectivity block
user@host# set juniper-enhanced profile junos-wf-enhanced-default
fallback-settings timeout block
set juniper-enhanced profile junos-wf-enhanced-default fallback-settings
too-many-requests block
```

12. Enter a timeout value in seconds.

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile junos-wf-enhanced-default timeout 10
```

13. Disable the safe-search option.

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile junos-wf-enhanced-default no-safe-search
```

14. Configure a UTM policy for the web-filtering HTTP protocol and attach this policy to a security profile to implement it.

```
[edit security utm]
user@host# set utm-policy mypolicy web-filtering http-profile my_ewfprofile01
```

15. Configure a security policy.

```
[edit security]
user@host# set policies from-zone utm_clients to-zone mgmt policy 1 then permit
application-services utm-policy mypolicy
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm feature-profile** command. If the output does not display the intended configuration, repeat the instructions in this example to correct.

```
[edit]
user@host# show security utm
feature-profile{
web-filtering {
url-whitelist custwhitelist;
url-blacklist custblacklist;
type juniper-enhanced;
juniper-enhanced {
cache {
timeout 1800;
size 500;
```

```
}
server {
 host rp.cloud.example.com;
 port 80;
}
profile junos-wf-enhanced-default {
 category {
 Enhanced_Hacking {
 action log-and-permit;
 }
 Enhanced_Government {
 action quarantine;
 }
 }
 site-reputation-action {
 very-safe permit;
 moderately-safe log-and-permit;
 fairly-safe log-and-permit;
 harmful block;
 suspicious block;
 }
 default block;
 custom-block-message "***access denied ***";
 fallback-settings {
 default block;
 server-connectivity block;
 timeout block;
 too-many-requests block;
 }
 timeout 10;
 no-safe-search;
}
utm-policy mypolicy {
 web-filtering {
 http-profile my_ewfprofile01;
 }
}
}
```

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the Status of the Web Filtering Server on page 6070](#)
- [Verifying the Increase in Web Filtering Statistics on page 6071](#)

---

### Verifying the Status of the Web Filtering Server

<b>Purpose</b>	Verify the web filtering server status.
<b>Action</b>	From the top of the configuration in configuration mode, enter the <b>show security utm web-filtering status</b> command.

### Verifying the Increase in Web Filtering Statistics

<b>Purpose</b>	Verify the increase in Web filtering statistics.
<b>Action</b>	From the top of the configuration in configuration mode, enter the <b>show security utm web-filtering statistics</b> command.

### Understanding the Quarantine Action for Enhanced Web Filtering

UTM Enhanced Web Filtering supports block, log-and-permit, and permit actions for HTTP/HTTPS requests. In addition to this, UTM Enhanced Web Filtering now supports the quarantine action which allows or denies access to the blocked site based on the user's response to the message.

The following sequence explains how the HTTP or HTTPS request is intercepted, redirected, and acted upon by the quarantine action:

- The HTTP client requests URL access.
- The device intercepts the HTTP request and sends the extracted URL to the Websense Thread Seeker Cloud (TSC).
- The TSC returns the URL category and the site reputation information to the device.
- If the action configured for the category is quarantine, the device logs the quarantine action and sends a redirect response to HTTP client.
- The URL is sent to the HTTP server for redirecting.
- The device shows a warning message stating that the access to the URL is blocked according to the organization's security policies and prompts the user to respond.
- If the user response is "No," the session is terminated. If the user response is "Yes," the user is allowed access to the site and such access is logged and reported to the administrator.

**NOTE:** On all branch SRX Series devices, the quarantine action is supported only for UTM Enhanced Web Filtering or Juniper enhanced type of Web filtering.

#### Quarantine Message

The quarantine message sent to the HTTP client is user-configurable and is of the following types:

- Default message

The default quarantine message is displayed when a user attempts to access a quarantined website and it contains the following information:

- URL name
- Quarantine reason
- Category (if available)
- Site-reputation (if available)

For example, if you have set the action for `Enhanced_Search_Engines_and_Portals` to quarantine, and you try to access `www.search.yahoo.com`, the quarantine message is as follows:

**\*\*\*The requested webpage is blocked by your organization's access policy\*\*\***

- Syslog message.

The syslog message will be logged by the system when the user access the web page that has already been quarantined and marked as block or permit.

The corresponding syslog message on the device under test is:

```
Jan 25 15:10:40 rodian utmd[3871]: WEBFILTER_URL_BLOCKED: WebFilter:
ACTION="URL Blocked" 99.99.99.4(60525)->74.125.224.114(80)
CATEGORY="Enhanced_Search_Engines_and_Portals" REASON="by predefined
category(quarantine)" PROFILE="ewf-test-profile" URL=www.search.yahoo.com
OBJ=/

```

## Example: Configuring Site Reputation Action for Enhanced Web Filtering

This example shows how to configure the site reputation action for both categorized and uncategorized URLs.

- [Requirements on page 6073](#)
- [Overview on page 6073](#)

- [Configuration on page 6073](#)
- [Verification on page 6076](#)

## Requirements

Before you begin, you should be familiar with Web Filtering and Enhanced Web Filtering. See [“Web Filtering Overview” on page 6056](#) and [“Understanding Enhanced Web Filtering Process” on page 6058](#).

## Overview

In this example, you configure Web Filtering profiles to URLs according to defined categories using the site reputation action. You set the URL whitelist filtering category to url-cat-white and the type of Web Filtering engine to juniper-enhanced. Then you set the cache size parameters for Web Filtering and the cache timeout parameters to 1.

Then you create a juniper-enhanced profile called profile ewf-test-profile, set the URL whitelist category to cust-cat-quarantine, and set the reputation action to quarantine.

You enter a custom message to be sent when HTTP requests are quarantined. In this example, the following message is sent: **\*\*\*The requested webpage is blocked by your organization's access policy\*\*\***.

You block URLs in the Enhanced\_News\_and\_Media category and permit URLs in the Enhanced\_Education category. Then you quarantine the URLs in the Enhanced\_Streaming\_Media category and configure the device to send the following message: **\*\*\*The requested webpage is blocked by your organization's access policy\*\*\***.

In this example, you set the default action to permit. You select fallback settings (block or log and permit) for this profile in case errors occur in each configured category. Finally, you set the fallback settings to block.

## Configuration

### Configuring Site Reputation Action

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile web-filtering set url-whitelist url-cat-white
set security utm feature-profile web-filtering juniper-enhanced cache size
set security utm feature-profile web-filtering juniper-enhanced cache timeout 1
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
category cust-cat-quarantine action quarantine
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
category Enhanced_News_and_Media action block
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
category Enhanced_Education action permit
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
category Enhanced_Education reputation-action harmful block
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
category Enhanced_Streaming_Media action quarantine
```

```

set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
default permit
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
default quarantine-message "*** The requested webpage is blocked by your
organization's access policy***".
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
fallback-settings server-connectivity block
set security utm feature-profile web-filtering juniper-enhanced profile ewf-test-profile
fallback-settings timeout block

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the site reputation action:

1. Configure the Web Filtering URL whitelist.
 

```

[edit security utm feature-profile web-filtering]
user@host# set url-whitelist custwhitelist

```
2. Specify the Enhanced Web Filtering engine, and set the cache size parameters.
 

```

[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced cache size

```
3. Set the cache timeout parameters.
 

```

[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced cache timeout 1

```
4. Create a profile name, and select a category from the whitelist categories.
 

```

[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile ewf-test-profile category
cust-cat-quarantine action quarantine

```
5. Create a profile name, and select a category from the whitelist categories.
 

```

[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile ewf-test-profile category
Enhanced_News_and_Media action block
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile ewf-test-profile category
Enhanced_Education action permit
user@host# set juniper-enhanced profile ewf-test-profile category
Enhanced_Education action harmful block
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile ewf-test-profile category
Enhanced_Streaming_Media action quarantine

```
6. Enter a warning message to be sent when HTTP requests are quarantined.
 

```

[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile ewf-test-profile
quarantine-custom-message "***The requested webpage is blocked by your
organization's access policy ***"

```

7. Select a default action (permit, log and permit, block, or quarantine) for the profile, when no other explicitly configured action (blacklist, whitelist, custom category, predefined category or site reputation ) is matched .

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile ewf-test-profile default permit
```

8. Select fallback settings (block or log and permit) for this profile.

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-enhanced profile ewf-test-profile fallback-settings
server-connectivity block
user@host# set juniper-enhanced profile ewf-test-profile fallback-settings timeout
block
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** command. If the output does not display the intended configuration, repeat the instructions in this example to correct.

```
[edit]
user@host# show security utm
feature-profile{
web-filtering {
url-whitelist url-cat-white;
type juniper-enhanced;
traceoptions;
flag all;
}
juniper-enhanced {
cache {
timeout 1
}
profile ewf-test-profile {
category {
cust-cat-quarantine {
action quarantine;
}
Enhanced_News_and_Media {
action block;
reputation-action;
}
Enhanced_Education {
action permit;
reputation-action;
{
harmful block;
}
}
Enhanced_Streaming_Media {
action quarantine;
}
}
default permit;
quarantine-custom-message "****The requested webpage is blocked by your
organization's access policy****".
fallback-settings {
```

```
server-connectivity block;
timeout block;
}
}
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Status of UTM Service on page 6076](#)
- [Verifying the Status of UTM Session on page 6076](#)
- [Verifying the Status of UTM Web Filtering on page 6076](#)
- [Verifying the Statistics of UTM Web Filtering on page 6077](#)

### Verifying the Status of UTM Service

---

**Purpose** Verify the UTM service status.

**Action** From operational mode, enter the **show security utm status** command.

## Sample Output

```
user@host>show security utm status
UTM service status: Running
```

### Verifying the Status of UTM Session

---

**Purpose** Verify the UTM session status.

**Action** From operational mode, enter the **show security utm session** command.

## Sample Output

```
user@host>show security utm session
UTM session info:
Maximum sessions: 4000
Total allocated sessions: 0
Total freed sessions: 0
Active sessions: 0
```

### Verifying the Status of UTM Web Filtering

---

**Purpose** Verify the UTM Web filtering status.

**Action** From operational mode, enter the **show security utm web-filtering status** command.

## Sample Output

```
user@host>show security utm web-filtering status
```

UTM web-filtering status:  
 Server status: Juniper Enhanced using Websense server UP

### Verifying the Statistics of UTM Web Filtering

**Purpose** Verify the Web filtering statistics for connections including whitelist and blacklist hits and custom category hits.

**Action** From operational mode, enter the **show security utm web-filtering statistics** command.

### Sample Output

```
user@host>show security utm web-filtering statistics
UTM web-filtering statistics:
 Total requests: 2594
 white list hit: 0
 Black list hit: 0
 Queries to server: 2407
 Server reply permit: 1829
 Server reply block: 0
 Server reply quarantine: 517
 Server reply quarantine block: 0
 Server reply quarantine permit: 8
 Custom category permit: 0
 Custom category block: 0
 Custom category quarantine: 0
 Custom category quarantine block: 0
 Custom category quarantine permit: 0
 Site reputation permit: 0
 Site reputation block: 0
 Site reputation quarantine: 0
 Site reputation quarantine block: 0
 Site reputation quarantine permit: 0
 Site reputation by Category 0
 Site reputation by Global 0
 Cache hit permit: 41
 Cache hit block: 0
 Cache hit quarantine: 144
 Cache hit quarantine block: 0
 Cache hit quarantine permit: 1
 Safe-search redirect: 0
 Web-filtering sessions in total: 16000
 Web-filtering sessions in use: 0
 Fallback: log-and-permit block
 Default 0 0
 Timeout 0 0
 Connectivity 0 1
 Too-many-requests 0 0
```

## Understanding Integrated Web Filtering

---

With integrated Web filtering, the firewall intercepts every HTTP request in a TCP connection and extracts the URL from the HTTP request. Each individual HTTP request is blocked or permitted based on URL filtering profiles defined by you. The decision making is done on the device after it identifies a category for a URL.

A URL category is a list of URLs grouped by content. URL categories are predefined and maintained by SurfControl or are defined by you. SurfControl maintains about 40 predefined categories. When defining your own URL categories, you can group URLs and create categories specific to your needs.

You define your own categories using URL pattern list and custom URL category list custom objects. Once defined, you can select your categories when you configure your Web filtering profile. Each category can have a maximum of 20 URLs. When you create a category, you can add either the URL or the IP address of a site. When you add a URL to a user-defined category, the device performs DNS lookup, resolves the host name into IP addresses, and caches this information. When a user tries to access a site with the IP address of the site, the device checks the cached list of IP addresses and tries to resolve the hostname. Many sites have dynamic IP addresses, meaning that their IP addresses change periodically. A user attempting to access a site can type an IP address that is not in the cached list on the device. Therefore, if you know the IP addresses of sites you are adding to a category, enter both the URL and the IP address(es) of the site.

NOTE: If a URL appears in both a user-defined category and a predefined category, the device matches the URL to the user-defined category.

NOTE: Web filtering is performed on all the methods defined in HTTP 1.0 and HTTP 1.1.

This topic contains the following sections:

- [Integrated Web Filtering Process on page 6078](#)
- [Integrated Web Filtering Cache on page 6079](#)
- [Integrated Web Filtering Profiles on page 6079](#)
- [Profile Matching Precedence on page 6080](#)

### Integrated Web Filtering Process

This is a general description of how Web traffic is intercepted and acted upon by the Web filtering module.

1. The device intercepts a TCP connection.
2. The device intercepts each HTTP request in the TCP connection.
3. The device extracts each URL in the HTTP request and checks its URL filter cache.
4. Global Web filtering whitelists and blacklists are checked first for block or permit.
5. If the HTTP request URL is allowed based on cached parameters, it is forwarded to the webserver. If there is no cache match, a request for categorization is sent to the SurfControl server. (If the HTTP request URL is blocked, the request is not forwarded and a notification message is logged.)
6. In the allowed case, the SurfControl server responds with the corresponding category.
7. Based on the identified category, if the URL is permitted, the device forwards the HTTP request to the webserver. If the URL is not permitted, then a deny page is sent to the HTTP client.

## Integrated Web Filtering Cache

By default, the device retrieves and caches the URL categories from the SurfControl CPA server. This process reduces the overhead of accessing the SurfControl CPA server each time the device receives a new request for previously requested URLs. You can configure the size and duration of the cache, according to the performance and memory requirements of your networking environment. The lifetime of cached items is configurable between 1 and 1800 seconds with a default value of 300 seconds.

**NOTE:** Caches are not preserved across device reboots or power losses.

## Integrated Web Filtering Profiles

You configure Web filtering profiles that permit or block URLs according to defined categories. A Web filtering profile consists of a group of URL categories assigned one of the following actions:

- Permit — The device always allows access to the websites in this category.
- Block — The device blocks access to the websites in this category. When the device blocks access to this category of websites, it displays a message in your browser indicating the URL category.
- Blacklist — The device always blocks access to the websites in this list. You can create a user-defined category.
- Whitelist — The device always allows access to the websites in this list. You can create a user-defined category.

**NOTE:** A predefined profile is provided and can be used if you choose not to define your own profile.

A Web filtering profile may contain one blacklist or one whitelist, multiple user-defined and/or predefined categories each with a permit or block action, and an *Other* category with a permit or block action. You can define an action for all *Other* categories in a profile to specify what to do when the incoming URL does not belong to any of the categories defined in the profile. If the action for the *Other* category is block, the incoming URL is blocked if it does not match any of the categories explicitly defined in the profile. If an action for the *Other* category is not specified, the default action of permit is applied to the incoming URL not matching any category.

## Profile Matching Precedence

When a profile employs several categories for URL matching, those categories are checked for matches in the following order:

1. If present, the global blacklist is checked first. If a match is made, the URL is blocked. If no match is found...
2. The global whitelist is checked next. If a match is made, the URL is permitted. If no match is found...
3. User-defined categories are checked next. If a match is made, the URL is blocked or permitted as specified. If no match is found...
4. Predefined categories are checked next. If a match is made, the URL is blocked or permitted as specified. If no match is found...
5. The Other category is checked next. If a match is made, the URL is blocked or permitted as specified.

### Related Documentation

- [Example: Configuring Integrated Web Filtering on page 6080](#)

---

## Example: Configuring Integrated Web Filtering

This example shows how to configure integrated Web filtering.

- [Requirements on page 6080](#)
- [Overview on page 6081](#)
- [Configuration on page 6081](#)
- [Verification on page 6088](#)

## Requirements

Before you begin, learn more about Web filtering. See “[Web Filtering Overview](#)” on page 6056.

## Overview

In this example you configure integrated Web filtering custom objects, integrated Web filtering feature profiles, and integrated Web filtering UTM policies. You also attach integrated Web filtering UTM policies to security policies.

In the first example configuration you create a custom object called `urllist3` that contains the pattern `http://www.example.net 1.2.3.4`. The `urllist3` custom object is then added to the custom URL category `custurl3`.

In the second example configuration, you configure the Web filtering feature profile. You set the URL blacklist filtering category to `custblacklist`, set the whitelist filtering category to `custwhitelist` and the type of Web filtering engine to `surf-control-integrated`. Then you set the cache size parameters for Web filtering to 500 KB, which is the default, and the cache timeout parameters to 1800.

You name the Surf Control server as `surfcontrolserver` and enter 8080 as the port number for communicating with it. (Default ports are 80, 8080, and 8081.) Then you create a surf-control-integrated profile name called `surfprofile1`.

Next you select a category from the included whitelist and blacklist categories or select a custom URL category list you created for filtering against. Then you enter an action (permit, log and permit, block) to go with the filter. You do this as many times as necessary to compile your whitelists and blacklists and their accompanying actions. This example blocks URLs in the `custurl3` category.

Then you enter a custom message to be sent when HTTP requests are blocked. This example configures the device to send an `***access denied***` message. You select a default action (permit, log and permit, block) for this profile for requests that experience errors. This example sets the default action to block. You select fallback settings (block or log and permit) for this profile, in case errors occur in each configured category. This example sets fallback settings to block.

Finally, you enter a timeout value in seconds. Once this limit is reached, fail mode settings are applied. The default is 10 seconds, and you can enter a value from 10 to 240 seconds. This example sets the timeout value to 10.

In the third example configuration, you create UTM policy `utmp5` and attach it to profile `surfprofile1`.

In the final example configuration, you attach the UTM policy `utmp5` to the security policy `p5`.

## Configuration

- [Configuring Integrated Web Filtering Custom Objects on page 6082](#)
- [Configuring the Integrated Web Filtering Feature Profiles on page 6083](#)
- [Configuring Integrated Web Filtering UTM Policies on page 6086](#)
- [Attaching Integrated Web Filtering UTM Policies to Security Policies on page 6087](#)

## Configuring Integrated Web Filtering Custom Objects

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm custom-objects url-pattern urllist3 value http://www.example.net
set security utm custom-objects url-pattern urllist3 value 1.2.3.4
set security utm custom-objects url-pattern urllistblack value http://www.untrusted.com
set security utm custom-objects url-pattern urllistblack value 13.13.13.13
set security utm custom-objects url-pattern urllistwhite value http://www.trusted.com
set security utm custom-objects url-pattern urllistwhite value 7.7.7.7
set security utm custom-objects custom-url-category custurl3 value urllist3
set security utm custom-objects custom-url-category custblacklist value urllistblack
set security utm custom-objects custom-url-category custwhitelist value urllistwhite
```

**WARNING:** Custom category does not take precedence over predefined categories when it has the same name as one of the predefined categories. We do not recommend having a custom category name be the same as the predefined category name.

### Step-by-Step Procedure

To configure integrated Web filtering:

1. Create custom objects and create the URL pattern list.  

```
[edit security utm]
user@host# set custom-objects url-pattern urllist3 value [http://www.example.net 1.2.3.4]
```
2. Configure the custom URL category list custom object using the URL pattern list.  

```
[edit security utm]
user@host# set custom-objects custom-url-category custurl3 value urllist3
```
3. Create a list of untrusted sites  

```
[edit security utm]
user@host# set custom-objects url-pattern urllistblack value [http://www.untrusted.com 13.13.13.13]
```
4. Configure the custom URL category list custom object using the URL pattern list of untrusted sites.  

```
[edit security utm]
user@host# set custom-objects custom-url-category custblacklist value urllistblack
```
5. Create a list of trusted sites.  

```
[edit security utm]
user@host# set custom-objects url-pattern urllistwhite value [http://www.trusted.com 7.7.7.7]
```

6. Configure the custom URL category list custom object using the URL pattern list of trusted sites.

```
[edit security utm]
user@host# set custom-objects custom-url-category custwhitelist value urllistwhite
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm custom-objects** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this show command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
userhost#show security utm custom-objects
url-pattern {
 urllist3 {
 value [http://www.example.net];
 }
 urllistblack {
 value [http://www.untrusted.com 13.13.13.13];
 }
 urllistwhite {
 value [http://www.trusted.com 7.7.7.7];
 }
}
custom-url-category {
 custurl3 {
 value urllist3;
 }
 custblacklist {
 value urllistblack;
 }
 custwhitelist {
 value urllistwhite;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring the Integrated Web Filtering Feature Profiles

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile web-filtering url-whitelist custwhitelist
set security utm feature-profile web-filtering url-blacklist custblacklist
set security utm feature-profile web-filtering surf-control-integrated cache timeout 1800
set security utm feature-profile web-filtering surf-control-integrated cache size 500
set security utm feature-profile web-filtering surf-control-integrated server host surfcontrolserver
```

```

set security utm feature-profile web-filtering surf-control-integrated server port 8080
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 category custurl3 action block
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 default block
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 custom-block-message "***access denied ***"
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 fallback-settings default block
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 fallback-settings server-connectivity block
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 fallback-settings timeout block
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 fallback-settings too-many-requests block
set security utm feature-profile web-filtering surf-control-integrated profile surfprofile1
 timeout 10
set security utm feature-profile content-filtering profile contentfilter1

```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure integrated Web filtering feature profiles:

1. Configure the Web filtering URL Black List.  

```
[edit security utm feature-profile web-filtering]
user@host# set url-blacklist custblacklist
```
2. Configure the Web filtering URL White List.  

```
[edit security utm feature-profile web-filtering]
user@host# set url-whitelist custwhitelist
```
3. Specify the surf-control-integrated Web filtering engine and set the cache size parameters.  

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated cache size 500
```
4. Set the cache timeout parameters.  

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated cache timeout 1800
```
5. Set the server name or IP address.  

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated server host surfcontrolserver
```
6. Enter the port number for communicating with the server.  

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated server port 8080
```
7. Create a profile name and select a category from the included whitelist and blacklist categories.  

```
[edit security utm feature-profile web-filtering]
```

```
user@host# set surf-control-integrated profile surfprofile1 category custurl3 action
block
```

8. Enter a custom message to be sent when HTTP requests are blocked.

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated profile surfprofile1 custom-block-message
"***access denied***"
```

9. Select a default action (permit, log and permit, block) for this profile for requests that experience errors.

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated profile surfprofile1 default block
```

10. Select fallback settings (block or log and permit) for this profile.

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated profile surfprofile1 fallback-settings default
block
```

```
user@host# set surf-control-integrated profile surfprofile1 fallback-settings
server-connectivity block
```

```
user@host# set surf-control-integrated profile surfprofile1 fallback-settings timeout
block
```

```
user@host# set surf-control-integrated profile surfprofile1 fallback-settings
too-many-requests block
```

11. Enter a timeout value, in seconds.

```
[edit security utm feature-profile web-filtering]
user@host# set surf-control-integrated profile surfprofile1 timeout 10
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm feature-profile** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
userhost#show security utm feature-profile
web-filtering {
 url-whitelist custwhitelist;
 url-blacklist custblacklist;
 type juniper-local;
 surf-control-integrated {
 cache {
 timeout 1800;
 size 500;
 }
 server {
 host surfcontrolserver;
 port 8080;
 }
 profile surfprofile1 {
 category {
 custurl3 {
 action block;
 }
 }
 }
 }
}
```

```

 default block;
 custom-block-message "***access denied***";
 fallback-settings {
 default block;
 server-connectivity block;
 timeout block;
 too-many-requests block;
 }
 timeout 10;
}
}
content-filtering {
 profile contentfilter1;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Integrated Web Filtering UTM Policies

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm utm-policy utmp5 web-filtering http-profile surfprofile1
```

#### Step-by-Step Procedure

To configure a UTM policy:

1. Create the UTM policy referencing a profile.

**[edit]**

```
user@host# set security utm utm-policy utmp5 web-filtering http-profile surfprofile1
```

#### Results

From configuration mode, confirm your configuration by entering the **show security utm utm-policy** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
userhost#show security utm utm-policy
...
 utm-policy utmp5 {
 content-filtering {
 http-profile contentfilter1;
 }
 web-filtering {
 http-profile surfprofile1;
 }
 }

```

If you are done configuring the device, enter **commit** from configuration mode.

### Attaching Integrated Web Filtering UTM Policies to Security Policies

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security policies from-zone trust to-zone untrust policy p5 match source-address any
set security policies from-zone trust to-zone untrust policy p5 match destination-address any
set security policies from-zone trust to-zone untrust policy p5 match application junos-http
set security policies from-zone trust to-zone untrust policy p5 then permit
application-services utm-policy utmp5
```

**Step-by-Step Procedure** To attach a UTM policy to a security policy:

1. Create and configure the security policy.  

```
[edit security policies from-zone trust to-zone untrust policy p5]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application junos-http
```
2. Attach the UTM policy to the security policy.  

```
[edit security policies from-zone trust to-zone untrust policy p5]
user@host# set then permit application-services utm-policy utmp5
```

**Results** From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
userhost#show security policies
from-zone trust to-zone untrust {
 policy p5 {
 match {
 source-address any;
 destination-address any;
 application junos-http;
 }
 then {
 permit {
 application-services {
 utm-policy utmp5;
 }
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the Configuration of Integrated Web Filtering Custom Objects on page 6088](#)
- [Verifying the Configuration of Integrated Web Filtering Feature Profiles on page 6088](#)
- [Verifying the Configuration of Integrated Web Filtering UTM Policies on page 6088](#)
- [Verifying the Attachment of Integrated Web Filtering UTM Policies to Security Policies on page 6088](#)

---

### Verifying the Configuration of Integrated Web Filtering Custom Objects

**Purpose** Verify the configuration of integrated Web filtering custom objects.

**Action** From the top of the configuration in configuration mode, enter the **show security utm custom-objects** command.

---

### Verifying the Configuration of Integrated Web Filtering Feature Profiles

**Purpose** Verify the configuration of integrated Web filtering feature profiles.

**Action** From the top of the configuration in configuration mode, enter the **show security utm feature-profile** command.

---

### Verifying the Configuration of Integrated Web Filtering UTM Policies

**Purpose** Verify the configuration of integrated Web filtering UTM policies.

**Action** From the top of the configuration in configuration mode, enter the **show security utm** command.

---

### Verifying the Attachment of Integrated Web Filtering UTM Policies to Security Policies

**Purpose** Verify the attachment of integrated Web filtering UTM policies to security policies.

**Action** From the top of the configuration in configuration mode, enter the **show security policies** command.

## Understanding Local Web Filtering

---

With local Web filtering, the firewall intercepts every HTTP request in a TCP connection and extracts the URL. The decision making is done on the device after it looks up a URL to determine if it is in the whitelist or blacklist based on its user-defined category. If the URL is in the url-blacklist, the request is blocked; if it's in the url-whitelist, the request is permitted. If the URL is not in either list, the defined default action will occur (block, log-and-permit, or permit). You can permit or block access to a requested site by binding a Web filtering profile to a firewall policy. Local Web filtering provides basic Web filtering without requiring an additional license or external category server.

This topic contains the following sections:

- [User-Defined URL Categories on page 6089](#)
- [Local Web Filtering Process on page 6089](#)
- [Local Web Filtering Profiles on page 6090](#)
- [Profile Matching Precedence on page 6090](#)

### User-Defined URL Categories

When defining your own URL categories, you can group URLs and create categories specific to your needs. Each category can have a maximum of 20 URLs. When you create a category, you can add either the URL or the IP address of a site. When you add a URL to a user-defined category, the device performs DNS lookup, resolves the hostname into IP addresses, and caches this information. When a user tries to access a site with the IP address of the site, the device checks the cached list of IP addresses and tries to resolve the hostname. Many sites have dynamic IP addresses, meaning that their IP addresses change periodically. A user attempting to access a site can type an IP address that is not in the cached list on the device. Therefore, if you know the IP addresses of sites you are adding to a category, enter both the URL and the IP address(es) of the site.

You define your own categories using URL pattern list and custom URL category list custom objects. Once defined, you assign your categories to the global user-defined url-blacklist (block) or url-whitelist (permit) categories.

**NOTE:** Web filtering is performed on all the methods defined in HTTP1.0 and HTTP 1.1.

### Local Web Filtering Process

This is a general description of how Web traffic is intercepted and acted upon by the Web filtering module.

1. The device intercepts a TCP connection.
2. The device intercepts each HTTP request in the TCP connection.

3. The device extracts each URL in the HTTP request and checks its URL against the user-defined whitelist and blacklist.
4. If the URL is found in the blacklist, the request is not permitted and a deny page is sent to the http client. If the URL is found in the whitelist, the request is permitted.
5. If the URL is not found in the whitelist or blacklist, the configured default fallback action is applied. If no fallback action is defined, then the request is permitted.

## Local Web Filtering Profiles

You configure Web filtering profiles that permit or block URLs according to defined custom categories. A Web filtering profile consists of a group of URL categories assigned one of the following actions:

- **Blacklist** — The device always blocks access to the websites in this list. Only user-defined categories are used with local Web filtering.
- **Whitelist** — The device always allows access to the websites in this list. Only user-defined categories are used with local Web filtering.

A Web filtering profile can contain one blacklist or one whitelist with multiple user-defined categories each with a permit or block action. You can define a default fallback action when the incoming URL does not belong to any of the categories defined in the profile. If the action for the default category is block, the incoming URL is blocked if it does not match any of the categories explicitly defined in the profile. If an action for the default action is not specified, the default action of permit is applied to the incoming URL not matching any category.

## Profile Matching Precedence

When a profile employs several categories for URL matching, those categories are checked for matches in the following order:

1. If present, the global blacklist is checked first. If a match is made, the URL is blocked. If no match is found...
2. The global whitelist is checked next. If a match is made, the URL is permitted. If no match is found...
3. User-defined categories are checked next. If a match is made, the URL is blocked or permitted as specified.

## Example: Configuring Local Web Filtering

---

This example shows how to configure local Web filtering.

- [Requirements on page 6091](#)
- [Overview on page 6091](#)
- [Configuration on page 6091](#)
- [Verification on page 6096](#)

### Requirements

Before you begin, learn more about Web filtering. See [“Web Filtering Overview” on page 6056](#).

### Overview

In this example you configure local Web filtering custom objects, local Web filtering feature profiles, and local Web filtering UTM policies. You also attach local Web filtering UTM policies to security policies.

In the first example configuration you create custom objects called `urllist5` and `urllist6` that contains the patterns `http://www.example.net 1.2.3.4` and `http://www.example.com 1.2.3.4` respectively. The `urllist5` and `urllist6` custom objects are then added to the custom URL category `custurl5` and `custurl6`.

In the second example configuration, you configure the Web filtering feature profile. You set the URL blacklist filtering category to `custurl4` and URL whitelist filtering category to `custurl3`. You set the type of Web filtering engine to `juniper-local`.

Then you create a `juniper-local` profile name called `localprofile1`. You select a default action (permit, log and permit, block) for this profile for requests that experience errors. This example sets the default action to permit.

Then you enter a custom message to be sent when HTTP requests are blocked. This example configures the device to send an `***Access to this site is not permitted***` message. You select fallback settings (block or log and permit) for this profile, in case errors occur in each configured category. This example sets fallback settings to block.

In the third example configuration, you create UTM policy `utmp5` and attach it to profile `localprofile1`.

In the final example configuration, you attach the UTM policy `utmp5` to the security policy `p5`.

### Configuration

- [Configuring Local Web Filtering Custom Objects on page 6092](#)
- [Configuring the Local Web Filtering Feature Profiles on page 6093](#)
- [Configuring Local Web Filtering UTM Policies on page 6094](#)
- [Attaching Local Web Filtering UTM Policies to Security Policies on page 6095](#)

### Configuring Local Web Filtering Custom Objects

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm custom-objects url-pattern urllist5 value http://www.example.net
set security utm custom-objects url-pattern urllist5 value 1.2.3.4
set security utm custom-objects url-pattern urllist6 value http://www.example.com
set security utm custom-objects url-pattern urllist6 value 1.2.3.4
set security utm custom-objects custom-url-category custurl5 value urllist5
set security utm custom-objects custom-url-category custurl6 value urllist6
```

**Step-by-Step Procedure** To configure local Web filtering using the CLI:

1. Create custom objects and URL pattern lists.

```
[edit]
user@host# set security utm custom-objects url-pattern urllist5 value
[http://www.example.net 1.2.3.4]
user@host# set security utm custom-objects url-pattern urllist6 value
[http://www.example.com 1.2.3.4]
```

2. Configure the custom URL category list custom object using the URL pattern list.

```
[edit]
user@host# set security utm custom-objects custom-url-category custurl5 value
urllist5
user@host# set security utm custom-objects custom-url-category custurl6 value
urllist6
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm custom-objects** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
userhost#show security utm custom-objects
url-pattern {
 urllist5 {
 value [http://www.example.net 1.2.3.4];
 }
 urllist6 {
 value [http://www.example.com 1.2.3.4];
 }
}
custom-url-category {
 custurl5 {
 value urllist5;
 }
 custurl6 {
 value urllist6;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring the Local Web Filtering Feature Profiles

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security utm feature-profile web-filtering url-whitelist custurl3
set security utm feature-profile web-filtering url-blacklist custurl4
set security utm feature-profile web-filtering type juniper-local
set security utm feature-profile web-filtering juniper-local profile localprofile1 default
 permit
set security utm feature-profile web-filtering juniper-local profile localprofile1
 custom-block-message "Access to this site is not permitted."
set security utm feature-profile web-filtering juniper-local profile localprofile1
 fallback-settings default block
set security utm feature-profile web-filtering juniper-local profile localprofile1
 fallback-settings too-many-requests block
set security utm feature-profile content-filtering profile contentfilter1
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure local Web filtering feature profiles:

1. Configure the Web filtering feature profiles.  

```
[edit security utm feature-profile web-filtering]
user@host# set url-whitelist custurl3
user@host# set url-blacklist custurl4
```
2. Select the Web filtering engine.  

```
[edit security utm feature-profile web-filtering]
user@host# set type juniper-local
```
3. Select a default action (permit, log and permit, block) for this profile for requests that experience errors.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-local profile localprofile1 default permit
```
4. Enter a custom message to be sent when HTTP requests are blocked.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-local profile localprofile1 custom-block-message "Access
to this site is not permitted"
```
5. Select fallback settings (block or log and permit) for this profile.  

```
[edit security utm feature-profile web-filtering]
user@host# set juniper-local profile localprofile1 fallback-settings default block
set security utm feature-profile web-filtering juniper-local profile localprofile1
 fallback-settings too-many-requests block
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm feature-profile** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
userhost#show security utm feature-profile
web-filtering {
 url-whitelist custurl3;
 url-blacklist custurl4;
 type juniper-local;
 juniper-local {
 profile localprofile1 {
 default permit;
 custom-block-message "Access to this site is not permitted.";
 fallback-settings {
 default block;
 too-many-requests block;
 }
 }
 }
}
content-filtering {
 profile contentfilter1;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Local Web Filtering UTM Policies

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
et security utm utm-policy utmp5 web-filtering http-profile localprofile1
```

**Step-by-Step Procedure** To configure a UTM policy:

1. Create the UTM policy referencing a profile.

```
[edit]
user@host# set security utm utm-policy utmp5 web-filtering http-profile localprofile1
```

**Results** From configuration mode, confirm your configuration by entering the **show security utm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this show command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
userhost#show security utm
utm-policy utmp5 {
```

```

web-filtering {
 http-profile localprofile1;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Attaching Local Web Filtering UTM Policies to Security Policies

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security policies from-zone trust to-zone untrust policy p5 match source-address any
set security policies from-zone trust to-zone untrust policy p5 match destination-address any
